## Invited, Keynote Speakers, Awards

### KEYNOTE ADDRESS

#### **Event 101 - Keynote - Petrus J. de Vries MBChB, FRCPsych, PhD**

#### **What Kind of Research Should We Do and Where Should We Do It?**

*P. J. de Vries, Centre for Autism Research in Africa, Division of Child & Adolescent Psychiatry, University of Cape Town, Cape Town, South Africa*

In 2001 the International Society for Autism Research (INSAR) was founded and held its first international conference. The 20<sup>th</sup> anniversary of INSAR is a good time to reflect on the kind of research we should be doing in the autism and neurodevelopmental community, and to consider where we should be focusing our research efforts over the next 20 years. In this keynote, we will discuss two related research journeys. The first is the story of Tuberous Sclerosis Complex (TSC)-Associated Neuropsychiatric Disorders (TAND) to illustrate how close partnership with the TSC community shaped our research questions and research strategies. The second is the story of autism in Africa to illustrate how the realization that 95% of people with autism live in low- and middle-income countries (LMIC) led to a paradigm shift in our research.

### KEYNOTE ADDRESS – LIFETIME AWARDEE

#### **Event 102 - Keynote – Helen Tager-Flusberg, PhD**

#### **INSAR Lifetime Awardee Keynote**

**Helen Tager-Flusberg**, *Department of Psychological and Brain Sciences, Boston University, Boston, MA*

### KEYNOTE ADDRESS

#### **Event 103 - Keynote - Tony Charman, PhD**

#### **Two Steps Forward, One Step Back: Lessons from Developmental Studies of Early Autism**

*T. Charman, Department of Psychology, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom*

The past few decades has seen great progress in early autism research. Thirty years ago the notion that autism could be prospectively identified in infancy, that early intervention could begin at the age of two or even before, and that we would be uncovering evidence on internal and external influences on outcomes from such an early age was restricted to a handful of optimists (and visionaries). I will review our work, and that of other groups, on population screening, early diagnosis and outcomes, studies of infants with a family history of autism, and early intervention trials. Whilst progress has been made, there are also salutary lessons to be learnt about whether we have been using the right methods or even asking the right questions.

---

**KEYNOTE ADDRESS****Event 104 - Keynote - Lucina Q. Uddin, PhD**

---

**Network Neuroscience of Autism**

*L. Uddin, University of Miami, Coral Gables, FL*

---

Recent advances in network neuroscience have paved the way for discoveries into the neurobiology of autism. Network neuroscience has introduced tools and conceptual frameworks that permit exploration of dynamic aspects of brain function *in vivo*. Over the past decade, “under-connectivity” theories of autism have given way to more nuanced characterizations of the neural basis of the disorder. I will review our recent functional neuroimaging studies investigating functional brain connectivity in autism through a developmental lens. I will further illustrate how analysis of brain dynamics can contribute to understanding flexible behaviors in autism. The talk will conclude with a discussion of some of our recent work parsing heterogeneity and comorbidity in neurodevelopmental disorders using individual connectome mapping.

---

**KEYNOTE ADDRESS****Event 105 - Keynote - Stormy Chamberlain, PhD**

---

**Mechanisms of Repression and Therapeutic Approaches for Angelman Syndrome**

*S. J. Chamberlain, Dept. of Genetics and Genome Sciences, University of Connecticut Health Center, Farmington, CT*

---

Angelman syndrome is a neurodevelopmental disorder caused by the loss of function from the maternal allele of *UBE3A*, a gene encoding an E3 ubiquitin ligase. The paternal allele of *UBE3A* is silenced by *UBE3A-ATS*, a long non-coding RNA expressed exclusively in neurons. Activation of the silent paternal allele offers a promising therapeutic approach for Angelman syndrome. Using human induced pluripotent stem cell models of Angelman syndrome, we have carefully studied the cellular phenotypes in AS neurons, and uncovered details of the mechanisms regulating the expression of *UBE3A-ATS* and repression of paternal *UBE3A*. This detailed understanding has aided the development of antisense oligonucleotide (ASO) therapeutics to activate paternal *UBE3A* in human AS neurons and revealed the mechanisms underlying this therapeutic approach. Based on our understanding of these mechanisms, we are beginning to explore the next generation of therapeutic strategies to activate paternal *UBE3A* by delivering shRNAs using viral vectors. This improved therapeutic approach combines the targeted activation of paternal *UBE3A* with the one-and-done benefits of gene therapy. As multiple therapeutics for Angelman syndrome are currently in or nearing clinical trials, Angelman syndrome is poised to be an important proof-of-principle for other neurodevelopmental disorders.

# Adult Outcome: Medical, Cognitive, Behavioral, Social, Adaptive, Vocational

## PANEL SESSION — ADULT OUTCOME: MEDICAL, COGNITIVE, BEHAVIORAL, SOCIAL, ADAPTIVE, VOCATIONAL

### Panel 201 - Barriers and Facilitators of Child, Teacher and System-Level Intervention Outcomes

**Panel Chair: Rebecca Landa**, *Center for Autism and Related Disorders, Kennedy Krieger Institute, Baltimore, MD*

**Discussant: Brian Boyd**, *Juniper Gardens Children's Project, University of Kansas, Kansas City, KS*

Community-based providers are the primary early intervention source for children with autism spectrum disorder (ASD). However, multi-level barriers threaten effective intervention delivery and children's outcomes. This panel's goal is to examine such barriers and multi-level risk and protective factors related to high fidelity EBP implementation and child treatment response. Results of four studies involving community providers' implementation of evidence-based intervention practices will be presented. Panelist 1 will focus at the child level, examining impact of phenotypic features on treatment response of preschoolers with ASD in a school-based randomized controlled trial. Panelist 2 will focus at the teacher level, examining factors that support and constrain resiliency in teachers of preschoolers with ASD, and how these factors relate to fidelity of Naturalistic Developmental Behavioral Intervention (NDBI) implementation. Panelist 3 will focus at the consultant level, examining how the qualities of consultants who support parent-teacher dyads in use of best practices affect children's IEP goal attainment. Panelist 4 will focus at the system level, examining relationships between climate, training, and fidelity outcomes. The Discussant will consider the implication of results for the design of intervention ingredients, professional development approaches, and organizational systems to promote resiliency at all levels to optimize child outcomes.

**201.001 (Panel) Risk and Protective Factors Related to Teachers' High Fidelity Intervention Implementation**

**R. Landa<sup>1</sup>** and **A. M. Englestad<sup>2</sup>**, *(1)Center for Autism and Related Disorders, Kennedy Krieger Institute, Baltimore, MD, (2)School of Education, Harvard University, Cambridge, MA*

#### Background:

Teachers of preschoolers with ASD are immersed in a complex, dynamic system. Within that system, barriers impact the relative success with which they attain high fidelity implementation of naturalistic developmental behavioral intervention (NDBI) strategies. These barriers may serve as cumulative risk factors, ultimately impacting teachers' well-being and retention in the workforce. Yet there is heterogeneity amongst teachers in the degree to which their fidelity of implementation is affected by barriers. Little is known about this heterogeneity. To address this knowledge gap, research is needed to define teacher characteristics associated with resiliency to previously reported barriers to high-fidelity implementation of evidence-based intervention strategies.

#### Objectives:

To define factors that constrain (risk factors) and support (protective factors) teacher resiliency to fidelity attainment barriers that have been previously defined in the literature.

#### Methods:

22 teachers of preschoolers with ASD, randomized to the NDBI training condition in a larger RCT, participated in this mixed-methods sub-study. Quantitative data included: (1) coach-completed survey documenting presence of barriers to fidelity attainment (defined in extant literature) after teachers completed 20 weekly job-embedded coaching sessions; (2) Behavior Rating Inventory for Executive Functions for Adults (BRIEF-A); (3) Maslach Burnout Inventory (MBI); (4) Autism Self-Efficacy Scale for Teachers (ASSET); and (5) monthly teacher fidelity of NDBI implementation coded blinded to group membership and date of collection. Teachers scoring at critical levels on the quantitative measures, defined by the measure (BRIEF-A), measure developers (MBI), or +1.25 standard deviations from the mean (ASSET, coach-report), were considered "high-risk" for vulnerability to fidelity attainment barriers. Association between baseline MBI, BRIEF-A, ASSET scores and Post-PD fidelity attainment was examined. Qualitative data were obtained from a focus group consisting of coaches. The field

guide was designed to define factors constraining or supporting teacher fidelity attainment. Transcripts were coded using a content analysis approach.

#### Results:

Coach-reported barriers and perceived impact on teacher fidelity attainment are presented in Table 1. Based on the teacher-reported and coach-reported measures, 50% of teachers in the sample met criteria for “high-risk.” Despite these barriers and risks, all but one teacher attained >80% fidelity of NDBI implementation after completing the PD program, and there was no evidence of a linear relation between baseline levels of teacher burnout, self-efficacy, or executive functioning and post-PD fidelity score. Qualitative data revealed 14 protective factors and six risk factors of teacher resiliency to barriers. Results inform a PD framework with embedded protective supports for teachers who are likely to face barriers to high-fidelity NDBI implementation.

#### Conclusions:

Results indicate that teachers of preschoolers with ASD face many barriers to high-fidelity NDBI implementation. NDBI coaches can address risk factors to support teachers’ resiliency to these barriers. Consistent, individualized, supportive job-embedded coaching to implement NDBI strategies in existing classroom instructional routines likely contribute to resiliency via offering teachers new perspectives and skills, boosting confidence in their ability to provide effective instruction, and providing increased social supports. Future research should examine causal effects of coaching strategies and bringing to scale personalized coaching approaches that support teacher resiliency and high-fidelity intervention implementation.

**201.002 (Panel) Which Children Are Responding and Why? a Novel Method to Understand Subtypes of Treatment Responders and Non-Responders**

*A. Wallisch<sup>1</sup> and B. A. Boyd<sup>2</sup>, (1)University of Kansas, Kansas City, KS, (2)Juniper Gardens Children's Project, University of Kansas, Kansas City, KS*

---

**Background:** While advancements in autism research have led to the development of evidence-based practices for children with autism spectrum disorder (ASD), we know there are children who continue to demonstrate minimal benefits from these interventions (Vivanti et al., 2014). A potential reason for non-responders to evidence-based interventions is the vast heterogeneity in symptoms and behaviors across the autism spectrum. To account for this heterogeneity, the idea of precision medicine, or personalized treatment, is pushing the field forward to understand how different treatments impact subgroups of populations in distinct ways (Hamburg & Collins, 2010). However, we still know little about how individual child differences impact treatment response in ASD. We examined how individual child differences impacted the efficacy of the Advancing Social Communication and Play (ASAP) intervention (Boyd et al., 2018). ASAP is a manualized, classroom-based intervention focused on coaching educational teams to improve the social communication and play skills of preschool-aged children with ASD.

**Objectives:** We examined how 1) children group by subtype based on child-level variables, and 2) subtype membership changed over time.

**Methods:** We performed a secondary analysis with data drawn from the cluster randomized controlled trial of ASAP to examine the heterogeneity of children in our sample and understand how that impacted treatment response. The data included 3-5 year old children with ASD (n=160) who were randomly assigned to ASAP or business as usual (BAU). We used latent class analysis to examine pre-treatment and post-treatment subtypes of children based on play skills, social communication skills, classroom engagement, challenging behavior, and autism severity. Next, we used a latent transition analysis (LTA) to determine which children transitioned subtypes, and if those children were in the ASAP or BAU group.

**Results:** After comparing fit statistics of a 2 to 6 class solution, results suggested a 3 class solution fit best for the pre-treatment and post-treatment models. All latent classes were differentiated by child characteristics. For example, the three latent classes divided into a higher (n= 22), middle (n= 95), and lower (n= 43) performing class based on social communication, play, and engagement skills, as well as challenging behavior and autism severity. Post-treatment latent classes followed a similar pattern of characteristics. The LTA indicated that 13 children in the ASAP group transitioned to a higher performing latent class, whereas 4 children in the BAU group transitioned to a higher latent class.

**Conclusions:** Using a data-driven approach to examine children’s pre-treatment characteristics may aid in understanding their response to intervention. Specific to the ASAP intervention, results suggest that 13 children in the ASAP group changed to a higher performing class, and these children were either transitioning from the lower-performing subtype to the mid-performing

subtype, or the mid-performing subtype to the higher performing subtype. ASAP may be less effective for children in the higher performing subtype, and more effective for children in the lower and mid-performing subtypes.

**201.003 (Panel)** School-Based Consultant Predictors of IEP Outcomes and Implementation Fidelity with Compass  
**L. A. Ruble<sup>1</sup>, L. N. Ogle<sup>1</sup> and J. H. McGrew<sup>2</sup>,** (1)Special Education, Ball State University, Muncie, IN, (2)Psychology, Indiana University - Purdue University Indianapolis, Indianapolis, IN

---

#### Background:

Schools are the primary source of intervention for children with ASD; yet, there is a notable research-to-practice gap. School-based interventions often fail to target key areas of social communication and learning skills associated with positive developmental outcomes. Further, workforce shortages of special educators, who have the highest attrition rates and often lack adequate knowledge on the use of evidence based practices, often result in children with ASD failing to receive the maximum benefit possible from their individual educational program (IEP). Thus, implementation strategies that help improve special education are paramount. One way to address the demand for more and better trained teachers is through consultation. Consultation possesses a unique multiplier effect by impacting many children efficiently. Trained consultants provide a direct avenue for incorporating EBPs that can be personalized to the student and their settings. COMPASS is an intervention specifically for children with ASD validated in three RCTs. Essentially doubling IEP outcomes, COMPASS brings together the parent and teacher for identifying personalized goals and intervention plans with facilitation from a consultant.

#### Objectives:

The purpose of this presentation is to describe school-based consultant predictors of child goal attainment outcomes and increased fidelity of implementation of COMPASS.

#### Methods:

Twelve school-based consultants (age 24-60) were recruited to help validate a COMPASS training package. The training package consisted of two in-person days and online materials on (a) conducting the initial goal setting and intervention planning consultation with parent-teacher dyads and (b) providing follow-up teacher coaching sessions. A total of 31 teachers and parents of children between ages of 4 and 13 years participated. Each dyad received a 3-hour consultation with the trained consultant, followed by data-driven supervision via video conferencing and written performance feedback following each consultation.

End of year researcher ratings of child goal attainment outcomes were correlated with consultant ratings of (a) consultation experience/skills, knowledge and attitude toward EBPs, and administrator support; researcher ratings of consultants' (b) quality of process skills and teaching plans, as well as fidelity to the consultation and first coaching session; and students' (c) ASD severity (SCQ and Vineland ratings).

#### Results:

Because of the small sample size, correlations at  $p \leq .10$  are reported (see Table). Variables that predicted end of year child IEP goal attainment outcomes included consultants' experience, teaching plan quality and EBP knowledge, and consultants' consultation fidelity and consultation skills. Variables that predicted implementation fidelity of the consultation included consultants' process skills, EBP knowledge, and teaching plan quality.

#### Conclusions:

Consultation is a complex skill that requires the ability to establish effective partnerships with teachers and parents as well as the ability to assess and integrate parent and teacher concerns into critical learning goals for children with ASD that are often neglected in IEPs yet are essential for positive developmental outcomes. Consultant factors of knowledge and application predicted child outcomes. High fidelity to the initial consultation was associated with child outcomes, process skills, teaching plan quality, and knowledge of EBPs. Overall, the results suggest that interpersonal and training factors are associated with increased fidelity and child outcomes.

**201.004 (Panel)** A Mixed Methods Evaluation of Implementation Climate and Leadership within Education Programs for Students with ASD

## **Background:**

Although EBP for ASD have been identified, leaders and educators report difficulty using these practices in their schools. The California Autism Professional Training and Information Network (CAPTAIN) is a multi-agency collaborative focused on increasing dissemination and implementation of EBP for ASD. Toward this aim, CAPTAIN emphasizes member use of high-quality training and coaching practices to improve outcomes.

**Objectives:** The purpose of this project was to explore relationships between implementation climate, implementation leadership and training outcomes within special education services for students with ASD.

## **Methods:**

### Qualitative methods

CAPTAIN members (n=30) participated in focus groups to discuss their experiences with practice implementation, interactions with administration, and the process of conducting trainings. Transcripts were coded to identify the most common themes regarding implementation climate and leadership.

### Quantitative methods

Education system leaders (n=264) completed quantitative measures characterizing their personal implementation leadership behavior and the implementation climate of their organization. Measures included the Implementation Leadership Scale (ILS; Aarons et al., 2014) and the Implementation Climate Scale (ICS; Ehrhart et al., 2014).

CAPTAIN members (n=200) reported on quantity and quality of training and coaching they provided throughout the 2018-2019 academic year. To quantify these CAPTAIN member outcomes, a performance score was calculated for each cadre member.

Associations between Leader ratings, aggregated by special education region, and CAPTAIN member performance scores were evaluated using ANOVA and bivariate correlations depending on the measures.

## **Results:**

Focus groups themes highlighted the importance of leadership, provision of educational supports and prioritizing EBP implementation. CAPTAIN members reported using a variety of strategies to gain leader buy-in including frequent communication and data-based presentations.

Overall, leaders had high ratings of their own implementation leadership (Mean = 3.09, SD = 0.52). In regards to implementation climate, selection for openness to EBPs was rated the highest (Mean = 3.00, SD = 0.79), while Rewards was rated the lowest (Mean = 1.14, SD = 0.77).

Overall, CAPTAIN members trained 88.21 (SD = 96.32) and coached 30.32 (SD = 58.54) providers (including special educators, paraeducators, general educators, and direct service providers). Performance scores were calculated (Mean = 44.3, SD = 20.3).

Higher self-rated ILS scores were associated with higher CAPTAIN member performance scores ( $p$ -values  $<.05$ ) indicating that leaders' self-perception of their own implementation behavior has an impact on CAPTAIN member performance. Similarly, higher scores on the ICS recognition scale (recognition use of EBP) was associated with coaching quality ( $p = .04$ ).

## **Conclusions:**

These findings contribute to the understanding of how system level factors impact dissemination and implementation of EBP for ASD in school programs. Across methodologies, leadership was identified as a key supportive factor. In contrast, the Rewards

domain of implementation climate was highlighted as a challenge.

**PANEL SESSION — ADULT OUTCOME: MEDICAL, COGNITIVE, BEHAVIORAL, SOCIAL, ADAPTIVE, VOCATIONAL**

**Panel 215 - Towards Cross- and Multimodal Biomarker Discovery in Autism – Updates from the AIMS2TRIALS Project**

**Panel Chair: Jan Buitelaar**, *Department of Cognitive Neuroscience, Donders Institute for Brain, Cognition and Behaviour, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands*

**Discussant: Jan Buitelaar**, *Department of Cognitive Neuroscience, Donders Institute for Brain, Cognition and Behaviour, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands*

Autism spectrum disorder (ASD) is among the most common neurodevelopmental conditions. Nonetheless, effective medical treatments for the core symptoms are still lacking. This is largely due to the great clinical and biological heterogeneity across the autism spectrum, which hinders our ability to detect significant efficacy signals. Consequently, over recent years, research efforts have increasingly focused on the identification and validation of biomarkers that allow the stratification of patient populations according to biological subtypes. As the largest multicenter, multidisciplinary autism project worldwide, the AIMS2TRIALS consortium provides an unprecedented opportunity to answer questions related to biomarkers. Specifically, the AIMS2TRIALS Longitudinal European Autism Project (LEAP) aims to improve our understanding of disease mechanisms to identify and validate stratification markers and targets for surrogate endpoints, and to guide the development of personalized precision medicine approaches in ASD. Here, we present an update on our most recent research efforts within LEAP across different imaging and neurocognitive modalities (EEG, eye-tracking, structural, task and resting-state fMRI), and introduce novel, innovative imaging methods (connectome-wide mega-analysis, normative modeling, task potency, linked independent component analysis, canonical correlation analysis). Combined, our findings highlight neurodevelopmental differences at different levels linked to outcome and represent potentially suited treatment targets.

**215.001 (Panel)** The N170 Face-Sensitive Brain Response: Toward a Stratification Biomarker for ASD

Background: Autism Spectrum Disorder (ASD) is a neurodevelopmental condition characterised by difficulties in social communication, but also great heterogeneity. To offer individualised medicine approaches, we need to better target interventions by stratification of people with ASD into subgroups with different biological profiles and/or prognoses. Since interpreting information from the human face is critical to successful social interaction, studying neural responses to faces may provide a neurobiological index of socially-acquired expertise. One well-characterised neural signal that has been previously reported to be atypical in ASD is the face-sensitive N170 event-related potential.

Objectives: We sought to test whether the N170 response to faces could have potential as a stratification biomarker in ASD by measuring neural (EEG) responses to faces in a large group of N=436 children and adults with and without ASD.

Methods:

Participants were enrolled in the European multisite LEAP study. EEG was recorded while participants watched pictures of upright and inverted faces, and standard techniques were used to extract the amplitude and latency of the N170 component. In addition, taking advantage of the multimodal nature of the LEAP study, we examined how N170 responses associated with i) the Vineland Socialisation scale and its subdomains as a measure of everyday social functioning at both baseline and at 12-24 month follow-up; ii) fMRI measures of social brain functioning (activation in the fusiform gyrus in response to faces); and iii) polygenic scores derived from common variants previously associated with ASD. We also used Gaussian mixed-model clustering to identify substructure within the ASD group.

#### Results:

The speed of early-stage face processing (N170 latency) was on average slower in ASD than age-matched controls ( $F(1,430)=9.43, p=0.002, \eta_p^2=0.021$ ; Figure 1). In addition, N170 latency was associated with responses to faces in the fusiform gyrus area (FG3 at MNI [30 -64 -10]) ( $t=3.93, P_{SVC}=0.032; R^2=.131, N170\ b=0.285, p < 0.001$ ) and polygenic scores (PGS) for ASD (Spearman's  $r^2=0.026; p=0.0031$ ; ASD  $r^2=0.022; p=0.039$ ; controls  $r^2=0.024; p=0.074$ ), triangulating links to social biology. Critically, within the ASD group N170 latency predicted change in adaptive socialisation skills over an 18-month follow-up period ( $r(141)=-0.235, p=0.005$ ; Bonferroni-corrected  $\alpha=0.02$ ). Data-driven clustering of the EEG waveform identified three subgroups (BIC=33483, AIC=33294; Cluster 1,  $n=118, 48\%$ ; Cluster 2,  $n=27, 11\%$ ; Cluster 3,  $n=101, 41\%$ ); Cluster 2 had slower N170 ( $F(2,245)=64.32, p < 0.001, \eta_p^2=0.975$ ; Figure 2) and poor social prognosis ( $F(2,144)=4.41, p=0.014, \eta_p^2=0.209$ ; Figure 2). Within Cluster 2, the association between N170 latency to upright faces at P7 and P8 explained over 25% of the variance in the change in the same subdomain Vineland Socialisation (Play and Leisure Time) scores between baseline and 18 month follow-up visit ( $r(19)=-0.517, p=0.023$ ).

Conclusions: Taken together, this provides converging evidence for the utility of the N170 as a potential stratification biomarker to identify biologically and prognostically defined subgroups in ASD, and may provide a blueprint for similar endeavours in other psychiatric conditions.

#### **215.002 (Panel) Social Attention in Complex Dynamic Scenes Relates to Symptom Severity in Children, Adolescents and Adults with ASD**

**L. Mason<sup>1</sup>, E. J. Jones<sup>1</sup>, J. Tillmann<sup>2</sup>, H. L. Hayward<sup>3</sup>, T. Charman<sup>4</sup>, E. Loth<sup>5</sup>, J. K. Buitelaar<sup>6</sup>, D. Murphy<sup>7</sup> and L. G. EEU-AIMS<sup>1</sup>,** (1)Centre for Brain and Cognitive Development, Birkbeck, University of London, London, United Kingdom, (2)Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (3)Forensic and Neurodevelopmental Sciences, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (4)Department of Psychology, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (5)Department of Forensic and Neurodevelopmental Sciences, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (6)Department of Cognitive Neuroscience, Donders Institute for Brain, Cognition and Behaviour, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands, (7)EU-AIMS Organization, London, United Kingdom

#### Background:

Autism is a neurodevelopmental disorder that affects social communication and flexible behavior. Theories including a role for compromised social attention are common, and metrics of social attention have been raised as putative biomarkers for variation in symptomatology within autism; however, we lack demonstrations that case-control effects reported in small diverse studies are robust and generalisable. Here, we examined social attention during viewing of complex social scenes in a large and heterogeneous sample of individuals with and without autism.

#### Objectives:

To assess differences between individuals with and without autism in attention to social content during naturalistic social scenes, and to determine the relationship of looking patterns to core and association concurrent and future symptomatology.

#### Methods:

Eye tracking data was collected during viewing of 3 complex dynamic video excerpts with music soundtrack (a clip from the 50 Faces series featuring one or two people in a set of street interviews; the cafeteria scene from the film "The Dollhouse"; and an excerpt of two characters in a music booth from the film Before Sunrise) by  $n=453$  autistic people and  $n=311$  neurotypical controls across 7 sites in Europe. Duration of looking to a-priori defined areas of interest (face, eyes, mouth) was computed and examined in relation to diagnostic group, age, IQ, and measures of core and associated symptoms.

## Results:

Autistic people looked less at faces versus bodies (Figure 1; 50 Faces:  $F(1,562)=19.042$ ,  $p<.001$ ; Dollhouse/Music Booth;  $F(1,722.184)=30.492$ ,  $p<.001$ ) but not eyes versus mouths (50 Faces:  $F(2,1124)=2.396$ ,  $p=.083$ ; Dollhouse/Music Booth;  $F(2,822.649)=1.799$ ,  $p=.166$ ) relative to neurotypical controls. Group differences were largely consistent across age and IQ within the typical range. We observed small but significant bivariate correlations in the ASD group between a factor representing less face vs body looking and higher scores on the ADI Social subscale,  $r(333)=-.19$ ,  $p=.002$ , and the ADOS Social Affect subscale,  $r(304)=-.21$ ,  $p<.001$ , weakly with the SRS t score, other:  $r(293)=-0.10$ ,  $p=0.089$ , self:  $r(142)=-0.18$ ,  $p=0.028$  and not with the Vineland Socialisation scale,  $r(299)=.093$ ,  $p=.113$ . These correlations became slightly stronger when controlling for age, ADI Social,  $r(330)=-.20$ ,  $p<.001$ ; ADOS Social Affect,  $r(301)=-.20$ ,  $p<.001$ ; SRS other,  $r(290)=-.14$ ,  $p=0.015$ ; SRS self,  $r(139)=-.17$ ,  $p=0.043$ . The strength of these associations did not vary with IQ (mild ID or no ID) or sex (male/female). Looking patterns were not associated with associated conditions like anxiety, ADHD or depression or with change in core symptoms over time ( $r's<.1$ ,  $p's>.1$ ). No significant phenotypic associations were observed with eyes vs mouth looking ( $r's<.1$ ,  $p's>.1$ ).

## Conclusions:

Reduced social attention during naturalistic scenes in autistic people does not vary with age or IQ but does relate to core symptoms, raising the possibility that it reflects a component or consequence of the experience of autistic symptomatology. Refined and optimised measures should be pursued to develop their potential as quantitative scalable assessments of autistic traits.

Background: Autism spectrum disorder (ASD) is a neurodevelopmental condition associated with difficulties in the domains of social communication, restricted and repetitive patterns of behaviours and interests, and sensory anomalies. This typically results in impaired adaptive behaviour, i.e. the ability to perform everyday tasks. However, the neurobiological mechanisms that underpin adaptive behaviour in ASD across the lifespan on a group and individual level remain poorly understood; and this hampers the development of effective pharmacological treatments.

Objectives: Hence, the aim of the present study was to examine, for the first time, the neuroanatomical and associated genetic substrates of change in adaptive behaviour in ASD from childhood to early adulthood.

Methods: In 204 autistic individuals (age range 6-30 years) we acquired magnetic resonance imaging (MRI) data at entry (T1); and adaptive behaviour scores using the Vineland Adaptive Behaviour Scale-II (VABS-II) at T1 and T2 (~12-24 months later).

Based on the VABS-II change between T1 and T2, and recently published Minimal Clinically Important Difference (MCID) scores, we grouped autistic individuals into three groups: (i) those whose scores increased ( $\Delta V \geq 4$ ), (ii) did not change ( $4 < \Delta V < 4$ ), and (iii) declined ( $-4 \geq \Delta V$ ). First, we compared baseline neuroanatomy between outcome groups. Next, using data from 279 age-matched neurotypicals, we examined if neuroanatomy, i.e. deviations from the neurotypical neurodevelopmental profile, predicts clinical outcome on an individual level. Then we examined the association between neuroanatomy (differences between clinical outcome groups and deviations from the typical profile) and genetic variation. Finally, we estimated the utility of these neuroanatomical findings as enrichment markers in simulated clinical trials.

**Results:** We identified spatially distributed patterns of neuroanatomical variability (including in frontal, temporal, parietal, and occipital regions) that are associated at the group level with change in adaptive behaviour over time. We also found that deviations from the typical neurodevelopmental profile are predictive of an individual's subsequent change in adaptive behaviour. Our gene enrichment analyses revealed that neuroanatomical group differences, especially between those individuals whose adaptive behaviour skills increased vs declined, were sensitive to underlying ASD-associated genomic mechanisms. Moreover, neuroanatomical deviation from the neurotypical profile correlated with autism polygenic scores restricted to genes expressed in these regions. Finally, we found that enriching simulated clinical trials for subjects with greater neuroanatomical abnormality improved our ability to detect fixed treatment effects.

**Conclusions:** In ASD, developmental differences in neuroanatomy and associated genetic factors may underpin and help predict variation in subsequent adaptive behaviour change. If validated, our findings may aid the future development and evaluation of better targeted ('personalised medicine') interventions in ASD.

#### **215.004 (Panel) Cross-Modal Analyses Define Atypical Connectivity Biomarkers in Autism**

**Background:** Autism Spectrum Disorder (ASD) is a highly heterogeneous condition and underlying biological mechanisms remain unknown. The most recent consensus is that ASD is a disorder of atypical neural connectivity across multifaceted neurobiology. While resting-state fMRI is ideally suited to investigate the disconnection nature of autism, multi-modal analyses are becoming increasingly important to tap into the system-level alterations involving several neurobiological features.

**Objectives:** To identify robust markers of quantitative biological 'connectivity' phenotypes across both resting-state fMRI and multi-modal features using novel imaging-methods.

**Methods:**

All analyses were based on different subsamples from the AIMS2TRIALS multisite Longitudinal European Autism Project (N between 340-1824 subjects; age 6-30 years). We applied a range of innovative methods ideally suited to derive biomarkers in large heterogeneous samples by conducting both **a)** uni-modal analyses using resting-state fMRI and **b)** multi-modal analyses integrating resting-state, task-, structural and diffusion MRI data. **a)** In Study 1, we conducted a connectome-wide mega-analysis aggregating data from both LEAP and ABIDE to map functional dysconnectivity across the entire brain in autism and related these to clinical symptomatology. In Study 2, we defined amygdala parcels based on its functional connectivity within three large-scale networks subserving distinct aspects of social functioning before testing the associations between polygenic scores/adaptive social functioning and parcel volumes. **b)** For multi-modal analyses, in Study 3 we used Linked Independent Component Analysis to integrate grey (VBM) and white (DTI) matter features. Canonical Correlation Analysis (CCA) was performed to explore the aggregated effects between all components of GM-WM covariations and symptom severity. In Study 4,

we used task potency to integrate resting-state fMRI with task-fMRI data across a range of different cognitive tasks. Multi-modal, individual-level task potency deviations were identified using normative modeling and followed up with CCA.

Results:

**Study 1)** Individuals with ASD showed widely distributed alterations of functional connectivity. While hypoconnectivity affected sensory and higher-order attentional networks and was associated with social impairments and repetitive behaviours, hyperconnectivity affected cortico-subcortical systems and the default mode network which was associated with social impairments. **Study 2)** We found a significant association between amygdala with ventromedial prefrontal cortex ( $p < 0.001$ ) and with anterior cingulate cortex (AAC) ( $p = 0.013$ ) and levels of adaptive social functioning. There was a significant interaction effect between polygenic scores and levels of ADHD traits ( $p = 0.02$ ) on AAC parcel volume. **Study 3)** We found a significant component associated with decreased density of bilateral insula, postcentral, angular and inferior temporal gyrus, and increased density of caudate and supra-/intra-calcarine cortex in autism while co-occurring altered WM diffusion features in superior longitudinal fasciculus ( $p = 0.040$ ). **Study 4)** We found greater levels of global task-potency atypicality for autism in each task ( $p < 0.001$ ). Furthermore, there were significant brain-behaviour modes of covariation between task potency atypicality spatial patterns and autism-related behavioural features.

Conclusions: Autism is associated with a complex pattern of both hypo- and hyperconnectivity. In order to achieve advances in our understanding of system-level atypicalities in ASD, integrating different structural and functional brain measures is the most promising method providing the basis for elucidating mechanisms through which interventions may improve functioning.

## PANEL SESSION — ADULT OUTCOME: MEDICAL, COGNITIVE, BEHAVIORAL, SOCIAL, ADAPTIVE, VOCATIONAL

### Panel 222 - Substance Use Among Adolescents and Adults on the Spectrum

**Panel Chair: Laura Graham Holmes**, *Boston University School of Public Health, Boston, MA, Hunter College, City University of New York, New York City, NY, Boston University School of Public Health, Boston, MA, Hunter College, City University of New York, New York City, NY*

Substance use disorder prevention is an important component of adolescent and adult health. Considering that an estimated 707,000-1,116,000 autistic youth will turn 18 years old by the year 2030, there is a tremendous deficit of information about substance use by autistic people. This panel presents the findings of four separate studies addressing questions about autistic adolescent and adult substance use. Collectively, these studies analyzed data from hundreds of autistic youth and adults using interview, survey, and secondary data analysis methods. Presentation 1 ( $n = 390$ ) presents a novel analysis of nationally representative data on U.S. school-based substance use disorder prevention education for U.S. students with autism, showing they are less likely to receive this service than youth without disabilities. Presentation 2 uses a large-scale cross-sectional study ( $n = 733$ ) to identify psychiatric conditions associated with substance use disorders in autistic individuals compared to clinical controls. Presentation 3 explores the thoughts and opinions of autistic young people ( $n = 40$ ) about their experiences with alcohol. Finally, Presentation 4 presents an analysis of U.S. states in which autism is a qualifying condition, and the results of a qualitative interview study of  $n = 40$  autistic youth about their cannabis use.

**222.001 (Panel)** School-Based Substance Use Education: Inclusion of Youth on the Autism Spectrum in a Representative U.S. Sample

**J. Rast<sup>1</sup>**, *L. Graham Holmes<sup>2,3</sup>, A. Roux<sup>4</sup> and E. F. Rothman<sup>4</sup>*, (1)*A.J. Drexel Autism Institute, Drexel University, Philadelphia, PA*, (2)*Boston University School of Public Health, Boston, MA*, (3)*Hunter College, City University of New York, New York City, NY*, (4)*Community Health Sciences, Boston University School of Public Health, Boston, MA*

Background:

This study provides an update on rates and predictors of substance abuse education (SAE) participation for autistic youth compared to other youth with and without individualized education plans (IEP) and 504 plans. Almost 800,000 youth classified as autistic are served by the U.S. special education system, with 92% enrolled in regular schools and most spending at least half of their time in general education classrooms. These students require health education providing the information and skills to make informed decisions about substance use. In 2000, data from the National Longitudinal Transition Study-2 showed autistic youth were the least likely across IEP classifications to receive SAE.

Objectives:

- 1) Estimate the percentage of students with an IEP classification of autism who have received SAE as compared to the percentage of students with no IEP and no 504 plan who have received SAE.
- 2) Identify factors associated with the receipt of SAE within and across IEP classifications.

#### Methods:

The National Longitudinal Transition Study-2012 was designed to yield nationally representative estimates of the experiences of U.S. youth served by the special education system. We compared rates of SAE across groups of youth who were 14 or older and able to self-report via survey who had: (a) an IEP classification of autism ( $n=390$ ) (b) other IEP classifications ( $n=4420$ ), (c) a 504 plan ( $n=350$ ), or (d) no IEP or 504 plan ( $n=980$ ). For each group, we conducted bivariate and multivariate regression analyses to identify characteristics of youth and educational experiences that were associated with receipt of SAE. Analysis was performed using Stata 15 and accounted for the complex survey design.

#### Results:

- 1) Students classified as autistic were significantly less likely to report SAE (49.6%) than students with no IEP/504 (57.4%).
- 2) For autistic youth, there were no bivariate or multivariate associations with receipt of SAE. In contrast, For youth in any other IEP category, youth attendance at an IEP meeting (OR 1.49, 95% CI 1.18-1.87), no trouble with conversation ability (OR 1.99, 95% CI 1.32-3.01), and no trouble getting to places outside the home (OR 1.59, 95% CI 1.21-2.09) were associated with higher odds of SAE receipt.

#### Conclusions:

Even as rates of drug abuse, dependence, and overdose deaths climb in the U.S., autistic students continue to be underserved when it comes to SAE. The lack of prevention services for autistic youth may result in poorer health trajectories across the lifespan. Research and policy advocacy are urgently needed to ensure that autistic youth have more access to SAE.

**222.002** (Panel) Substance Use Disorder in Autistic Adults: A Cross-Sectional Study of a National Mental Health Database  
**K. L. Unwin<sup>1</sup>, J. Underwood<sup>2</sup> and J. Hall<sup>1</sup>**; (1)Olga Tennison Autism Research Centre, La Trobe University, Melbourne, VIC, Australia, (2)Neurosciences & Mental Health Research Institute, Cardiff University, Cardiff, United Kingdom

---

#### Background:

Substance Use Disorders (SUDs) are diagnosed when the use of drugs, including alcohol, continues despite negative consequences. SUDs have a devastating effect on individuals lives and these effects are amplified when SUD co-occurs with autism. Studies have shown that concurrent SUD with autism not only negatively affects health and functioning, but also heightens risk of mortality. Evidence suggests that concurrent SUDs may stem from autistic individuals attempting to self-medicate, using substances to alleviate anxiety, social inhibition and sensory symptoms. Despite this, SUDs are reportedly underdiagnosed in autistic people, creating a barrier to services and support. There is also limited research in this area, particularly with regard to associations of SUDs within autism that could serve as red flags to support clinicians in the prevention or diagnosis of SUDs.

#### Objectives:

To investigate the psychiatric and neurodevelopmental conditions associated with SUDs in autistic individuals as compared to a clinical control group.

#### Methods:

Diagnostic and demographic data from 741 autistic adults (Male,  $n=397$ , 19-88 years) and 733 age- and gender-matched clinical controls were extracted from the National Centre for Mental Health database (Wales, UK). Data for this database were collected through standardized interview and clinical records. Binomial logistic regressions were used to assess associations with psychiatric and neurodevelopmental disorders across both groups.

## Results:

Ninety-eight of the autistic adults and 129 of the clinical controls had a co-occurring diagnosis of a SUD. In the autistic sample, SUDs were associated with Generalised Anxiety Disorder (Odds Ratio;  $OR=2.47$ , 95% C.I. 1.31-4.66), Bipolar Disorder ( $OR=2.58$ , 95% C.I. 1.37-4.85) and Emotionally Unstable Personality Disorder ( $OR=2.15$ , 95% C.I. 1.12-4.14). A concurrent ID or ADHD diagnosis was not statistically associated with SUD in either group. In the clinical control group, SUDs were associated with Generalised Anxiety Disorder ( $OR=2.31$ , 95% C.I. 1.33-4.00), Bipolar Disorder ( $OR=2.03$ , 95% C.I. 1.18-3.50), Depression ( $OR=4.38$ , 95% C.I. 2.08-9.25), Schizophrenia ( $OR=3.36$ , 95% C.I. 1.67-6.78) and Psychosis ( $OR=2.02$ , 95% C.I. 1.10-3.71), but not Emotionally Unstable Personality Disorder.

## Conclusions:

In this large-scale, cross-sectional study, we identified factors associated with SUDs in autistic individuals which could serve as potential indicators for either undiagnosed SUD, or the need for preventive strategies against SUD to be put in place. In particular, these potential risk factors include Generalised Anxiety Disorder, Bipolar Disorder and Emotionally Unstable Personality Disorder. These findings align with the self-medication explanation of SUDs in autism as those with autism and a concurrent mood disorder were more likely to have a SUD. Future work should further investigate risk factors for SUDs in autism, specifically exploring if there is a causal relationship between them.

### 222.003 (Panel) Underage Alcohol Use in Youth on the Autism Spectrum

**E. F. Rothman<sup>1</sup>** and **L. Graham Holmes<sup>2,3</sup>**, (1)Community Health Sciences, Boston University School of Public Health, Boston, MA, (2)Boston University School of Public Health, Boston, MA, (3)Hunter College, City University of New York, New York City, NY

---

#### Background:

Although autistic youth have previously been seen as protected from substance use disorders due to rule-following or lack of exposure to peer pressure, recent studies show that they do use alcohol. For example, between 23%-44% of autistic college students report using alcohol,<sup>1</sup> and a large survey of autistic adults ( $n=507$ ) indicated half of all drinkers reported binge drinking, and most perceived that alcohol had positive benefits including improved communication.<sup>2</sup> Further research about alcohol use among autistic people is needed in order to support substance use interventions for this population.

#### Objectives:

The purpose of this study was to explore the thoughts and opinions of a sample of U.S. autistic youth about motivations to use or abstain from alcohol, alcohol expectancies, refusal self-efficacy, family communication, peer use norms, rule-following, and risk perception; and in those with recent alcohol use, types of alcohol consumed, how procured, with whom and in what context, perceived effects, and consequences.

#### Methods:

Forty youth were recruited for a qualitative interview study via social media advertising and databases of prior research participants. Eligible youth were: (1) 16-20 years; (2) U.S. residents; (3) English-speakers; (4) Had a diagnosis of autism, verified by reviewing documentation; (5) Demonstrated ability to complete an interview; and (6) had a drink of alcohol in the past year ( $N=20$ ) or had not ( $N=20$ ). Participants or their parent completed the SRS-2. Interviews took place over Zoom, with the option of speaking aloud or using the chat feature to text (interview questions in Table 1). Interviews were recorded and transcribed, and Dedoose software was used to organize text into excerpts. Two independent raters coded excerpts using an inductive approach to identify themes, presented with illustrative quotes (Table 2).

Of 98 individuals interested in participation, 41 were eligible and 40 completed the interview (mean age=18 years). They were White non-Hispanic (81%), Asian (7%), Black (3%), Hispanic/Latino (2%), and multiracial (7%). Sixty-one percent were male, 29% female, and 10% non-binary gender. SRS-2 T-scores (mean=94.2,  $SD=10.3$ ) were consistent with autism symptoms in the severe (96.3%) or moderate (3.7%) range.

#### Results:

Drinkers described the effects of alcohol as enjoyable, relaxing, and disinhibiting. In general, youth stated that their parents hadn't communicated explicit rules about alcohol use. However, they described being affected by the alcohol culture in their homes, for example: envisioned themselves using alcohol in adulthood in a similar manner to their parents. Drinkers and non-drinkers both imagined that alcohol use decreases anxiety for autistic people, although some worried disinhibition would make them less socially effective. Several college youth described episodes of binge drinking or drinking to alleviate stress rather than for fun. One youth described a "special interest" in cocktail ingredients which facilitated college social relationships.

Conclusions:

Underage alcohol use is a normative aspect of the transition to adulthood. Youth on the spectrum are aware of and interested in alcohol, and some associated negative health effects or potential positives. Family communication about alcohol use may be minimal and could be strengthened for youth on the spectrum as they enter adulthood.

**222.004 (Panel)** Where Is Cannabis Legally Available to Autistic Youth and Adults in the U.S., and Why Do Autistic Youth Report Using Cannabis?

**L. Graham Holmes<sup>1,2</sup>** and **E. F. Rothman<sup>3</sup>**, (1)Boston University School of Public Health, Boston, MA, (2)Hunter College, City University of New York, New York City, NY, (3)Community Health Sciences, Boston University School of Public Health, Boston, MA

---

Background:

Autistic adults, and parents of autistic children, are targeted by the cannabis industry to use cannabis to address autism symptoms and co-occurring conditions that include problems with sleep, anxiety, irritability, seizure, self-harm, sensory processing, and alexithymia. Three experimental studies have found promising effects of cannabis on autism symptoms. However, cannabis may have negative effects that exacerbate autism symptoms, and one study has found that cannabis use may be more likely to lead to cannabis use disorder (CUD) among autistic people than neurotypical people. This study sought to address the information gap about the availability of legal cannabis to autistic people in the U.S., and why autistic youth report using cannabis.

Objectives:

The objectives of this two-part study were to: (1) Analyze U.S. state policies regarding recreational and medicinal use of cannabis for autistic people; and (2) Investigate experiences of cannabis use among autistic youth aged 16-20 years.

Methods:

To address our first objective, we reviewed U.S. state health websites and statutes to determine whether recreational and medicinal cannabis were legal and if legal, under what circumstances autistic adults or parents of autistic youth could obtain cannabis. To address our second objective, we interviewed n=40 autistic youth recruited via social media advertising and databases of prior research participants. Eligible youth were: (1) 16-20 years; (2) U.S. residents; (3) English-speakers; (4) Had a formal autism diagnosis, verified by reviewing documentation; and (5) Demonstrated ability to complete an interview. Participants or their parent completed the SRS-2. Zoom interviews were recorded and transcribed, and Dedoose software was used to organize text into excerpts. Two independent raters coded excerpts using an inductive approach to identify themes, presented with illustrative quotes (Table 1).

Of 98 potential participants, 41 were eligible and 40 completed the interview process (mean age=18 years). They were White non-Hispanic (81%), Asian (7%), Black (3%), Hispanic/Latino (2%), and multiracial (7%). Sixty-one percent were male, 29% female, and 10% non-binary gender. SRS-2 T-scores (mean=94.2, SD=10.3) were consistent with autism symptoms in the severe (96.3%) or moderate (3.7%) range.

Results:

1) There are 28 U.S. states in which autistic adults could obtain cannabis legally, and 19 states in which parents can obtain medicinal cannabis for autistic children (Figure 1).

2) Youth who used cannabis reported that they used it to improve sleep and gastrointestinal issues, to relieve stress and social anxiety, and have fun. Some said that they used it along with or enjoyed it more than alcohol. Users were open with parents or

had even received cannabis from parents. Youth perceived some potential harms, but generally thought it was less harmful than alcohol.

Conclusions:

Cannabis is widely available for autistic people in the U.S. Autistic young people use cannabis for medicinal and recreational purposes and may be unaware of potential harms. Given the ferocity of cannabis industry marketing techniques, we must begin to characterize how autistic adults and parents of autistic youth think about the state of the science about risks and benefits of cannabis, and how they choose whether to use it.

## PANEL SESSION — ADULT OUTCOME: MEDICAL, COGNITIVE, BEHAVIORAL, SOCIAL, ADAPTIVE, VOCATIONAL

### Panel 229 - Digitally Augmented Phenotyping of Autism Spectrum Disorders

**Panel Chair: Christine Falter-Wagner**, *Department of Psychiatry and Psychotherapy, LMU Hospital Munich, Munich, Germany*

**Discussant: Kai Vogeley**, *Department of Psychiatry and Psychotherapy, University Hospital Cologne, Cologne, Germany*

Differential diagnostics of autism spectrum disorders (ASD) currently relies mainly on (semi-standardised) behavioural observation. The diagnostic reliability of clinical impression formation depends heavily on in-depth clinical experience and represents a particular challenge for adult diagnostics. Methods of digital recording and analysis of behaviour promise high potential for more objective and economic ASD diagnostics based on the assessment of biological and behavioural markers. The approaches presented in this panel investigate the potential of digital assessment methods and machine learning for digitally augmented phenotyping of ASD. The contributions to the panel will discuss high resolution parameters of temporal coordination between gaze, gesture, verbal output and facial expression. Assessment methods comprise coupled eye-tracking and computerised movement detection, video analysis, computer vision approaches, machine learning amongst others. A balance of controlled laboratory settings and ecologically valid interpersonal interactions will be discussed. Such digital assessment methods could shape ASD diagnostics in the future by providing an objective, automatized phenotyping aid augmenting clinical decision making, providing more efficient diagnostic procedures and adding to cross-institutional reliability of clinical decisions.

**229.001 (Panel)** Temporal Patterns of Automatically Measured Nonverbal Communication in ASD  
**C. Bloch**, *Department of Psychiatry and Psychotherapy, LMU Hospital Munich, Munich, Germany*

Background: Interpersonal synchrony as a correlate of functional communication leads to prosocial effects such as sympathy, empathy and rapport. But what mechanisms underly interpersonal synchrony?

The timing of signals within persons in interaction could play an important role for the coordination of signals between subjects. The multimodal temporal coupling of different nonverbal channels describes the level of intrapersonal synchrony. Empirical evidence for motor and sensory timing peculiarities in autism-spectrum-disorder (ASD) imply that the intrapersonal temporal coupling of nonverbal channels in individuals with ASD may underly temporal mechanisms that could be discriminable from controls.

Objectives: Aim of this study is to investigate the temporal coupling of gaze with a pointing gesture as effect size of intrapersonal synchrony. Including adults with ASD and controls should reveal typical coupling mechanisms and potential deviations in the diagnosis group.

Methods: A preliminary sample of participants with F84.5 diagnosis ( $N = 15$ ) according to ICD-10 and an age, gender and IQ-matched control group ( $N = 15$ ) was raised. Patients have been recruited from an outpatient clinic for autism in adulthood where diagnosis was confirmed by consensus diagnostic of two independent clinicians.

During the study which was performed in a standardized interpersonal setup the experimental conductor took the role as the interaction partner of the participant. Conductor and participant sat opposite each other and a display was placed between them facing the participant. In 4 blocks with 30 trials each the task of participant was to let the interaction partner know on which side

a target appears by means of gaze and pointing gesture. Each trial started with mutual eye contact as initial shared attention after which the target was presented. An Eyelink 1000 plus (SR Research) controlled with a connection via Pylink (Psychopy) allowed for the detection of saccade onsets and pointing onsets by key release in a temporal resolution of 1000 fps. Objective of investigation was the temporal interval between the onsets of gaze and gesture.

Results: A linear mixed effects model including group as fixed factor and subjects as random factor for the temporal interval between gaze and gesture onset explains significantly more variance than the model without the group factor ( $\chi^2(1) = 4.89, p = .027$ ) indicating a significantly bigger temporal gap between the nonverbal signal onsets in the ASD group ( $M = 271.03$  ms,  $SD = 81.45$  ms) compared to controls ( $M = 211.58$  ms,  $SD = 62.67$  ms).

Conclusions: These preliminary results support the hypothesis of peculiar intrapersonal temporal coupling of nonverbal channels in ASD. The sample need to be filled and additional covariates need to be assessed in order to draw clear conclusions from this study.

**229.002** (Panel) A Computer Vision Approach for Classifying Autistic Behaviour during Dyadic Interactions  
*A. L. Georgescu, King's College London, London, United Kingdom*

---

Background: Successful social encounters depend unarguably to a large degree on the smooth exchange of nonverbal cues between two or more interaction partners. Impairments in exchanging nonverbal cues are characteristic of developmental disorders such as Autism Spectrum Conditions (ASC). Thus, modelling nonverbal behaviours is a well-fitting means for developing automatic diagnostic tools.

Objectives: The main goal of this work is to introduce a proof-of-concept method of automatic analysis of autistic behaviour in dyadic interactions between two human adults, which is minimally invasive and easily scalable.

Methods: In this paper we focus on the computational analysis of nonverbal behaviours in dyadic social interactions between two adults. There are three dyad types, composed of either two typical individuals (10 dyads), two autistic individuals (10 dyads) or one typical and one autistic individual (9 dyads). Each dyad interacts in five different scenarios. We extracted two 60 second clips from each scenario of each dyad. In this way, we obtained 11 short clips for each dyad group resulting in 317 clips in total. We then used computer vision tools like OpenPose and the Looking-At-Each-Other network to extract both individual features (i.e. head, hand and leg movement) and interpersonal features (i.e. mutual gaze and head, hand and leg synchrony) from videos, which were then used to train two classical machine learning methods (i.e. support vector machines and random forests).

Results: Our results show that the proposed approach can detect ASC (random forest) at a performance of 70% and recognise dyad type at a performance of 72%, which has implications for minimally invasive autism screening. For both classifiers, interpersonal features provided better results as compared to individual features and combining all the features clearly improved the performance. For example, when random forest was used for the classification of autism, combining all the features outperformed using the individual features by a margin of 12% and using the interpersonal features by a margin of 2%.

Conclusions: In a proof-of-concept study, we demonstrate that it is possible to classify adults with ASC from TD based on nonverbal behaviours using a computer vision approach. We also show that including dyadic nonverbal behaviours improves predictive performance.

**229.003** (Panel) Social Synchrony in Interpersonal Settings for Automatic Classification of Autism Spectrum Disorder  
*J. Köhler, LMU Munich, Munich, Germany*

---

Background: Fundamental deficits in social interaction and communication are characteristic for people on the autism spectrum. These deficits are visible, amongst others, in reduced temporal coordination with other individuals, frequently termed interpersonal synchrony. Rising prevalence rates as well as time-consuming diagnostic processes call for advancements in the diagnosis of ASD. Though often classified as a disorder of social interaction, integrating this interpersonal aspect into an objective diagnostic process for ASD remains a challenge. The increasing overlap between psychiatric research and machine learning techniques offers promising approaches to classify ASD from phenomenological, behavioral or biological data.

Objectives: A thorough investigation of these coordination deficits in naturalistic social settings and their potential use for (differential) diagnosis is currently lacking. The following studies aim at objectively capturing interpersonal synchrony in autistics adults across multiple modalities and ultimately combining machine learning techniques for classification to aid the diagnostic process.

**Methods:** Patients seeking diagnosis in two specialized autism outpatient clinics were filmed during their initial diagnostic interviews. Interpersonal movement synchrony between patient and diagnostician was measured using Motion Energy Analysis (MEA; Ramseyer & Tschacher, 2011). Importantly, the diagnosticians were naïve to diagnosis at the time of recording. Only after patients went through the full diagnostic process according to German S3- guidelines, they were allocated to the respective groups ASD+ (patients receiving an autism diagnosis) and ASD- (patients for whom any autism diagnosis was ruled out). Additionally, screening measures of autism symptom severity (autism quotient, empathy quotient, adult dyspraxia checklist) were collected. In a second study (Georgescu et al., 2019), a support vector machine classification algorithm was trained on INTRApersonal (between head and body movement) synchrony data of interaction dyads consisting of either one or two ASD patients as well as typically-developing control dyads. Further, this experimental setup is currently expanded to include additional behavioral and biological measures such as analysis of facial expression or speech as well as physiological and endocrinological parameters.

**Results:** Results for the first study showed significantly reduced movement synchrony between patient and diagnostician in the group of patients later diagnosed with ASD while there were no differences for the standard diagnostic screening tools, movement difficulties or the total amount of movement. In the second study, our classification algorithm was able to classify autistic and typically-developing adults with a balanced accuracy of 75.9%. The contribution of additional objective behavioral and biological parameters of social interactions to diagnostic classification remain to be investigated.

**Conclusions:** Combined with further (objective) behavioral and clinical parameters, social interaction settings provide opportunities to refine the diagnostic process for ASD. Furthermore, integrating social interaction data with machine learning techniques may aid in capturing the heterogeneous phenotype of ASD in the future.

**229.004 (Panel) Automated Analysis of Social Interaction Behavior in Autism Spectrum Conditions (ASC)**  
**H. Drimalla, University of Bielefeld, Bielefeld, Germany**

---

**Background:** Difficulties in social communication and interaction are a core diagnostic criterion of autism spectrum conditions (ASC). Objective measurement and quantification of social interaction abilities could improve diagnostic processes and support therapeutic interventions.

**Objectives:** Using two newly developed standardized tasks and automated video analysis we aimed to quantify the nonverbal communication abilities of people with ASC and neurotypical participants.

**Methods:** In two studies, we measured different aspects of social interaction behavior of people with ASC and neurotypical participants.

The first study used a newly developed naturalistic interactive task, that consists of a standardized 7-minute simulated dialogue via video and automated analysis of facial expression, gaze behavior and voice characteristics. We compared nonverbal social interaction behavior of 37 individuals with ASC and 43 healthy controls using automated analysis of this task and evaluated the task's diagnostic value.

The second study compared instructed facial imitation between 39 individuals with ASC and 41 healthy controls. Using computer-based face analysis and a newly developed emotion imitation and recognition test, we related individuals' voluntary facial imitation to their recognition abilities.

**Results:** The two new paradigms combined with automated video analysis allowed us to detect and quantify differences in social interaction behavior between individuals with ASC and neurotypical controls.

Using the naturalistic interactive task, we were able to identify individuals with ASC with an accuracy comparable to expert ratings, based on facial expressions and voice characteristics alone. Individuals with ASC were characterized by a reduced social smile and facial imitation, as well as a higher vocal base frequency and a higher harmonic noise ratio.

The imitation and recognition tasks showed that individuals with ASC recognized fewer emotions from facial expressions correctly and were slower and less precise in imitating the facial expressions than neurotypical individuals. In both groups, a stronger as well as a more precise imitation scaled positively with an participants' accuracy of emotion recognition.

**Conclusions:** The use of digital paradigms in combination with automatic video analysis and machine learning methods seems promising to measure social-interactive impairments more precisely and to understand them better. In a next step, we plan to

compare interaction behavior across different psychopathologies and assess the diagnostic specificity of digital interaction analysis.

## ORAL SESSION — ADULT OUTCOME: MEDICAL, COGNITIVE, BEHAVIORAL, SOCIAL, ADAPTIVE, VOCATIONAL

### Oral 301 - Social, Sexual and Neuropsychiatric Health in Autistic Adults

**301.001** (*Oral*) Healthy Relationships for Autistic People: Intervention Development

**E. F. Rothman<sup>1</sup>** and **L. Graham Holmes<sup>2,3</sup>**, (1)Community Health Sciences, Boston University School of Public Health, Boston, MA, (2)Boston University School of Public Health, Boston, MA, (3)Hunter College, City University of New York, New York City, NY

#### **Background:**

Research has established that for many autistic youth, loneliness, social isolation, peer harassment, and dating and sexual aggression victimization are significant problems.<sup>1-5</sup> One in four experiences bullying by peers.<sup>2</sup> Neurotypical people also experience challenges in their relationships, so these problems are not unique to autistic individuals, but autistic youth may have fewer opportunities to engage in informal learning from peers about how to establish and maintain healthy relationships. Moreover, school-based healthy relationships promotion programs are rare, and autistic youth likely have even less access to these types of programs than neurotypical peers. Importantly, “healthy relationships” programs (i.e., how to avoid toxic relationships) are very different from social skills interventions that teach the mechanics of meeting people and holding polite conversations. There is a critically important gap in the field: healthy relationships programs for autistic youth are urgently needed.

#### **Objectives:**

The purpose of this study was to gather formative data to inform a new healthy relationships intervention for autistic youth.

#### **Methods:**

Twenty-five youth 16-22 years old were recruited for a qualitative interview study via social media advertising and databases of prior research participants. Youth were eligible if they were: (1) 16-22 years old; (2) living in the U.S.; (3) English-speakers; (4) Had a diagnosis of autism from a professional, verified by reviewing documentation; (5) Had  $\geq 1$  close friend; and (6) Demonstrated ability to complete an interview. Eligible participants or their parent completed the SRS-2. Interviews took place over Zoom. Participants were given the option of speaking aloud with the camera on or off, or using the chat feature to text. Interview questions are available in Table 1. Spoken interviews were audio-recorded and transcribed. We used Dedoose software to organize text into excerpts. Two independent raters coded each excerpt using an inductive approach to identify themes. Illustrative quotations that exemplified each theme were selected for presentation (see Table 2).

Of 61 individuals interested in study participation, 35 were eligible. Ten did not complete the interview scheduling process. Of the 25 interviewed, 72% were white, 12% were multiracial, 8% were Black and 8% were Asian. Forty-four percent were male, 44% female, and 12% non-binary gender. The mean age was 18 years old. Participant SRS-2 T-scores (mean=92.3, SD=11.2) were consistent with autism symptoms in the severe (96%) or moderate (4%) range.

#### **Results:**

Participants reported that healthy relationships were ones in which they could be their authentic selves without “conforming,” where there was reciprocity, they listened to one another’s problems, and they could “vent.” Some expressed a desire for advice about dating as an asexual person, expressed that they lacked training on consent and sexual boundary setting, navigating breakups, and coping with hurt. Participants expressed a preference for a class co-taught by a neurotypical and autistic adult and favored mixed gender students.

#### **Conclusions:**

The content of the intervention in development should emphasize the importance of feeling like one's natural self in healthy relationships, how to set boundaries and negotiate consent, feature autistic and neurotypical team teaching, and be offered to mixed gender groups.

### **301.002** (Oral) The Sexual Preferences and Sexual Health of Autistic Adults

*E. Weir, C. Allison and S. Baron-Cohen, Autism Research Centre, Department of Psychiatry, University of Cambridge, Cambridge, United Kingdom*

---

**Background:** Autistic individuals, and particularly autistic females, may identify with a wider diversity of sexual orientations than others.<sup>1,2</sup> Although the majority of autistic individuals are interested in sexual or romantic relationships, there is some evidence that autistic individuals may have reduced sexual libido or be more likely to identify as asexual.<sup>2,3</sup> Studies also suggest that autistic individuals may have reduced likelihood of contracting sexually transmitted infections (STIs) than non-autistic individuals;<sup>4,5</sup> however, no existing studies consider whether asexuality or lack of sexual activity may explain this reduced risk.

**Objectives:** To explicate the sexual preferences, activity, and health of autistic adults, as well as to identify the sex differences in these patterns. In addition, we hoped to clarify the relative risk of STIs among sexually active autistic individuals.

**Methods:** We disseminated an anonymized, online survey to n=2,386 adults (n=1,183 autistic) aged 16-90 years of age. We employed unadjusted (Fisher's exact tests) and adjusted (Binomial Logistic Regression) models to describe the sexual activity, risk of contracting STIs, and sexual orientation of autistic and non-autistic adults. We used z-scores to estimate relative differences between females and males to identify sex differences in these areas.

**Results:** For every ten non-autistic people who report ever being sexually active, only four autistic people report the same (OR: 0.383; 95% CI: 0.283–0.517; FDR:  $2.18 \times 10^{-9}$ ). In addition, autistic adults are three to nine times more likely to be asexual, homosexual, or 'other' sexuality; similarly, they were less likely to be heterosexual. There were no differences in age of sexual activity onset or self-reported contraction of STIs; full results are provided in Table 1. When evaluating sex differences, autistic males are uniquely likely to be bisexual (OR: 3.382; 95% CI: 1.716 – 6.666; p-value:  $4.478 \times 10^{-4}$ ), whereas there are no significant differences in rates of bisexuality between autistic and non-autistic females (OR: 1.263; 95% CI: 0.942 – 1.695; p-value: 0.119). Conversely, autistic females are uniquely likely to be homosexual (OR: 3.275; 95% CI: 1.922 – 5.579; p-value:  $1.341 \times 10^{-5}$ ), with no difference in rates of homosexuality between autistic and non-autistic males (OR: 0.708; 95% CI: 0.408 – 1.228; p-value: 0.219). Full results of sex differences are provided in Table 2.

**Conclusions:** Autistic males or females are more likely to identify as asexual, bisexual, and homosexual, as well as less likely to identify as heterosexual; these patterns vary based on sex. Further, though a majority reported being sexually active, both autistic males and females were less likely than others to have been sexually active. Crucially, there were no differences in age of sexual activity onset or likelihood of contracting STIs among sexually active individuals. This is the largest study of sexual health and preferences of autistic adults, and of autistic females without intellectual disability. Sexual education and sexual health screenings of autistic adults must remain priorities; healthcare professionals should focus on using language that affirms a diversity of sexual preferences and orientations and supporting autistic patients who may be experiencing minority stress due to this intersectionality.

### **301.003** (Oral) Functional Impacts of Co-Occurring ADHD Symptoms in Autism across Adulthood

*S. C. Duane<sup>1</sup>, B. E. Yerys<sup>2</sup>, G. McQuaid<sup>3</sup>, N. R. Lee<sup>4</sup> and G. L. Wallace<sup>1</sup>, (1)The George Washington University, Washington, DC, (2)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (3)G, Washington, DC, (4)Drexel University, Philadelphia, PA*

---

**Background:**

Adults with autism spectrum disorder (ASD) self-report attention-deficit/hyperactivity disorder symptoms (ADHD) more frequently than the general population. Nevertheless, very little research has examined the presence of ADHD symptoms in ASD and their potential impact on quality of life and adaptive skills during adulthood. In childhood and adolescence, co-occurring ADHD in the context of ASD has been linked with poorer quality of life and more limited adaptive functioning compared to those without ADHD.

**Objectives:**

Examine the association between co-occurring ADHD and measures of subjective quality of life and adaptive skills in autistic adults.

Methods:

Participants (n=731) were recruited via Simons Powering Autism Research and Knowledge (SPARK) and included adults with a professional diagnosis of ASD (58% female) ranging in age from 18-83 (M=40) years. Participants completed questionnaires online, including measures of ADHD symptoms, subjective quality of life, and adaptive skills. ADHD was treated as both a categorical variable (self-report yes [ASD+ADHD] or no [ASD-ADHD] for an accompanying ADHD diagnosis based on a previously given or current diagnosis) and dimensional variable (ADHD symptom screen). For categorical analyses, three analyses of covariance (ANCOVAs), accounting for the effects of age, sex assigned at birth, socioeconomic status, autistic traits, anxiety symptoms, and depression symptoms, were used to examine ASD+ADHD vs. ASD-ADHD differences in subjective quality of life and adaptive skills. For dimensional analyses, five linear regressions examined associations between continuous ADHD symptoms and subjective quality of life and adaptive skills using the same covariates. Bonferroni corrections were applied to the ANCOVAs (adjusted threshold:  $p < .0167$ ) and regression analyses (adjusted threshold:  $p < .01$ ) to adjust for multiple comparisons.

Results:

Utilizing a lifetime ADHD diagnosis to delineate groups (39% yes in this sample) revealed lower physical health quality of life among ASD+ADHD as compared to ASD-ADHD, after accounting for the entered covariates ( $F=4.25, p=.04, h_p^2=.007$ ); however, this did not survive correction for multiple comparisons. Examining continuous ADHD symptoms and their contribution to variance in quality of life and adaptive skills showed considerably more effects. Increasing ADHD symptoms (even after accounting for the effects of all covariates and an adjusted  $p$  value) were significantly associated with decreased physical health ( $t=3.50, p<.001, \Delta R^2=.01$ ) and environmental (home, resources, etc.) health ( $t=3.96, p<.001, \Delta R^2=.02$ ) quality of life and with poorer daily living skills ( $t=5.88, p<.001, \Delta R^2=.04$ ).

Conclusions:

Although a large number of adults with ASD in the current study reported having a current or prior diagnosis of ADHD, this categorical delineation was not predictive of adult outcomes. In contrast, a dimensional examination revealed that higher current ADHD symptoms were associated with poorer subjective quality of life and adaptive daily living skills among ASD adults. Therefore, rather than qualitative distinctions among ASD adults based on the presence/absence of an ADHD diagnosis, a dimensional perspective might better inform our understanding of adult outcomes and ways to improve them. Targeting ADHD may have important implications for improving both independent living and quality of life for ASD adults. Future studies also should evaluate outcomes for 'well-treated' versus treatment-resistant ADHD in ASD adults.

**301.004 (Oral)** Are Parkinsonism Features in Autism during Middle and Older Adulthood Linked with Poor Outcomes?  
**G. L. Wallace<sup>a</sup>** and **G. McQuaid<sup>b</sup>**, (1)The George Washington University, Washington, DC, (2)G, Washington, DC

---

Background:

Emerging evidence links Parkinsonism (i.e., motoric features associated with Parkinson's Disease [PD], such as limb stiffness and bradykinesia) with autism spectrum disorder (ASD), above and beyond usage of antipsychotics. For example, several studies have found increased rates of PD diagnoses in both younger and older ASD adults and one study has found elevated Parkinsonism features in two samples of older ASD adults. However, research to date has yet to examine whether adults with both ASD and elevated Parkinsonism features experience worse outcomes than those without these motor symptoms.

Objectives:

Examine associations between parkinsonism features and middle and older adult outcomes in ASD.

Methods:

406 adults with ASD (57% female) ranging in age from 40-83 (M=52) years were recruited via Simons Powering Autism Research and Knowledge (SPARK). They each completed a battery of questionnaires online. The presence of parkinsonism features was evaluated using the weighted cut-off score from the Parkinsonism Screening Questionnaire (PSQ) resulting in

ASD+Park and ASD-Park groups. Subjective quality of life was measured using the four dimensions (physical health, psychological health, social relationships, and environmental health) of the World Health Organization Quality of Life-BREF questionnaire and the complementary Autism Quality of Life scale. Adaptive functioning was measured using the Waisman Activities of Daily Living scale. Memory abilities were assessed using the Prospective/Retrospective Memory Questionnaire. A series of analyses of covariance (ANCOVAs) accounting for the effects of age, sex assigned at birth, autistic traits, and current antipsychotics usage were used to examine ASD+Park vs. ASD-Park differences in subjective quality of life, adaptive skills, and memory functioning. In complementary analyses, multiple linear regressions examined links between (unweighted) continuous PSQ ratings and subjective quality of life, adaptive skills, and memory functioning, separately, using the same covariates.

#### Results:

135 (33%) of these ASD adults met screening criteria for parkinsonism on the PSQ. The ASD+Park group reported significantly poorer subjective quality of life across all dimensions ( $F_s > 5.18$ ,  $p_s < .05$ ,  $\eta^2_s > .015$ ), including the autism-specific scale ( $F = 10.00$ ,  $p = .002$ ,  $\eta^2 = .03$ ), more limited adaptive skills ( $F = 14.33$ ,  $p < .001$ ,  $\eta^2 = .04$ ), and poorer memory ( $F_s > 11.97$ ,  $p_s < .001$ ,  $\eta^2_s > .035$ ) compared to the ASD-Park group. Similarly, linear regression analyses revealed that increasing parkinsonism features in the entire ASD sample were significantly predictive of decreased subjective quality of life, adaptive skills, and memory ( $t_s > 5.20$ ,  $p_s < .001$ ,  $\Delta R^2_s \geq .06$ ) after accounting for covariates.

#### Conclusions:

Converging with prior studies, we find elevated rates of parkinsonism features among middle and older adults with ASD. Extending this work, the current study provides the first evidence that elevated parkinsonism features are linked with poor outcomes across domains important for everyday functioning during middle and older adulthood in ASD. This study therefore highlights the importance of further investigating parkinsonism risk and etiology in ASD, particularly given the rising numbers of adults with ASD, whether newly diagnosed or those aging with a pre-existing diagnosis.

## ORAL SESSION — ADULT OUTCOME: MEDICAL, COGNITIVE, BEHAVIORAL, SOCIAL, ADAPTIVE, VOCATIONAL

### Oral 315 - Contributing Factors and Pathways to Autistic Adult Mental, Behavioral and Social Outcomes

**315.001** (Oral) Predicting Uncertain Multi-Dimensional Adulthood Outcomes from Childhood and Adolescent Data in People Referred to Autism Services

*G. Forbes<sup>1</sup>, C. Lord<sup>2</sup>, R. Elias<sup>2</sup> and A. Pickles<sup>1</sup>, (1)King's College London, Institute of Psychiatry, Psychology and Neuroscience, London, United Kingdom, (2)University of California, Los Angeles, Los Angeles, CA*

#### Background:

Due to the heterogeneous nature of autism spectrum disorder (ASD) it is difficult to provide a long term prognosis for a child. Nonetheless, the question of what the future may hold is important - to support planning, identify areas for intervention, and to provide insight into a diagnosis. A well rounded description of a child's adult outcome requires a diverse set of measures, including cognitive function, mental health and well being, behavioral domains, the extent of autism symptoms, and a persons work and living situation. We consider the challenge of making individual predictions of the multi-faceted adult outcome for a child referred to autism services, based on assessments made throughout childhood and adolescence. This allows us to better identify aspects of the outcome that are likely determined by early childhood, predictable only by measures taken in late adolescence, or aspects less amenable to prediction.

A comprehensive personalized prediction of potential adult outcomes for an individual may present challenges in interpretation due to the number of outcomes measures that can be considered. We also explore predicting a single personalized outcome created from the priorities across adult outcomes measures for a particular individual.

#### Objectives:

To assess which aspects of the adult outcome are predictable and from which ages good predictions can be made. Secondly to consider whether priorities for a particular individual can be incorporated into predictions of adult outcomes by forming a personalized outcome.

## Methods:

We used data from 123 adults participating in the Autism Early Diagnosis Cohort. Participants were recruited from autism programs in North Carolina, Chicago, and Michigan, from age 2 and followed up repeatedly through childhood and adolescence to adulthood. We predicted 14 adult outcome measures including cognitive, behavioral and well being measures. Continuous outcomes were modeled using lasso regression and ordinal outcomes were modeled using proportional odds regression. Optimism corrected predictive performance was calculated using cross-validation or bootstrap. We also illustrated the prediction of an overall composite formed by weighting outcome measures by priorities elicited from parents.

## Results:

We found good predictive performance from age 9 for verbal and non-verbal IQ, and daily living skills. Predictions for symptom severity, hyperactivity and irritability improved with inclusion of behavioral data collected in adolescence but remained modest. For other outcomes covering well being, depression, and positive and negative affect we found no ability to predict adult outcomes at any age. Predictive performance is shown in figures 1. Predictions of composites based on parental priorities differed in magnitude and precision depending on which parts of the adult outcome were given more weight.

## Conclusions:

Verbal and non-verbal IQ, and daily living skills can be predicted well from assessments made in childhood. For other adult outcomes, it is challenging to make meaningful predictions from assessments made in childhood and adolescence using the measures employed in this study. Future work should replicate and validate the present findings in different samples, investigate whether the availability of different measures in childhood and adolescence can improve predictions, and consider systematic differences in priorities.

### 315.002 (Oral) Sources of Sexuality and Relationship Education for Adults in the United States

*E. T. Crehan<sup>1,2</sup>, J. Rocha<sup>1</sup> and S. R. Dufresne<sup>1</sup>, (1)Eliot-Pearson Department of Child Study & Human Development, Tufts University, Medford, MA, (2)Department of Psychiatry, AARTS Center, Rush University Medical Center, Chicago, IL*

---

## Background:

Sexuality and relationship education (SRE) is designed to provide positive physical, mental, and social outcomes. Understanding where adults look for and find SRE knowledge is key to continued development and dissemination of accessible and tailored SRE programming. Especially for autistic adults who are less likely to have comprehensive SRE experiences, characterizing the utilization rates of sources of information across various SRE content areas is necessary to inform educational models moving forward.

## Objectives:

To identify sources of SRE for adults with and without autism.

## Methods:

A total of 132 US-based adults were included in the final sample, of which 44 participants were previously diagnosed with ASD and 88 were neurotypical (NT), based on self-report. Participants had a mean age of 25.96 years (SD = 5.88) and represented 23 states. Genders reported included: 49% women, 31.2% men, 3% non-binary, 16.6% chose not to identify. 63% of respondents were White, 5% Hispanic/Latino, 7.5% Black, 4.5% Asian, 4.5% as Multiracial, and 14.3% chose not to identify. The average Autism Quotient-10 score was 4.77 (SD 2.29).

Participants were recruited through social media to complete an anonymous online survey. Autistic and NT adults were compared on sources of SRE information by topic. Sources of information included internet website of verifiable quality, internet website of non-verifiable quality, romantic partner, similar-age peer (e.g., within two years of own age), friend more than two years younger, friend more than two years older, parents, siblings, mentors, care providers, other). Topics included gender identity, sexual orientation, partnered sexual acts, non-partnered sexual acts, kissing, flirting, dating, consent, assertiveness.

## Results:

Autistic adults were significantly less likely to learn information about Flirting (41.5% ASD vs. 65.9% NT;  $\chi^2(1, N = 132) = 8.14, p < .01$ ), Dating (41.5% ASD vs 65.9% NT;  $\chi^2(1, N = 132) = 8.14, p < .01$ ), and Consent (32.1% ASD vs. 54.9% NT;  $\chi^2(1, N = 132) = 7.04, p < .01$ ) from similar age peers than their neurotypical counterparts. For partnered sexual behaviors, romantic partners were endorsed as a source of information by a significantly lower percentage of the autistic respondents (37.7 %) than of the NT participants (60.4%) ( $\chi^2(1, N = 132) = 6.92, p < .01$ ). Across the remaining five content areas, no diagnostic group differences emerged across the surveyed sources of information. Figure 1 shows break down of sources of information combined across diagnostic groups. For these content areas, the internet emerged as the significantly most consulted source, followed by peers, followed by parents, providers, and mentors.

## Conclusions:

Diagnostic group differences reflect that autistic adults have less access to the peer-based, informal learning that promotes SRE knowledge. Autistic people would benefit from SRE that augments learning in these content areas since traditional peer sources of information may be underutilized. Of note, the internet was the most used source of information across topics and diagnostic groups. This highlights the need for including internet literacy as part of SRE programs and for increasing comfort and resources for parents, providers, and mentors on SRE topics so that they can serve as alternative sources of information.

**315.003** (Oral) Is Camouflaging Autistic Traits Associated with Defeat, Entrapment and Suicidal Thoughts? Expanding the Integrated Motivational Volitional Model of Suicide.

**S. A. Cassidy<sup>1,2,3</sup>, E. McLaughlin<sup>1</sup>, R. McGranaghan<sup>1</sup>, M. K. Pelton<sup>1</sup>, S. Baron-Cohen<sup>2</sup>, R. O'Connor<sup>4</sup> and J. Rodgers<sup>3</sup>,** (1)School of Psychology, University of Nottingham, Nottingham, United Kingdom, (2)Autism Research Centre, Department of Psychiatry, University of Cambridge, Cambridge, United Kingdom, (3)Population Health Sciences Institute, Newcastle University, Newcastle upon Tyne, United Kingdom, (4)Coventry University, Coventry, United Kingdom, (5)University of Glasgow, Glasgow, United Kingdom

---

## Background:

Camouflaging autistic traits to 'fit in' in social situations is associated with suicidal thoughts and behaviours, but it is unclear why. One potential reason could be that camouflaging autistic traits contributes to feelings of defeat and entrapment – known risk markers for suicidal thoughts in the general population, as outlined in the Integrated Motivational Volitional Model of Suicide. For example, if one continues to experience social difficulties and exclusion despite one's best efforts to camouflage, leading to feelings of a failed social struggle (defeat), and that this situation will never change (entrapment).

## Objectives:

1) To test whether camouflaging autistic traits is associated with feelings of defeat and entrapment; 2) To test whether camouflaging and feelings of defeat and entrapment together are associated with suicidal thoughts; 3) To test whether camouflaging autistic traits is associated with suicidality through defeat and entrapment.

## Methods:

180 UK undergraduate students (76.7% female, 18-67 years) completed a cross-sectional online survey from 5<sup>th</sup> February – 23<sup>rd</sup> March 2020 including self-report measures of defeat and entrapment, autistic traits, current depression and anxiety symptoms, camouflaging autistic traits, and lifetime suicidal thoughts and behaviours. Multiple hierarchical regression explored whether autistic traits and camouflaging predicted defeat and entrapment. Logistic regression explored whether defeat and entrapment, and camouflaging, predicted lifetime suicidal thoughts. Serial mediation analysis explored whether the association between autistic traits and lifetime suicidality was significantly mediated by camouflaging, defeat and entrapment.

## Results:

After controlling for age, gender, current depressive and anxiety symptoms, autistic traits accounted for significantly more of the variance in defeat and entrapment (1.1%), and camouflaging accounted for a further 3.2% of the variance. After controlling for age, gender, current depression and anxiety symptoms, defeat and entrapment (but not camouflaging) accounted for significantly more variance in lifetime suicidal thoughts. However, the interaction between defeat and entrapment and camouflaging accounted for significantly more variance in lifetime suicidal thoughts than either variable alone. The association between autistic traits and lifetime suicidality was significantly mediated by camouflaging, defeat and entrapment.

Conclusions:

This is the first study to show that camouflaging autistic traits in order to fit in social situations, is associated with feelings of defeat and entrapment, and lifetime suicidal thoughts, as predicted by the IMV. Results are consistent with the interpretation that camouflaging autistic traits together with feelings of a failed social struggle (defeat) and that this situation will never change (entrapment), are particularly associated with increased risk of suicidal thoughts. This suggests that it is perhaps when social difficulties continue despite one's best efforts with a perception that this situation will never change, that particularly increases vulnerability to suicidal thoughts.

**315.004 (Oral)** The Role of Social Competence and Quality Interactions on Autism Stigma

*M. Sait<sup>1</sup>, N. E. Scheerer<sup>2</sup>, R. A. Stevenson<sup>3</sup>, T. Q. Boucher<sup>4</sup> and G. Iarocci<sup>1</sup>, (1)1151 Richmond St, Western University, London, ON, Canada, (2)Psychology, Western University, London, ON, Canada, (3)Brain and Mind Institute, University of Western Ontario, London, ON, Canada, (4)Psychology, Simon Fraser University, Burnaby, BC, Canada*

---

**Background:** One of the predominant factors contributing to autism stigma is the breakdown in social communication between that of an autistic individual and a typically-developing individual. As such, autistic individuals often have trouble navigating social environments. This often leads to the formation of both negative perceptions of, and discriminatory behaviours towards, autistic individuals by typically-developing individuals. Fortunately, research has demonstrated that quantity and quality of contact with autistic individuals may decrease autism stigma. However, the extent to which autism stigma is reduced is unclear. Further, it is unclear whether additional factors may also reduce autism stigma.

**Objectives:** The objective of this study is to assess whether a relationship exists between autism stigma and the following three variables: social competence, the level of contact with autistic individuals, and the quality of contact with autistic individuals.

**Methods:** Participants (N=242, Mage=18.48, SDage=2.60) were recruited from university and high school in British Columbia. Participants were asked to participate in the autism stigma task, designed by Sasson and colleagues (2017) where they rated ten second clips of autistic and non-autistic individuals auditioning for a game show. Participants were asked to rate the individuals in the video clips on various traits such as attractiveness and intelligence, as well as rate their (participants) own behavioural intentions and attitudes towards the individuals in the video clips such as their willingness to spend time with them. Following this task, participants were asked to fill out a series of questionnaires assessing their own social competence and their quality and level of contact with autistic individuals.

**Results:** Autistic individuals were rated more negatively overall on both traits ( $t(241)=-21.12, p<.001$ ) and behavioural intentions ( $t(241)=-16.3, p<.001$ ). Correlational analyses also indicated a significant relationship between autism trait stigma and social competence ( $r(240)=.2, p=.002$ ) but not autism trait stigma and quality of contact ( $r(240)=-.107, p=.100$ ). Additionally, a correlation was found between autism behavioural intention stigma and social competence ( $r(240)=.194, p=.003$ ), as well as autism behavioural intentions stigma and quality of contact ( $r(240)=-.182, p=.005$ ). There was no significant relationship between autism stigma overall and level of contact.

**Conclusions:** The positive relationship between social competence and both autism trait and behavioural intention stigma indicates that individuals who are more socially competent tend to have stronger biases against autistic individuals. This is likely due to the fact that individuals who are more socially competent are better at identifying social faux pas in other individuals. However, those who are higher in social competence tend to demonstrate higher levels of social motivation. Creating opportunities for these individuals to engage with autistic individuals may represent an effective way to reduce autism stigma. Additionally, given the significant relationship between quality of contact and autism behavioural intentions, interventions designed to decrease autism stigma should focus on creating environments wherein quality interactions between autistic and typically developing individuals can occur.

**POSTER SESSION — ADULT OUTCOME: MEDICAL, COGNITIVE, BEHAVIORAL, SOCIAL, ADAPTIVE, VOCATIONAL**

**401.001 (Poster)** "Realizing the Problem Wasn't Necessarily Me": An Exploration of the Meaning of Childhood Adversity and Resilience in the Lives of Autistic Adults

**Background:** Little is known about the influence of childhood adversity and resilience on children on the autism spectrum, despite evidence that they experience more adversity than their peers. The high incidence of adversity in the lives of children on the autism spectrum arguably influences their lifelong mental health and emotional well-being. Furthermore, the development and characterization of resilience in children on the spectrum is not understood. Therefore, to improve lifelong mental health outcomes among individuals on the autism spectrum, it is vital to understand how they experience adversity and resilience, and the role of these phenomena on their well-being.

**Objectives:** Interpretative phenomenological analysis (IPA) was used to understand the influence of childhood adversity on the well-being of adults on the autism spectrum, and the meaning of resilience in their lives. Specifically, we asked autistic adults to describe their experiences of childhood adversity, the impact of those experiences, and the characteristics and quality of resilience in their lives.

**Methods:** This study involved two phases. First, to align the study with the desires and perspectives of the autistic community, five advisors from the autistic and autism communities were consulted to ensure a rigorous research design. Their advice informed recruitment and data collection methods, and provided cultural understanding through which to conduct data analysis. Subsequently, four adult women, aged 19-27, diagnosed with autism prior to age 18, participated in semi-structured indepth interviews. Participants were offered several interview options based on their preference. Ultimately, data were generated through one recorded video interview, two recorded telephone interviews, and one online chat-based interview. Data were analyzed case by case and then across cases; participants' descriptions of their lived experiences were interpreted and synthesized thematically.

**Results:** Participants described childhood experiences which they viewed as significantly adverse, and ongoing and pervasive impacts of these experiences on their social, emotional, and mental well-being. Overall, adversity influenced 1) social disconnection, 2) emotional and mental health well-being, 3) development into young adulthood, and 4) sense of self. Despite negative childhood experiences, participants found resilience in places of refuge, both externally among attentive adults, accepting communities, and places to belong, and internally by engaging in interests, talents and imaginations; and from within their own identities, through self-understanding, determination, and a sense of pride. Finding resilience was meaningful for future growth and development, as participants described developing new social connections, the ability to adapt and change, and moving forward with their young adult lives.

**Conclusions:** By offering insights into childhood adversity, these findings increase awareness about the importance of considering childhood adversity in determining future directions for supporting the mental health of individuals on the autism spectrum. Also valuable are key findings about resilience and its role in autistic children and adults' ongoing well-being. This knowledge provides evidence and hope that the deleterious effects of adversity may be mitigated by promoting resilience-fostering experiences for children on the autism spectrum. These findings offer consideration regarding means to promote positive social, emotional, and mental health outcomes for individuals on the autism spectrum.

**401.002 (Poster)** A Comparison of Gender Differences in Self-Reported Camouflaging of Autistic Traits between Diagnosed Autistic, Autistic High-Trait and Non-Autistic Young Adults.

*V. L. Milner, E. Colvert and F. Happé, Social, Genetic and Developmental Psychiatry Centre, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom*

---

**Background:**

Camouflaging is a term used to describe conscious or unconscious behavioural strategies used to enable a person to "fit in" with a specific environment or conform to social norms (Hull, 2017). Although it is known that everyone will camouflage at some point in their lives (e.g. during a job interview), evidence suggests that autistic individuals camouflage more than the non-autistic population. Other studies have claimed that autistic females are more likely to camouflage than autistic males (Jorgenson et al, 2020), and this may contribute to the under-diagnosis of autism in girls and women (REF).

Addressing several limitations of the current camouflaging literature as flagged by Fombonne (2020), this study includes non-autistic comparison groups and uses a systematically recruited and longitudinal sample.

**Objectives:**

This study aims to compare self-reported scores on the Camouflaging Autistic Traits Questionnaire (CAT-Q) (Hull et al, 2019) between diagnosed autistic (Dx), high trait (HT) and non-autistic groups (NA), and between genders.

Hypotheses include:

1. Females will have higher scores on the CAT-Q regardless of sample group
2. There will be group differences for individual subdomains (masking, assimilation, compensating) of the CAT-Q

Methods:

A total sample of 435 participants were recruited from the Social Relationships Study (SR Study), a population based twin cohort and the Gender Differences in Social Coping (G-DISC) study, an online survey study. The sample consisted of 35 Dx males, 43 Dx females, 89 HT males, 88 HT females, 49 NA males and 131 NA females. All participants were aged between 20-25 years and lived in the UK.

Participants completed an online survey which included the CAT-Q and the Social Responsiveness Scale (SRS). For the diagnosed group, formal autism diagnosis was confirmed by participant and their parent.

Results:

A two-way ANOVA revealed significant main effect of group, but not sex on CAT-Q total and all subdomain scores. Post-hoc analysis revealed for total score, and the compensation and assimilation subdomains, the Dx and HT groups were significantly different to the NA group but not each other (all  $p < 0.001$ ). For the masking subdomain, HT groups had the highest scores and were significantly different to NA groups ( $p < 0.001$ ), but not Dx groups.

Conclusions:

Results indicate that people with high autistic traits camouflage their traits as much, if not more than, diagnosed autistic people. The increased rates of masking for the high trait group may be a barrier to diagnosis for some autistic people. Future directions for this work include exploring consequences associated with camouflaging such as loneliness and quality of life.

**401.003** (Poster) A Meta-Analysis and Critical Review of Metacognitive Accuracy in Autism Spectrum Disorder  
*K. Carpenter and D. M. Williams, University of Kent, Canterbury, United Kingdom*

---

**Background:** Metacognitive monitoring refers to awareness of our own mental states (Flavell, 1979). It is crucial for how we live our lives, and it underpins how we make sense of, predict, and control our own actions. There is a rich history of theorising about a potential link between metacognitive monitoring and mindreading (the ability to represent mental states in others). While some theories claim metacognition relies on the same cognitive processes as mindreading (Carruthers, 2009), others claim they rely on distinct processes (Nichols and Stich, 2003). Therefore, it is important for clinical practice and theory building to study metacognition in neurodevelopmental conditions, such as autism, which involve difficulties with mindreading.

**Objectives:** The aim of the current meta-analysis is to draw together all the research examining metacognitive monitoring accuracy in individuals diagnosed with autism to increase our understanding of the relationship between mindreading and metacognition, and to establish if individuals diagnosed with autism have difficulties with metacognition.

**Methods:** A literature search was conducted using Web of Science, PubMed and PsychInfo using the search terms “autism” AND “metacognition” for all articles published prior to June 2020. Eligible studies included participants of any age with a diagnosis of autism spectrum disorder and neurotypical controls. The tasks within the studies had to involve online explicit (i.e., verbal) metacognitive judgements and did not include any aspect that could result in improved metacognitive performance such as feedback or training. This resulted in a final sample of 17 independent studies with 20 different effect sizes.

**Results:** A total of 412 ASD and 453 NT control participants were included in the meta-analysis and a random effects model was used. The weighted effect size for the between-group difference in meta-monitoring ability was  $-0.39$  (SE 0.14, 95% CI -0.69 to 0.08) and statistically significant,  $z = 2.67$ ,  $p < .01$ . This suggests a moderate impairment of metacognitive accuracy in ASD. However, the homogeneity test was significant ( $Q = 77.23$ ,  $p < .001$ ), indicating that the variance across the effect sizes was greater than expected by sampling error. The heterogeneity suggests that deficits in metacognitive accuracy may be domain

specific rather than domain general. A subgroup analysis showed that metacognitive task may explain some of this variability, other issues including the age of the samples and will also be discussed.

**Conclusions:** The meta-analysis suggests there is a moderate difference in meta-cognitive accuracy among those diagnosed with autism and neurotypical controls. However, further analysis showed that these differences may be domain specific. Implications of the results for both theory development and clinical practice will be discussed, as will other important issues that require consideration when interpreting case-control studies of meta-cognition in ASD.

#### **401.004 (Poster) A Novel Measure of Adaptive Functioning in Young Adults with ASD**

*R. A. Wulff<sup>1</sup>, M. K. Krug<sup>1</sup>, A. M. Iosif<sup>2</sup>, P. D. Harvey<sup>3</sup> and M. Solomon<sup>4</sup>, (1)Department of Psychiatry & Behavioral Sciences, UC Davis MIND Institute, Sacramento, CA, (2)Public Health Sciences, University of California Davis, Davis, CA, (3)University of Miami, Miami, FL, (4)Department of Psychiatry and Behavioral Sciences, The Medical Investigation of Neurodevelopmental Disorders (MIND) Institute, UC Davis School of Medicine, University of California Davis, Sacramento, CA*

---

#### Background:

While adaptive functioning, or one's ability to accomplish tasks necessary for independent life in society, has repeatedly been shown to be impaired in individuals with autism spectrum disorders (ASD), virtually all adaptive functioning measures are parent or self-report questionnaires. In this study, we implemented a more ecologically valid computer administered laboratory task called i-Function, which can be used to both assess and train adults in skills that are important for independence (e.g., using an ATM, buying Metro tickets, renewing prescriptions), and has been validated in older adults with mild cognitive impairment and schizophrenia (Harvey et al., 2020; Czaja et al., 2017). Two task modules from i-Function were pilot tested in a group of adolescents and young adults with ASD to determine if i-Function detects deficits in the ASD group compared to the typically developing group (TYP) and if it validly measures adaptive functioning.

#### Objectives:

1. Determine if this high-IQ ASD group performs more poorly than the TYP group on i-Function.
2. Validate i-Function in ASD by examining its associations with other self-report questionnaire and laboratory measures of adaptive functioning.

#### Methods:

Participants were part of a longitudinal study of ASD and brain development. 25 ASD (Age  $\mu$  = 20 years (2.8); FSIQ4  $\mu$  = 103(15)) and 25 TYP participants (Age  $\mu$  = 19 years (3.2); FSIQ4  $\mu$  = 110(10)) completed the preassessment portion of the ATM and Metro Ticket Machine modules, in which seven written scenarios prompted participants to operate a virtual machine designed to simulate a real world task. The number of errors and total time to completion were recorded. Autism diagnosis was confirmed using the Autism Diagnostic Observation Schedule-2 (ADOS-2) and the Social Communication Questionnaire (SCQ). Participants completed the Adaptive Behavior Assessment System, Self-Report (ABAS-3). The general adaptive composite (GAC) and Community Use subscale, which includes ATM use, are reported. The Maps Task (McLaughlin et al., 2016), another ecologically valid laboratory based adaptive functioning measure involving completing fictional errands, first developed for use in psychosis, was also administered.

#### Results:

Errors and time were averaged across the two modules. A Wilcoxon rank sum test revealed the ASD (median=5.5) group made significantly more errors than the TYP (median=3.5) group ( $z=3.04$ ,  $p<.01$ ), but time did not differ between groups (Fig. 1). In the ASD group, Spearman's correlations showed that higher ADOS severity scores, higher errors on the Maps task, lower Verbal IQ, and lower ABAS Community Use subscale scores were significantly associated with longer completion times. Higher average errors were associated significantly with lower ABAS GAC scores and Maps Task Capacity Scores (combines error rate and time) (Table 1).

#### Conclusions:

While the ASD group did not on average take longer to complete the modules, they made significantly more errors. Associations with scores on both the Maps and the ABAS-3 (a well-validated self-reported inventory) suggests i-Function does measure adaptive functioning. Future work should further investigate i-Function performance in those with lower IQs and determine if the

training portions improve performance in ASD.

**401.006 (Poster)** Adults with Autism Spectrum Disorder Show Steeper Age Relationships with Decreasing Amygdala Size: Sex Differences and Associations with Autism Symptoms

**B. A. Pagni<sup>1</sup>, N. Guerithault<sup>1</sup>, M. Walsh<sup>1</sup>, J. R. Cook<sup>1</sup> and B. B. Braden<sup>2</sup>, (1)Arizona State University, Tempe, AZ, (2)College of Health Solutions, Arizona State University, Tempe, AZ**

---

**Background:** While abnormal amygdala volumes have been observed in various age groups of individuals with autism spectrum disorder (ASD), little research has explored how volumes change across the adulthood lifespan, whether men and women have different aging trajectories, and what changes in symptomatology coincide. Children with ASD have enlarged amygdala which reach neurotypical size around adolescence and becomes smaller in adulthood, suggesting the developmental arc in ASD is altered compared to neurotypicals (NTs). Amygdala sizes strongly correlate with anxiety and social symptoms in ASD, however it is still unclear if age-related changes in volume have consequences on these symptoms.

**Objectives:** In this cross-sectional study of adults ages 18-71 years, amygdala volumes in men and women with ASD (n=143) were examined and compared to aging trajectories in NT men and women (n=86). We also explored relationships between amygdala size and ASD and anxiety symptoms in adults with ASD.

**Methods:** Participants completed self-report measures for anxiety (State-Trait Anxiety Inventory, STAI) and ASD symptoms (Social Responsiveness Scale-2, SRS-2) and T1 MRI images were processed in FreeSurfer and amygdala volume estimations were corrected by total intracranial volume.

**Results:** A MANOVA for left and right amygdala volume revealed a significant three-way diagnosis-by-sex-by-age interaction ( $F(7,106)=2.147, p=0.045$ ). Post-hoc correlations showed a significant negative relationship between age and amygdala volume bilaterally for men with ASD (right:  $r(98)=-0.517, p<0.001$ ; left:  $r(98)=-0.481, p<0.001$ ) and in the right hemisphere for women with ASD ( $r(34)=-0.343, p=0.021$ ). Age correlations in this age range did not reach significance for NT men or women. Behavioral correlations showed relationships between amygdala volumes and SRS-2 subscales 'Awareness' (right hemisphere:  $r(128)=-0.187, p=0.034$ ), 'Cognition' (right hemisphere:  $r(128)=-0.291, p=0.001$ ; left hemisphere:  $r(128)=-0.261, p=0.003$ ), and 'Communication' (right hemisphere:  $r(128)=-0.207, p=0.019$ ) for adults with ASD. Surprisingly, there were no significant correlations with anxiety symptoms in adults with ASD.

**Conclusions:** These findings support a larger body of work which suggests an altered developmental arc in neuroanatomical structures in ASD and extend our knowledge by showing age-related volumetric changes in the amygdala are associated with ASD symptoms across the adult lifespan. Future work should seek to confirm these findings using longitudinal designs. Understanding age and sex effects may provide insights into the contribution of the amygdala in symptom presentation in ASD.

**401.007 (Poster)** Ageing on the Autism Spectrum: Mental Health and Quality of Life across the Adult Lifespan

**A. Roestorf<sup>1</sup>, P. Howlin<sup>2</sup> and D. M. Bowler<sup>1</sup>, (1)Autism Research Group, Department of Psychology, City, University of London, London, United Kingdom, (2)King's College London, London, United Kingdom**

---

**Background:** Research in Autism Spectrum Disorders (ASD) has shown that mental health and physical health conditions are common in at least half of autistic adults. In the general population, poor mental health is known to adversely affect functional abilities and is a common contributor to poorer quality of life and greater social isolation. Stress and anxiety-related difficulties have substantial implications for the social, cognitive, and adaptive functioning of autistic individuals. Mental health and wellbeing are further adversely affected by intolerance of uncertainty, emotional aversiveness and difficulties identifying and interpreting emotions. Relatively little is known about how/if these conditions change or affect quality of life of autistic adults as they grow older. It is, therefore, crucial to consider the long-term effects of mental health conditions, and the implications for service provision to support autistic people across the lifespan.

**Objectives:** Aims: to find out how mental health and physical health conditions affect the quality of life of autistic adults in older age. Our objectives were to understand the extent of: (i) autistic traits, co-existing physical and mental health conditions between younger and older autistic adults; and (ii) their impact on everyday living and QoL.

**Methods:** We worked with a community group of younger (mean age 58.5 years, SD 7.6 years) and older adults (mean age 58.5 years, SD 7.6 years) across 4 years. Fifty-two autistic adults (6 F: 46 M; age 18-79 years) participated in the first study (Time 1); 28 (6 F: 22 M) took part in a follow-up (Time 2; mean retest interval 2.5 years). Participants completed standardised self-report

questionnaires of autistic traits (ADOS-2; SRS-2), mental health (anxiety, depression), physical health and QoL at both time-points.

**Results:** The reliable change index (RCI) was used to establish individual and group-level changes over time. At T1 and T2, over half of autistic adults experienced at least one co-existing condition, and over a third met criteria for 3+ conditions, including anxiety (74%), depression (69%), alexithymia (41%), sleep disturbances, and hypersensitivities (85%). Depression symptoms were particularly high in autistic women. Both younger and older adults reported the impact on their daily lives as “somewhat” to “very difficult”, but few had access to any health or social care supports. Mental health difficulties and autistic traits were strong and consistent predictors of poor QoL at Time 1 and Time 2, for both younger and older autistic adults.

**Conclusions:** Most autistic adults in the study experienced mental health difficulties from multiple co-occurring conditions. These conditions also persisted into older age and did not reduce over time. Findings also highlight reduced access to health and social care services for community-dwelling autistic adults. Further work is urgently needed to mitigate the long-term impacts of poor mental health for autistic adults, particular for individuals with complex co-occurring conditions. We suggest how individual differences in mental health and wellbeing – such as those between men and women at various life stages – could be explored in future work to support autistic adults as they grow older.

**401.008 (Poster) Aging and Autism: A Qualitative Exploration of Quality of Life in Older Age.**

**D. L. Francis<sup>1</sup>, G. R. Stewart<sup>2</sup>, R. A. Charlton<sup>3</sup> and F. Happé<sup>2</sup>;** (1)King's College London, London, United Kingdom, (2)Social, Genetic and Developmental Psychiatry Centre, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (3)Psychology, Goldsmiths University of London, London, United Kingdom

---

**Background:** Previous research has indicated that younger autistic adults report lower quality of life than non-autistic adults. Despite older age also being associated with lower quality of life in some respects, little is known about the experiences and influences of quality of life in older autistic adults.

**Objectives:** This study used semi-structured interviews to explore the factors that influence quality of life in both autistic and non-autistic older adults.

**Methods:** A total of 33 participants (autistic n = 15) aged 50 to 89 years were interviewed. Participants were asked a set of semi-structured interview questions covering a broad range of topics, including social connections, health, any recent personal life changes, environmental factors, support needs, and hobbies and interests. A final open-ended question asked about any other undiscussed factors that might influence their quality of life. Responses were thematically analysed, and group themes were compared to identify similarities and differences between the autistic and non-autistic groups.

**Results:** The autistic and non-autistic groups reported many similarities in their quality of life experiences; however, subtle differences were found. For both groups, family bonds and friendships were an important influence on quality of life. While both groups reported similar social network sizes that decreased with age, the non-autistic group were less satisfied with their social life throughout adulthood.

Health was also an important factor. Both groups expressed concerns about their physical health and sleep changing with age; however, the autistic group more often discussed mental health difficulties throughout adulthood and how this influenced their wellbeing now in older age. The autistic group also discussed their difficulties coping with change, and their sensitivities to environmental factors (e.g. noise) throughout their lives. These experiences were reported to often lead to burnout.

Acceptance was also a common theme related to age-related changes, with both groups frequently discussing the need to adopt support-seeking behaviours as they have aged. However, the autistic group expressed more willingness to ask for support when required, while the non-autistic group were often reluctant to ask for additional support, which was felt to represent a loss of their independence.

**Conclusions:** The findings of the current study highlight similarities and differences in aspects relevant to quality of life for autistic and non-autistic older adults. While the two groups shared many similarities, the autistic group experienced subtle differences in their lived experiences. These experiences - such as with social connections and coping with change – could be possible targets for increased support and intervention, which could improve the quality of life and experiences of older autistic adults.

**401.009 (Poster) Alexithymia, Autistic Traits, and Depression Predicts Poorer Quality of Life**

**Background:** Quality of life (QOL) has been extensively examined with autistic samples; findings often report that QOL is significantly lower for autistic people compared to general population norms. Relatively few studies have explored how autistic traits are related to QOL with general population samples. To the authors' knowledge, no studies have examined the role of alexithymia in predicted QOL alongside autistic traits; which is important because alexithymia predicts poorer QOL in general population samples and, alexithymia is more common in autistic samples than rates reported in the general population.

**Objectives:** To examine whether alexithymia predicted QOL in addition to autistic traits. Moreover, to test whether an interaction effect between autistic and alexithymic traits (such that the effect of alexithymic traits on QOL would be greater with higher levels of autistic traits) was supported.

**Methods:** A total of 163 responders completed our survey. Participants were aged between 18 and 72 (mean age=31.9, SD=13.1); there were 41 males (25.2%), 109 females (66.9%), and 13 (7.9%) who reported some other gender identity. There were 141 autistic participants (86.5%), only 13.5% (N=22) of the sample reported having no diagnosis, nor did they self-identify as autistic. Participants provided demographic information (e.g. employment) and completed the Autism Quotient-10 (AQ-10), Toronto Alexithymia Scale (TAS-20), Patient Health Questionnaire-9 (PHQ-9), Generalised Anxiety Disorder-7 (GAD-7), World Health Organisation Brief QOL (WHOQOL-BREF) measure, and the Autism Specific QOL (ASQOL) measure.

**Results:** As expected, each QOL domain (Physical, Psychological, Social, Environment, Autism Specific) were significantly inter-correlated (rs ranged from .42 to .71). AQ-10, TAS-20, PHQ-9, and GAD-7 scores were all significantly negatively correlated with all QOL domains (neither AQ-10 nor TAS-20 scores correlated with Environment QOL) with rs ranging from -.35 to -.77. Physical, Psychological, and Social QOL was negatively predicted by PHQ-9 score. AQ-10 was a significant predictor of these domains in subsequent models, these models did not explain a significantly greater amount of variance. Planned analyses with just AQ-10 and TAS-20 scores (plus their interaction) revealed that both AQ-10 and TAS-20 scores predicted Physical and Psychological QOL (accounting for 22% and 26% of the variance, respectively); neither predicted Social or Environment QOL. A MANOVA analysis revealed that, whilst diagnosis was a significant main effect, the groups only significantly differed on Physical QOL (those in the diagnosed group reported significantly lower QOL). No analyses identified a significant interaction between autistic traits and alexithymic traits.

**Conclusions:** This study found that, whilst considered in isolation, alexithymic traits and autistic traits significantly predict some QOL domains (Physical and Psychological QOL). However, depression appears to attenuate this relationship. Thus, it seems that, when considered dimensionally, depression has a bigger effect on QOL than either autistic traits or alexithymic traits. However, when examining those low in PHQ-9 scores but high in TAS-20 scores, correlation coefficients between QOL domains and TAS-20 scores increased. This may suggest that alexithymia is still an important factor pertaining to QOL for those with low depression scores. Future research, with larger samples, may shed more light on this potentially important finding.

**401.011 (Poster)** An Exploration of Caregiver-Reported Strengths and Challenges of Adults with Autism and/or Intellectual Disability

*E. Wilkinson<sup>1</sup>, L. T. V. Vo<sup>2</sup>, S. Wilson<sup>3</sup>, Z. London<sup>1</sup> and V. H. Bal<sup>1</sup>, (1)Graduate School of Applied and Professional Psychology, Rutgers University-New Brunswick, Piscataway, NJ, (2)Western New England University, Springfield, MA, (3)Genetics, Rutgers University, Piscataway, NJ*

---

**Background:** It is essential to acknowledge that individuals develop new skills throughout childhood and into adulthood (Bal et al., 2018). Yet, aside from savant skills, there is limited autism research exploring strengths in adults. While two studies interviewed autistic participants and parents on personal strengths, they limited ages to 16-22 years (Carter et al., 2015; Teti et al., 2016). Samson and Antonelli surveyed autistic adults (18-58 years) on several character strengths but focused analyses on humor (2013). More research is needed to advance understanding of strengths and positive qualities in autism. A better understanding of an autistic individual's strengths can inform education, treatment and employment (Kapp, 2018; Riosa, 2017) and foster well-being (Diener et al., 2015; Lanau et al., 2012).

**Objectives:** 1) To examine what themes emerge when caregivers of adults with autism and/or Intellectual Disability (ID) are given open-ended prompts querying the strengths and challenges of their adult child. 2) To explore the associations between number/type of strengths and challenges and other individual characteristics.

**Methods:** Participants were 68 individuals ranging from 15 to 30 years old with diagnoses of ASD-only (52.9%), ASD+ID (20.6%), or ID-only (26.5%; see Table 1). Qualitative analysis of two open-ended questions from the CBCL/ABCL were used to

identify strengths and challenges: “Please describe the best things about him/her,” and “What concerns you most about him/her?” Seven themes emerged for strengths (sociability, personality characteristics, community participation, interests or activities, work ethic and motivation, specific skills and other) and five for challenges (social, independent daily living skills, future concerns, health/mental health and other; Table 2).

Results: Almost all individuals had at least one reported strength ( $n=66$ ; 97%) and challenge ( $n=62$ ; 91%). Groups did not differ on number of positive qualities ( $F(2,65)=0.19$ ,  $p=0.83$ ) or challenges ( $F(2,65)=1.99$ ,  $p=0.15$ ).

Personality characteristics, such as kind, positive, humorous, were the most commonly reported strength for all groups. Sociability was next most common for the ASD-only and ID-only groups. No demographic or clinical characteristics were associated with number of strengths. Work ethic and motivation were associated with older age ( $t(64)=-2.09$ ,  $p=0.04$ ) and specific skills with higher nonverbal IQ ( $t(63)=-2.27$ ,  $p=0.03$ ). Those with reported positive personality characteristics had higher ADI-R RRB scores ( $t(59)=-2.30$ ,  $p=0.03$ ).

The most frequently reported challenge for the ASD-only group was independent daily living skills, while social challenges were most commonly reported for both the ASD+ID and ID-only groups. Number of caregiver-reported challenges was associated with ABCL/CBCL Total Problem domain score ( $r=.33$ ,  $p=.01$ ).

Conclusions: The majority of caregivers in each of the three groups reported both strengths and challenges for their adult child, highlighting the need to assess strengths in individuals across the ability range. Themes identified were similar to previous studies of younger samples, with personality characteristics the most commonly reported strength. Somewhat surprisingly, sociability was also commonly reported. Further understanding of individual strengths in adults with ASD and/or ID is important to build supports and foster well-being. Future studies must incorporate autistic adults’ perspectives on their own strengths.

**401.012 (Poster)** Assessing Theory of Mind in Young Adults Who Have Lost the ASD Diagnosis Using the Social Attribution and Reading the Mind in the Eyes Tests

**E. Taverna<sup>1</sup>**, R. P. Thomas<sup>2</sup>, L. R. Naigles<sup>2</sup>, M. J. West<sup>2</sup>, A. Mohan<sup>2</sup>, M. F. Dieckhaus<sup>2</sup>, J. Crutcher<sup>2</sup>, M. J. Stabile<sup>2</sup>, D. A. Fein<sup>2</sup> and I. M. Eigsti<sup>2</sup>, (1)Department of Psychological Sciences, University of Connecticut, Storrs, CT, (2)Psychological Sciences, University of Connecticut, Storrs, CT, (3)NIMH, Bethesda, MD

Background: The ability to infer others’ mental states and intentions, known as theory of mind (ToM), shows delayed development in autism spectrum disorder (ASD). ToM has implications for social relationship skills (Bauminger et al., 2010). Some individuals diagnosed with ASD in early childhood later lose their diagnosis; by adolescence, they display no or minimal symptoms of ASD, and their language and social abilities are generally indistinguishable from those of typically developing (TD) peers (Fein et al., 2013). When assessed at 5-9 years, children with this ‘loss of autism diagnosis’ (LAD) outcome showed subtle ToM deficits (Kelley et al., 2006). This study evaluates ToM abilities in young adults with LAD, compared to peers with ASD or typical development (TD). The Social Attribution Test (SAT) assesses the ability to attribute intentionality and mental states to geometric shapes in a silent animation by answering 19 multiple-choice questions. Individuals with ASD perform less accurately on the SAT (Burger-Caplan et al., 2016). The Reading the Mind in the Eyes Task (RMET) probes emotional theory of mind by asking participants to select an emotion label to describe 36 facial displays (eyes only) of mental states. The RMET task differentiates ASD and TD, and performance is inversely related to autistic traits in TD individuals (Baron-Cohen et al., 2001).

Objectives: We compared SAT and RMET performance among individuals with LAD, ASD, and TD, and evaluated associations with verbal abilities.

Methods: Participants were adolescents and young adults with a history of LAD ( $n=9$ ), ASD ( $n=10$ ), or TD ( $n=17$ ), ages 18-23 (Table 1); data collection, interrupted by COVID-19, is ongoing. Measures, administered via Qualtrics, included the SAT, RMET, and estimates of nonverbal IQ [Computerized Ravens Progressive Matrices (CRPM); Gur et al., 2001] and verbal abilities [Verbal Reasoning Task (VRT); *ibid*]. Many TD participants participated during a prior study; VRT or CRPM data were unavailable for this subset.

Results: A one-way MANOVA revealed group differences on RMET and VRT, but not SAT or CRPM; Table 1. Post-hoc t-tests showed that REMT scores were higher for LAD versus ASD groups; the LAD>TD group difference approached significance. VRT scores were significantly lower in ASD compared to LAD and TD groups. RMET and VRT were correlated for the LAD group only,  $r(DF)=.78$ ,  $p=.02$ .

Conclusions: Results suggest that young adults with LAD outperform those with current ASD on an emotional ToM task (and were non-significantly more accurate than TD controls). Contrary to previous reports (Burger-Caplan et al., 2016), groups did not differ in the less-verbal intention attribution SAT task. The results are preliminary and underpowered, given small current sample sizes, but in contrast to previous reports of residual ToM deficits in children with LAD (Kelley et al., 2006), our results indicate age-appropriate emotional ToM skills in young adults with LAD, potentially reflecting superior knowledge of emotional vocabulary words. Next steps will compare cognitive (e.g. contemplative, reflective) versus affective (e.g. upset) RMET labelling across groups, to test the hypothesis that individuals with current ASD will show relatively more difficulty in identifying emotions as compared to cognitive states.

**401.013 (Poster)** Associations between Social Communication Difficulties, Genetic Risk of Autism and Adult BMI in a Population-Based Cohort

*A. Ly<sup>1</sup>, J. Heron<sup>2</sup>, E. Stergiakouli<sup>3</sup> and D. Rai<sup>2</sup>, (1)Population Health Sciences, Bristol Medical School, MRC Integrative Epidemiology Unit, Bristol, United Kingdom, (2)Population Health Sciences, Bristol Medical School, Centre for Academic Mental Health, Bristol, United Kingdom, (3)MRC Integrative Epidemiology Unit, Bristol Medical School, University of Bristol, Bristol, United Kingdom*

---

Background:

Overweight and obesity in adulthood are risk factors for adverse health outcomes such as cardiovascular diseases and cancers. In previous studies, autism has been associated with elevated BMI in childhood, adolescence, and adulthood. However, many of these studies are limited by cross sectional designs, recruitment of selected clinical samples, and lack of a control group.

Early puberty is associated with adult overweight and obesity. Early onset of puberty itself is associated with childhood BMI. It is not known whether autistic adolescents are more likely to experience early puberty and whether this increases their risk of being overweight/obese in adulthood.

Objectives:

1. Assess the associations between genetic liability to autism and the phenotypic expression of autism as social communication difficulties on adult BMI in a large, prospective longitudinal birth cohort.
2. Assess whether differences in pubertal growth mediate associations of interest.

Methods:

Genotypic and phenotypic data were from child participants in the Avon Longitudinal Study of Parents and Children (ALSPAC) birth cohort study, United Kingdom. The latest autism GWAS summary statistics data were used to construct standardized, weighted polygenic risk scores (PRSs) at 12 p-value thresholds. Pronounced social communication difficulties (SCDC) identified at age ~7.5 years, and PRSs were exposures of interest. BMI at age ~25 years was the outcome of interest.

Seven repeated measurements of height spanning from 9 to 20 years were included in sex-specific longitudinal analysis. We used Super Imposition and Translation and Rotation (SITAR) to derive age at peak height velocity (APV) and peak height velocity (PV) which quantify individual-level differences in pubertal growth.

Multivariable regression was used to assess whether there were associations between the autism-related exposures and adult BMI. PRS analyses were adjusted for 10 genetic principal components whilst non-genetic analyses were adjusted for socioeconomic measures, maternal age, total gestational weight gain and pre-pregnancy BMI. We performed mediation analysis with APV and PV within a Structural Equation Modelling framework.

Results:

The sample size was up to 3,055 in analyses. Social communication and genetic risk for autism were associated with higher adult BMI in the combined sample (SCDC: mean difference  $\beta$  1.10 [95% CI 0.37, 1.82];  $p=0.003$ ; PRS: standardized difference  $\beta$  0.26 [95% CI 0.08, 0.44];  $p=0.004$ ). These associations are driven by associations observed in males. The relationship between social communication and elevated adult BMI in males was not mediated by APV or PV (indirect effect of APV: mean difference  $\beta$  0.07 [95% CI -0.15, 0.28];  $p=0.54$ , and PV:  $\beta$  0.04 [95% CI -0.09, 0.17];  $p=0.55$ ). However, there was strong evidence that the association between genetic risk of autism and elevated adult BMI was mediated by onset of rapid pubertal growth (indirect effect of APV: standardized difference  $\beta$  0.15 [95% CI 0.08, 0.22];  $p<0.001$ , and PV:  $\beta$  -0.05 [95% CI -0.06, -0.002];  $p=0.07$ ).

## Conclusions:

Adults with genetic risk of autism and pronounced social communication difficulties are at risk of elevated BMI. The association of autism genetic risk with elevated adult BMI is partially mediated by earlier than average pubertal onset.

**401.015** (Poster) *Autistic-Led Post-Diagnostic Peer Support for Adults: A Qualitative Examination of Community Priorities.* **C. J. Crompton<sup>1</sup>, S. Hallett<sup>2</sup>, A. C. Stanfield<sup>1</sup> and S. Fletcher-Watson<sup>3</sup>, (1)Division of Psychiatry, University of Edinburgh, Edinburgh, United Kingdom, (2)Autistic Mutual Aid Society Edinburgh, Edinburgh, United Kingdom, (3)Salvesen Mindroom Research Centre, University of Edinburgh, Edinburgh, United Kingdom**

---

**Background:** Diagnosis in adulthood can be a life changing event, impacting identity, relationships, and mental health. The lack of post-diagnostic support has been highlighted by autistic adults, the families of autistic people, clinicians, and service providers. The unavailability of post-diagnostic support can be a source of distress for autistic adults, reinforcing feelings of social isolation and rejection.

Peer support may be a cost-effective, flexible and sustainable model to provide community-based support for autistic adult. Research has found that social interaction improves autistic people's mental health, and that interactions with other autistic people may be particularly effective: autistic adults have described interacting with other autistic people as comfortable, fulfilling and validating. Self-acceptance and pride in being neurodivergent is linked to lower depression scores, and feeling part of an autistic community is related to lower suicide risk. However, there is little evidence base for peer support for autistic adults, despite calls for peer support research from the autism community.

**Objectives:** The first step to creating a post-diagnostic peer support framework is to identify what autistic adults would want from peer support. This qualitative research explored autistic experiences and needs post-diagnosis, identifying the specific ways that peer support may benefit them, and exploring the limitations of peer support.

**Methods:** Twelve autistic adults (4M, 1 NB; age mean = 45, range 30-66) completed a semi-structured interview specifically developed by the research team in consultation with autistic collaborators, which focused on the diagnostic experience, post-diagnostic support needed and provided, engagement with the autistic community, and post-diagnostic peer support. All participants had received an autism diagnosis in adulthood through the NHS between 2-10 years prior. Hour long interviews were conducted in person, via skype, or phone.

**Results:** Thematic analysis of interview transcripts resulted in four themes extracted from the data:

- **Mismatch in post-diagnostic support needed and provided:** currently, services do not meet the needs of autistic adults post-diagnosis. Support should involve advocacy, strategies for wellbeing, and communicating with non-autistic people. Autistic-led peer support could offer unique insights and methods of support that are currently not being offered.
- **Community connection:** engaging with other autistic people enhances self-understanding, reduces internalised stigma and ableism, and builds connections with others.
- **Flexible and personalised support:** peer support offers a flexible way to meet the needs of autistic people over time which may vary between and within individuals, for example 1:1 or group support, online or in person, covering a variety of issues and topics.
- **Sustainability:** to ensure peer support is sustainable, training, payment and supervision for peer facilitators is essential, alongside administrative support and secure long-term funding. It is important to recognise the boundaries and limitations of peer support and acknowledge that autistic adults may require additional support from other healthcare providers including mental health care.

**Conclusions:** Peer support may be a useful mechanism to support autistic adults post-diagnosis, and offers unique opportunities not available through other support channels. Though informal peer support exists, participants felt it could be more sustainable and effective if well-supported and funded.

**401.016** (Poster) *Being an Autistic Parent : Benefits and Challenges* **M. Désormeaux-Moreau<sup>1</sup>, V. Rochon<sup>2</sup>, S. Powell<sup>3</sup>, M. H. Poulin<sup>3</sup>, C. L. Normand<sup>4</sup>, E. Héroult<sup>5</sup> and M. Couture<sup>6</sup>,** (1)École de réadaptation, Université de Sherbrooke, Sherbrooke, QC, Canada, (2)Université de Sherbrooke, Sherbrooke, QC, Canada, (3)Psychoéducation, UQAT, Rouyn-Noranda, QC, Canada, (4)Psychoéducation et psychologie, Université du Québec en

**Background:** As researchers increasingly investigate autistic adults' experience, varieties of roles need to be addressed, exceeding those of employees or workers that have been studied until now. Very few studies have looked at the reality associated with the role of parents, as experienced by autistic adults (Pohl et al. 2020). Two focussed on motherhood - more specifically, on pregnancy and childbirth (Donovan 2017; Gardner et al, 2016), while others were interested in satisfaction with parenthood (Lau & Peterson, 2010) and parenting efficacy (Lau, Peterson, Attwood, Garnett & Kelly, 2016). It is only recently that the experience of raising children was investigated by Pohl et al. (2020).

**Objectives:** To explore (1) the benefits and (2) the challenges of being an autistic parent from the perspective of mothers and fathers with ASD.

**Methods:** This study was part of a broader study on social participation, by autistic adults in Quebec, Canada (n= 316). Participants (16-40 years old) answered an online survey about their life habits and social roles, within the theoretical framework of the Disability Creation Process (Fougeyrollas et al., 2010). Four open-ended questions pertained to parenthood and answers were analyzed through an inductive content analysis (Mucchielli, 2006). Data were independently co-coded and validated by three authors and subdivided into categories and sub-categories as the analysis progressed.

**Results:** A sample of 47 participants answered the questions related to parenting, most of those being mothers (89%) over 31 years old. Five participants stated being fathers. Participants were parents of one child (30%), two (34%), three (23%) or four or more children (13%). Nearly two-thirds (64%) of the parent sample reported having at least one autistic child. Participants related the benefits of being an autistic parent to personal characteristics as well as the creation of a strong emotional bond with the child, especially when he was also autistic. The experience of being an autistic parent was associated with: 1) an opportunity to access and apply knowledge; 2) an understanding of the child(ren)'s needs; 3) an ease to foster and support one's child(ren)'s development; 4) an inclination toward unconditional acceptance of one's child(ren). On the other hand, participants reported challenges of being an autistic parent. The parent's as well as the child's personal characteristics were stated, but more importantly, environmental factors were described as challenging. These referred to: the management of: 1) emotions; 2) energy; 3) everyday family life; as well as to 4) communication and social interactions; 5) understanding and responding to the family's needs; 6) lack of appropriate support; 7) negative perception of one's parental ability by others; as well as that perception's impact on 8) one's sense of parenting competence.

**Conclusions:** Being a parent can be challenging for everyone at times. Indeed, most of the participants mentioned challenges that are similar to those experienced by non-autistic parents. However, the benefits are different due to the shared reality and experience of autistic parents and their autistic child(ren). This study provides a new and unique insight into the lived experience of autistic adults.

**401.017 (Poster) Biology Interrupted: How Autistic Adults Develop Anxiety through an Intolerance of Uncertainty Framework**  
*K. M. Normansell-Mossa<sup>1</sup>, J. Rodgers<sup>2</sup>, M. Freeston<sup>3</sup>, N. C. Russell<sup>4</sup> and M. South<sup>5</sup>, (1)Clinical Psychology, Brigham Young University, Provo, UT, (2)Population Health Sciences Institute, Newcastle University, Newcastle upon Tyne, United Kingdom, (3)School of Psychology, Newcastle University, Newcastle upon Tyne, United Kingdom, (4)Psychology, Brigham Young University, Provo, UT, (5)Psychology & Neuroscience, Brigham Young University, Provo, UT*

---

**Background:** Recent studies have suggested that at least 20.1% percent of autistic adults have a co-occurring anxiety disorder, compared to around 8.7% of neurotypical adults. Models of the overlap of anxiety in autistic adults have proposed relationships between autistic traits, including restricted interests and repetitive behaviors and atypical sensory processing alongside alexithymia and intolerance of uncertainty (IU). Several models have focused on the role of IU, which has biological and evolutionary bases, as a cognitive explanation for the high prevalence of anxiety in autism. This framework suggests that all people are born with a healthy level of intolerance of uncertainty, and as we develop, this intolerance is lessened as we learn when situations are safe and begin to understand and manage the uncertainty.

**Objectives:** To examine the competing models regarding the relationships between intolerance of uncertainty, atypical sensory processing, anxiety, and autistic traits in a sample of autistic and neurotypical adults.

**Methods:** Data from a group of 254 adults (55 autistic, 199 neurotypical) were examined. We report the data for the two groups combined, as regression plots of the means of the groups showed no significant differences in slope between groups. We conducted two path analyses. The first model tested the idea that disruptions in intolerance of uncertainty, as an evolutionary phenomenon common for all people, could explain some of the cognitive aspects of anxiety in autism. This model suggests that

intolerance of uncertainty increases sensory sensitivity and sensory seeking behaviors, which then add to feelings of anxiety, which may together contribute to some core autistic traits. The second model suggests that primary neurodevelopmental differences associated with autistic traits underlie the sensory sensitivity and sensory seeking behaviors, which in turn increase intolerance of uncertainty and subsequent anxiety.

Results: The “biological uncertainty” model, with intolerance of uncertainty at the beginning of the model, had poor fit,  $\chi^2(2) = 31.22$ ,  $p < .001$ ; RMSEA = .24; CFI = .93 (see Figure 1a). The “neurodevelopmental” model, with autistic traits at the beginning of the model, had much better fit,  $\chi^2(2) = 5.58$ ,  $p = .06$ ; RMSEA = .08; CFI = .99 (see Figure 1b).

Conclusions:

Discussion: These results suggest that the neurodevelopmental impact of higher levels of autistic traits could moderate a neurotypical trajectory of learning to manage uncertainty as children develop and understand that uncertainty is common and acceptable. For adults with higher levels of autistic traits and atypical sensory processing, uncertainty is frightening and leads to elevated levels of anxiety.

#### **401.018 (Poster) COVID-19 Effects on the Transition Support Networks of Autistic Young Adults and Their Parents**

**E. McGhee Hassrick<sup>1</sup>, M. Potros<sup>2</sup>, J. Ventimiglia<sup>3</sup>, S. Murphy<sup>4</sup> and E. Marta<sup>2</sup>.** (1)A..J. Drexel Autism Institute, Drexel University, Philadelphia, PA, (2)Drexel University, Philadelphia, PA, (3)AJ Drexel Autism Institute, Drexel University, Philadelphia, PA, (4)A..J. Drexel Autism Institute, Drexel University, Philadelphia, PA

---

Background: The COVID-19 pandemic has greatly impacted people’s social networks, due to lock-downs, school closures and restricted interactivity due to social distancing and other preventative measures. Autistic youth who were experiencing transition during the COVID-19 pandemic potentially faced severe restrictions on their transition engagements, due to reduced or revoked access to services (Manning, Billian, Matson, Allen, & Soares, 2020). In non-pandemic conditions, many autistic youth experience poor outcomes post-secondary school. Over 66% of young adults on the autism spectrum are disconnected from opportunities for work or schooling in the first few years after high school, especially low-income young adults on the spectrum (Shattuck et al., 2012). They experience a “service cliff”(Shattuck et al., 2012) which often includes disruptions in access to needed supports as they age out of eligibility for school-based and pediatric care. We conducted a preliminary analysis to investigate if COVID-19 impacted transition support networks of autistic young adults and their parents.

Objectives: To investigate changes in transition support network contact during COVID-19 for autistic youth and their parents.

Methods: A social network survey was conducted with autistic youth (N=22) and their parents (N=22), where they were asked to name transition supporters and changes in their interactions during COVID-19. A multi-level ordinal linear regression was fit to predict change in frequency of interaction for the young adults and their parents in our sample. Sociograms were configured for each youth for visual analysis of network structure and COVID-19 related changes in contact.

Results: Analysis of COVID-19 network data demonstrated that approximately 1% of connections for young adults and 2.4% of connections for caregivers were developed post-COVID-19 outbreak. A dependent samples t-test between parents and young adult networks was used to compare the mean change in contact,  $t(19)=.967$ ,  $p=.350$ . This shows that even though parents on average had a 7.5% lower network frequency contact, there was no significant difference in their frequency in contact with their networks after COVID-19. Among alters (people named as supporters in the youth or parent transition network), family members and cohabitators showed significantly more contact while community members and professionals showed decrease in contact (Figure 1).

Additionally, we created a sociogram visualizing each young adult’s social network to qualitatively investigate the location of people in the network who increased, decreased or stayed the same during the first three months of the COVID-19 pandemic. Figure 6 illustrates the sociogram of one of our autistic young adult participants, suggesting that the most central people in the young adult’s network were family members and increased in contact with others in the youth’s transition support network. The central people in the youth’s network were also connected to professionals and educators who decreased in contact with the youth during COVID-19 (Figure 2).

Conclusions: We provide preliminary evidence suggesting that expanding networks and maintaining contacts with professionals during the COVID-19 pandemic is limited. Longitudinal data and future non-COVID-19 impacted cohorts will establish necessary comparisons. Further investigation of the role that central people play in transition support networks for autistic youth.

**401.019** (Poster) Camouflaging in Autistic Adults: A Qualitative Study Exploring Camouflaging Onset, Continuity, Change over Time and Psychosocial Influences

**B. Loo<sup>1</sup>, T. Teo<sup>1</sup>, D. J. Leong<sup>2</sup> and I. Magiati<sup>1</sup>,** (1)Dept. of Psychology, National University of Singapore, Singapore, Singapore, (2)Disabled People's Association, Singapore, Singapore

---

**Background:** Some autistic people have developed strategies over time to mask underlying autism-related neurocognitive, social/communication and/ or behavioural differences in order to achieve goals such as establishing and maintaining social relationships, seeking and maintaining employment, or accomplishing daily tasks for independent living within predominantly non-autistic societies. These strategies have come to be known as social camouflaging. To date, most research on camouflaging has been conducted with autistic adults, but there is emerging observational and qualitative evidence that autistic children and adolescents also engage in camouflaging. Camouflaging in autistic children has also been implicated as one plausible explanation for why many autistic adults, especially women, may be missed in childhood and only diagnosed later in life. Indeed, autistic adults have described camouflaging as a “lifetime of conditioning, [training] to act normal”, involving “years of effort and practice”, suggesting that camouflaging occurs over the autistic person’s lifespan. Yet, little is so far known about the onset, course, continuity and changes in camouflaging behaviours over autistic people’s lives. Furthermore, though recent research suggests that autistic people’s motivations to camouflage may evolve over time, along with the strategies they employ, no study to date has explicitly explored the psychosocial factors that may influence these trajectories over time.

**Objectives:** In an exploratory qualitative study interviewing autistic adults in depth about their life experiences in relation to camouflaging, we aimed to understand when and why autistic adults begin to camouflage, how their motivations change or remain the same over time, how their strategies dynamically evolve over time and what individual and social factors may influence or explain continuity and change in their camouflaging motivations and strategies.

**Methods:** Eleven Singaporean autistic adults (aged 22-45 years) participated in an in-depth semi-structured individual interview with (i) questions relating to participants’ earliest memories of camouflaging; and (ii) questions on how participants’ camouflaging has remained the same, or changed and developed over time at different periods in their lives. Braun and Clarke’s (2006) six phases of reflexive thematic analysis were applied to all interviews, with data analysed inductively and themes identified semantically and explicitly.

**Results:** Two core themes (camouflaging motivations; camouflaging strategies) and 34 subthemes were identified and organized into four developmental phases of camouflaging, namely (i) pre-camouflaging, (ii) origins, (iii) continuity and (iv) change. We found that the earliest motivations to camouflage were relational, and linked to the development of a negative self-identity after experiencing repeated negative social sanctions from others. Overall, the autistic adults reported their camouflaging strategies increasing in complexity over time, and becoming better integrated to one’s sense of self. They also described learning to camouflage selectively over time, with some opting for disclosure of their condition and needs in some contexts.

**Conclusions:** These findings highlight the role of social pressure and experiences triggering the motivation for and onset of camouflaging. They also emphasize the need for individual psychological and societal-level changes from pathologizing and stigmatizing autistic differences towards acceptance and inclusion, in order to alleviate pressure on autistic youth and adults to camouflage.

**401.021** (Poster) Combining Statistical Approaches to Capture Age-Related Cognitive Differences in Autistic Adults

**C. Torenvliet, A. P. Groenman, T. A. Radhoe, J. Agelink van Rentergem and H. M. Geurts,** University of Amsterdam, Amsterdam, Netherlands

---

**Background:** Cognitive aging in autistic adults has become of increasing interest in autism research. Whilst our first high-powered study (Lever & Geurts, 2016) on age-related cognitive effects showed largely parallel (similar) aging, and even protective (less) aging, other studies have found contrasting results. Therefore, we conducted a follow up study to determine which findings will be replicated in an independent sample.

**Objectives:** (1) We hypothesize to replicate our previous findings of mostly parallel or protective aging in several separate cognitive domains (2) Furthermore, we explore whether using a multivariate approach (multivariate normative comparisons; MNC) would enable us to detect differences on an individual level which would typically remain undetected.

**Methods:** We combine the methods of two pre-registered analyses plans (#28816 and #40091 on AsPredicted.org). In a sample of 87 autistic adults and 106 non-autistic comparisons (age range: 30-85 years), we first assess group differences and its interaction

with age on six different cognitive tasks (visual and verbal memory, working memory, generativity, theory of mind (ToM) and processing speed). After which we combine data from the previous, and current study ( $N_{TOT} \sim 423$ ,  $N_{ASC} \sim 198$ ) to perform MNC.

Results: Preliminary results indicated worse performance for the ASC group on verbal memory, generativity, and ToM ( $p < .05$ ), however only the latter survived multiple comparisons corrections ( $p < .01$ ). Worse performance was associated with older age for processing speed, and verbal- and visual memory. No age x group interactions were observed, thus we did not replicate certain protective aging effects (i.e. ToM, visual memory). Due to delays caused by the COVID-19 pandemic, results from the second part are yet to be analysed and will be presented at INSAR 2021. However using MNC in a subsample, we detected a distinct group of 26 out of 111 autistic individuals (23.4%) with a deviant cognitive profile, compared to a group of only 3 out of 118 (2.5%) in the comparison group.

Conclusions: Even though group-based statistics do not give much evidence for altered age-related effects in ASC adults, MNC showed that there might be a systematically lower performing group within the ASC sample.

#### **401.022 (Poster) Community Participation in Autistic Young Adults**

**B. Tomaszewski<sup>1,2</sup>, L. J. Hall<sup>3</sup>, J. R. Steinbrenner<sup>4</sup>, L. E. Smith DaWalt<sup>5</sup>, K. Hume<sup>1</sup> and S. L. ---

Background: Many autistic adults experience poor postsecondary outcomes, including limited community and social participation (Roux et al., 2017). Participation in community activities declines as high school students transition into adulthood (Myers et al., 2015). Identification of barriers to participation from multiple reporters may identify essential targets for developing services and programs to promote community participation.

Objectives: The objectives of this study were to (a) describe community participation in young autistic adults who have recently exited high school, (b) compare community participation from self and parent reports, (c) examine barriers to participation, and (d) examine differences among participation patterns by biological sex, income level, and race and ethnicity.

Methods: Participants included 160 autistic adults ages 17-25 ( $M = 20.31$   $SD = 1.61$ ). 83.5% of the sample identified as Male, 15.8% as Female, and .70% as Nonbinary, and 69.8% were White. Young autistic adults and parents each completed the Adolescent and Young Adult Activity Card Sort (AYA-ACS; Berg et al., 2015) by identifying a) the activities the young adult engaged in during the previous six months, then b) if the activities not engaged in were of interest and c) if so, the barriers to participation. The AYA-ACS uses photographs to capture participation in 63 everyday life activities in 6 domains (chores, leisure, social, health, education, and work) and has demonstrated reliability in autistic adults without intellectual disability (McCollum et al., 2016). A paired-samples t-test was used to compare total participation between self- and parent-reports. Nonparametric statistics were used across participation domains to examine participation profiles, compare reporters, and evaluate group differences.

Results: Young adults ( $M = 44.12$ ,  $SD = 9.50$ ) reported a higher number of activities than parents ( $M = 41.48$ ,  $SD = 9.88$ ),  $t(83) = 2.34$ ,  $p = .02$ . Figure 1 shows participation frequencies. Wilcoxon Signed Rank Tests showed that autistic adults and parents reported similar frequency of chores, health and wellness, education and learning, and work. Young adults reported more social activities,  $z = 3.54$ ,  $p < .001$ , and leisure activities,  $z = 2.74$ ,  $p = .01$ , than parents. Young adults and parents reported that autistic adults were most interested in going on a date and being in a long-term relationship. Young adults also reported wanting to learn to drive. Young adults and parents reported a similar number of overall barriers but differential types of barriers. Young adults were more likely to report that they were not able to (e.g., no transportation, no opportunity, others do it for them),  $z = 3.84$ ,  $p < .001$ , and parents were more likely to report it made the young adult uneasy (too crowded, environmental sensitivities, anxiety),  $z = 3.47$ ,  $p = .001$ , and that they needed support from others,  $z = 2.22$ ,  $p = .03$ . Types of barriers differed by racial and ethnic groups and income but not biological sex.

Conclusions: Young autistic adults and their parents report a range of participation in activities following high school. Differential patterns of barriers among reporters highlight the importance of including self-report of community participation in autistic adults. Romantic relationships and transportation were identified as important areas to target barriers to support participation. Targeting preferences and barriers may lead to increases in community participation outcomes for autistic adults.

#### **401.023 (Poster) Comparing Fitness Levels of College Students with and without Autism Spectrum Disorder**

*T. Todd, N. Miodrag, J. Jensen, N. Nnoli, J. Bricker and B. Endinjok, (1)Kinesiology, California State University, Northridge, CA, (2)Child and Adolescent Development, California State University Northridge, Northridge, CA, (3)Kinesiology, California State University Northridge, Northridge, CA, (4)California State University Northridge, Northridge, CA*

---

**Background:**

Young children and adolescents with the Autism Spectrum disorder (ASD) demonstrate a lifestyle with high levels of sedentary behavior and low levels of physical activity (Memari & Must, 2013; 2014). While the information on children and adolescents with ASD is vast, the literature does not demonstrate whether these behaviors continue into young adulthood and the college years. Researchers suggest that poor motor skills, social skills impairments, and sensory challenges may contribute to low levels of physical activity (Curtin & Zuckerman, 2014) and that these challenges may be barriers to engaging in regular physical activity. Regular participation in physical activity is a key indicator of good health, therefore it is important to assess physical activity and fitness levels in young adults with ASD. The purpose of this study is to compare the fitness levels of college students with and without ASD.

**Objectives:**

The purpose of this study is to better understand health-related fitness in college students with ASD.

**Methods:**

Twenty college students with and without ASD between the ages of 18-30 years were recruited for the study (7 males, 3 females without ASD; 7 males, 3 males with ASD). Participants were matched based on sex and age. Informed consent and the Physical Activity Readiness Questionnaires (PAR-Q) were signed by all participants. Participants performed fitness testing, which included aerobic fitness (VO<sub>2</sub> Max), muscular strength and endurance (push-ups and sit-ups), and flexibility (sit-and-reach). Fitness variables were analyzed with an independent sample *t*-test.

**Results:**

A comparison of estimated VO<sub>2</sub> max using an independent sample *t*-test revealed a statistical significance difference between college students without ASD ( $M = 48.94$ ) and college students with ASD, ( $M = 37.15, p = .012$ ). There was also a statistically significant difference in the number of completed push-ups between the group without ASD ( $M = 11.60$ ) and the group with ASD (Mean = 25.6,  $p = .007$ ). There was no significance in the number sit-ups completed and the sit-and-reach test.

**Conclusions:**

These results suggest that college students with ASD have poor cardiorespiratory fitness and less upper body muscular strength than college students without ASD. This provides a basis to begin to understand health disparities and create evidence-based physical activity interventions for college students with ASD.

**401.024 (Poster) Comparison of Age of Diagnosis and Sex Differences in Parent Report of Autism Characteristics**  
*C. Shulman, The School of Social Work, The Hebrew University of Jerusalem, Jerusalem, Israel*

---

**Background:** One of the most consistent differences reported in the literature is that many females with autism spectrum disorder (ASD) are diagnosed later than males, leading to missed opportunities for early supports which have been associated with better outcomes. It is therefore critical that researchers and clinicians alike understand diagnostic expression in females as early as possible. Conflicting results have emerged in studies examining sex differences in ASD diagnostic profiles. Zwaigenbaum et al. (2012) found that females showed slightly fewer ASD symptoms using the Autism Diagnostic Interview-Revised (ADI-R: LeCouteur Lord, & Rutter, 1994), while Koenig and Tsatsanis (2005) emphasized that even the gold standard diagnostic instruments are not sensitive enough to the differences in presentation of ASD in females and males. Lai et al. (2019) found that girls tended to be more interested in other people and imitated more than boys imitate. They also evidenced more echolalia and continual questioning, both features of language that develop earlier in girls than in boys (Andersson, Gillberg, & Miniscalco, 2013). The language and social imitation skills of females with ASD may mask a core ASD deficit, thus resulting in later diagnosis for females.

**Objectives:** The objectives of this study included comparing parental report of ASD symptomatology at age of diagnosis on the ADI-R, in males and females who receive an initial diagnosis between 3-5 and those who receive an initial diagnosis between the

ages of 8-10. Given the under-representation of females in ASD, it is possible that current diagnostic instruments are not sensitive enough to detect the subtleties of ASD symptoms in females and that the profiles of females who are diagnosed later are different from those of females who are referred at a younger age.

**Methods:** Forty boys and 40 girls were matched on developmental functioning and age, with 20 boys and 20 girls receiving their initial diagnosis of ASD between the ages of 3-5 (early diagnosis group), and 20 boys and girls who received their initial diagnosis of autism between the ages of 8-10 (late onset group). Sex differences as assessed on the algorithm domains of the ADI-R parental interview.

**Results:** Significant differences emerged on the ADI-R algorithm scores, with girls receiving higher pathology scores in the social-affect domain and lower pathology scores in the communication domain. The only significant difference between the early and later diagnosis group emerged in the communication domain, with significantly more pathology emerging in the early diagnosis group. Comparing all four groups revealed that girls who received an early ASD diagnosis manifested significantly more impairment in the communication domain while no differences emerged among the other three groups.

**Conclusions:** The results of this study suggest that age and sex have an impact on the manner in which ASD is expressed. The reexamination of diagnostic profiles in females can provide the groundwork for possible changes in the male-female bias in prevalence, and should be a research priority. This will allow for earlier identification of ASD, associated with better outcomes, in females.

**401.025 (Poster) Comparison of Gender Cognition, Gender Dysphoric Feelings, Mentalising, and ASD Traits Among Neurotypical Cisgender, Neurotypical Transgender, and Autistic Cisgender Individuals.**  
*A. Kallitsounaki and D. M. Williams, University of Kent, Canterbury, United Kingdom*

---

**Background:**

In recent years, increasing evidence has emerged for a link between autism spectrum disorder (ASD) and gender incongruence. Yet, it remains unclear whether or not this link reflects true comorbidity, with the same underlying cause or some of the core features of ASD predispose autistic people to discontent with their birth-assigned gender.

**Objectives:**

We conducted a case-control study to identify similarities and differences in gender cognition, mentalising, ASD traits, gender dysphoric feelings, and cross-gender behaviour in childhood, among neurotypical cisgender, neurotypical transgender, and autistic cisgender individuals. We also explored, for the first time, the role of alexithymia in the link between ASD and gender incongruence.

**Methods:**

One hundred and four neurotypical cisgender, 78 neurotypical transgender, 112 autistic cisgender, and 26 autistic transgender adults took part. Participants completed explicit and implicit measures of gender cognition, plus the Reading the Mind in the Eyes measure of mentalising, the Autism-spectrum Quotient, the Gender Identity/Gender Dysphoria Questionnaire, the Recalled Childhood Gender Identity/Gender Role Questionnaire, and the Toronto Alexithymia Scale.

**Results:**

In keeping with predictions, neurotypical transgender and autistic cisgender participants showed different patterns of gender-related cognition. Autistic cisgender participants reported significantly more current gender dysphoric feelings ( $p < .001$ ,  $d = 1.10$ ) and cross-gender behaviour in childhood ( $p < .001$ ,  $d = 0.67$ ), than neurotypical cisgender people. Furthermore, neurotypical transgender individuals reported significantly more ASD traits, than neurotypical cisgender individuals ( $p < .001$ ,  $d = -0.55$ ). However, further analysis revealed that increased levels of alexithymia among neurotypical transgender individuals had confounded these results. In contrast to predictions, neurotypical transgender participants did not show any impairment in mentalising ability ( $d = -0.09$ ,  $p = .536$ ), whereas both autistic groups did as expected. Among autistic cisgender individuals, performance on the mentalising task was positively associated with the number of gender dysphoric feelings reported (high scores on the Gender Identity/Gender Dysphoria Questionnaire = less gender dysphoric feelings;  $r = .47$ ,  $p < .001$ ) and partially mediated the relation between explicit gender cognition and current gender dysphoric feelings. However, this was not the case among neurotypical transgender people.

## Conclusions:

Results provide evidence that ASD and gender incongruence do not share the same underlying causes. They also support the hypothesis that mentalising might be one of the possible mechanisms that increase autistic people's liability to discontent with their birth-assigned gender and tendency to develop gender dysphoria. Implications of results for clinical practice, as well as theory-building, will be discussed.

**401.026** (Poster) Coping Strategies and Service Needs of Autistic Adults in the SPARK Cohort during the COVID-19 Pandemic  
*N. Nagpal<sup>1</sup>, S. Xiao<sup>2</sup>, K. Diehl<sup>3</sup>, A. Daniels<sup>3</sup>, J. K. Law<sup>3</sup>, C. W. Lehman<sup>3</sup>, P. Feliciano<sup>4</sup>, S. Consortium<sup>5</sup> and W. K. Chung<sup>6</sup>, (1)160 5th Ave, 7th FL, Simons Foundation, New York, NY, (2)Simons Foundation, New York, NY, (3)Maryland Center for Developmental Disabilities, Kennedy Krieger Institute, Baltimore, MD, (4)SFARI, Simons Foundation, New York, NY, (5)SPARKForAutism.org, New York, NY, (6)Department of Pediatrics, Columbia University, New York, NY*

---

**Background:** In daily life, many adults with autism have difficulty coping with change compared to a neurotypical population (Blomquist and Hirvikoski, 2015). Studies indicate that in comparison to children and adolescents, ASD adults are less likely to receive services, while also reporting a greater need for services (Turcotte et al. 2016). Little is known about the coping strategies of ASD adults to the COVID-19 pandemic's stay-at-home mandates and shutdowns of non-essential services.

**Objectives:** To use a qualitative approach to identify the most commonly reported coping mechanisms and greatest service needs reported by independent adults with ASD in early April 2020 during the early phase of the COVID-19 pandemic.

**Methods:** SPARK is a U.S. based online research study with a cohort of over 97,000 individuals with autism. From March 30 through April 10, 2020, SPARK surveyed independent adults to examine the impact of COVID-19 on their lives. 407 participants completed the surveys and 338 participants responded to open text questions about the impact on service needs and coping strategies. Participants without completed Background History Questionnaires previously collected from SPARK were excluded. A qualitative approach was used to code the remaining 278 open-text comments using a 3-step process of open, axial, and selective coding. Comments were coded and inter-coder reliability was established.

**Results:** Table 1 includes demographic information on the respondents.

A total of 35 codes emerged from open coding methods from 278 open text comments. Specific coping mechanism codes were categorized into broader categories established in the Coping Inventory for Stressful Situations (CISS): 1) task-oriented, 2) emotion-oriented, 3) avoidance-oriented. Definitions and frequencies of codes can be found in Table 2. 72% of avoidance-oriented codes were related to task-oriented avoidance, with the remaining 28% pertaining to person-oriented avoidance. Person-oriented avoidance also included reports of the desire to employ person-oriented avoidance (e.g. calling a friend), but having no social support available resulted in emotional distress.

Autistic adults reported a variety of service-related needs, broadly categorized into comments on service implementation, service access, and attitudes and perceptions on services received. Comments on telehealth delivery methods (including phone calls and video conferencing) were varied. While some individuals had positive experiences with telehealth, others reported discomfort due to concerns over lack of privacy and unreliable connections resulting in unsatisfactory visits.

**Conclusions:** This study provides insight into the coping mechanisms and service needs of independent adults with ASD during the onset of the COVID-19 pandemic. 13% of participants reported using task-oriented coping mechanisms, highlighting a need for strategies to cope with the negative impact of the pandemic on their mental health. These findings also underscore the need to quickly disseminate data to service providers and autism organizations to better serve independent adults with ASD during the pandemic or, more broadly in periods of elevated stress. Additional qualitative studies are needed to identify which coping mechanisms and telehealth services are effective for autistic adults as COVID-19 disruptions continue.

**401.027** (Poster) Decreased GABA Concentration in Supplementary Motor Area Disrupts Hand-Foot Coordination Movements in Individuals with Autism Spectrum Disorder  
*Y. Umesawa<sup>1,2</sup>, K. Matsushima<sup>3</sup>, R. Fukatsu<sup>1</sup>, Y. Terao<sup>3</sup> and M. Ide<sup>1</sup>, (1)Department of Rehabilitation for Brain Functions, Research Institute of National Rehabilitation Center for Persons with Disabilities, Tokorozawa, Saitama, Japan, (2)Department of Medical Physiology, Faculty of Medicine, Kyorin University, Mitaka, Tokyo, Japan, (3)Faculty of Medicine, Kansai Medical University, Hirakata, Osaka, Japan*

---

Background: Most individuals (79%) with autism spectrum disorder (ASD) exhibit difficulty in coordinated movements (Green et al., 2009). When healthy individuals moved their limbs (e.g., left hand and left foot) rhythmically, opposite directional movements tended to shift to same directional movements (“directional constraint”: Baldissera et al., 1982). Supplementary motor area (SMA) is suggested to be an essential brain area that inhibit “directional constraint” (Nakagawa et al., 2016) and our previous study showed that lower gamma-aminobutyric acid (GABA) concentration in SMA was associated with poorer skills of coordinated movements (Umesawa et al., 2020). Based on these, we hypothesized that decreased inhibitory metabolite, such as GABA levels in SMA are associated with strong “directional constraint” that resulted in lower skills of coordinated movements of individuals with ASD. Objectives: We investigated whether stronger “directional constraint” between rhythmic movements of two limbs are more pronounced in individuals with ASD. We also determined if lower skills of coordinated movements and decreased GABA levels in SMA were associated with the higher degree of “directional constraint.” Methods: We recruited 18 ASD (mean age, 21.7±3.1 years; 7 females, 11 males) and 27 typically developing (TD) participants (mean age, 22.6±4.1 years; 16 females, 11 males) in this study. The participants performed rhythmic movements of two limbs in the opposite direction (antiphase movements) in three separate limb combinations (bilateral hands, contralateral hand and foot, and ipsilateral hand and foot). To evaluate the degree of “directional constraint,” we defined the index of absolute errors (AEΦ) of the relative phase of two limbs from the target relative phase (i.e., 180°). Ten individuals with ASD and 14 TD participants were assessed for coordinated movement skills using a clinical assessment tool (Bruininks-Oseretsky Test of Motor Proficiency Second Edition: BOT-2). GABA levels in SMA were measured in 11 patients with ASD and 12 TD participants using 1H-magnetic resonance spectroscopy (1H-MRS). Results: ASD participants showed significantly greater AEΦ than TD participants in the opposite directional movement with contralateral hand and foot combination ( $t(43) = 4.11, p < 0.01$ ), and ipsilateral hand and foot combination ( $t(43) = 2.37, p = 0.02$ ). In the pooled data of the ASD and TD groups, participants who showed greater AEΦ in those conditions exhibited poorer coordinated movement skills as assessed by BOT-2 (bilateral hand and foot:  $r = -0.48, p = 0.02$ ; ipsilateral hand and foot:  $r = -0.51, p < 0.01$ ). Moreover, GABA levels in SMA tended to correlate with AEΦ in the ipsilateral hand and foot condition in all participants ( $r = -0.34, p = 0.10$ ). Conclusions: Our results suggest that “directional constraint” of two limbs is higher in individuals with ASD. Additionally, lower GABA levels in SMA may underlie stronger degree of “directional constraint.” Since previous studies showed that reduced neural activity in SMA causes strong “directional constraint” (Steyvers et al., 2003), we can speculate that impaired modulation of neural activation in SMA due to decreased inhibitory metabolites (GABA) causes difficulties in inhibiting “directional constraint,” and this may disrupt hand-foot coordination in individuals with ASD.

**401.028 (Poster)** Defining Autistic Burnout Using Grounded Delphi Method: Autistic Burnout through the Eyes of Experts By Lived Experience

**J. Higgins<sup>1,2</sup>, J. Weise<sup>1</sup>, J. N. Trollor<sup>1</sup>, E. Pellicano<sup>3</sup> and S. Arnold<sup>1</sup>,** (1)Department of Developmental Disability Neuropsychiatry, UNSW, Sydney, NSW, Australia, (2)Cooperative Research Centre for Living with Autism (Autism CRC), Brisbane, QLD, Australia, (3)Macquarie School of Education, Macquarie University, Sydney, NSW, Australia

Background:

Autistic burnout is commonly described by autistic people, as evidenced by fervent discussion of #AutBurnout on social media. Yet, the lack of research on this topic means we know virtually nothing about its causes, correlates or consequences. Anecdotal links have been noted with autistic ‘camouflaging’, ‘masking’ and health status in autism.

Objectives:

We sought to redress this lack of academic research. This project aimed to create a thick description (Geertz, 2017) and definition of autistic burnout using Grounded Delphi Method (GDM; Howard, 2018).

Methods:

GDM combines the Delphi method, useful in emerging research areas, with grounded-theory, useful for conceptualisation and theory building. We surveyed autistic adults, as experts by experience. Over three survey rounds, we asked them to report on their experiences of autistic burnout and reached consensus on a definition. Twenty-two experts were surveyed, all had been formally diagnosed with autism and were above cut-off on the Autism Quotient-28.

Round 1 began with open-ended questions asking for experts’ experiences and then targeted questions e.g. differentiating between depression and burnout. We analysed responses from round 1 using grounded-theory concepts. To ensure no dominance of neurodivergent or neurotypical interpretations, open coding was completed independently by the project co-leaders, then, across multiple video conferencing sessions, a consensus on the coding framework was reached and axial coding completed.

An initial definition of autistic burnout was shared with experts and used as the basis for the round 2 survey. In the round 2 analyses, qualitative responses were subjected to a basic template analysis (Brooks et al., 2015), and quantitative analysis to determine degree of consensus to specific features of the draft definition. Few changes were required, and overall consensus was reached in round 3.

#### Results:

Our Phase 1 experts described autistic burnout as preceded by fatigue from camouflaging or masking, cognitive overload and other stressors. It results in exhaustion and interpersonal withdrawal, reduced executive and overall functioning, potentially fugue or dissociation, suicidal ideation and increased visibility of autistic traits. Withdrawal primarily functions as a coping mechanism. A conceptual model developed using grounded theory approaches highlights the overarching impact on energy levels of interactions within an unaccommodating neurotypical world. A DSM-5 style definition has been created aimed at the clinician and autistic communities.

#### Conclusions:

Autistic burnout appears to be a debilitating condition with onset linked to everyday stressors faced by autistic people in an unaccommodating world. The condition appears distinct from non-autistic burnout or depressive episodes. In common with non-autistic burnout, research is needed to establish further whether this condition might be a non-typical presentation of depression, chronic fatigue syndrome or another condition. A follow-up study is underway to validate the definition, by making direct comparisons to the definition from Raymaker et al. (2020), and establishing convergent and discriminant validity.

Therapeutic strategies such as behavioural activation (e.g., encouraging socialisation; Tindall et al., 2017) would be contraindicated in autistic burnout. Understanding commonalities and risk factors related to autistic burnout should inform mental health and preventative health measures for autistic adults.

**401.029** (Poster) Development of the Suicide Ideation Attributes Scale-Modified (SIDAS-M) in Autistic Adults

---

**Background:** There are currently few instruments specifically designed or adapted to assess suicide risk in the autistic population. The Suicidal Ideation Attributes Scale (SIDAS) is a 5-item assessment of suicidal ideation that is commonly used and well-validated in suicide research. Unlike other instruments that primarily assess past suicidal behavior (e.g., Suicide Behaviors Questionnaire-Revised; SBQ-R), SIDAS focuses on recent (4-week) ideation making it useful for identifying current risk. SIDAS demonstrates a single factor, good internal consistency, and convergent validity. In addition to strong psychometric properties, its clear questions and straightforward design make it a strong candidate for suicide risk assessment in the autistic population. Therefore, we followed current gold-standard recommendations for measurement development and modification, as well as co-production with autistic people, to derive and validate a modified version of the instrument (SIDAS-M) specifically adapted for use with autistic adults with a diverse range of abilities.

**Objectives:** 1) Describe the co-production of SIDAS-M; 2) Compare SIDAS-M with SBQ-R and Patient Health Questionnaire (PHQ-9) in a sample of autistic adults.

**Methods:** The study was approved by the university ethics committee (#HEC20235). Preliminary data are reported for 11 (6 female, 4 male, 1 non-binary) autistic adults aged 21 to 56 years ( $M=30.33$ ,  $SD=13.40$ ) who were participating in a larger suicide prevention study. The present study examined relationships between SIDAS-M, SBQ-R and PHQ-9.

**SIDAS-M.** A panel of content experts, including the original author of the SIDAS, academic and clinical psychologists, a psychiatrist, suicide prevention experts, an autistic academic, and an autistic consultant with lived experience, and a panel of 10 autistic adults (who represent gender, cultural, mental health, suicide behavior, and ability diverse populations), revised the original SIDAS based on recommended guidelines. The instrument was circulated amongst all members, incorporating revisions

and recommendations, until consensus on the final version was reached. Modifications to the original version included improved clarity of language and item wording, a visual analogue scale, and addition of response exemplars.

**Results:** Data collection is ongoing, preliminary/pilot data are reported here. Participant scores ranged from mild to severe on the PHQ-9, and eight participants were in the risk range ( $\geq 7$ ) on SBQ-R. Mean scores on the SIDAS-M ranged from 0 to 26 ( $M=6.73$ ,  $SD=8.31$ ; possible range 0—50), revealing a wide range of suicidality from minimal to high risk. SIDAS-M was significantly associated with SBQ-R Total,  $r=.605$ ,  $p=.049$ , BCa 95% CI [.248, .906], and item 1 (lifetime suicide ideation and attempt),  $r=.765$ ,  $p=.006$ , [.360, .983], but was only weakly associated with PHQ-9 Total,  $r=.483$ ,  $p=.133$ , [-.019, .915], and item 9 (thoughts of self-harm),  $r=.440$ ,  $p=.175$ , [-.002, .979].

**Conclusions:** Our study describes the development and co-production of the newly modified SIDAS-M, designed for assessing suicidal thoughts in autistic people. Preliminary data for 11 participants revealed good concordance with SBQ-R, but a weak association with PHQ-9. Future comprehensive validation will include the application of classic test and item response theories to evaluate the factor structure and invariance across key factors of interest (e.g., sex, cognitive functioning) as well as development of optimal cut scores.

**401.030 (Poster) Diagnosis of Autism in Girls: Evidence from India**

**P. Malhi<sup>1</sup> and P. Singh<sup>2</sup>,** (1)Department of Pediatrics, Post Graduate Institute of Medical Education and Research, Chandigarh, India, (2)Department of Pediatrics, Post Graduate Institute of Medical Education and research, Chandigarh, India

Background:

A consistent finding in the literature is the predominance of autism spectrum disorder (ASD) among boys as compared to girls. Few studies, especially from developing countries, have examined how autism presents in boys and girls and whether this poses a problem in diagnosis.

Objectives:

To examine gender differences among the high functioning autism spectrum disorder (ASD) children with respect to age of diagnosis and clinical characteristics.

Methods:

A retrospective analysis was conducted of the case records with a diagnosis of high functioning autism (HFA) maintained at the outpatient Pediatric Psychology Clinic of the Department of Pediatrics of a tertiary care teaching hospital. Information regarding demographic, socio-economic variables, clinical characteristics such as presence of restricted repetitive behaviors (RRBs), history of developmental regression, hyperactivity, self injurious behaviors and deficits in social emotional reciprocity was extracted from the case records of the patients and scored. Inclusion criterion was children who fulfilled the diagnostic criteria for ASD based on the DSM criteria and an IQ of 70 and above. Children with incomplete records and co-morbid neurological condition such as epilepsy were excluded. The sample retrospectively included a total of 313 cases (256 boys and 57 girls) and the mean age of the sample was 5.02 yrs ( $SD=2.70$ ). Approval to the retrospective study was granted by the ethics committee of the institute.

Results:

Boys constituted 81.8% ( $N=256$ ) of the sample and the M: F ratio was 4.49: 1. The HFA boys and girls were well matched on cognitive functioning. There was a significant difference in the age of diagnosis by gender ( $t=2.79$ ,  $P=0.006$ ) and HFA girls were diagnosed 1.10 years later than boys. No gender differences were found on socio-economic background characteristics (all  $P>.05$ ). The HFA boys and girls differed on several clinical features including presence of RRBs ( $\chi^2=6.06$ ,  $P=.014$ ) and severity of social emotional reciprocity deficits ( $\chi^2=7.11$ ,  $P=0.008$ ). Some of the possible reasons for later age of diagnosis among girls include bias in the way the diagnostic criteria are applied, culturally prevalent gender bias in seeking medical help for girls, physician's bias or lack of knowledge of how autism presents in girls, and social camouflaging skills of girls. Indeed, evidence indicates that girls can maintain brief social interactions and escape early detection, due to better social skills relative to boys.

Conclusions:

Girls with high functioning autism are at a significant risk of being under-recognized and diagnosed at a later age than boys in India. Identifying the gender specific differences in autism symptomatology in high functioning children will help in paving the way for better detection and assessment of autism in girls so as to increase their access to support and intervention services.

**401.031** (Poster) Diagnostic Timing and Gender Diversity: Impacts on Camouflaging Behaviors in Autism

**G. McQuaid<sup>1</sup>**, N. R. Lee<sup>2</sup> and G. L. Wallace<sup>3</sup>, (1)George Mason University, Fairfax, VA, (2)Department of Psychology, Drexel University, Philadelphia, PA, (3)The George Washington University, Washington, DC

---

**Background:** Camouflaging in autism spectrum disorder (ASD) refers to behaviors that mask autism-related social challenges. Factors associated with camouflaging in ASD are beginning to emerge, with particularly strong evidence that those assigned female sex at birth demonstrate elevated camouflaging. Further, relative to cisgender ASD individuals, gender non-binary ASD individuals may also exhibit greater camouflaging. Qualitative reports, which indicate that camouflaging modifies the presentation of core ASD social and communication features, suggest a role for camouflaging in late and missed diagnosis, particularly among ASD females.

**Objectives:** Therefore, the current study seeks to: a) replicate prior findings of increased camouflaging in ASD females; b) examine whether gender diverse ASD individuals report elevated camouflaging; and c) investigate if adult-diagnosed ASD individuals exhibit elevated camouflaging compared to those diagnosed in childhood/adolescence.

**Methods:** 406 ASD individuals aged 18-39 years were recruited via Simons Powering Autism Research and Knowledge (SPARK) to complete a battery of online questionnaires. Measures analyzed here include a question inquiring about age of ASD diagnosis, questions querying gender identity and sex assigned at birth, and the Camouflaging Autistic Traits Questionnaire (CAT-Q). Participants were grouped into those who received an ASD diagnosis during childhood/adolescence ( $n=229$ ) and those who received a diagnosis in adulthood ( $n=177$ ). Multivariate Analysis of Variance (MANOVA) was used to evaluate potential differences in camouflaging between: a) males versus females, b) gender diverse versus gender non-diverse, c) ASD child/adolescent- compared to adult-diagnosed individuals, and d) interactions among a-c. Dependent variables were CAT-Q factors: Assimilation, Compensation and Masking.

**Results:** The MANOVA revealed significant main effects of sex ( $F=8.96, p<.001$ ), gender diversity ( $F=2.87, p=.04$ ), and age of diagnosis ( $F=8.48, p<.001$ ), as well as a significant diagnostic age group  $\times$  gender diversity interaction ( $F=3.19, p=.02$ ). No significant interactions were found with sex assigned at birth ( $ps>.05$ ). Follow-up ANOVAs (Bonferroni corrected  $p<.0167$ ) revealed ASD females reported higher camouflaging across all three factors: Assimilation ( $F=22.12, p<.001$ ), Compensation ( $F=13.27, p<.001$ ) and Masking ( $F=9.84, p=.002$ ). ASD gender diverse individuals also reported greater Compensation than gender non-diverse individuals ( $F=6.38, p=.01$ ). Adult-diagnosed ASD individuals reported higher Assimilation ( $F=24.02, p<.001$ ) and Compensation ( $F=11.29, p<.001$ ) than those diagnosed in childhood/adolescence. Finally, a diagnostic age group  $\times$  gender diversity interaction was found for Assimilation ( $F=6.52, p=.01$ ), wherein ASD gender diverse individuals diagnosed as adults reported the highest levels of this camouflaging factor.

**Conclusions:** Here we replicate findings of elevated camouflaging among ASD females. Our novel findings center around additional factors that distinguish camouflaging utilization among ASD adults. Specifically we find that gender diverse individuals, particularly those diagnosed as adults, report elevated Assimilation compared to gender non-diverse ASD individuals. Specifically, gender diverse adults report that they engage in more behavioral approaches to 'blend in' during social situations. Finally, we find that compared to those diagnosed in childhood/adolescence, adult-diagnosed ASD adults exhibit both greater efforts to 'blend in' as well as strategies that include learning about social interactions by watching and modeling others, and practicing body language and gestures in order to moderate social challenges.

**401.032** (Poster) Earlier MMN Peak in Unaffected Siblings of Taiwanese Adults with Autism Spectrum Disorder

**Y. L. Chien<sup>1</sup>**, M. H. Hsieh<sup>2</sup> and S. S. F. Gau<sup>3</sup>, (1)National Taiwan University, Taipei, Taiwan, (2)Department of Psychiatry, National Taiwan University Hospital, Taipei, Taiwan, (3)Department of Psychiatry, National Taiwan University Hospital & College of Medicine, Taipei, Taiwan

---

**Background:** The paradigms of mismatch negativity (MMN) and P3a are frequently used to measure the brain response of novelty discrimination and attention re-orienting. Individuals with autism spectrum disorder (ASD) tend to detect the trivial changes in the environment and are shown to have abnormal MMN response. Our previous study also demonstrated that ASD individuals showed an earlier P3a peak compared to typically developing controls (TDC).

**Objectives:** Given that unaffected siblings of ASD probands may share similar brain function with their affected siblings, this study aims to investigate the MMN and P3a response in the unaffected siblings of ASD probands.

**Methods:** This study recruited 43 unaffected siblings of ASD probands (aged 17.0) and 51 TDC (aged 16.7). All the participants underwent the event-related potential procedures including MMN and P3a paradigms of both duration and frequency deviants. We then compared the peak latency and peak amplitude of MMN and P3a of both duration (dMMN and dP3a) and frequency (fMMN and fP3a) paradigms between the unaffected siblings of ASD probands and TDC groups controlling for sex, age, and full-scale IQ.

**Results:** We found that the unaffected siblings of ASD probands showed an earlier fMMN peak consistently at the electrodes Fz, Fcz, and Cz compared to TDC. Besides, unaffected siblings also showed a trend of shorter dP3a latency compared to TDC. As for the clinical correlates of the fMMN peak latency, we found these parameters were associated with stereotyped behaviors, social emotion problems (of the Social Responsiveness Scale) and mindreading deficits (on the Autism Spectrum Quotient) of the whole sample.

**Conclusions:** The unaffected siblings of ASD probands may have an earlier MMN response towards frequency deviants that may be correlated with their autistic traits. These findings warrant further studies to validate.

#### **401.033 (Poster) Effects of Elevated Autistic Traits on the Aging Cerebellum**

**A. Job Said<sup>1</sup>, B. B. Braden<sup>2</sup>, B. Woodruff<sup>3</sup>, R. J. Caselli<sup>1</sup> and G. L. Wallace<sup>1</sup>,** (1)The George Washington University, Washington, DC, (2)College of Health Solutions, Arizona State University, Tempe, AZ, (3)Mayo Clinic Arizona, Scottsdale, AZ, (4)Mayo Clinic Arizona, Phoenix, AZ

---

**Background:** Our knowledge of middle and older age adults with autism spectrum disorder (ASD) is scant. The studies that have been completed are limited by cohort effects and other confounds that obscure our understanding of the relationship between autistic behavior and brain structure in middle and later adulthood. One approach to circumventing these obstacles is to examine the impact of the Broader Autism Phenotype (BAP) on the brain during middle and later adulthood. The BAP represents elevated subclinical autistic traits occurring in approximately 5-10% of the population<sup>1</sup>. Our own research has shown that the BAP during older adulthood (60-91 years) is associated with more executive function and social cognitive challenges<sup>2,3,4</sup>.

**Objectives:** The current study extends this line of inquiry to brain structure. More specifically, for the first time, this study examines links between cerebellar structure (given robust findings of reduced cerebellar gray matter in ASD<sup>5</sup> and aging-related declines in cerebellar gray matter during neurotypical development<sup>6</sup>) and the BAP during middle and older adulthood.

**Methods:** 166 community dwelling adults (76% female) ranging in age from 49-81 ( $M=64$ ) years completed a neuropsychological battery and provided a Magnetization Prepared-Rapid Gradient Echo (MP-RAGE) magnetic resonance imaging (MRI) scan. The BAP was assessed using self-ratings from the Autism Quotient (AQ<sup>7</sup>). Volumes of the cerebellum and its subcomponents (28 regions) were quantified using a novel algorithm, ACAPULCO<sup>8</sup>, and compared between the highest quartile of AQ scorers (BAP;  $n=47$ ) and the other 72% of the sample (non-BAP;  $n=119$ ) using multivariate analysis of covariance (MANCOVA) accounting for the effects of age, gender, and total intracranial volume (ICV).

**Results:** There was a significant 3-way interaction between cerebellar region, hemisphere, and group (BAP vs. non-BAP;  $F=2.59, p=.02, \eta^2=.016$ ) after accounting for covariates. Follow-up analyses revealed that BAP adults had decreased cerebellar volume compared to the non-BAP group in Right Crus I and in Left Lobule VI ( $F_s>4.32, p_s<.04, \eta^2_s>.025$ ), after co-varying the influences of age, gender, and ICV.

**Conclusions:** This study provides the first evidence that the BAP could increase risk for cerebellar gray matter volume reductions during a period of development (middle and older adulthood) when tissue loss is already occurring<sup>6</sup>. Strikingly, similar findings of decreased gray matter of Right Crus I in particular have been shown repeatedly in the literature, including meta-analytic studies of children and young adults with ASD<sup>5</sup>. The BAP might therefore exacerbate aging effects that result in cerebellar volumetric reductions, particularly in areas like Right Crus I, which have been linked previously with clinical expressions of the autistic phenotype<sup>5</sup>. This convergence across subclinical (BAP) and clinical (ASD) samples lends validity to the investigation of the BAP in adult development to inform neurobiological effects of aging in ASD.

#### **401.034 (Poster) Employment Related Changes Following COVID-19: A Longitudinal Examination of Mental Health and Work-Related Need Satisfaction of Autistic Employees**

**Y. Goldfarb<sup>1</sup>, E. Gal<sup>2</sup> and O. Golan<sup>3</sup>,** (1)Department of Occupational Therapy, University of Haifa, Haifa, Israel, (2)Occupational Therapy, University of Haifa, Haifa, Israel, (3)Department of Psychology, Bar-Ilan University, Ramat-Gan, Israel

---

**Background:** The COVID-19 ongoing crisis introduces employment related challenges worldwide. Along with soaring unemployment rates, effects on employees who remain employed are also reported. Common implications are changes in working hours, increased work demand, wage reduction, and changes in working conditions and environments, such as working from home (Restubog et al., 2020; Solomon, 2020). Forced changes in work environments could lead to deterioration in work satisfaction, work motivation, satisfactions of employment needs and well-being (Gagné, 2020). Consequences of COVID-19 may be especially challenging for autistic people. Swift changes forced by the pandemic, along with characteristic intolerance to uncertainty and high levels of anxiety, suggest negative psychological outcomes resulting from the pandemic (Cassidy et al., 2020). In the employment arena, outcomes of autistic people are relatively poor to begin with (Nicholas et al., 2019), making this population especially vulnerable at times of employment instability.

**Objectives:** To explore autistic adults' employment related changes, experiences and mental health following COVID-19, compared to pre-COVID measures.

**Methods:** Data were collected from 23 participants diagnosed with ASD (4 females), aged 20–49, who answered an online administered survey at two timepoints: a few months prior to the COVID-19 outbreak, and during the outbreak. Self-reports included measures of background and employment status; mental health (General Health Questionnaire-12); job satisfaction (Minnesota Satisfaction Questionnaire); and satisfaction of psychological needs at work (Psychological Need Satisfaction and Frustration – Work domain).

**Results:** Among the 23 participants who answered the follow-up survey, sixteen (69.6%) were employed, of whom ten (43.5%) reported physically going to work and six (26.1%) worked remotely from home; four participants (17.4%) were in furlough, and three (13%) were unemployed. T1 to T2 comparisons employing Wilcoxon tests for paired samples indicated a significant increase in participants' emotional distress. However, the separate examination by employment status revealed a significant effect among participants who do not work, a marginally significant effect among participants working from home, and no significant change in mental health scores among participants who physically report to work (see Figure 1). Furthermore, while employees physically attending work did not present differences in need satisfaction, employees working from home presented a significant decline in the satisfaction of the needs for competence and autonomy following COVID-19 related restrictions (See Figure 2).

**Conclusions:** Results highlight the positive effects of a stable employment for autistic people, helping to preserve emotional stability even at times of uncertainty. Remote work from home may hold advantages and allow autistic employees to sustain their jobs under COVID-19 restrictions, but possible shortcomings may also arise, such as deterioration in psychological need fulfillment and increased levels of distress. More research is needed to achieve a broader understanding of remote work for autistic employees, and how their employment needs should be best supported.

**401.035 (Poster) Evaluating Employment Outcomes & Perceptions in Adolescents and Young Adults with ASD**  
*N. A. Dalloul<sup>1</sup>, A. Davis<sup>2</sup>, A. C. Cho<sup>3</sup>, R. A. Wulff<sup>4</sup> and M. Solomon<sup>5</sup>, (1)UC Davis Psychiatry and Behavioral Sciences, Sacramento, CA, (2)UC Davis MIND Institute, Sacramento, CA, (3)Human Development & Psychology, University of California, Los Angeles, Los Angeles, CA, (4)Department of Psychiatry & Behavioral Sciences, UC Davis MIND Institute, Sacramento, CA, (5)Department of Psychiatry and Behavioral Sciences, The Medical Investigation of Neurodevelopmental Disorders (MIND) Institute, UC Davis School of Medicine, University of California Davis, Sacramento, CA*

---

**Background:** The employment rate for adolescents and young adults with ASD is extremely low, and poorer than the rate for other disability groups and ex-convicts (Solomon, 2020). The negative implications of this issue extend past financial instability because having a job provides daily structure, socialization opportunities, and mental health benefits. While those with ASD may exhibit non-normative behaviors and social deficits that deter employers during hiring, they are often highly reliable and efficient employees (Scott et al., 2017). In order to reduce misinformation, understand support needs, and improve ASD employment outcome, it is imperative to understand the vocational experiences and self-perceived limitations of adolescents and young adults with ASD.

**Objectives:**

1. Identify differences in employment outcomes between adolescents and young adults ages 16-24 years with and without ASD.
2. Investigate underlying perceptions that influence these differences.

**Methods:** As part of a more extensive study of cognition and adult outcomes, typically-developing participants (TYP;  $n=49$ ; FSIQ4 -  $M(sd)=110.2(13.12)$ ) and participants with gold standard diagnoses of ASD ( $n=49$ ; FSIQ4 -  $M(sd)=101.6(12.6)$ )

completed a self-reported social functioning questionnaire (Birchwood Social Functioning Scale [SFS]; Birchwood et al., 1990). Items from the SFS's employment section were analyzed using a combination of between-group independence tests and within-group *t*-tests. *IQ* (Wechsler Abbreviated Scale of Intelligence-II [WASI-II]; Wechsler, 2011), ASD symptom severity (Social Communication Questionnaire [SCQ]; Rutter, 2003), and psychopathology (Achenbach System of Empirically Based Assessment [ASEBA]; Achenbach & Rescorla, 2003) measures were then used to identify potential underlying associations with group differences in employment outcomes.

Results: There was a significant difference between distributions of ASD and TYP participants in their responses to "Are you in regular employment?" where TYP was 2.5 times more likely to report they were employed ( $\chi^2 P = 0.0019^{**}$ ; Figure 1a). For both groups, within-group *t*-tests showed that older participants were more likely to report they were employed (ASD  $P = .003^{**}$ ; TYP  $P = .015^*$ ; Table 1). Within the TYP group, participants with lower full-scale IQ ( $P = .025^*$ ), non-verbal IQ ( $P = .034^*$ ) and ASEBA Depression scores ( $P = .026^*$ ) were more likely to report they were employed (Table 1).

Those who were unemployed answered additional questions (TYP – [n = 22]; ASD – [n = 38]). In response to "Are you capable of some sort of employment?", only 63% of ASD participants answered, "definitely capable", relative to 100% of TYP (Fisher's  $P = .0001^{***}$ ; Figure 1b). For the ASD group, those who responded "definitely" had a higher mean SCQ score than those who responded, "would have difficulty" ( $P = .006^{**}$ ; Table 1).

In response to "How often do you make attempts to find a job?", ASD participants primarily responded "never" whereas TYP primarily responded "sometimes". However, this difference was not statistically significant ( $p = .288$ ; Figure 1c).

Conclusions: Adolescents and young adults with ASD (16-24 years) were employed less frequently and expressed they were less capable of working than age-matched TYP. Future analyses will include more detailed participant and parent reports. Within-group interactions with IQ, depression, and social communication scores will be further explored.

**401.036 (Poster)** Every Cloud Has a Silver Lining: Three Case Studies of Community Participation Change in Adults with ASD Following the Onset of the COVID-19 Pandemic  
*J. Nagle<sup>1</sup>, A. Pearl<sup>2</sup>, M. Salzer<sup>3</sup> and D. Alexander<sup>1</sup>, (1)Psychiatry, Penn State College of Medicine, Hershey, PA, (2)Department of Psychiatry/Division of Autism Services, Penn State Hershey/Penn State College of Medicine, Hershey, PA, (3)Temple University, Philadelphia, PA*

Background: Community participation is engagement in natural contexts with others with or without disabilities within the general community outside of supported environments. Following the recommendation for social distancing and the shutdown of many community activities in March, 2020, many people experienced a significant decrease in community participation. Data from 2017 suggests that adults with Autism Spectrum Disorder (ASD) report fewer days of and less varied community participation compared to neurotypical individuals. It is unknown as this time if there was a change in community participation for adults with ASD as was experienced by most neurotypical individuals during this time.

Objectives: To examine changes in community participation in adults with ASD from January-February, 2020 (pre-COVID-19 restrictions) to October-November, 2020 (continued COVID-19 restrictions).

Methods: A randomized controlled trial (RCT) to examine the impact of an intervention to increase community participation in adults with ASD opened in October, 2019. Individuals were enrolled and completed a baseline assessment of their levels of community participation. This project was halted in March, 2020 as a result of the COVID-19 pandemic. The project was re-opened as a longitudinal design in October, 2020. Three individuals who had previously enrolled and were assigned to the treatment have re-enrolled (baseline data is currently being collected). At both time points, participants completed the Temple University Community Participation (TUCP; Salzer et al., 2014) measure which assesses in the past month the number of days spent participating in the community and types of activities. Also, participants completed the Visual Activity Sort (VAS; O'Day, 2020), a card sort of 90 activities which they were asked to sort two ways: feelings towards the activity (like, neutral, dislike) and desire to engage in the activity (want to do more, want to do, currently do, do less, don't want to do). At time 2, each participant will complete a semi-structured qualitative interview including questions such as "How did your participation in community activities change during COVID-19?"

Results: It is hypothesized that the TUCP will reflect preliminary findings of low community participation and low activity variability with little change from early 2020 to late 2020. To date, preliminary findings from the VAS point to higher desire to engage in community activities identified as neutral/like and want to do more/want to do, which is significantly higher than expected given the TUCP results. We expect that this will continue; however, we anticipate that more activities will shift to "want to do more" and "want to do" categories. Finally, we anticipate that conducting a follow-up qualitative assessment will

contribute to the explanation for any changes in community participation following the onset of the COVID-19 pandemic community restrictions.

Conclusions: Capitalizing on a naturalistic experiment examining changes in community participation following the onset of the COVID-19 pandemic, community participation restrictions in adults with ASD is a silver lining. Findings from these case studies may point to the impact of the COVID-19 pandemic on adults with ASD, which may or may not be similar to those of most neurotypical individuals during this stressful time.

**401.038 (Poster)** Executive Functioning and Adjustment to College in Students with and without Autistic Traits  
**D. Davidson<sup>1</sup>, A. Winning<sup>2</sup>, E. Hilvert<sup>3</sup> and D. Morales<sup>3</sup>, (1)Psychology, Loyola University Chicago, Chicago, IL, (2)Loyola University Chicago, Chicago, IL, (3)Loyola University, Chicago, IL**

---

Background:

Studies estimate that college students may exhibit autism symptomatology without awareness of it in themselves or by others. Thus, this population is often underserved by student accessibility offices, yet encounter similar issues as college students with a formal diagnosis, including executive functioning challenges and adjustment issues (Davidson & Morales, 2020).

Objectives:

The primary objectives were to examine group differences in executive dysfunction and adjustment to college (i.e., academic, social, personal-emotional, institutional attachment) in students with and without autistic traits. Also explored were the relations between executive dysfunction and adjustment.

Methods:

Following IRB approval, 144 college students from a Psychology 101 subject pool participated. Students with autistic traits ( $n = 57$ ;  $M = 19;10$ , range 18;04 – 25;02) and without autistic traits ( $n = 87$ ;  $M = 19;08$ , range 18;10 – 22;07) were determined using T-scores from the Social Responsiveness Scale (SRS-2). The SRS-2 has been shown to be a robust instrument for detecting the presence and severity of social impairment and restrictive/repetitive behaviors associated with autism (Constantino & Gruber, 2012). Students did not differ on gender (72% female), race (65% Caucasian), year in school (first, second), or GPA ( $M = 3.3$ ).

The Behavior Rating Inventory of Executive Functioning (BRIEF-Adult Self Report) and the Student Adaptation to College Questionnaire (SACQ; Baker & Siryk, 1989, 2017) were administered. The BRIEF-A-SR is a standardized, self-report measure that assesses adults' views of their own executive functioning in their everyday environment (Roth et al., 2005).

The SACQ is a widely used measure that examines academic adjustment (beliefs about adequacy of studying and academic efforts), social adjustment (beliefs about successful integration into the social milieu of college), personal-emotional adjustment (students' psychological and physical well-being) and institutional attachment (students' emotional attachment to their university).

Results:

Results for the BRIEF-A-SR and the SACQ are displayed in Table 1. Students with autistic traits exhibited greater executive dysfunction than neurotypical students and were more likely to exceed the clinical threshold on the BRIEF-A-SR. Students with autistic traits also scored significantly lower on social and personal-emotional adjustment than neurotypical students. Students did not differ on academic adjustment or institutional attachment. Executive dysfunction was negatively related to personal-emotional adjustment,  $r(142) \geq .29$ ,  $p \leq .01$ , but only in students with autistic traits.

Conclusions:

Students with autistic traits showed lower social and personal-emotional adjustment to college but did not differ from neurotypical students in terms of academic adjustment. Students with autistic traits also demonstrated worse executive functioning. These findings suggest that students with autistic traits may struggle in ways similar to students with a formal diagnosis of autism (Jackson et al., 2018). Moreover, given the negative association between executive dysfunction and personal-emotional adjustment, the BRIEF-A-SR may help to identify and target treatments for students at risk of experiencing college

adjustment issues

**401.039 (Poster)** Experiences of Social Isolation and Loneliness in Middle-Aged and Older Autistic Adults

**G. R. Stewart<sup>1</sup>, E. Luedecke<sup>2</sup>, R. A. Charlton<sup>3</sup> and F. Happé<sup>1</sup>.** (1)Social, Genetic and Developmental Psychiatry Centre, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (2)King's College London, London, United Kingdom, (3)Psychology, Goldsmiths University of London, London, United Kingdom

---

**Background:** Research examining the experiences of autistic children and younger adults have often indicated increased rates of social isolation and loneliness when compared to non-autistic populations. Despite both social isolation and loneliness being associated with older age in non-autistic populations, few studies have examined whether middle-aged and older autistic adults are at an increased likelihood of these experiences.

**Objectives:** This study explored differences in the experience of social isolation and loneliness among middle-aged and older autistic adults with an age and sex-matched non-autistic comparison group. The influence of age, gender, and symptoms of poor mental health was also examined in relation to the experience of social isolation and loneliness.

**Methods:** Using a cross-sectional online survey, a total of 428 adults (autistic  $n = 265$ ) aged 40-93 (mean age = 60.50 years) completed standardised questionnaires related to their experiences of poor social connectedness (i.e. social isolation) and loneliness, and current symptoms of depression and anxiety. Group differences and associations in social isolation and loneliness were examined. These group differences and associations were then examined in relation to age, gender, and symptoms of depression and anxiety.

**Results:** Those in the autistic group reported being less socially connected (i.e. more socially isolated) and lonelier than the non-autistic group. While there were no gender differences in the experiences of social isolation, women reported being lonelier than men in both the autistic and non-autistic group. A similar pattern of results was found when controlling for age and current symptoms of depression and anxiety. Furthermore, social isolation was found to be positively associated with age in the autistic and non-autistic groups. However, loneliness was only found to be positively associated with age in the autistic group. For both social isolation and loneliness, the associations with age were significantly stronger in men than women.

**Conclusions:** The findings from the current study suggest that autistic adults may be particularly susceptible to social isolation and loneliness in older age. Autistic women were found to experience elevated rates of loneliness when compared to autistic men. However, autistic men may be at a greater risk than autistic women of increasing social isolation and loneliness with age. This study highlights the need for evidence-based interventions to address social isolation and to reduce loneliness for autistic people as they age.

**401.040 (Poster)** Exploring Problematic Internet Use and Gaming in Young Adults with Autism Spectrum Disorder

**C. L. Normand<sup>1</sup>, M. H. Fisher<sup>2</sup>, S. M. Fecteau<sup>3</sup>, E. Roy<sup>4</sup>, K. Tremblay<sup>5</sup> and M. H. Poulin<sup>6</sup>.** (1)Psychoéducation et psychologie, Université du Québec en Outaouais, Gatineau, QC, Canada, (2)Counseling, Educational Psychology, and Special Education, Michigan State University, East Lansing, MI, (3)Psychoéducation et psychologie, Université du Québec en Outaouais, St-Jérôme, QC, Canada, (4)Psychoéducation and Psychology, Université du Québec en Outaouais, Gatineau, QC, Canada, (5)Développement humain et social, UQAT, Rouyn-Noranda, QC, Canada, (6)Psychoéducation, UQAT, Rouyn-Noranda, QC, Canada

---

**Background:** Restricted interests in technology, combined with greater ease in communicating online than face to face could result in young adults with autism spending large amounts of time on internet and potentially becoming addicted to the internet. Despite positive correlations between autistic traits and problematic internet use, few studies have examined problematic internet use in clinical samples of individuals with autism spectrum disorder (ASD).

**Objectives:** 1- To determine how many individuals with ASD in our sample scored within the clinical range of problematic internet use or gaming disorder, 2- to explore whether certain demographic characteristics were related to problematic internet use or gaming.

**Methods:** A convenience sample of individuals with ASD between the ages of 16 and 30 years old was recruited through social media posts and organizations providing services to people with ASD in Canada. Sixty-five individuals with autism spectrum disorder (mean age = 23.77, SD = 4.3) completed an online survey. There were 34 female and 29 male respondents according to birth sex (2 missing data). Two thirds of the participants reported at least one co-occurring mental health condition. The most

common conditions were anxiety disorder (38.8%,  $N = 26$ ), attention deficit hyperactivity disorder (ADHD; 35.8%,  $N = 24$ ) and depression (29.9%,  $N = 20$ ). The survey was designed to measure substance and non-substance use as well as known risk and protective factors to substance related and addictive disorders among individuals with ASD. For the current study, responses were analyzed to determine the number of participants meeting criteria for problematic internet use or gaming disorder. Exploratory analyses examined whether scores were associated to gender, age, employment status, or co-occurring mental health conditions.

Results: Six participants (9.3%) had problematic internet use, while only two (3%) scored above the suggested cut-off for gaming disorder. Both were among the youngest participants (17-year-old males). Exploratory analyses found no relation between problematic internet use or gaming disorder symptoms and gender, age, employment status or co-occurring diagnoses of anxiety, ADHD or depression.

Conclusions: Our data suggest that problematic internet use is more frequent than gaming disorder in a community sample of young adults with autism. Further research is needed and most importantly, a larger number of clinical cases of problematic internet use is necessary, to compare non-cases to cases according to sociodemographic and other mental health variables in autistic compared to non-autistic adults.

**401.041 (Poster)** Exploring the Experiences of Social Interaction and Communication in Autistic Adults: A Qualitative Approach

*E. Deane<sup>1,2</sup>, D. Smith<sup>1,2</sup>, G. Wiltshire<sup>1,2</sup>, E. Yates<sup>1,2</sup>, W. Lawson<sup>1,2,3</sup> and M. H. Black<sup>1,2</sup>, (1)School of Occupational Therapy, Social Work and Speech Pathology, Curtin University, Perth, WA, Australia, (2)Curtin Autism Research Group, Curtin University, Perth, WA, Australia, (3)Cooperative Research Centre for Living with Autism (Autism CRC), Brisbane, QLD, Australia*

---

Background:

Social communication and interaction challenges are perhaps one of the most well recognised characteristics of the Autism Spectrum (Disorder) (AS). While a large body of research has previously attempted to understand how autistic individuals experience their social world, this research lacks the personal voice and individualised experiences of the autistic community. Qualitative research identifies an individual's perspectives, experiences, and values, allowing for a deeper understanding and additional insight into autistic adults' social experiences.

Objectives:

This study sought to explore social interaction and communication from the perspectives of autistic adults, exploring their thoughts and feelings, before, during, and after engaging in social interaction.

Methods:

A qualitative study adopting an Interpretive Phenomenological Analysis (IPA) approach and semi-structured interviews, was used to achieve the aim of exploring the experiences of social interaction and communication in autistic adults. A total of 12 autistic adults participated in the study including eight females and four males. The mean age of participants was 30.57 years (SD 12.159 years).

Results:

Thematic analysis resulted in a total of 13 sub-themes under the themes of 1) before social interaction, 2) during social interaction and 3) after social interaction which described the participant's thoughts, feelings, and actions before, during, and after engaging in social interactions with autistic and non-autistic adults. Feelings of anxiety and apprehension were common prior to social interactions, with participants using practice and rehearsal to prepare 'socially appropriate' responses and increase their confidence. During social interaction participants reported feeling anxious and uncomfortable, with frequent reports of self-monitoring and adaptive morphing. Participants reported that the environment influenced their comfort in social interactions with quiet settings and conversing with familiar people and other autistic adults found to be less anxiety-provoking. Conversation topics which had a clear purpose and focused on passions, interests and areas of knowledge were more enjoyable than topics such as 'small-talk' which was perceived as meaningless. Reports of negative self-reflection following social interaction was common, with many participants finding social interaction exhausting and contributing to social fatigue.

Conclusions:

Exploration of the experiences of social interaction from the perspective of autistic adults revealed that contextual factors such as person, topic and the environment has influence on autistic individuals' perception on whether a social interaction was successful. Anxiety was identified to be a major factor impacting social interaction for autistic adults. Attempts to conform to non-autistic styles of communication resulted in frequent reports of rehearsal and adaptive morphing. Consequence of this monitoring and anxiety left participants feeling exhausted and social fatigue following conversations.

**401.042** (Poster) Factor Structure and Construct Validity of the Transition Readiness and Employability Evaluation  
**K. Bowman**<sup>1</sup>, **B. Tomaszewski**<sup>2</sup>, **C. B. Klein**<sup>1</sup>, **S. M. Matherly**<sup>1</sup> and **L. G. Klinger**<sup>1</sup>, (1)TEACCH Autism Program; Psychiatry, University of North Carolina, Chapel Hill, NC, (2)TEACCH Autism Program, Psychiatry, University of North Carolina, Chapel Hill, NC

---

**Background:** There is an increasing number of individuals with Autism Spectrum Disorder (ASD) entering the workforce. Adults with higher cognitive ability levels have worse employment outcomes than those with an intellectual disability. “Soft skills” in the workplace, such as executive functioning and social communication, are significant challenges for individuals with ASD without co-occurring intellectual disability (Baker-Ericzen et al., 2018). A systematic review of employment readiness evaluations for individuals with disabilities found that few reliable behavioral rater-administered assessments of “soft skills” exist (Di Rezze et al., 2018). With the growing need to support individuals with ASD in the workforce, valid and reliable objective measures are needed to assess employment readiness.

**Objectives:** The objectives of the current study were to (a) assess the factor structure of the *Transition Readiness and Employability Evaluation (TREE)*, an observation measure of employment readiness for adolescents and young adults with ASD, and (b) examine associations among parent and self-report measures.

**Methods:** The TREE is a 26-item behavioral assessment used to evaluate employment readiness in transition-aged individuals. The assessment consists of two 15-minute entry-level job tasks (i.e., data entry and collating tasks) involving a series of “soft skills” presses for employment-related social communication skills including responses to corrective feedback, interruptions, and conversations. Forty percent of videos were coded for reliability ( $ICC=.87$ ). Participants included 52 adolescents and young adults with ASD ( $M_{age}=18.1$ ;  $SD=1.40$ ) and an IQ above 80 ( $M=104.67$ ;  $SD=15.64$ ). Participants were enrolled in a larger, transition intervention study and completed self-report questionnaires of coping skills (CSE; Chesney et al., 2010) and anxiety (STAI; Spielberger et al., 1983). Parents completed assessments of workplace skills (BWAP; Becker, 2005) and executive function (BRIEF-A; Roth et al., 2005). Item statistics and exploratory factor analysis (EFA) were used to determine the TREE's preliminary factor structure. Because the TREE measures employment readiness on an ordinal scale (e.g., 0,1,2; lower score indicating less impairment), categorical EFA with weighted least squares with mean-variance adjustment using Varimax rotation.

**Results:** Corrected item-total correlations and inter-item correlations were examined. Items with negative correlations and low corrected item-total correlations were removed, resulting in 16-items. A three-factor model best characterized workplace readiness skills as measured by the TREE. This model was supported by fit statistics,  $\chi^2(75)=83.34$ ,  $p=.24$  and  $RMSEA=.05$ . Item loadings on the three-factor solution resulted in the following factor loadings: Factor 1, Social Initiation (6 items), .34-.79, Factor 2, Task Organization and Accuracy (3 items), .29-1.18, and Factor 3, Social Problem Solving (7 items), .26-.93. Internal consistency for these factors was found (Cronbach's  $\alpha$ 's=0.7-0.72). Significant correlations were found between Social Initiation and Verbal IQ ( $r_s=-.338$ ,  $p<.05$ ), Task Organization and Accuracy and Full-Scale IQ ( $r_s=-.372$ ,  $p<.05$ ), and Social Problem Solving and CSE Problem-Focused Coping ( $r_s=-.357$ ,  $p<.05$ ).

**Conclusions:** The results provide support for a 3-factor structure of the TREE and demonstrated internal consistency as a measure of employment readiness including associations with cognitive abilities and coping behaviors. Future research should examine the validity of the TREE in documenting intervention effectiveness and in measuring supervisor-report measures of employment skills.

**401.044** (Poster) Financial Wellbeing of Autistic Adults in Australia  
**R. Y. Cai**<sup>1</sup>, **K. P. Haas**<sup>2</sup>, **E. Gallagher**<sup>2</sup>, **A. M. Love**<sup>1</sup> and **V. Gibbs**<sup>2,3</sup>, (1)Aspect Research Centre for Autism Practice, Autism Spectrum Australia, Melbourne, VIC, Australia, (2)Aspect Research Centre for Autism Practice, Autism Spectrum Australia, Sydney, NSW, Australia, (3)Faculty of Medicine and Health, University of Sydney, Sydney, NSW, Australia

---

**Background:** Many autistic adults experience unemployment or under-employment, which may impact their financial wellbeing due to reduced income. Financial wellbeing is a large component of people's overall wellbeing; poor financial wellbeing has been linked to financial hardship and high levels of stress and anxiety. However, no research has been conducted to examine the financial wellbeing of autistic adults.

**Objectives:** The aim of this study was to explore the subjective and objective financial wellbeing of a sample of autistic adults.

**Methods:** Fifty-five autistic adults aged 18 to 67 years ( $M_{\text{age}} = 32.89$ ,  $SD_{\text{age}} = 10.98$ ; 55% female) completed a set of questions relating to their financial circumstances, Autism Spectrum Quotient – Short, and Reported Financial Wellbeing Scale. Mann-Whitney U and Kruskal-Wallis tests, correlational analyses with bootstrapping, and general linear modelling were used.

**Results:** The median financial wellbeing value of our autistic sample was 40.00, which is much lower than the value of 55.00 identified in a sample of 5,682 Australians. The subject financial wellbeing scores of autistic adults were not associated with being employed, higher education attainment, having a co-occurring condition, age or gender. Higher levels of subjective financial wellbeing predicted higher income, greater savings, and being able to comfortably repay debts or having no debt predicted (objective measures of financial wellbeing).

**Conclusions:** Our study has showed for the first time that financial wellbeing of autistic adults is much lower than those of the general population. These research findings have implications on how we can improve the financial wellbeing of autistic adults.

---

**Background:** Children with autism spectrum disorder (ASD) often have additional health conditions that persist into adolescence and require greater coordination among healthcare service providers. However, major gaps exist in knowledge about the health, functioning, and healthcare needs of children with ASD as they transition to adolescence. This information is particularly important for ensuring a planned transition from pediatric to adult healthcare.

**Objectives:** To address this gap, a follow-up study is being conducted on adolescents age 12–16 years who were previously enrolled at age 2–5 years in the Study to Explore Early Development (SEED) and identified as having ASD or as population controls (POP) during that time.

**Methods:** Although data collection is on-going, this analysis includes data collected through January 2020. Follow-up surveys, completed by the adolescent's caregiver or guardian, included standardized questions and scales about the adolescent's health and mental conditions, physical difficulties, sleep problems, health and mental healthcare needs, and the transition from pediatric to adult healthcare.

To examine differences in health outcomes among adolescents in the ASD and POP groups, adjusted prevalence ratios (aPR) and 95% confidence intervals (95% CI) were calculated using a modified Poisson regression. The regression models included study group (ASD vs. POP) as the primary predictor and were adjusted for the following sociodemographic variables: mother's education, mother's country of birth, adolescent's sex, adolescent's race/ethnicity, federal poverty level, and type of insurance (e.g., private vs. public).

**Results:** The analytic sample consisted of 296 participants (ASD:  $n = 112$ ; POP:  $n = 184$ ). The average age of adolescents was 14.7 years old (interquartile range = 14.3–15.0 years). Compared to adolescents from the POP group, a higher percentage of adolescents with ASD had 1 or more medical or mental health conditions (aPR = 1.61, 95% CI = 1.21, 2.15), physical difficulties (aPR = 10.94, 95% CI = 4.04, 29.62), sleep problems (aPR = 1.44, 95% CI = 1.12, 1.87), and unmet medical and mental health service needs (aPR = 10.32, 95% CI = 2.02, 52.70; aPR = 3.84, 95% CI = 1.15, 12.90, respectively). Across both ASD and POP study groups, few adolescents received the recommended guidance for transitioning from pediatric to adult healthcare (ASD = 6.3%; POP = 13.0%; aPR = 0.53, 95% CI = 0.19, 1.47).

**Conclusions:** In the current study, adolescents with ASD identified in early childhood were more likely to have poorer health-related outcomes and greater health and mental health service needs compared to adolescents identified as population controls. Additionally, few adolescents in both the ASD and the POP group received the recommended healthcare transition planning from

their doctor or healthcare provider. These findings highlight the need for greater coordination and training among healthcare programs and services to improve adolescent health and well-being, increase the number of adolescents who successfully transition from pediatric to adult healthcare, and to address the unique medical and mental healthcare needs of adolescents with ASD.

**401.046** (Poster) Heterogeneity in Adults with Autism Spectrum Conditions (ASC): Subgroup Identification and Validation  
*T. A. Radhoe, J. Agelink van Rentergem, C. Torenvliet, A. P. Groenman and H. M. Geurts, University of Amsterdam, Amsterdam, Netherlands*

---

**Background:** Autism spectrum condition (ASC) is considered to be marked by heterogeneity, which complicates the search for causes and support for individuals with an ASC diagnosis. This led to the idea that different subgroups may exist in the population of autistic individuals with separate outcomes.

**Objectives:** We aim to identify homogeneous subgroups based on behavioral data in autistic adults using community detection. Furthermore, we aim to test the subgroups' validity by (1) comparing them on external variables and (2) by testing differences between subgroups in their underlying network structures.

**Methods:** Self-report questionnaire data were collected as part of a larger longitudinal study. The input for the community detection analyses were 14 variables: behavioral measures of ASC traits, demographic, and psychological characteristics. As preregistered (AsPredicted #34234 and #49209) we determined subgroups in a data set of N=549 adults (30-85 years, 52% males; 262 ASC, 287 controls). This community detection analysis was repeated for just the autistic participants after which we compared the subgroups on three measures not included in subgroup detection (i.e., external validation). Finally, the network structure was estimated in the identified subgroups using Gaussian Graphical Models.

**Results:** Two subgroups were identified: Subgroup 1 included mainly autistic adults (90%); Subgroup 2 included mainly controls (92%). Within the ASC group, three distinct subgroups were identified ( $N_{\text{subgroup1}}=102$ ,  $N_{\text{subgroup2}}=82$ ,  $N_{\text{subgroup3}}=78$ ), which is a replication of our previous results using a separate training dataset. The subgroups did not differ in age. Subgroup 1 included more women (65%), the other two subgroups included fewer women (40% and 45%). Regarding external validation: Subgroup 1 experienced the most cognitive failures, mental health problems, and reported the lowest wellbeing compared to subgroups 2 and 3. Subgroup 2 experienced the least cognitive failures, mental health problems, and reported the highest wellbeing compared to subgroup 1 and 3.

**Conclusions:** Based on these preliminary findings we can conclude that community detection applied to behavioral data results in three valid ASC subgroups. These subgroups differed in severity of experienced difficulties. Whether these findings can be corroborated with qualitative differences among the underlying network structures will be determined before the INSAR 2021 meeting.

**401.047** (Poster) Identity after an Autism Diagnosis: Gender, Self-Esteem and Wellbeing  
*K. Corden<sup>1</sup>, R. Brewer<sup>1</sup> and E. Cage<sup>2</sup>, (1)Department of Psychology, Royal Holloway, University of London, Egham, United Kingdom, (2)Department of Psychology, University of Stirling, Stirling, United Kingdom*

---

**Background:** Personal identity can be conceptualised as an individual's cognitive and emotional perception of themselves. There is currently a gap in the literature regarding the impact of acquiring a diagnosis of autism on personal identity development, and how this relates to measures of psychological health and functioning, such as self-esteem and wellbeing. These factors are of particular interest given the widely acknowledged prevalence of mental health difficulties in the autistic population. Furthermore, diagnoses of autism are increasingly being sought by adults and females, who have historically been underrepresented in empirical literature. Little is known, therefore, about their experiences of diagnosis and identity.

**Objectives:** The current study therefore aimed to examine several aspects of personal identity development following a diagnosis of autism, particularly for those late diagnosed and for females. First, the study aimed to investigate the relationship between personal autistic identity and psychological functioning (self-esteem and wellbeing). Second, the study aimed to understand relationships between personal autistic identity and the age and recency of diagnosis, in view of understanding the impact of receiving a late diagnosis on personal identity development processes.

**Methods:** One-hundred and fifty-two autistic adults (118 female, 30 male, 4 non-binary or transgender; mean age = 31.41) from the United Kingdom completed an online survey including measures of self-esteem and wellbeing, plus a measure of two aspects of personal autism identity: autism pride (reflecting perceived importance of or pride in autism being part of oneself) and

'exclusion/dissatisfaction' (reflecting perceived challenges or sense of shame linked to autism being part of oneself). Fifty-four participants also answered a qualitative question about the impact of receiving an autism diagnosis on their sense of self.

**Results:** Hierarchical regression analyses found that personal autistic identity significantly predicted self-esteem and wellbeing in autistic adults. Specifically, higher levels of 'autism pride' (positive affirmations of autism as part of one's identity) predicted higher self-esteem ( $p = .014$ ). Higher levels of 'exclusion/dissatisfaction' (sense of shame attached to autism being part of one's identity) predicted lower self-esteem ( $p = .001$ ) and lower wellbeing scores ( $p = .002$ ). Multiple regression analyses found that age of diagnosis positively predicted agreement with 'exclusion/dissatisfaction' ( $p = .022$ ). Furthermore, recency of diagnosis positively predicted agreement with 'autism pride' ( $p = .029$ ), whilst negatively predicting 'exclusion/dissatisfaction' ( $p = .003$ ). Content analysis of participants' self-reported experiences of their identity post-diagnosis support these findings and are suggestive of an emotive post-diagnostic adjustment process.

**Conclusions:** Greater self-acceptance of autism as part of one's identity related to higher self-esteem and wellbeing in the current study. Age and time since diagnosis also related to the incorporation of autism into self-identity. The results add to the literature concerning the diagnostic experiences of autistic adults and highlight potential mechanisms for improving psychological functioning through identity-based interventions. However, these findings should be understood within the current context of often inadequate provision of post-diagnostic services. Subsequently, recommendations are made with regards to future research on understanding the causal nature of the factors associated with developing personal autistic identity, leading to the design and evaluation of identity-focussed interventions.

**401.048 (Poster)** Impact of COVID-19 on Community Mobility and Participation for Individuals with Autism Spectrum Disorders

**B. Pfeiffer<sup>a</sup>, E. Brusilovskiy<sup>b</sup>, M. Salzer<sup>c</sup> and A. Pomponio<sup>c</sup>, (1)Rehabilitation Sciences, Temple University, Philadelphia, PA, (2)Temple University, Philadelphia, PA**

---

**Background:** COVID-19 has created an unprecedented, rapidly changing environment that has significantly impacted daily life for all. Necessary restrictions have significantly disrupted, limited, or completely shut down participation in occupations related to leisure, work, education, and social participation. While COVID-19 has affected the entire population, people with Autism Spectrum Disorders (ASD) have been more extensively impacted. Not only are people with developmental disorders at higher risk for becoming infected (CDC, 2020), many have co-occurring medical conditions (Jones, 2015) that put them at increased risk of severe illness from COVID-19 (CDC, 2020). People with ASD also experience the social and mental health consequences of COVID-19 restrictions on participation more acutely than the general population (Galea 2020; Serafini 2020). Community mobility is one domain of participation where COVID-19 restrictions have had a significantly impact on people with ASD. New guidelines for transit systems combined with event cancellations and sustained closures or remote operation of schools, programs, and services, limit means or reasons to travel and possible destinations.

**Objectives:** The objective of this study was to use GPS methods and ecological momentary assessment to explore the impact of COVID-19 on activity space use, community mobility and participation in young adults with ASD.

**Methods:** Researchers used a single subject design to examine patterns of change over time in activity space as measured by GPS. Additionally, changes in transportation modes and participation activities were measured by ecological momentary assessment. Six transitional age youth and young adults with ASD between the ages of 21 to 27 (4 males, 2 females) participated in the study. Participants were collecting data using cell phones with the AccuTracking app for another study, allowing researchers to have access to both pre-COVID and post-COVID GPS data. Additionally, participants completed daily activity and transportation logs on the cell phones through Qualtrics. Data was available for two weeks pre-COVID and collected four weeks immediately after post-COVID restrictions were implemented statewide. Data was analyzed using common single subject methodology through visual analysis and a standard deviation band method.

**Results:** Visual analysis identified that all participants demonstrated a decreased in activity space area from pre- to post-COVID time periods. The same trend was observed with the amount of participation in activities in the community. In addition to a decrease in community participation, there was a trend observed in the types of community activities. Participants continued activities often deemed as essential including instrumental activities of daily living (IADLs) and employment, although at a decreased level. Participation in other community activities such as recreational and social activities decreased to very low levels or were non-existent across participants. A decrease in participation in medical and therapeutic services was also identified as a trend for all participants.

**Conclusions:** This study identified important considerations for understanding the impact of the COVID-19 pandemic on community mobility and participation for individuals with ASD. As there are long lasting implications of the current pandemic

and concerns for future ones, it is necessary to understand participation patterns to identify needed supports and resources.

**401.049 (Poster) Impact of Life Events on the Mental Health of Adults with ASD**

**M. Hollocks<sup>1</sup>, G. Baird<sup>2</sup>, C. Lord<sup>3</sup>, A. Pickles<sup>4</sup>, T. Charman<sup>5</sup> and E. Simonoff<sup>1</sup>,** (1)King's College London, London, United Kingdom, (2)Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom, (3)University of California, Los Angeles, Los Angeles, CA, (4)King's College London, Institute of Psychiatry, Psychology and Neuroscience, London, United Kingdom, (5)Department of Psychology, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom

---

**Background:**

People with autism spectrum disorder (ASD) are at increased risk of developing co-occurring mental health difficulties across the lifespan. There are several environmental and family factors which may make those with ASD vulnerable to experiencing life events as particularly stressful and thus contribute to the development of mental health difficulties.

**Objectives:**

This study investigates the impact of adverse life events and levels of parental stress and mental health difficulties on emotional and behavioural problems in young adults with ASD. Using longitudinal data, the strength of these associations in early adulthood will be considered accounting for the severity of mental health symptoms in childhood and adolescence.

**Methods:**

115 young adults with ASD derived from a population-based longitudinal study were assessed at three time-points (12, 16, and 23-years) on measures of emotional and behavioural problems. Exposure to adverse life events and parental stress/mental health were measured at age 23. We used structural equation modelling to investigate the stability of emotional and behavioural problems over time, and the impact of adverse life events and parental stress and mental health, on emotional and behavioural outcomes at 23-years.

**Results:**

Our results indicate that exposure to adverse life events significantly predicted increased emotional and behavioural problems in young adults with ASD, while controlling for symptoms in childhood and adolescence. Higher reported parental stress and mental health difficulties were associated with a higher frequency of behavioural, but not emotional problems, and did not mediate the impact of adverse life events.

**Conclusions:**

These results suggest that child and adolescent emotional and behavioural problems, exposure to life events and parent stress and mental health are all independently associated with co-occurring mental health difficulties in young adults with ASD.

**401.050 (Poster) Improving Online Employment Training for Transition Aged Youth with ASD/IDD**

**R. L. Dodds<sup>1</sup>, L. Fisler<sup>1</sup> and H. J. Kuo<sup>2</sup>,** (1)Special Education & Counseling, California State University Los Angeles, Los Angeles, CA, (2)Department of Counseling, Educational Psychology and Special Education, Michigan State University, East Lansing, MI

---

**Background:** It is known that the employment rate for individuals with intellectual and developmental disabilities (IDD) and autism spectrum disorder (ASD) is disproportionately low compared to those with a different disability or without a disability (Brooke et al., 2018). Ample research has stressed that the gap was not a result of these individuals' functional capacity but poor employment readiness, such as the lack of interview skills and work-related social skills.

**Objectives:** Traditional didactic face-to-face training faces two constraints: geographic limitation and poor real-life connection. In response, our aim is to develop a comprehensive pre-employment training that incorporates mixed reality technology. The mixed reality technology was chosen for its immersive features, better generalizability and knowledge translation. In addition, due to the growing needs, the intervention is designed to take place completely online. In this presentation, the authors will share the adopted iterative developmental process and findings from the pilot data.

Methods: A pilot study was conducted in Spring 2020, a survey study is in progress, and a development and innovation trial for a new employment skills training program is planned. The first phase was conducted to assess the acceptability of the mixed reality technology as a tool for the practice of learned employment-related social skills. Five undergraduate students with a clinical diagnosis of ASD participated in an online instructional session, followed by a mixed reality practice session. Participants completed self-report measures of social skills, self-efficacy and rated their satisfaction with training and mixed reality practice sessions. The second phase is an online survey of transition-age youth with ASD and IDD to better understand their online learning patterns and preferences. Participants will report on the types of learning that they engage in currently, and their desired training topics. The final phase that is planned will work with stakeholders to develop, assess and refine a comprehensive online employment training program that utilizes mixed reality practice sessions to improve short and long-term employment outcomes for young people with ASD and IDD.

Results: Nine individuals with ASD were participated in the feasibility and acceptability study. The majority considered the training and mixed reality practice session to be helpful rather than stressful. The survey of online learning patterns and preferences is in data collection with a target sample of 200 transition-age youth with ASD or IDD. Hypothesized findings will identify the electronic means of participating is a familiar and comfortable setting for many youth and young adults. These data will inform the development of the intervention for which federal grant funding is under review and the applied nature of this project will be discussed.

Conclusions: Together, these studies exhibit the commitment of the research team to improve the flexibility, generalizability and efficacy of employment skills training for youth with ASD or IDD. The identification of both the need for these supports as well as the feasibility of the mixed-reality simulation software reach an increased capacity for serving this population of youth. Increasing the employment rate of this group is crucial to improving their long-term wellbeing and independence.

**401.052** (Poster) Interventions for Toe Walking in Individuals with Autism Spectrum Disorders: A Systematic Review  
*G. Valagussa<sup>1,2</sup>, S. Baruffini<sup>2</sup>, V. Panzeri<sup>2</sup>, D. Piscitelli<sup>2,3</sup>, E. Grossi<sup>1</sup>, C. Cornaggia<sup>2</sup> and C. Perin<sup>2</sup>, (1)Autism Research Unit, Villa Santa Maria Foundation, Tavernerio, Italy, (2)Program in Physical Therapy, University of Milano-Bicocca, School of Medicine and Surgery, Monza, Italy, (3)School of Physical and Occupational Therapy, McGill University, Montreal, QC, Canada*

---

Background: Autism spectrum disorder (ASD) is a complex neurodevelopmental disorder. Despite motor impairment is not currently included in the diagnostic criteria or evaluation of ASD, there is increasing evidence that subjects with ASD also have motor impairments, including gait alterations. Toe walking (TW) is a possible finding during gait observation in about 20% of subjects with ASD. TW persistence can contribute to a secondary shortening of the Achilles' tendon.

Objectives: This systematic review aims to summarize the evidence about TW interventions in individuals with ASD.

Methods: The study followed the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) recommendations and was prospectively registered in the International Prospective Register of Systematic Reviews (registration no. CRD42020176335). The literature search was performed up to July, 24<sup>th</sup> 2020 on Medline (via PubMed), CINAHL, PsycINFO, The Cochrane Library, Google Scholar and OpenGrey, from the inception of these databases. No restrictions regarding language, year of publication, and age of population were applied. Two reviewers independently screened titles and abstracts for eligibility; then independently screened full-text of potentially eligible studies. A hand searching of the reference list of included studies was also performed (Figure 1). Assessment of the studies' completeness has been conducted using the CARE checklist

Results: After the selection process, a total of 7 articles were included. They were all case reports, considering a total sample of 11 subjects (11 males; age range of 4-9 years). Five studies assessed the effectiveness of behavioural interventions using acoustical feedback or tactile stimulus in addition to positive reinforcement. One study proposed serial casting, and the one evaluated the efficacy of a lymphatic drainage technique. In all 7 studies, a reduction of TW frequency has been reported. A follow-up assessment was conducted only in 2/7 studies.

Conclusions: There is a lack of high-quality studies with a sufficiently large and well-characterized sample to assess the effectiveness of treatments for TW in individuals with ASD. These findings strongly support the need for future research in this area.

**401.053** (Poster) Labor and Delivery Experiences of Autistic Women: A Qualitative Research Study  
*L. F. Lewis, A. M. Cestrono, H. R. Scheibner, E. R. Beaudoin and H. L. Schirling, College of Nursing & Health Sciences, University of Vermont, Burlington, VT*

---

## Background:

Little is known about the experiences of autistic women during childbirth. Current literature emphasizes a lack of support, anxiety around appointments, concerns about being an adequate mother, and sensory overload during pregnancy and delivery. Previous studies also show that healthcare professionals lack sufficient training and knowledge about autism, and autistic mothers frequently feel misunderstood and isolated by health care workers.

## Objectives:

The purpose of this qualitative study was to examine narratives of autistic mothers' birth stories to determine how these women make sense of these events in their lives. Narrative analysis was also used to identify problem areas where health care providers can intervene or provide additional support.

## Methods:

Participants were recruited via online groups and forums relevant to autism. An international sample of 16 autistic women shared 19 written birth stories via an online survey tool. Asynchronous online interviewing strategies were used to ask follow-up clarifying and probing questions. Narratives were analyzed using Burke's narrative analysis, which focuses on a pentad of components considered core to a story, including scene (when/where), agents (who), act (what), agency (how), and purpose (why). Problem areas were identified as aspects of the story where two of these five components were out of balance, called ratio imbalances.

## Results:

Ratio imbalances were most frequently identified between act and agency in these birth narratives. Many participants shared stories in which the health care professional took a necessary action to assist in the delivery (act) but inappropriately communicated this action to the participant or carried out the action in a way that was uncomfortable for the participant (agency). Participants shared examples in which they felt their wishes were ignored, they were not listened to or believed, and they did not understand the rationale for health care actions taken. These imbalances often undermined participant trust in their health care team. Participants shared particular challenges coping with sensory aspects of childbirth, communicating their needs in the midst of an overwhelming situation, expressing and adequately managing pain, and feeling violated by physical touch related to vaginal exams and delivery. In some birth narratives, a balance in act and agency was restored when a support partner advocated on behalf of the participant to ensure her wishes were met.

## Conclusions:

Birth narratives shed light on the unique challenges of autistic women during childbirth. Findings emphasize a need for further training of labor and delivery professionals in working with this underrepresented population. Importantly, the disconnect between act and agency indicates that the primary cause of distress for women on the spectrum is not necessarily what providers are doing, but how they are doing it. Interventions such as developing a specific birth plan during antepartum care and educating women on what to expect during childbirth prior to onset of labor may inform patient expectations and increase provider understanding of patient needs. Presence of a support person during delivery who is informed about the birth plan may also improve the birth experience.

**401.054** (Poster) Levels of Autism Spectrum Traits Are Inversely Correlated with Psychological Resilience Factors during the COVID-19 Pandemic

**S. C. Taylor**<sup>1,2,3</sup>, **Z. L. Smernoff**<sup>1,3</sup>, **B. N. Gehringer**<sup>1,3</sup>, **H. C. Dow**<sup>1,3</sup>, **A. Langer**<sup>1,3</sup>, **E. Rawot**<sup>1,3</sup>, **S. Steeman**<sup>1,3</sup>, **O. Eshraghi**<sup>1,3</sup>, **L. Almasy**<sup>1</sup>, **D. J. Rader**<sup>4</sup>, **M. Bucan**<sup>1</sup>, **R. Barzilay**<sup>3,4</sup> and **E. S. Brodtkin**<sup>1,3</sup>, (1)Department of Genetics, University of Pennsylvania, Philadelphia, PA, (2)Neuroscience Graduate Group, University of Pennsylvania, Philadelphia, PA, (3)Department of Psychiatry, University of Pennsylvania, Philadelphia, PA, (4)Department of Child and Adolescent Psychiatry and Behavioral Science, Children's Hospital of Philadelphia, Philadelphia, PA

Background: Psychological resilience is the ability to buffer stress and cope effectively with challenges and crises that may arise (Barzilay et al., 2020). While much of the previous work on psychological resilience in the field of autism research focuses on the resilience of family members of autistic individuals, much less has been published about the resilience of autistic individuals themselves or about the relationship of autistic traits to resilience in the general population. We sought to better understand the relationship of resilience factors to autistic traits, depression, and anxiety during the ongoing stresses of the COVID-19 pandemic.

**Objectives:** To evaluate the relationship between autistic traits, severity of anxiety and depression, and resilience factors during the COVID-19 pandemic in adults across the autism spectrum and in the general population.

**Methods:** One hundred sixty-three participants from the Autism Spectrum Program of Excellence (ASPE) genetics study at the University of Pennsylvania, including autistic adults and their family members, were recruited during the COVID-19 pandemic for this study of resilience (60.1% female, 82.8% white, mean of 44.7 ( $\pm 15.3$  SD) years old). Additionally, 596 adults (89.5% female, 90.2% white, mean of 53.4 ( $\pm 14.9$  SD) years old) were recruited online from the U.S. general population during the COVID-19 pandemic. Participants completed self-report questionnaires about their autistic behaviors (SRS-2-Adult), anxiety (GAD7), depression (PHQ2), and a resilience survey probing for five factors: Self-Reliance; Emotion Regulation; Trust and Hostility in close relationships; and perception of Neighborhood Environment (Barzilay et al., 2020).

**Results:** Pearson correlations showed strong negative associations between total resilience factors and autistic traits as measured by the SRS-2-Adult ( $r = -0.62, p < 0.01$ ), anxiety severity ( $r = -0.51, p < 0.01$ ), and depression severity ( $r = -0.46, p < 0.01$ ) in the ASPE study sample, which is enriched for autism spectrum traits. In the general population sample, these negative associations between resilience and autistic traits ( $r = -0.62, p < 0.01$ ), anxiety ( $r = -0.58, p < 0.01$ ), and depression ( $r = -0.54, p < 0.01$ ) were replicated. Hierarchical regression demonstrated that, autistic traits, anxiety, and depression, all independently explain a significant amount of variance in resilience in both samples (see Tables 1 and 2). Autism spectrum traits explain the most variance in resilience in each sample (38-39%), followed by anxiety (8-10%), and then by depression (1-2%).

**Conclusions:** We found that autism spectrum traits explain over a third of the variance in resilience during the COVID-19 pandemic in each of our samples. Additionally, we found anxiety and depression partially explain resilience, though to a lesser degree. Future analyses will examine more specific domains related to autism spectrum behaviors (ex. social motivation, restricted repetitive behaviors) that may be driving the relationship with psychological resilience. We will also seek to expand the generalizability of our results by increasing the racial and gender diversity of our sample. These initial results suggest an inverse relationship between autism spectrum traits and resilience that should be explored to better understand how to reduce the impact of COVID-19 pandemic-associated stress in autistic adults.

**401.055 (Poster)** Longitudinal Investigation of the Impact of Minority Stress and Autistic Community Connectedness on Mental Health in the Autistic Community

**M. Botha<sup>a</sup>, B. Dibb<sup>b</sup>, P. Rusconi<sup>c</sup> and D. M. Frost<sup>d</sup>,** (1)Psychology, University of Stirling, Stirling, United Kingdom, (2)University of Surrey, Guildford, United Kingdom, (3)School of Psychology, University of Surrey, Guildford, United Kingdom, (4)Thomas Coram Research Unit, University College London, London, United Kingdom

---

**Background:** Autistic people often have worse mental health and wellbeing than non-autistic people and are at greater risk of suicide. The minority stress (MS) model postulates that belonging to a marginalised group results in an increased stress burden, which can translate into health disparities. Minority stress includes exposure to victimisation, everyday discrimination, expectation of rejection, outness (such as disclosure), concealment (like hiding autistic behaviours), and internalised stigma. The MS model has shown utility in understanding this mental health disparity, as it explains a large proportion of wellbeing for autistic people, even when controlling for general life-stress and demographics in cross-sectional studies. Furthermore, research shows that autistic community connectedness (ACC) appears to moderate the impact of MS on mental health in cross-sectional studies too. To date, no longitudinal studies have been conducted.

**Objectives:** This study aimed to investigate the effect of MS and ACC on mental health, over time using a two-wave, longitudinal study. It was hypothesized that higher minority stress at time one would be associated with worse mental health at time two, while higher ACC at time one would be associated with better mental health at time two, despite controlling for demographics, general life stress, and mental health scores at time one.

**Methods:** A sample of 99 autistic people from a worldwide sample took part in both the first and second wave of this study. Validated measures of general life stress, mental health, MS, and ACC were administered twice, nine months apart. Mental health measures included a measure of psychological distress, depression, and measures of social, emotional, and psychological wellbeing.

**Results:** Regression analysis showed that despite controlling for time one mental health, demographics, and general life stress, higher minority stress scores at time one was associated with significantly worse mental health, and lower wellbeing at time two, across all mental health and wellbeing measures. In particular, higher exposure to everyday discrimination, the expectation of rejection, and internalised stigma was associated lower wellbeing, and higher psychological distress. Higher ACC at time one was consistently associated with higher wellbeing, and lower psychological stress at time two. Interestingly although outness (disclosing being autistic) is associated with worse mental health in cross-sectional studies, over time it was associated with

*better* mental health. The models accounted for a large amount of the variance in wellbeing and mental health scores. Reverse causality was also tested to test support for the hypothesized directions of effects, and the models were non-significant, suggesting support for the hypotheses.

**Conclusions:** Minority stress continues to be a useful model for understanding mental health in the autistic population, and over time increased exposure may be related to worse mental health. Community connectedness may play a protective role against the effects of discrimination and stigma in the autistic community. Interestingly, while outness predicts worse mental health in cross-sectional studies, over time it is associated with better mental health. This may be because disclosing can allow for increased support, and decreased burden of camouflaging.

**401.057 (Poster)** Maternal Autism: Parental Reflective Functioning, Family Adjustment and Children's Outcomes  
*F. N. Acar, K. Slowinska and S. Anns, University of Sussex, Brighton, United Kingdom*

---

Background:

Autistic mothers face unique difficulties as parents and are more likely to experience postnatal depression, find motherhood isolating and report not coping (Pohl et al., 2020). Higher autistic traits are associated with parenting difficulties mostly unique to autistic parents, such as difficulty coping with sensory stimuli, modelling and teaching behaviours (Dissanayake et al., 2019). Yet higher autistic traits are not related to parenting efficacy (Dissanayake et al., 2019) and autistic mothers' self-reported parenting efficacy is not significantly different from neurotypical mothers' when parenting autistic children (Lau et al., 2016). Nevertheless, autistic mothers face stigma, feeling unable to seek support (Pohl et al., 2020). In spite of these additional burdens, no study to our knowledge has yet investigated the impact of maternal autism and its associated challenges on children's outcomes.

Objectives:

(1) To examine the relationship between maternal autism and children's outcomes. (2) To investigate the impact of the interaction between mother's autism diagnosis and child's autism diagnosis on children's outcomes. (3) To explore the differences of parenting and wellbeing factors between autistic and neurotypical mothers which may be helpful in developing tailored support.

Methods:

295 mothers completed an online survey, collecting demographic information and autistic traits using The Social Responsiveness Scale (SRS-2; Constantino & Gruber, 2012). Mothers were split into three groups; those who self-reported an autism spectrum condition (ASC) diagnosis and scored over the cut-off of 70 on the SRS ( $n = 117$ ); those who self-diagnosed (SD) as autistic and scored over 70 in SRS ( $n = 77$ ); and those who were neurotypical (NT), scoring under 70 in SRS ( $n = 101$ ). Participants completed the Depression, Stress and Anxiety Scale (DASS-21; Lovibond & Lovibond, 1995), Parental Reflective Functioning Questionnaire (PRFQ; Luyten et al., 2017), Parenting and Family Adjustment Scale (PAFAS; Sanders et al., 2014), and reported their youngest child's difficulties through the Strengths and Difficulties Questionnaire (SDQ; Goodman, 1997).

Results:

A significant effect of mothers' autism on children's total difficulties scores was found,  $F(2, 292) = 23.38, p < .001$ . There was a conditional effect of child autism on children's difficulties scores. The effect of mothers' autism on children's difficulties was only significant when parenting a neurotypical child, with no significant group differences when parenting an autistic child. When comparing NT mothers to all autistic mothers in parenting and wellbeing factors, there was a significant multivariate group effect,  $F(3, 291) = 30.25, p < .001, \eta_p^2 = 0.24$ . Autistic mothers reported significantly poorer psychological wellbeing and less optimal parenting and family adjustment but did not differ from NT mothers in parental reflective functioning.

Conclusions:

Preliminary findings indicate that maternal autism diagnosis may be related to higher children's difficulties. However, maternal autism was not related to higher difficulty scores when the child was autistic. Self-diagnosed mothers with neurotypical children reported the highest difficulty scores, suggesting that they may require support in accessing services, a diagnosis, and tailored support. Psychological wellbeing and family adjustment may be important target areas for specific support for autistic mothers.

**401.058 (Poster)** Medication Frequency and Health Services Utilization in Latin-American Adults with Autism

**D. Lecusay<sup>1</sup>, A. Torres<sup>2</sup>, D. Valdez<sup>3</sup>, A. Rattazzi<sup>4</sup>, A. Rosoli<sup>5</sup>, G. Garrido<sup>6</sup>, S. H. Cukier<sup>7</sup>, C. S. Paula<sup>7</sup>, R. A. Garcia<sup>8</sup> and C. Nava<sup>8</sup>,** (1)Psychology Department, University of Texas Rio Grande Valley, Edinburg, TX, (2)Psychological Science, University of Texas Rio Grande Valley, Edinburg, TX, (3)Universidad de Buenos Aires- FLACSO, Buenos Aires, Argentina, (4)PANAACEA, Buenos Aires, Argentina, (5)Projects, Organizacion Estados Iberoamericanos, Santo Domingo, Dominican Republic, (6)Universidad de la República, Montevideo, Uruguay, (7)Developmental Disorder Program, Universidade Presbiteriana Mackenzie, São Paulo, Brazil, (8)Clínica Las Condes, Santiago, Chile., Santiago, CHILE

---

**Background:** Autism spectrum disorder (ASD) is a lifelong neurodevelopmental disorder typically diagnosed in childhood. The presentation of ASD varies with each individual yet the disorder's permanence highly impacts the various need for health services which are less available as the individual transitions into adulthood. Latino adults with ASD experience significant barriers accessing health services and are associated with high medication use and comorbid epilepsy diagnosis.

**Objectives:** This study aimed to analyze the relationship of medication frequency by age group in six Latin-American countries and the use of health services received among emerging and middle-aged adults with ASD.

**Methods:** The total sample consisted of 295 caregivers of adults with ASD from six Latin American and Caribbean Countries. Adults with ASD were predominantly males 75.6% (n= 223), with age ranging from 18 to 50 years (x=24.3, SD=6.6). Participants completed the Caregiver Needs Survey (CNS) that gathers information about sociodemographic data, individual characteristics, comorbid conditions, service encounters, and caregiver perceptions. Survey inquired about the weekly number of hours of varied health services , including frequency of medication. Weekly hours of services were categorized using the Council of Autism Service Providers (CASP) recommendations.

**Results:** The analysis of medical comorbidities shows that 73.2% (n=201) of adults had at least one comorbid diagnosis . 48.5% (n=143) of the participants were using medication at the time of the study, more frequent for those with comorbid epilepsy (61.8%, n=55). Of those participants with a reported diagnosis of epilepsy, (23.8%, n=34) reported to have been currently using medication. In contrast, most individuals receiving health services were in the “Zero hours per week” category (84.4-95.6%).

**Conclusions:**

Transition into adulthood for individuals with ASD requires sustenance from a variety of health-related disciplines. Our results indicate an increasing need for adequate health services for Latin-American emerging and middle-age adults with ASD. This population remains highly underserved as medication frequency is higher than the use of health services for both groups. The majority of the sample was not receiving services at the time of the study. In contrast almost half was using medication which could suggest a high reliance on pharmacotherapy in the treatment of ASD symptomology and comorbid disorders. These results need to be understood in the socioeconomic and political context of the region as well. Public spending on mental health is insufficient in Latin American countries, with limited resources available for mental health treatment and provider education. In countries with limited epidemiological resources, caregiver surveys provide a rich source of information on the demographic and clinical characteristics of caregivers and individuals with ASD. The results point out the need for new research looking at how sociocultural variables influence health-related use and frequency in Latino adults with ASD.

**401.059 (Poster) Mental Health Crisis Assessment Among Adults with Autism Spectrum Disorder in an Outpatient Neuropsychiatry Clinic**

**E. A. Berich-Anastasio<sup>1,2</sup>, A. Ready<sup>3</sup>, A. Maclay<sup>3</sup>, R. Wisner-Carlson<sup>4</sup>, R. Schloesser<sup>4</sup> and L. Kalb<sup>1,5</sup>,** (1)Point-of-Care Research & Innovation, Sheppard Pratt, Towson, MD, (2)Mental Health, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (3)Data Management, Analysis and Reporting, Sheppard Pratt, Towson, MD, (4)Center for Autism and Related Disorders, Kennedy Krieger Institute, Baltimore, MD, (5)Department of Mental Health, Johns Hopkins University, Baltimore, MD

---

**Background:**

The prevalence of Autism Spectrum Disorder (ASD) has been notably increasing over recent decades. Consequently, as children with ASD approach and reach adulthood, mental health services will need to adapt to meet the needs of this burgeoning population. Prevailing literature suggests that persons with ASD are more likely to suffer from mental health crises and comorbid psychiatric disorders (Cassidy, Bradley, Shaw, & Baron-Cohen, 2018; Chen et al., 2017; Joshi et al., 2010; Kalb, Hagopian, Gross, & Vasa, 2018; Nayfack et al., 2014; Turcotte et al., 2016; Vasa, Hagopian, & Kalb, 2020; White, McMorris, Weiss, & Lunsky, 2012). Given the increased likelihood of psychiatric emergencies among persons with ASD, and the rising prevalence of adults with this neurodevelopmental disorder, information is needed regarding mental health crises among adults with ASD.

**Objectives:**

To better understand the prevalence and characteristics of mental health crises among adults with ASD, utilizing the Mental Health Crisis Assessment Scale (MCAS). Specifically, the goals of this study are to: 1) assess the criterion validity of the MCAS, 2) determine the prevalence of and behaviors related to crisis, and 3) examine potential correlates of crisis.

#### Methods:

Data were gathered from adults with ASD receiving treatment in a specialty outpatient neuropsychiatry clinic who were part of an on-going Autism Registry and Bio-Repository Project at Sheppard Pratt (n=60). The MCAS was administered at the point-of-care during clinical encounters, which allowed for immediate clinical use of this assessment. The psychiatrist was able to review MCAS data during the appointment and provide a concurrent rating of crisis. The MCAS rating of crisis was compared to the clinician rating of crisis, considered to be the “gold standard” in this context. Sensitivity, specificity, positive and negative predictive values, as well as area under ROC curve, have been calculated, according to a determined optimal cutoff point for the MCAS total score.

#### Results:

86.6% of patients were correctly classified by the MCAS when compared to clinician rating of crisis. Optimal cutoff score resulted in a ROC score of .925, 100% Sensitivity, 84.9% Specificity, 46.7% Positive Predictive Value and 100% Negative Predictive Value. The prevalence of crisis, per the MCAS, was 13.33%. Verbal Aggression, Disobedience, Tantrum(s), and Self-Injury were the most commonly identified problematic behaviors associated with crisis. Gender, age and education were not associated with crisis, though being of Caucasian race was observed to be associated with crisis ( $p = 0.02$ ).

#### Conclusions:

This study is one of the first to assess mental health crisis through a standardized assessment in a population solely consisting of adults with ASD. The MCAS appears to have strong alignment with mental health providers in the identification of crisis behaviors, and thus, has utility as a clinical screening tool and in characterizing the presentation of psychiatric crisis in this population. Because of the increased psychiatric comorbidity in ASD, such insight into the needs of adults with ASD is essential as the prevalence of this neurodevelopmental disorder in adulthood grows, and the need for appropriate mental healthcare and emergency services similarly increases.

#### **401.060** (Poster) Moving (as an) Autistic Person- Preliminary Findings

**D. Mason, V. L. Milner and F. Happé, Social, Genetic and Developmental Psychiatry Centre, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom**

---

**Background:** Independent living outcomes for autistic people tend to be poor. Whilst estimates vary, it is often the case that autistic people rarely live independently from their parents. Many studies have explored the predictors of independent living status. Yet, to our knowledge, no study has explored the actual decision-making process involved in finding somewhere to live, and the consequent moving experience, of autistic people. It could be that uncertainty around these processes is a barrier to independence for autistic people.

**Objectives:** To explore the moving home processes and experiences of autistic people.

**Methods:** We have been conducting an online survey since May 2020 of both autistic and non-autistic residents of the United Kingdom. The survey comprised demographic information (e.g. age, gender, location, employment); closed questions (e.g. number of times the participant has moved); and open questions (e.g. “How did you realise you wanted to, or needed to, move living place?”). We asked participants to report their stress levels across 5 domains; the decision-making process, finding a new place to live, the moving process, being in the new living place, or other. To date, 213 participants have completed the survey, aged 18–71 (mean=35.5, SD=12.9). In total, 161 participants reported having a formal diagnosis of autism, or self-identified as autistic (75.8%) and 37 reported no such diagnosis/self-identity (17.2%). There were 44 males (20.8%), 119 females (56.1%), 30 who reported another gender identity (14.1%).

**Results:** The autism and comparison groups did not differ on the reported stress for making the decision to move (Hedge's  $g=0.30$ ). However, autistic participants reported significantly greater stress for finding a new living place (65.4 vs 50.8, Hedges  $g=0.50$ ); the moving process (75.7 vs 47.6, Hedge's  $g=0.99$ ); being in one's new living place (58.4 vs 33.2, Hedge's  $g=0.79$ ); and “other” stresses (75.8 vs 20.8, Hedge's  $g=1.70$ ). Visual inspection of the open text responses for the autistic group suggested that paperwork/organisation, loneliness, and uncertainty about the decision were common stressors.

Conclusions: Our initial findings indicate that several facets of moving home, decided a-priori by the research team, are reported to be very aversive for autistic people compared to control participants. Both groups appear to find the decision process equally stressful. However, autistic people find the moving process extremely aversive. Our qualitative responses (to be fully analysed) indicate this may be due to organisation difficulties. Intriguingly, being in one's new living home was reported to be moderately stressful (and more so than for the comparison group, with a large effect size). This could be explained by an intolerance of uncertainty (data to be analysed). The other stressors reported by autistic people are consistent with other findings in the literature. That money came up is not surprising given the employment and overall socio-economic prospects for autistic people. In sum, these preliminary data suggest there are systematic differences in how stressful autistic and non-autistic people experience the process of moving home. Further exploration of the data is underway.

**401.061** (Poster) Objective and Subjective Psychosocial Outcomes in Adults with Autism Spectrum Disorder: A 6-Year Longitudinal Study

*A. M. Scheeren<sup>1</sup>, M. Buil<sup>1</sup>, P. Howlin<sup>2</sup>, M. Bartels<sup>1</sup> and S. Begeer<sup>1</sup>, (1)Vrije Universiteit, Amsterdam, Netherlands, (2)King's College London, London, United Kingdom*

---

Background:

Many autistic adults find it difficult to attain socially “normative” life goals such as holding a job, living independently or finding a romantic partner (Billstedt, Gillberg, & Gillberg, 2011; Howlin & Moss, 2012; Roux et al., 2013). Where some individuals do exceptionally well, many, including those of average or above average intellectual ability, require care and support throughout adulthood (Hofvander et al., 2009; Lord et al., 2020). However, studies of adult outcomes are mostly based on cross-sectional data in primarily male samples (Lord et al., 2020) and sample size is typically small.

Objectives:

The aim of the present 6-year longitudinal study, incorporating five waves of measurement, is to examine the development and predictors of psychosocial functioning, operationalized both objectively and subjectively, in autistic men and women (18 to 65 years).

Methods:

The sample consisted of 917 adults (425 men, 492 women) with a mean age of 43.5 years, recruited through the Netherlands Autism Register (NAR).

A composite measure of objective psychosocial functioning was based on employment, independent living and friendship ratings, with a total score ranging from 0 (very poor outcome) to 8 (very good outcome). Participants' subjective well-being was rated on a 5-point scale. Predictor variables included age, gender, autism traits (Autism Quotient-Short), intellectual ability, age of ASD diagnosis, parental educational level, and presence of co-occurrent psychiatric conditions.

Latent growth curve models (LGM) were used with the intercept representing the initial level of objective or subjective functioning, and the slope term representing increases or decreases from the intercept with each wave.

Results:

On the objective psychosocial measure, averaged across the five waves, 32.6% of the adults demonstrated a (very) good outcome, 53.5% had a fair outcome, and 13.9% had a poor outcome. On the subjective measure, an intermediate level (3) of subjective wellbeing was reported.

LGM's showed small, but significant growth in objective psychosocial functioning and subjective wellbeing across 6 years. Level and change in objective functioning were correlated with level and change in subjective wellbeing (see Figure 1). Predictors of a good initial objective outcome, explaining 23% of variance, were: higher intellectual ability, absence of co-occurrent psychiatric conditions, fewer autism traits, and older age. Predictors of higher initial subjective wellbeing, explaining 13% of variance, were: lower intellectual ability, absence of co-occurrent psychiatric conditions and fewer autism traits. Men and women did not differ in initial levels of or overall change in objective and subjective outcomes over time.

Conclusions:

In comparison with previous research, our findings provide a more positive outlook for autistic men and women with average to high intellectual abilities by showing a fair to good level of objective psychosocial functioning and a small increase in objective functioning and subjective wellbeing over 6 years. The positive, but modest correlations between levels and change in objective and subjective outcomes suggests that societal success may promote subjective wellbeing and/or high subjective wellbeing increases chances of societal success.

**401.062 (Poster) Online Peer Support for Autistic Medical Doctors**

**M. Doherty<sup>1</sup>, A. Foss<sup>2</sup>, C. Brown<sup>3</sup>, M. Johnson<sup>4</sup>, L. Carravallah<sup>5</sup>, K. Rabenstein<sup>6</sup> and W. Ross<sup>2,7</sup>,** (1)Anaesthesia, Our Lady's Hospital, Navan, Ireland, (2)Jefferson Center for Autism & Neurodiversity, Philadelphia, PA, (3)University Hospital Southampton NHS Foundation Trust., Southampton, United Kingdom, (4)Goyt Valley Medical Practice, High Peak, United Kingdom, (5)Department of Paediatrics and Human Development, Michigan State University, East Lansing, MI, (6)East Sussex healthcare Trust, East Sussex, United Kingdom, (7)Autism Inclusion Resources, Wynnwood, PA

---

**Background:** Autistic medical doctors face specific challenges including difficult social interactions with coworkers, sensory issues in the workplace, and mental health conditions commonly co-occurring with autism. This study aims to evaluate the feasibility of providing a support network for autistic doctors via Facebook, collecting data on participant doctors and their backgrounds, common usage patterns for such a support network, and preliminary qualitative data on the experiences of autistic doctors as they navigate their individual employment experiences.

**Objectives:** This study aims to 1) evaluate the suitability of an online platform for autistic doctors to share experiences, 2) identify usage patterns for this platform and examine how use of the platform changes over time, and 3) identify needs and priorities of this population to inform future study.

**Methods:** A platform available by invite only on Facebook was created and made accessible to doctors identifying as autistic through social media and direct personal contact. The activity of participants on this platform was monitored over the course of a year, with measurements including total members, active members, total comments, and total reactions. Participants were asked to describe the benefits of membership and to comment on their experiences as autistic doctors. Through quantitative data on group usage and qualitative data via user responses, we addressed each of the key objectives.

**Results:** The group comprised 53 members at the initiation of the study and grew to 197 members. An average of 55% of members were active on any given day and this percentage remained steady across the course of the study. Activity was fairly constant, with an average of 20 messages posted to the group per day; over the course of the year, no month averaged fewer than 15 messages per day. Themes in qualitative responses included appreciation of a support group of people with the same experiences, concern about how they were perceived by others, and the difficulty of working with an invisible struggle that others might not understand, with responses including:

- I have found a safe source of support in navigating an NT [neurotypical] world where I don't need to worry about being misinterpreted
- I've gone from struggling being an autistic doctor to being ok with being an autistic doctor to being proud to be an autistic doctor. I used to worry about who to tell I was autistic. Now I tell everyone. It's my identity and I love it
- I've never been able to truly compare the things I find difficult with other doctors before. It's a huge relief, and confirmation that I'm not 'broken'

**Conclusions:** An online group proved to be a feasible and successful setting for autistic doctors to share experiences, support one another, and discuss common issues. While overall usage of the boards did not increase during the year, total membership grew steadily and the majority of members were regularly active. Users were eager to share their priorities, needs, and interests for future research, indicating that future study and advocacy will be feasible and include a population of interested participants.

**401.063 (Poster) Parenting on the Spectrum: A Systematic Scoping Review of Parenting Experiences and the Mental Health of Parents with ASD or Autistic Traits**

**M. R. A. Putri<sup>1</sup>, K. Williams<sup>1,2</sup> and G. R. Cox<sup>1,3</sup>,** (1)Department of Paediatrics, Monash University, Melbourne, VIC, Australia, (2)Monash Children's Hospital, Clayton, VIC, Australia, (3)Neurodevelopment and Disability, Royal Children's Hospital, Melbourne, VIC, Australia

---

**Background:** As our knowledge and detection of Autism Spectrum Disorder (ASD) has improved over recent decades, the number of people diagnosed with ASD in their adult years has also increased. Little research has been conducted into the parenting experiences, and mental health status of parents who either have a diagnosis of ASD, or show a number of sub-

diagnostic autistic traits, commonly referred to as the 'Broader Autism Phenotype' (BAP). To our knowledge, there are no reviews that bring together the current literature in this area.

**Objectives:** This systematic scoping review aims to explore the literature regarding parenting experiences of parents who either have a diagnosis of ASD, or those who self-report has having a number of sub-diagnostic autism traits (BAP), as well as the prevalence of mental health difficulties in this population. Findings from this review will be used to help identify gaps in the research literature pertaining to parenting on the spectrum, and whether parenting programs may need to be adapted to serve the specific needs of this population.

**Methods:** This systematic scoping review follows the PRISMA Extension for Scoping Reviews (PRISMA-ScR) checklist. In September 2020, PsycINFO, Cochrane Library, MEDLINE, EMBASE, and SCOPUS were searched, using the following broad search terms, adapted for each database as needed: (ASD OR autism OR autistic OR child development disorders OR Childhood schizophrenia OR child\* OR pervasiv\* OR kanner\* OR Pervasive development\* disorder\* OR PDDs OR PDD-NOS OR autism spectrum disorder OR asperger syndrome, autistic disorder) AND (parent\* OR difficult\* OR problem\* OR issue\* OR emotion\* OR Family function\* OR coping OR stress\* OR psychopatholog\* OR mental health OR mental wellbeing\* OR psychological OR psychopathology OR mental health OR mental disorders OR adaptation OR emotional adjustment OR feedback OR personality). Articles were uploaded into the COVIDENCE software for title and abstract screening, followed by full text screening. For an article to be included in the final review, the following criteria must be met 1) at least one parent of any age and sex identifiable with ASD or BAP; 2) Quantitative or qualitative data on the mental wellbeing of the parent, parenting problems or experiences or issues/difficulties in the family functioning and; 3) the parent can have a typically developing child or have a child with ASD or BAP.

**Results:** 15,244 articles were located initial search. After the duplicates are removed, 8,948 articles are currently being screened by 2 review authors.

**Conclusions:** Despite the rising number of adults with ASD or BAP, little research has focused on the parenting experiences of these individuals, or the impact that this can have on the parent-child relationship, mental wellbeing of the parent or wider family functioning. The initial search has revealed that some research has been conducted in this area, and a narrative synthesis of this will significantly add to the limited research in this area, to support best clinical practice with these parents.

**401.064 (Poster) Peas in a Pod: Oral History Reflections on Autistic Identity in Family and Community By Late-Diagnosed Adults**

**R. Lilley<sup>1</sup>, W. Lawson<sup>1,2</sup>, G. Hall<sup>1,2</sup>, J. Mahony<sup>1,2</sup>, S. Arnold<sup>2,3</sup>, J. N. Trollor<sup>2,3</sup>, M. Yudell<sup>4</sup> and E. Pellicano<sup>1,2</sup>, (1)Macquarie School of Education, Macquarie University, Sydney, NSW, Australia, (2)Cooperative Research Centre for Living with Autism (Autism CRC), Brisbane, QLD, Australia, (3)Department of Developmental Disability Neuropsychiatry, UNSW, Sydney, NSW, Australia, (4)Dornsife School of Public Health, Drexel University, Philadelphia, PA**

**Background:** This paper reports on an oral history study documenting the lives of late-diagnosed Autistic adults in Australia. This qualitative study, co-produced with Autistic researchers, offers insight into the lived experience of Autistic adults.

**Objectives:** A qualitative oral history methodology was adopted to document the experiences of Autistic adults who grew up in an era when autism was not well known. The overall objective of this project was to increase understanding about the lives of late-diagnosed Autistics. This study analyses Autistic perceptions of the self and ideas about shared identity that emerged as salient themes in these interviews.

**Methods:** Twenty-eight participants were recruited. All were born before 1975 and received a clinical autism diagnosis after the age of 35. All interviews (M length = 129 minutes) were conducted by Autistic researchers, transcribed and then thematically analysed by a team of Autistic and non-autistic researchers using the six-step process outlined by Braun and Clarke. The team met weekly to discuss coding, themes and subthemes to co-produce an iterative and reflexive analysis of the data.

**Results:** We identified three major themes within these oral history reflections relating to shared Autistic identity. The first theme, 'conceptualising the Autistic family', included reflections on both immediate and extended family. Interviewees talked about how they identified with their children diagnosed with autism, describing themselves as 'peas in a pod'. They also spoke about retrospectively identifying other family members as Autistic. The second theme, 'creating Autistic community', refers to a sense of shared identity participants expressed in relation to Autistic communities, both online and face-to-face. This sense of community was often referred to using the metaphor of 'tribe'. Interviewees also stated that they had developed an ability to identify other people as Autistic thereby extending the idea of community to potentially encompass others not formally identified by diagnostic professionals. The third theme, 'Contesting Autistic identity', suggests that these processes of identity formation and community creation are not always straightforward. Sometimes other people, including family members and professionals,

rejected the Autistic identity of interviewees. This rejection was reported to cause considerable distress. At other times, interviewees indicated that there have been times when they have questioned their own identity as Autistic or even the coherence of the current diagnostic construct of 'Autism Spectrum Disorder'.

**Conclusions:** These themes reflect the complexity of all processes of identity construction, including membership in diagnostic categories. In identifying family members and others as Autistic, our participants asserted the value of their own embodied understanding of autism, providing an implicit alternative to the dominance of professional diagnostic practices. Their accounts of finding a 'home' in Autistic communities extend the idea of family, creating a safe space in which to belong. Reports of questioning Autistic identity provide insights into identity formation as both processual and, on occasion, contested. Overall, these ideas about identity and community challenge orthodox understandings of autism, which is understood as an increasingly common and, as one interviewee expressed it, 'natural part of the human spectrum'.

**401.065 (Poster)** Perceived Negative Impact in Caregivers of Individuals with Autism Spectrum Disorders: A Longitudinal Study from Late Childhood to Early Adulthood

**K. Christopher, R. Elias and C. Lord, University of California, Los Angeles, Los Angeles, CA**

---

**Background:** Research demonstrates caregivers raising a child with autism experience increased parental burden and stress, often resulting in negative effects on families and relationships. Similar to parental burden, perceived negative impact is the degree to which a caregiver reports negative experiences (i.e., financial, social, or emotional burden) due to having a child with a disability (Messer et al., 1996) and is considered a significant predictor of long-term parenting stress (Trute & Hiebert-Murphy, 2005).

**Objectives:** This longitudinal study aims to define distinct, parental perceived negative impact trajectory classes across three time points making comparisons between classes.

**Methods:** Participants ( $n = 209$ ) were drawn from an ongoing longitudinal sample, comprised of caregivers whose child received an early ASD diagnosis or had developmental delay (see Lord et al., 2006). Perceived negative impact was assessed at three times ( $Mage = 10, 13, 19$ ) via caregiver interview using Child and Adolescent Impact Assessment (CAIA; Messer et al., 1996). Characteristics examined include autism severity, adaptive skills, race, gender, caregiver education, cognitive abilities, and social support.

**Results:** Latent class growth modeling determined three trajectory classes (i.e., low impact decreasing ( $n = 68, 31.7\%$ ), medium impact fluctuating ( $n = 98, 45.8\%$ ), and high impact decreasing ( $n = 43, 22.5\%$ ) (See Figure 1 for trajectory groups). Chi-square test of independence revealed non-white caregivers ( $X^2(2, N = 209) = 15.93, p < .00$ ), with less than a bachelor's degree ( $X^2(2, N = 209) = 15.16, p < .00$ ), and strong social supports ( $X^2(2, N = 115) = 7.96, p < .02$ ), to more likely be in the low impact class. Significant differences were found between classes in autism severity ( $F(2,128) = 5.57, p = 0.005$ ) and adaptive functioning ( $F(2,142) = 4.96, p = 0.008$ ). Post hoc comparisons revealed the low impact class (ADOS-2:  $M = 4.23, SD = 2.36$  & VABS-II:  $M = 72.23, SD = 23.49$ ) to be statistically significantly different from the medium and high impact class in autism severity (ADOS-2:  $M = 5.71, SD = 2.17, p = 0.005$ ; ADOS-2:  $M = 5.59, SD = 2.35, p = 0.043$ , respectively), and adaptive functioning (VABS-II:  $M = 60.68, SD = 20.87, p = 0.027$ ; VABS-II:  $M = 57.2, SD = 57.23, p = 0.012$ , respectively).

**Conclusions:** This longitudinal study extends our knowledge of trajectory classes in perceived negative impact into young adulthood. Results indicated perceived negative impact decreases across time, but at varying degrees. In this sample, caregivers in the low impact trajectory were more likely to be minorities, less educated, more socially supported, and have young adults with less severe autism and higher adaptive skills. These findings are consistent with previous research (Bishop, Richler, Cain, & Lord, 2007; Carr & Lord, 2012). In contrast, high negative impact class was more likely to have young adults with low adaptive skills and increased autism symptomology. In sum, information gathered from this study may improve clinicians' ability to understand families, may inform clinical practices and interventions to improve the lives of individuals with autism.

**401.066 (Poster)** Performance on the Transition Readiness and Employability Evaluation (TREE) in Transition-Age Youth with and without Autism Spectrum Disorder

**C. B. Klein<sup>1</sup>, K. Bowman<sup>1</sup>, S. M. Matherly<sup>1</sup>, B. Tomaszewski<sup>2</sup> and L. G. Klinger<sup>1</sup>, (1)TEACCH Autism Program; Psychiatry, University of North Carolina, Chapel Hill, NC, (2)TEACCH Autism Program, Psychiatry, University of North Carolina, Chapel Hill, NC**

---

**Background:** Although many adults with autism spectrum disorder (ASD) are cognitively capable of obtaining competitive employment, they are often unemployed or underemployed (Taylor&Dawalt,2017). Self-reported "soft skills" related to

employment success in individuals with and without ASD have been previously identified (Gal et al., 2015), but few measures are available to identify specific differences in transition skills between adolescents and young adults with and without autism. An objective measure that documents specific challenges experienced by individuals with ASD is needed.

**Objectives:** 1) Compare differences in transition readiness using the *Transition Readiness and Employability Evaluation (TREE)* and 2) Characterize the samples on level of coping skills, executive function, and anxiety.

**Methods:** Participants included 52 students with ASD ( $M_{age}=18.1, SD=1.40$ ; 78.8%-male) and 20 university students without ASD ( $M_{age}=19.10, SD=1.05$ ; 25%-male). Students with ASD were assessed before participation in a college-based intervention, the T-STEP. Non-ASD participants were excluded if their Social Responsiveness Scale score (SRS-2 self-report; Constantino & Gruber, 2012) was above the clinical cutoff ( $n=2$ ). Participants completed the TREE, an objective behavioral assessment of employment readiness consisting of two typical office tasks (e.g., data entry, collating skills) with a series of social communication presses to assess employment readiness soft skills (e.g., corrective feedback, disruptions to work, conversation). The TREE factor structure derives three domains (Social Initiation, Task Organization and Accuracy, and Social Problem Solving) with higher scores indicating more impairment. SRS-2 profiles (informant or self-report) were compared between the groups using independent samples t-tests. Performance on the TREE, Coping Self Efficacy Scale (CSE), Behavior Rating Inventory of Executive Function for Adults (BRIEF-A), and Trait Anxiety Scale (STAI) was compared between groups using Mann-Whitney U tests.

**Results:** The SRS-2 confirmed the presence of autism features in the ASD group ( $M_{ASD}=67, SD=9.68$ ;  $M_{Non-ASD}=48.94, SD=5.36$ ),  $t(52)=-8.88, p<.001$ . Results on the TREE indicated that Social Initiation ( $U=630.5, p=.028$ ) and Social Problem Solving ( $U=636, p=.009$ ) scores were lower in the non-ASD group, with no significant difference in Task Organization and Accuracy ( $U=591.5, p=.079$ ; see Figure 1). Mann-Whitney tests indicated that those in the non-ASD group had higher scores on the CSE problem-focused coping ( $U=115, p<.001$ ) and get support from friends and family ( $U=169, p=.006$ ) subscales. Young adults in the non-ASD group had fewer difficulties on the BRIEF-A behavior regulation ( $U=450, p=.036$ ) and metacognition indices ( $U=582, p<.001$ ). Clinical levels of anxiety were high in both groups (82.4%-ASD, 70.6%-non-ASD).

**Conclusions:** TREE results demonstrate impairment in employment readiness in ASD in social workplace functioning (Social Initiation and Social Problem Solving domains). The similar work quality in both groups (Task Organization and Accuracy domain) highlights the many strengths in adults with ASD in the workplace (e.g., attention to detail, memory skills; Russell et al., 2019). Analyses revealed differences in students with and without ASD in coping skills (e.g., seeking social support and problem-focused coping) and executive function (e.g., ability to regulate behavior and emotion, planning, organizing, problem-solving). Both groups presented with high anxiety and similar abilities in emotion-focused coping. These results indicate that “soft skills” are an important area for intervention in transition-age youth with ASD and the TREE might be a good objective measure of social initiation and problem-solving challenges.

**401.067 (Poster)** Physical Health and Quality of Life Differ By Biological Sex and Age of Autism Diagnosis in an Adult SPARK Sample.

**J. K. Richards<sup>1</sup>, S. E. Transue<sup>1</sup> and K. O. Gotham<sup>2</sup>,** (1)Department of Psychology, Rowan University, Glassboro, NJ, (2)Psychiatry and Behavioral Sciences, Vanderbilt University Medical Center, Nashville, TN

**Background:** Autistic adults appear to experience more physical health problems (Croen et al., 2015; Cashin et al., 2017) and poorer quality of life (QoL; Mason et al., 2018) than their neurotypical counterparts. Recent findings suggest that autistic women may be susceptible to poorer QoL (Holmes et al., 2020) and physical health (Weir et al., 2020) than autistic men; it is unclear how this relates to evidence that autistic women are underdiagnosed or diagnosed later in life in comparison to their male peers (Hull et al., 2020).

**Objectives:** We aimed to examine whether birth-assigned sex and age of first autism diagnosis were associated with physical health symptoms and QoL in a large autistic adult sample. We hypothesized that female sex and later diagnosis each would be associated with a greater number of physical health symptoms and lower QoL, and we planned to test the interaction of these predictors.

**Methods:** N=749 participants (age 18-46 years, M=31 years; n=473 females) were recruited through the Simons Foundation Powering Autism Research (SPARK) registry to complete online questionnaire batteries as part of a larger study. Mean age of autism diagnosis was 19.64 years. The Patient Health Questionnaire (PHQ-15; Kroenke et al., 2002), World Health Organization Quality of Life assessment (WHOQoL-BREF; WHO, 1998), and the Autism-Specific Quality of Life assessment (ASQoL; McConachie et al., 2018) were used to operationalize physical health, general quality of life, and autism-specific quality of life respectively. Linear regression models were used to examine whether sex, age of autism diagnosis, and their interaction predicted

PHQ, WHOQoL, and ASQoL scores. We controlled for chronological age in the PHQ model, and for PHQ scores in the QoL models.

**Results:** Birth-assigned sex was a significant predictor of physical health symptoms ( $\beta=-0.217$ ,  $t(738)=-6.079$ ,  $p<0.001$ ), with females ( $M=7.44$ ,  $SD=4.52$ ) experiencing greater physical health problems than males ( $M=5.44$ ,  $SD=4.02$ ). Greater physical health symptoms ( $\beta=-0.272$ ,  $t(738)=-7.524$ ,  $p<0.001$ ) and later age of diagnosis ( $\beta=-0.137$ ,  $t(738)=-2.930$ ,  $p=0.003$ ) were significantly associated with lower WHOQoL scores. Physical health symptoms ( $\beta=-0.272$ ,  $t(738)=-7.737$ ,  $p<0.001$ ), age of autism diagnosis ( $\beta=-0.203$ ,  $t(738)=-4.466$ ,  $p<0.001$ ), and biological sex ( $\beta=0.090$ ,  $t(738)=2.585$ ,  $p=0.01$ ) each predicted ASQoL scores, with female sex, later age of diagnosis, and greater physical health symptoms independently associated with lower ASQoL scores.

**Conclusions:** Birth-assigned female sex was associated with greater physical health problems and poorer autism-specific quality of life, though it was not associated with general quality of life. Greater physical health symptoms and later age of autism diagnosis were both independently associated with poorer general and autism-specific quality of life. Notably, we observed no significant interactions between female sex and later age of diagnosis on these outcome variables within our regression models. These findings suggest that detecting ASD earlier in life may provide long-term benefits that ultimately lead to better quality of life in adulthood. More research is needed to understand the mechanisms by which autistic women (vs. men) may experience poorer physical health and more difficulties related to autistic status.

#### **401.068 (Poster) Positive ASD-Traits: The Self-Perceptions of Adults with ASD**

*M. Dean<sup>1</sup> and N. Mueller<sup>2</sup>, (1)Education, California State University, Channel Islands, Camarillo, CA, (2)Education, California State University Channel Islands, Camarillo, CA*

---

**Background:** Autism spectrum disorder (ASD)-traits are commonly described using deficit language. The focus on deficit contributes to stigma around ASD (Gillespie-Lynch et al., 2017; Kapp et al., 2013; Kenny et al., 2016). Feelings of stigmatization may prevent individuals with ASD from disclosing their diagnosis, and advocating for higher education or workplace accommodations (Anderson, 2013). A body of research seeks to reframe the deficit language narrative using a strength-based approach to recontextualize ASD-traits (Kapp, Gillespie-Lynch, Sherman & Hutman, 2013). The current study examines the extent to which individuals with ASD identify with positive ASD-trait descriptors.

**Objectives:** This study examined a taxonomy of positive ASD-trait descriptors (Wong et al., 2019), and the degree to which specific traits and categories within the taxonomy are relevant to adults with ASD. Secondary aims explored the relationship between self-perceptions of positive ASD-traits, and the extent to which adults with ASD disclose their diagnosis, and advocate and receive higher education and employment accommodations.

**Methods:** A convenience sample of participants with ASD ( $n=85$ ; age 18+, with 64% > age 29) was recruited through social media (Twitter, Reddit). Participants reported a formal diagnosis of ASD (80%), or a self-diagnosis (20%). A majority of participants (57%) had a minimum of a 2-year college degree, and 69% were employed ( $n=59$ ; 39=full time, 20 part-time).

Participants completed the ASD-ness Taxonomy (Wong et al., 2019) questionnaire online. The ASD-ness Taxonomy asked participants to review a list of 38 positive ASD-trait descriptors listed within eight different categories, and to select the descriptors to which they identified. Participants also responded to 22 questions about (a) their perceptions of positive ASD-traits, and (b) the extent to which they disclosed their diagnosis and advocated for higher education and workplace accommodations. Frequency data per unique response, category, and trait were calculated. A rank order categorical unique response determined the relevance of each trait-category, and each individual trait descriptor per participant. Regression analysis was used to examine the predictive ability of beliefs about positive ASD-traits on disclosure and self-advocacy

**Results:** Participants rated all ASD-ness trait descriptors as relevant. The categorical ranking identified the following trait-categories as most relevant: (a) Focus (80%), Fair/Just (76%), Cognitive/Visual (73%), and Humor (73%). The highest rated individual trait descriptor included: Prefer to spend time alone (91%), Unconventional, open minded and tolerant (88%), and Retain/Absorb large amounts of information about specific topics of interest. Linear regression analysis revealed a significant positive relationship between individual perception of positive ASD-trait endorsement and disclosure,  $R^2=.225$ ,  $F(1,83) = 24.10$ ,  $p = .000$ . A majority of participants (80%) reported a need for workplace or school accommodations, but few participants (28%) reported having accommodations available.

**Conclusions:** The findings corroborate prior research advocating for a strengths-based ASD-trait descriptors (Kapp, 2020; Russell et al., 2019), as the majority of participants identified with the positive ASD-ness taxonomy. The relationship between

perceptions of positive ASD-trait and disclosure, as well as the discrepancy between the need for and access to accommodations, suggests that efforts to promote positive ASD-trait descriptors may be useful to reduce ASD stigma.

**401.069 (Poster)** Post-High School Daily Living Skills in Autism Spectrum Disorder

**E. B. Clarke<sup>1</sup>, J. B. McCauley<sup>2</sup> and C. Lord<sup>1</sup>,** (1)University of California, Los Angeles, Los Angeles, CA, (2)Saint Mary's College of California, Moraga, CA

---

**Background:** Daily living skills are predictive of positive outcomes in individuals with autism spectrum disorder (ASD), yet little is known about trajectories of daily living skills in adults with ASD. Further, longitudinal research on DLS in ASD is relatively rare. The current literature suggests DLS age equivalents, though not necessarily standard scores, tend to increase throughout childhood, but the DLS of children with ASD are lower and increase more slowly than in typical children and children with ID. It has been suggested that DLS age equivalents may begin to decline as individuals with autism enter their mid- to late-twenties, though evidence for this is inconclusive. Given the relationship between higher DLS and positive outcomes, this is troubling. This study investigated the impact of high school exit on participants' trajectories of daily living skills age equivalent (DLS-AE) scores from ages 2-26 and the relationship between DLS-AE trajectories and employment and education outcomes.

**Objectives:** To investigate the impact of high school exit on participants' trajectories of daily living skills age equivalent (DLS-AE) scores from ages 2-26 and the relationship between DLS-AE trajectories and employment and education outcomes.

**Methods:** 98 adults with ASD were drawn from an ongoing longitudinal study. The Vineland Adaptive Behavior Scales were administered 8 times from ages 2-26. Employment and education data were compiled from parent-report demographic forms. Group-based trajectory modeling was used to identify trajectories in DLS development. Binary logistic regressions were used to examine the relationship between DLS trajectories and post-high school education and employment outcomes.

**Results:** A two-group model was determined to be the best fit, based on the percentage of variance explained (Figure 1). The Lower DLS-AE group's linear trajectory was characterized by slow gains from ages 2-21, with a small dip in DLS-AE at age 26. The higher-DLS group's quadratic trajectory was characterized by an increase in DLS-AE from ages 2-18, followed by a marginal increase in DLS-AE at age 21 and a decrease in DLS-AE at age 26. Participant characteristics by trajectory are presented in Table 1. DLS-AE trajectories increased with age prior to exiting school, at which point DLS-AE trajectories plateaued, then declined. A significant ( $p < .01$ ) decrease occurred in the slope of DLS-AE trajectories following school exit. DLS-AE scores predicted participation in post-secondary education ( $\chi^2(5, n = 73) = 27.83, p < .001$ ). Autism symptom severity predicted participation in employment ( $\chi^2(5, n = 58) = 27.54, p < .001$ ).

**Conclusions:** These findings provide evidence that DLS declines in adults with ASD, specifically after school exit, and highlight the importance of DLS in normative adult outcomes. Extending prior work in this sample, we found participants' DLS-AE trajectories increased prior to leaving the school system, at which point DLS-AE trajectories appeared to plateau, then decline. High DLS-AE scores predicted participation in post-secondary education, though ADOS CSS was a stronger predictor of obtaining employment after school exit. Future work is needed to examine the trajectories of DLS in later adulthood and to consider intervention targets for bolstering DLS following school exit.

**401.070 (Poster)** Postsecondary Education Achievement and Employment Success in Adults with Self-Reported Autism Diagnosis

**S. Y. Park<sup>1</sup>, M. South<sup>2</sup> and E. Smith<sup>1</sup>,** (1)Clinical Psychology, Brigham Young University, Provo, UT, (2)Psychology & Neuroscience, Brigham Young University, Provo, UT

---

**Background:** There is a rapidly growing number of adults entering adulthood with an autism diagnosis. This means that there are more autistic adults who are seeking postsecondary education and employment opportunities. Previous studies indicate that, regardless of cognitive and verbal ability, autistic adults have a more difficult time than non-autistic adults in entering work and educational settings and tend to have a less successful experiences in these settings. Despite these well-known difficulties, only a limited number of studies have examined the specific predictors of unfavorable outcomes in postsecondary education and employment. Even fewer studies to date have examined multiple predictors at once.

**Objectives:** The present study aims to add to the literature by looking at interactions of several key variables that contribute to the postsecondary and employment outcomes and their relationships in verbally-fluent autistic adults, including intolerance of uncertainty, camouflaging (masking autistic traits to mimic neurotypical styles), depression and anxiety.

**Methods:** The present study sampled 300 autistic adults (200 who were recruited from social media, and an additional 100 recruited from our previous studies including ADOS-2 confirmation of autism diagnosis). Structural equation modeling included Mental Health as a latent variable comprising scores from the NIH PROMIS anxiety and depression measures. Vocational and education success (called Outcome from this point on) was represented as a latent variable comprising of scores from the Vocational Index and the WHODAS 2.0. The SEM contained three mediational analyses: intolerance of uncertainty (IUS) mediating the relationship from autism traits (AQ) to Mental Health; Mental Health as a mediator for the relationship from AQ to Outcome; and Mental Health as a mediator for the relationship from camouflaging (CATQ) to outcome. Sex (male or female) was also included in the model as a possible predictor. We added additional questions about the effect of the COVID-19 on overall well-being.

**Results:** All pathways were in the expected direction showing particularly strong impact from IUS and camouflaging to mental health, and links from mental health to job and educational outcomes. Sex did not significantly predict for Outcome. Qualitative analysis showed that participants have experienced added burdens regarding unemployment, financial constraints, increased stress and anxiety, and loss of health due to the COVID-19 pandemic.

**Conclusions:** Many activities of independent living, such as successfully navigating a job interview, require meeting expectations of neurotypical interaction styles, and organizing complex workloads. Yet research including our results shows that camouflaging behavior negatively impacts mental health which negatively impacts job and educational success, resulting in a difficult tension. Our results suggest that effective supports for long-term independent living outcomes in autism must account for the “building blocks” of mental health that have specificity for autism including IUS and camouflaging.

**401.072 (Poster) Predictors of Perceived Stress Among Independent Adults with Autism during the COVID-19 Pandemic**  
**S. Xiao<sup>1</sup>, N. Nagpal<sup>1</sup>, A. Daniels<sup>1</sup>, J. K. Law<sup>2</sup>, C. W. Lehman<sup>1</sup>, P. Feliciano<sup>3</sup>, S. Consortium<sup>4</sup> and W. K. Chung<sup>5</sup>,** (1)Simons Foundation, New York, NY, (2)Maryland Center for Developmental Disabilities, Kennedy Krieger Institute, Baltimore, MD, (3)SFARI, Simons Foundation, New York, NY, (4)SPARKForAutism.org, New York, NY, (5)Department of Pediatrics, Columbia University, New York, NY

---

**Background:** The COVID-19 pandemic has been disrupting daily life and routines, resulting in stress for many adults with autism. Research indicates that individuals with ASD are more vulnerable to developing comorbid anxiety and mood disorders compared to neurotypical individuals (Hofvander et al., 2009, Kanai et al., 2011). However, less is known about the impact of prolonged stressful life events on perceived distress and factors that may affect an individual’s likelihood of perceiving higher distress. One study has shown that emotional vulnerability in people with ASD varies according to gender and age, with adult females at high risk (McGillivray & Evert, 2014).] Our study sought to identify the differences in self-reported distress experienced during the COVID-19 pandemic by independent adults with autism in the SPARK cohort.

**Objectives:** To identify demographic predictors of distress among independent adults in the SPARK study during the COVID-19 pandemic.

**Methods:** SPARK is an online research study of individuals with a professional diagnosis of autism and their family members. SPARK surveyed 636 independent adults with autism from 3/10/20–4/10/20 and 396 adults again from 5/27/20–6/9/20 to better understand the impact of COVID-19. Data for this study are from the second timepoint. Participants without Background History Questionnaires previously collected were excluded from analysis. Ordinal regression analysis was used to identify predictors of the level of family distress. The primary dependent variable was the single-item scale from the Brief Family Distress Scale. Responses were categorized into 3 levels of impairment: none, moderate, and marked. Independent variables used for analysis included age, race, household income, sex at birth, education level, and sexual orientation. Analyses were completed using SPSS.

**Results:** A total of 321 autistic adults between 18-74 years old were included in the study. Table 1 includes demographic information on the participants. The majority of participants did not endorse any distress (59%); 21% endorsed moderate distress and 10% marked distress.

Significant predictors of higher perceived distress included being female, identifying as non-heterosexual, and having lower income ( $p < .05$ ). Independent adults who identify as non-heterosexual were 1.96 times more likely to report higher distress compared to heterosexuals (95% CI: 1.22, 3.13). Having higher income protected against experiencing distress, with those in the lowest income bracket 3.2 times more likely to report distress than those in the highest bracket ( $> \$81K$ ; 95% CI: 0.16, 0.62). Females were 1.6 times more likely to report higher distress compared to male counterparts (95% CI: 1.02, 2.67).

**Conclusions:** This study found that female at birth, non-heterosexual sexual identity, and lower income level were associated with greater perceived distress among autistic adults. Autism researchers, community partners, and healthcare providers should be aware of the distress experienced by independent adults with autism during the COVID-19 pandemic and create accessible

resources for patients to help identify and manage distress. Special attention should be dedicated to investigating specific risks for autistic adults with intersectional identities.

**401.073 (Poster)** Preliminary Evidence of Dynamic Control Differences in Curve Negotiation in Drivers with and without Autism Spectrum Disorder

**G. M. Sherrod<sup>1</sup>, R. K. Kana<sup>2</sup>, B. McManus<sup>1</sup>, H. M. Bednarz<sup>1</sup>, A. M. Svancara<sup>1</sup>, P. M. Pawar<sup>1</sup> and D. Stavrinou<sup>1</sup>,** (1)Department of Psychology, University of Alabama at Birmingham, Birmingham, AL, (2)Department of Psychology, University of Alabama, Tuscaloosa, AL

---

Background: Negotiating horizontal curves is a high-risk tactical control maneuver when operating a motor vehicle, as drivers must simultaneously and adeptly control their steering adjustment, speed, and lane positioning, as well as accurately perceive the curvature of the road segment and adjust to proprioceptive cues. Given known differences in upper body motor control, coordination, proprioception, and attention, this maneuver may be particularly difficult for drivers with autism spectrum disorder (ASD). However, no study to date has investigated how curve negotiation among these drivers may differ from that of their typically-developing (TD) counterparts.

Objectives: The objective of this study is to examine how vehicle dynamic variables differ during horizontal curve negotiation among drivers with ASD compared to TD drivers. Given that effective curve negotiation involves employing various tactical skills at different segments of the curve, it is also of interest to explore how steering control differs at varying segments of a curve.

Methods: Thirty-one licensed adolescent and emerging adult drivers ( $n_{ASD} = 13$ ,  $n_{TD} = 18$ ) matched on age ( $M = 20.00$  years;  $SD = 2.75$ ), gender (61.3% male), and IQ ( $M = 105.97$ ;  $SD = 16.12$ ) were recruited. Participants completed a 13-mile experimental drive in a high-fidelity driving simulator. During this drive, participants navigated 2 residential horizontal curves (1 left, 1 right) with a radius of approximately 200m, an angle of approximately 60°, and a distance of approximately 510m. For analysis, the curves were segmented into 6 sections to compare driving performance at each segment (curve approach, curve entry, apex entry, apex exit, curve exit, exit tangent). Outcome measures of interest included longitudinal velocity (mean and SD) and longitudinal acceleration (mean and SD).

Results: Driving performance was averaged across the 2 curves. A 2 (Group) x 6 (Curve Segment) mixed-model analysis of variance (ANOVA) revealed a significant Group x Curve Segment interaction for mean acceleration,  $F(4.1, 110.73) = 2.82$ ,  $p = .03$ , partial eta-squared = .10. Drivers with ASD had a faster average acceleration than TD drivers at apex exit ( $M_{ASD} = .001$ mph/s,  $M_{TD} = -.00006$  mph/s), and a slower acceleration at curve exit ( $M_{ASD} = -.002$  mph/s,  $M_{TD} = 0$  mph/s). Other variable comparisons were non-significant, all  $p > .05$ .

Conclusions: When navigating curves, drivers typically begin accelerating slowly at the apex of a curve and continue to accelerate through the end of the curve, allowing the driver more time to visually scan and limit potential vulnerability to opposing traffic during the curve (Hough 2008). There is evidence to suggest that drivers with ASD may follow a different acceleration profile than TD drivers. Drivers with ASD may have curve negotiation profiles similar to novice drivers, whose turns are started earlier as opposed to delayed apexing in experienced drivers. Further investigation into the nature of steering control within this population is needed to better understand how this population maintains a controlled vehicle heading throughout curve negotiation. Better quantification of difference can help inform future training and education protocols to ensure safe driving among young drivers with ASD.

**401.075 (Poster)** Quality of Life and Associated Factors in Adolescents and Young Adults with Autism Spectrum Disorder: Evaluation of Self-Reports and Parent Proxy-Reports in a Danish Clinical Cohort Followed for 8-18 Years.

**S. H. Avlund<sup>1,2</sup>, L. Clausen<sup>3,4</sup>, D. Schendel<sup>5</sup>, P. H. Thomsen<sup>6</sup> and M. Joergensen<sup>7,8</sup>,** (1)Department of Child and Adolescent Psychiatry, Research Unit, Aarhus University Hospital, Psychiatry, Aarhus N, Denmark, (2)Child and Adolescent Psychiatry, Aalborg University Hospital, Aalborg, Denmark, (3)Department of Child and Adolescent Psychiatry, Research Unit, Aarhus University Hospital, Psychiatry, Aarhus N, Denmark, (4)Department of Clinical Medicine, Aarhus University, Faculty of Health, Aarhus N, Denmark, (5)Aarhus University, Aarhus, Denmark, (6)Department of Child and Adolescent Psychiatry, Research Unit, Aarhus University Hospital, Psychiatry, Aarhus N, Denmark, (7)Central Region Denmark, Special Area Autism, Hinnerup, Denmark, (8)Aarhus University Hospital, Psychiatry, Aarhus N, Denmark

---

Background: Quality of life (QoL) and factors associated with QoL, considering the perspectives of both parents and their offspring, are not well understood in adolescents and young adults (AYA) with autism spectrum disorders (ASD), despite that ASD is known to have a persistent adverse effect on physical and mental health.

**Objectives:** Examine self-reported and parent proxy-reported QoL and factors associated with QoL in a clinical cohort of AYAs diagnosed with ASD in childhood and followed for 8-18 years.

**Methods:** The study cohort comprised all consecutive referrals for an ASD evaluation of children  $\leq 7$  years old and residing in Aarhus County, Denmark, 2000-2010, and who received an ASD diagnosis before the end of follow-up in 2016 (n=621). Analysis was restricted to AYA with ASD and/or parents (n=194; 31%) who completed a questionnaire survey, Oct 2018 - Jan 2019, on QoL and other factors. Data for analysis included diagnoses, cognitive level and clinical features at initial assessment; registry-reported demographic and health information; and questionnaire data on QoL (KIDSCREEN-27), autism symptoms (Social Communication Questionnaire SCQ) and other behavioral symptoms (Social Difficulties Questionnaire SDQ), social relationships and bullying. QoL reports were compared with normative data (z-test of proportion) and between AYA-parent pairs (intra-class correlation coefficient ICC). Multivariate linear regression models assessed the effects of demographic characteristics, autism symptoms, co-occurring symptoms, parental educational level and social relationships on QoL.

**Results:** Characteristics of AYA with ASD at follow-up comprised: mean age 18 years; 79% male; 81% IQ>70 at baseline; co-occurring ADHD 28% (most frequent co-occurring diagnosis); 81% lived with at least one parent; 57% with at least one parent with  $\geq 15$  years of education; mean SCQ lifetime score 19.2; and mean SCQ current score 13.2. Compared to normative levels for the KIDSCREEN-27, AYA with ASD and their parents reported significantly lower QoL in *physical wellbeing*, *psychological wellbeing*, *social support and peers*, while *autonomy and parent relations* were similar; for *psychological wellbeing* and *social support and peers*, AYAs with ASD scored on average a full standard deviation below the mean of the normative data. Agreement between AYA and parents on most QoL dimensions was moderate (ICC 0.50-0.70). All factors, except age, IQ and parental educational level, were individually associated with QoL. In fully adjusted models and both self-reports and parent proxy reports, *emotional problems* (SDQ emotional domain score regression coefficient, self-report -15.47, 95%CI (-23.2;-7.8), parent report -6.84, 95% CI (-13.1; -0.6)), *peer problems* (SDQ peers domain score regression coefficient, self-report -6.43, 95%CI (-11.8; -1.0), parent report -5.12, 95% CI (-9.5; -0.8)), and *bullying* (regression coefficient, self-report -6.06, 95%CI (-10.5; -1.6), parent-report -5.13, 95% CI (-9.7; -0.6)), explained most of the variance in QoL total scores.

**Conclusions:** For a complete picture of QoL in autistic youth both AYA and parent perspectives are important. Interventions targeting symptoms of emotional disorders, peer problems and bullying may have greatest QoL impact in AYA with ASD.

**401.077 (Poster) Ready 2 Work: Development of a User-Informed Employment Website for Job Seekers with Autism**  
**J. Phan<sup>1</sup>, L. Whittingham<sup>1</sup>, C. Bishop<sup>1</sup>, N. Kenyeres<sup>2</sup>, R. Ensor<sup>1</sup>, B. Jichici<sup>1</sup>, W. Roberts<sup>3</sup>, B. Di Rezze<sup>4</sup>, N. E. Walker<sup>5</sup>, J. Seymour<sup>6</sup> and P. Burnham Riosa<sup>1</sup>,** (1)Brock University, St. Catharines, ON, Canada, (2)HelpScout Canada, St. Catharines, ON, Canada, (3)isand, Toronto, ON, Canada, (4)School of Rehabilitation Science, McMaster University, Hamilton, ON, Canada, (5)Kerry's Place Autism Services, Aurora, ON, CANADA, (6)York ASD Partnership, Toronto, ON, Canada

**Background:** Employment success has been identified as a top priority for people with autism in Canada, both locally and nationally. Despite evidence indicating that people with autism are motivated to obtain employment, rates of unemployment and underemployment remain among the highest in the country. Considerable research has focused on personal and social characteristics that contribute to meaningful employment for people with autism; however, an exploration of the complimentary skills or tools that job seekers with autism need to engage in the job-seeking process is lacking. Online resources may be helpful; however, little is known about what people with autism need to effectively engage in job-seeking, networking, and marketing of their skills to potential employers. **Objectives:** The purpose of this research is to 1) understand what job seekers with autism, caregivers, and employment professionals perceive to be important for job seekers with autism to successfully enter the workforce (Phase 1) and to use this end-user feedback to develop an online employment platform (Phases 2 and 3). **Methods:** In Phase 1, five focus groups were conducted with 29 participants (i.e., 7 autistic self-advocates, 6 caregivers of people with autism, 16 professionals from relevant vocational and employment organizations) about the employment needs of job seekers with autism that could be addressed through an online platform. A thematic analysis of the focus group data was conducted. Currently, these results are being used to develop (Phase 2) and refine (Phase 3) an online platform that will be assessed by collecting additional survey, interview, and website analytics data from participants who will be interacting with it. **Results:** The participants from the Phase 1 focus groups described a variety of structural (e.g., unavailability of suitable positions) and social barriers (e.g., negative attitudes toward people with autism) that job seekers with autism face. Participants provided several recommendations for helpful website content including career exploration and assessment, employment accommodations, advocacy and disability rights in the workplace, networking, and job skills training. Participants highlighted the value of including distinct resources for family members and support persons (e.g., how to support a job seeker in their employment search), job seekers (e.g., how to dress for an interview), and employers looking to hire job seekers with autism (e.g., understanding job accommodations). Regarding the interface of the platform, participants indicated a preference for clear and interactive multi-media options to present content (e.g., pictures, videos, straightforward text) in addition to an interactive and dynamic section for networking (e.g., discussion board). Website development, factoring in the findings from our focus groups, is currently underway. **Conclusions:** This innovative research approach to developing an online employment resource focuses on engaging end-users and key stakeholders throughout

the process. The results of this study will add to the limited knowledge about the work readiness skills and resources that are tailored to the idiosyncratic needs of job seekers with autism.

**401.078 (Poster)** Remembering to Remember: Contextual References As a Mechanism to Support Time-Based Prospective Memory in Autistic Adults

*A. Roestorf, D. M. Williams<sup>2</sup> and C. Grainger<sup>1</sup>, (1)Psychology, University of Stirling, Stirling, Scotland, United Kingdom, (2)University of Kent, Canterbury, United Kingdom*

---

**Background:** Time-based prospective memory (TBPM) is remembering to perform an intended action, at an appropriate future time. TBPM is essential for autonomous living and everyday functioning. For instance, TBPM is when we remember to turn the oven off after an hour or attend a medical appointment next week. A growing body of research suggests that both autistic children and adults experience difficulties with TBPM. Research within the typically developing literature has investigated ways to improve prospective memory. For example, by simply giving individuals an idea of the context in which a future task will occur. However, crucially, to date no studies have explored the extent to which such techniques can improve TBPM difficulties for autistic individuals.

**Objectives:** Aims: to investigate how contextual references can be used as a mechanism to facilitate improved TBPM for autistic individuals.

**Methods:** A community sample of 80 autistic (AS, n=40) and non-autistic (NT; n=40) adults completed online TBPM tasks (counterbalanced between-subjects; see Figure 1). Groups were matched on age, gender, and IQ across conditions.

We compared TBPM accuracy for no contextual information (baseline) vs accurate (Correct Context) or inaccurate (False Context) information. The TBPM task was embedded in a 6-minute online computer task to sort words (block 1) and pictures (block 2) as food or non-food items (ongoing task). Participants were instructed to monitor time via the on-screen timer (press 'z'). The TBPM action was to 'log the time' (press 'space') when the clock showed 3-minutes (target time, +/-10s lenience). In the Correct Context and False Context conditions, participants were given information (cue) that the target time would likely appear in block 2. In the case of the former this cue was correct, but incorrect in the latter. If the switch to block 2 did serve as a cue to make the TBPM response, then we predicted improved TBPM accuracy in the Correct Context condition.

**Results:** Partial analysis of (fully collected) data (2 (Group) x 3 (context) ANOVA) are reported for TBPM accuracy and time monitoring. Preliminary data (AS=30; NT=17) show, on average, that TBPM accuracy for both groups was within +/-10s, across conditions. AS adults were more vigilant in time monitoring (i.e., more clock checks) and showed improved PM accuracy in the Correct Context (~25%) compared to No/False Context conditions ( $t(28) 2.58, p=.02, d=.48$ ).

Further analyses of individual differences are ongoing (to be completed January 2021), and some findings may be subject to change.

**Conclusions:** The preliminary findings indicate that the use of targeted contextual information may help to ameliorate TBPM difficulties for autistic adults. Furthermore, where autistic adults monitored the time more often, this might suggest important differences in reliance on external supportive strategies (e.g., more clock checks) as well as contextual information, rather than strategically self-monitoring their internal memory. Our discussion of these findings will provide important implications for novel strategies that can support TBPM to facilitate autonomy in everyday life.

**401.080 (Poster)** Seeing in the Mind's Eye. a Study of Aphantasia in Relation to Episodic Memory and Episodic Future Thinking in Autistic Adults

*A. Roestorf, D. M. Williams<sup>2</sup> and C. Grainger<sup>1</sup>, (1)Psychology, University of Stirling, Stirling, Scotland, United Kingdom, (2)University of Kent, Canterbury, United Kingdom*

---

**Background:** Autistic individuals are reported to have specific difficulties related to episodic memory (EM; personally experienced past events), episodic future thinking (EFT; thinking about oneself in the future) and prospective memory (PM; remembering to perform an intended action, at an appropriate future occasion). A core component of PM, EM and EFT tasks is the ability to mentally visualise oneself in relation to past or future potential events (i.e., self-generating future thinking visualisations). Recent research has shown how this ability falls on a spectrum from substantially impoverished mental visual content (*Aphantasia*) to high clarity of vivid imagery (*Hyperphantasia*). It is, therefore, important to establish whether autistic people experience greater levels of Aphantasia and whether EM or EFT are more difficult for autistic people because of more

pervasive difficulties in visualisation (the ability to create vivid mental imagery). To our knowledge, this is the first study of Aphantasia in autism.

**Objectives:** We explored whether (i) autistic adults have increased Aphantasia, and (ii) if Aphantasia might be related to EM and EFT difficulties.

**Methods:** 200 autistic (AS; n=102) and non-autistic (NT, n=97) adults completed online questionnaires of autistic traits, Aphantasia, Episodic Memory and Future Thinking (Table 1). Other questionnaires required participants to complete sentence stems related to how they think about themselves in terms of past (episodic memory) and future experiences (episodic future thinking), and measures of autistic traits. The questionnaires took approximately 20 minutes to complete.

**Results:** Preliminary analysis showed significant Group differences in Autistic traits and Aphantasia (Table 1; all  $F(2,201) \geq 5.68$  all  $p \leq .018$ , all  $\eta^2_p > .03$ ), with AS adults showing greater visualization difficulties than NT adults. Furthermore, AS reported greater difficulties with mentalizing, social anxiety and sensory reactivity aspects of autism. Regression analysis indicated that social anxiety was the strongest predictor of Aphantasia, in both AS and NT adults ( $F(1,47) = 20.51, p < .001, R^2 = .30$ ).

Post-hoc Bayesian analysis confirmed the likelihood of these effect sizes, indicating 'decisive' ( $BF_{10} > 100$ ) to 'moderate' ( $BF_{10} > 3$ ) evidence to support visualization difficulties related to Mentalizing ( $BF_{-0} = 236.4$ ), and Social Anxiety ( $BF_{-0} = 8.75$ ) and Sensory Reactivity ( $BF_{-0} = 3.47$ ), respectively (Figure 1). However, the distribution of scores requires further investigation to individual differences in autistic adults.

We investigated how Aphantasia is related to EM and EFT (Table 2). Analyses of (fully collected) data are underway, with transcription of responses and reliability coding to be completed by January 2021.

**Conclusions:** The preliminary findings suggest that autistic adults experience greater difficulties in generating mental imagery (Aphantasia) than non-autistic adults. Aphantasia was strongly related to high levels of autistic traits, specifically mentalizing and social anxiety. It also appears to affect Episodic Future Thinking, but further analysis is required (and currently underway) to confirm the strength of association. These findings offer promising insights to the pattern of cognitive variability that might explain some of the differences and related prospective memory difficulties that autistic people experience. With these insights we hope to inform potential indicators for future targeted interventions to support autistic people in everyday remembering.

#### 401.081 (Poster) Self-Advocacy in Autistic and Non-Autistic College Students

S. P. Santhanam<sup>1</sup>, K. Wilson<sup>2</sup>, M. Paige<sup>2</sup> and A. Craft<sup>2</sup>, (1)Dept. of Speech, Language, Hearing Sciences, Metropolitan State University of Denver, Denver, CO, (2)Towson University, Towson, MD

---

#### Background:

It is important for adults on the autism spectrum to be their own self-advocates in a post-secondary setting. Self-advocacy leads to a better quality of life, including better adaptation to college environments, career success, maintenance of a positive identity, and management of stress in college students on the autism spectrum (Kim, 2019). A prior study looked at students' beliefs about self-advocacy (Gillespie-Lynch et al., 2017). However, students' engagement in self-advocacy has not been explored. In the current study, students on the autism spectrum and their non-autistic peers, including those with a learning disability and those without a known diagnosis, were asked to rate their self-advocacy practices in the college environment.

#### Objectives:

The purpose of this preliminary study was to understand if college students on the autism spectrum differed from their peers in their self-advocacy practices.

#### Methods:

This study adopted a survey design. Participants included adult-aged (18 years of age or older) students enrolled in 4-year-universities in the United States with college-level reading and writing abilities. See Table 1 for demographic details. The self-advocacy questionnaire (Kosine, 2006) was used to collect data on students' use of self-advocacy in classrooms and within the university campus. This questionnaire includes 22 items. Example statements include: "I feel comfortable talking to my instructors." and "I am afraid to talk in class discussions."

Results:

Results below are based on preliminary data collection. We will complete data collection in March 2021. Our research questions were:

1. **What common challenges are reported by college students?**

All participants self-reported greatest challenges in motivating themselves to study. Interacting with professors and making friends were reported as challenges by a greater percentage of autistic participants. A smaller percentage of autistic participants reported accessing resources and finding the motivation to study as challenges.

2. **Do college students on the autism spectrum differ in self-advocacy practices from their peers?**

When all three groups were combined, 60% of the students rated their overall self-advocacy as “average”; 25% rated it as “above average”, and 16% provided a “poor” rating. Between group differences can be observed in Figure 1. Students in the two non-autistic groups were similar in their overall rating of self-advocacy. However, a greater number of autistic students (N=11) reported poor self-advocacy when compared to the other two groups.

3. **What factors relate to perceptions of low self-advocacy for college students?**

61% of participants who had a diagnosis (autism or other diagnosis) and 50% of participants who were not employed reported poor self-advocacy scores. Factors such as gender, having a friend or not, and education status did not impact self-advocacy ratings.

Conclusions:

Although our caveat is having unequal sample sizes in each group, this preliminary analysis indicates that autistic students experience more challenges in social aspects than academic aspects of college. While a large number of autistic students reported having low self-advocacy, autistic students are more similar than different when compared to their peers in their self-reported rating of self-advocacy. Therefore, education on self-advocacy may be important for all students irrespective of their diagnostic status.

**401.082** (Poster) Self-Determination As a Mediator between Autism Traits and Quality of Life

*H. E. Andrews, D. Hedley and S. M. Bury, Olga Tennison Autism Research Centre, School of Psychology and Public Health, La Trobe University, Melbourne, VIC, Australia*

---

**Background:** Autistic people report lower quality of life (QoL) than non-autistic people (Ayres et al., 2018), with a similar association between autistic traits and QoL found in the general population (Lawson et al., 2020). One factor that may explain this relationship is self-determination. Self-Determination Theory is a meta-theory of motivation, that reflects the perception of oneself as a causal agent (Deci & Ryan, 1985), and is suggested to develop through the satisfaction of three psychological needs: autonomy, competence and relatedness (Deci & Ryan, 2000). Self-determination has been positively associated with QoL (Ayres et al., 2018), and autistic people tend to report lower self-determination than the general population (Ayres et al., 2018).

**Objectives:** This study aimed to test whether meeting the psychological needs of autonomy, competence and relatedness (i.e., self-determination), mediated the relationship between autism traits and four domains of QoL (psychological, social, physical and environment; see Figure 1).

**Methods:** Participants were 262 people (167 Females) from the general population recruited through Prolific, aged 18 to 71 years of age (Mean 37.6, SD 11.92). Participants completed an online survey measuring autistic traits (AQ-28; Hoekstra 2011), psychological needs (Basic Psychological Needs Satisfaction Scale – General; Gagné, 2003), and four domains of QoL (WHOQOL-BREF; Orley et al., 1997). Executive functioning (The Adult Temperament Questionnaire-Short-Effortful Control Subscale; Rothbart et al., 2000) and a self-created item measuring the impact of COVID-19 on daily life (1 – has become a lot worse, 5 – has become a lot better) were expected to influence QoL and included as covariates.

**Results:** Correlational analysis between all variable indicated that executive functioning was significantly associated with autistic traits,  $r = -.33, p < .001$ , psychological needs  $r_s = -.30$  to  $-.50, p_s < .001$ , and QoL domains,  $r_s = -.25$  to  $-.46, p_s < .001$ . The impact

of COVID-19 was only significantly associated with all QoL domains,  $r_s = .15$  to  $.28$ ,  $p_s < .001$  to  $.018$ . Importantly autistic traits were significantly associated with all psychological needs,  $r_s = -.37$  to  $-.49$ ,  $p_s < .001$ , and QoL domains,  $r_s = -.21$  to  $-.38$ ,  $p_s < .001$ , and all psychological needs were significantly associated with all QoL domains,  $r_s = .38$  to  $.70$ ,  $p_s < .001$ . Model 4 of The Process Macro for SPSS (Hayes, 2018), was used to test four separate parallel mediation models. Overall, the direct relationship between autistic traits and QoL was only significant for Social QoL (Table 1). While the total indirect effect was significant for all QoL domains, the individual paths via psychological needs told a more nuanced story. While all psychological needs mediated the relationship between autistic traits and Environmental QoL, only competence and relatedness were significant mediators for both the Psychological and Social QoL domains, and autonomy and competence for the Physical QoL domain.

**Conclusions:** This study suggests that individuals with higher autistic traits may have poorer QoL, in part, because they have difficulties meeting important psychological needs. While these findings need to be tested in an autistic populations, it suggests that interventions targeting self-determination, may improve QoL in autistic people.

#### **401.083 (Poster) Self-Reported Mood-Changing Life Experiences in Adults with Autism: What Makes Them Happy and Unhappy?**

**C. Parenteau<sup>1</sup>**, S. Zheng<sup>2</sup>, L. A. Lampinen<sup>3</sup>, S. S. Ghods<sup>3</sup>, F. Pezzimenti<sup>4</sup>, R. Adams<sup>5</sup>, J. L. Taylor<sup>6</sup> and S. Bishop<sup>3</sup>, (1)University of California, San Francisco, San Francisco, CA, (2)Psychiatry, University of California, San Francisco, San Francisco, CA, (3)University of California San Francisco, San Francisco, CA, (4)Psychiatry and Behavioral Sciences, Vanderbilt University Medical Center, Nashville, TN, (5)Cincinnati Children's Hospital Medical Center, Cincinnati, OH, (6)Vanderbilt Kennedy Center, Nashville, TN

---

#### Background:

Life experiences can affect mood and have a downstream impact on mental health. Studies in the general population have identified life factors, such as social relationships and self-perceptions, that influence people's mood and perceived happiness (Singh & Jha, 2008; Cheng & Furham, 2002; Vanderhorst & McLaren, 2005). Moreover, adults with autism encounter unique life experiences that might further contribute to changes in mood. While previous studies have focused on self-reported lived experiences of individuals with autism (Depape & Lindsay, 2015; Russell et al., 2019; Ward & Webster 2017; Milner et al., 2019; Humphrey & Symes, 2010), findings do not extend to the impact of life experiences on mood. Understanding the effects of possible mood-changing life experiences could provide significant information for potential treatment targets to improve mental health and life satisfaction in adults with autism.

#### Objectives:

To describe self-identified everyday life experiences that make adults with autism happy and unhappy using qualitative data.

#### Methods:

315 self-reporting independent adults (age 18 to 35 years old, 52% male) with a childhood diagnosis of autism recruited from a national research registry completed an online survey with the open-ended questions: "Looking back at the past week, what are some of the things that made you unhappy?" and "What are some of the things that made you happy?" The open text responses for each question were coded for themes using the inductive coding approach, and the final coding scheme was derived based on consensus discussions within the research team through an iterative process of reviewing and revisiting the responses and coding structure. Once the consensus was reached for the final coding structure, the codes were organized by their relationship to "Happy" and/or "Unhappy" mood.

#### Results:

Adults with autism reported a range of life experiences that made them happy and unhappy when reflecting on the past week (see Figure 1). Themes reported by participants that made them both happy and unhappy include relationships and interactions with social partners, work, school, finances, social supports, and perceptions of self-efficacy. There were also factors that were exclusively identified as making them happy, such as achievements, positive social interactions, participation in individual or social activities, and practicing self-care. Likewise, participants reported additional life factors only related to feeling unhappy, including common themes of communication difficulties and misunderstanding, negative or lack of social interactions and mistreatments by others, lack of activities, and disruptions in routine.

#### Conclusions:

Adults with autism experience and recognize a range of life experiences that affect their mood on a day to day basis. Participants reported life experiences that had both positive and negative impact on mood and were largely consistent with predictors for life satisfaction and perceived happiness found in the general population. Life factors specifically related to happy-mood could provide avenues to foster positive experiences; whereas life aspects unique to unhappy-mood may have implications on intervention to target improvement of mood and mental health in adults with autism.

**401.084 (Poster)** Self-Reported Real-World Executive Function Skills and Associations with Anxiety and Depression in Autistic Adults

**S. A. Stahl<sup>1</sup>, L. R. Guy<sup>2</sup>, E. M. Lamarche<sup>1</sup>, B. Tomaszewski<sup>3</sup> and B. B. Maddox<sup>1</sup>,** (1)Psychiatry, UNC TEACCH Autism Program, Chapel Hill, NC, (2)Psychiatry, UNC TEACCH Autism Program, Greensboro, NC, (3)Frank Porter Graham Child Development Institute, University of North Carolina at Chapel Hill, Chapel Hill, NC

---

**Background:** Executive function (EF) difficulties in youth on the autism spectrum persist into adulthood, but literature on EF in autistic adults is limited and largely reliant on lab-based tasks. A more ecologically valid EF measure is the Behavior Rating Inventory of Executive Function Report-Adult version (BRIEF-A; Roth et al., 2005). In a sample of 35 autistic adults, Wallace et al. (2016) found that inflexibility was associated with increased anxiety, while planning/organization difficulties were associated with increased depression. However, they used only informant reports. It is important to include the perspectives of autistic adults to better understand their perceived strengths and challenges.

**Objectives:** Among autistic adults, we aimed to examine 1) real-world EF profiles utilizing the self-report version of the BRIEF-A, and 2) associations between EF, anxiety, and depression.

**Methods:** Diagnostic evaluations were conducted across statewide autism clinics. Data from 52 autistic adults (71% male; 71% white; age:  $M = 30$  years, range 18-59; IQ:  $M = 104$ , range 74-147) who provided consent to participate were included. Participants completed the BRIEF-A Self-Report, the Adult Self-Report (ASR; Achenbach & Rescorla, 2003) as a measure of depression and anxiety, and an IQ assessment. A one-sample  $t$ -test was used to examine autistic adults' level of impairment on BRIEF-A subscales, relative to the population mean. A repeated measures ANOVA assessed the profile of EF scores across subscales. We also conducted hierarchical multiple regressions to examine the effects of EF on depression and anxiety symptoms, controlling for participant age, IQ, and sex. To measure EF in these models, we first used the Behavioral Regulation Index (BRI) and the Metacognition Index (MCI) of the BRIEF-A. We then repeated the analyses with the peak subscale from each index.

**Results:** Across all nine subscales of the BRIEF-A, we found EF impairments relative to the population mean of 50 ( $ps < .001$ ). Participants showed a variable EF profile ( $F = 10.12, p < .001$ ), with the greatest difficulties in Working Memory and Shift (Figure 1). Working Memory was significantly higher than all other subscales ( $ps < .02$ ), except for Shift. As shown in Table 1, BRI was a significant predictor of depression ( $p < .01$ ), but not anxiety, and the MCI did not emerge as a significant predictor. Working Memory predicted both anxiety ( $p = .02$ ) and depression ( $p < .01$ ), whereas the Shift was not a significant predictor.

**Conclusions:** This study is one of the first to show that autistic adults without intellectual disability exhibit self-reported real-world EF difficulties, with the greatest impairments in working memory and flexibility. These findings differ from recent research with the informant report of the BRIEF-A, suggesting the need for future EF research directly comparing autistic adults' and their parents' perspectives. Although overall behavioral regulation skills were associated with depression, working memory from the metacognition index emerged as a significant predictor of anxiety and depression (above and beyond the influence of sex, age, and IQ). Targeting EF, specifically working memory, in treatment could have a cascading effect on improving autistic adults' mental health.

**401.086 (Poster)** Sibling Relationships in Families of Children with and without Autism: Specificity and Commonality

According to the Siblings' and the Mothers' Perspectives

**Y. Rum<sup>1</sup>, D. A. Zachor<sup>2</sup>, Y. Armony<sup>1</sup>, E. Daniel<sup>3</sup> and E. Dromi<sup>4</sup>,** (1)Tel Aviv University, Tel Aviv, Israel, (2)The Autism Center/ALUT, Pediatrics, Tel Aviv University/Shamir (Assaf Harofeh) Medical Center, Zerifin, Israel, (3)Constantiner School of Education, Tel-Aviv University, Tel Aviv, Israel, (4)Constantiner School of Education, Tel Aviv University, Tel Aviv, Israel

---

Background:

Sibling relationships are often the most enduring life-long relationships, influencing development (Brody, 2004). Sibling relationship qualities such as companionship and intimacy, alongside conflict and rivalry, are common across families (Furman &

Buhrmester, 1985). Research on families of children with autism has yielded mixed results regarding the nature and quality of the sibling relationship and their similarity to typical sibling relationships. This study investigates specificity and commonality in sibling relationships in families of children with and without autism, according to the siblings' and the mothers' perspectives.

Objectives:

To compare children's perspectives on their relationship with their siblings (diagnosed with autism *or* typically developing [TD]) to that of their mothers.

Methods: Seventy-five families participated. Twenty-nine TD children whose younger siblings were diagnosed with autism and their mothers constituted the 'autism group'. Forty-six TD children with younger TD siblings and their mothers constituted the 'TD group'. Children and mothers completed the Sibling Relationship Questionnaire (SRQ; Furman & Buhrmester, 1985) and participated in an open-ended interview. Thematic analysis was used to identify key elements of the participants' perspectives of the sibling relationship.

Results:

Siblings of children with autism reported less intimacy and quarreling than siblings in the comparison group. Mothers of children with autism reported their children to have less warmth/closeness, conflict, intimacy, quarreling, prosociality, sibling nurturance, similarity, and competition in the siblings' relationships than mothers in the comparison group (table 1). Children and mothers in the autism group correlated only in self-reported conflict between siblings ( $r_{(29)}=-.457, p<.05$ ). Children and mothers in the TD group correlated in conflict ( $r_{(46)}=.410, p<.01$ ) and warmth/closeness ( $r_{(46)}=.472, p<.01$ ) between the siblings.

Thematic analysis revealed two themes common to mothers and children in both groups: '**Inseparable**' - references to the siblings' joint routine, things in common, enjoyment, affection, quarrels, and statements on the connections between these; '**The younger versus older**' - references to each sibling's role, disparities, and asymmetry in the relationship. One theme, specific to mothers in both groups ('**The bigger picture**'), referred to changes and processes in the relationship. One theme, specific to the autism group, included references to the younger sibling's condition without explicitly mentioning the term 'autism' ('**The unsaid word**').

Conclusions:

We asked whether sibling relationships fundamentally differ in families with and without autism according to the mothers' and the siblings' perspectives, or are there commonalities regardless of autism. Children's reports illustrate more commonalities than specificity across groups, while mothers' reports indicate specificity. More disagreement was found between mothers and children in families with autism than in families without autism. Consistent with previous literature (Braconnier et al., 2018), children's perspectives of their relationship with a sibling with autism were more positive than those of their mothers.

The qualitative analysis pointed to the importance of further investigating autism disclosure in the family.

The different perspectives of parents and children, as evidenced by questionnaire analyses, and the specificity and commonality in the foci of parents and children, as suggested by the qualitative analysis, should be considered in research and intervention in families of children with autism.

**401.087** (Poster) Social Connection and Assurance, Anxiety, and Autism in Adulthood

**S. R. Dufresne, O. Ward and E. T. Crehan, Eliot-Pearson Department of Child Study & Human Development, Tufts University, Medford, MA**

---

Background: We know that there are inherent social communication challenges in autism (American Psychiatric Association, 2013). We also know that autistic individuals have higher rates of anxiety and other internalizing symptoms (Levy & Perry, 2011). Studies have shown a mediating effect of social relationships on internalizing symptoms such as depression and loneliness (Mazurek, 2014), but less attention has been paid to anxiety and the specific domains of social connectedness and assurance, which have implications for intervention work. This study examines the relationship between these intrapersonal social domains and anxiety symptoms in adults with and without autism.

Objectives:

- To understand the relationship between social connectedness and assurance and anxiety symptoms in adults
- To determine if there is a difference in this relationship for neurotypical versus autistic adults

Methods: A total of 132 adults participated in this study from across the United States, representing 23 states and most geographic regions. Participants included both adults with autism spectrum disorder (ASD) without intellectual disability (44 ASD) and neurotypical adults (88 NT). Diagnostic group was based on self-report. Mean age was 26.89 (SD = 5.929). Participants completed a set of anonymous online surveys; measures for this survey included the Social Connectedness and Social Assurance Scales (SCSAS; Lee & Robbins, 1995), the Beck Anxiety Inventory (BAI; Beck & Steer, 1993), and the Autism Spectrum Quotient (AQ-10; Allison, Auyeung & Baron-Cohen, 2012). Pearson's correlation coefficients were calculated for the whole sample as well as within diagnostic groups.

Results: The AQ-10 was significantly positively correlated with the BAI for the whole sample ( $r = .459, p < .001$ ) and within groups (NT  $r = .225, p < .01$ ; ASD  $r = .436, p < .01$ ). The AQ-10 and SCSAS were significantly negatively correlated for the whole sample ( $r = -.282, p < .01$ ) and the NT group ( $r = -.316, p < .01$ ). The BAI and SCSAS were significantly negatively correlated for the whole sample ( $r = -.309, p < .001$ ) and the NT group ( $r = -.434, p < .001$ ). While not statistically significant, the BAI and SCSAS were positively correlated for the ASD group ( $r = .288, p = .058$ ).

Conclusions: Difficulty with social connection and anxiety are both pressing issues facing the autistic population. Despite research showing the mediating effects of social connectedness on mental health (Stice & Lavner, 2019), this study showed a positive relationship between social connectedness and assurance and anxiety for the autistic but not neurotypical population. Though we cannot know causation between these variables, the fact that autistic adults who experience higher anxiety also feel more socially connected and assured indicates that they may not be avoiding social connection due to anxiety feelings in the same way that was indicated by the neurotypical sample in this study. Future exploration into the other domains of social functioning, including quantity and quality of friendships, frequency of social interactions, and other interpersonal areas may lead to a better understanding of the connection between anxiety and social functioning as well as implications for interventions that address both factors.

#### **401.088** (Poster) Social Support and Psychological Distress in Autistic Adults in Quebec

*N. Jeanneret<sup>1,2</sup>, V. Caron<sup>3</sup>, M. Giroux<sup>4</sup>, L. Guerrero<sup>5</sup>, M. Ouimet<sup>6</sup>, B. Forgeot d'Arc<sup>6</sup>, I. Soulieres<sup>3</sup> and I. Courcy<sup>2</sup>, (1)CIUSSS Nord-de-l'Île-de-Montréal, Montréal, QC, Canada, (2)Département de Sociologie, Université du Québec à Montréal, Montréal, QC, Canada, (3)Département de Psychologie, Université du Québec à Montréal, Montréal, QC, Canada, (4)Aut'Créatifs, Montréal, QC, Canada, (5)Neurodiversité, Montréal, QC, Canada, (6)Département de Psychiatrie, Université de Montréal, Montréal, QC, CANADA*

Background: Autistic people often deal with anxiety or mental health difficulties and can be expected to have a higher level of psychological distress than the general population. Social support is recognized as a factor of protection. However, little is known about psychological distress and social network support for autistic people in Quebec.

Objectives: This descriptive research aims to measure psychological distress reported by autistic adults in Quebec and its association with social aspects such as formal support, social network, perceived violence, and stigmatization in everyday life.

Methods: An online questionnaire was completed by 226 autistic adults from Quebec (19-74 years old,  $\mu=37.0$  and  $SD=11.1$ , female: 58%, male: 30%, identifying with other gender identities: 12%) (convenience sample). Questions addressed mental diagnosis, interests and social aspects (socio-demographics, unmet needs regarding professional and social support [ASSIS, Barerra 1981], violence and stigmatization). Psychological distress was measured with the K6 scale ( $\alpha=.89$ ;  $\alpha=.84$  in this study) (Kessler et al. 2003).

Results: 79% of respondents received a formal diagnosis of autism and the others were self-diagnosed. Many had anxiety (42%), mood, bipolar or depressive disorders (24%), learning disabilities or AD(H)D (28%). Most of them had a job (67%). One third (32%) had an annual income of less than \$15K CAD (\$11K US approx.).

Respondent's psychological distress mean score was 12.4 (SD=4.72), which corresponds to the presence of "mild-moderate mental health problems".

Many reported that they were not able to see a professional as often as they would have liked (health care: 43%, psychosocial services: 58%) and experienced significant unmet needs: recreational activities (40%), advice on social interaction (34%), information (24%), intimate interactions (20%), physical assistance (16%) and material assistance (12%). The majority (68%)

reported having people who made them “feel bad” in their entourage. However, 64% said that they have someone to share their interests with. Nevertheless, more than half (53%) felt they cannot devote enough time to their interests.

Regarding stigmatization, 41% consider their qualities are “not at all” or “a little” recognized and many felt that they are somehow ashamed of being autistic (48%) or found it difficult to talk about their autism (72%). Some respondents reported being victims of physical violence (10%) in everyday life and violence on social media (29%), and one third (34%) attributed this violence to being autistic.

All these variables were significantly associated with psychological distress, except for gender (no difference between the three groups) and physical violence (too few participants in this category). Furthermore, not having an official diagnosis was associated with a higher mean of psychological distress but this difference was not significant.

Conclusions: This research reports a high level of psychological distress among autistic adults in Quebec. Part of this could be explained by the amount of unmet needs for support, perceived violence and stigmatization, and mental health diagnosis. Further analysis is required to fully understand the role of social support in the development of psychological distress in autistic people and the lack of differences between gender groups.

**401.089 (Poster)** Speech Rhythm Hierarchy: Towards Understanding of Phonological Characteristics in Autism Spectrum Disorder

**T. Daikoku<sup>1</sup>, S. Kumagaya<sup>2</sup>, S. Ayaya<sup>2</sup> and Y. Nagai<sup>1,3</sup>**, (1)International Research Center for Neurointelligence, The University of Tokyo, Tokyo, Japan, (2)Research Center for Advanced Science and Technology, The University of Tokyo, Tokyo, Japan, (3)Institute for AI and Beyond, The University of Tokyo, Tokyo, Japan

---

Background: Speech rhythm consists of a nested hierarchy of phonological units including prosody, syllable, and phoneme. This hierarchy can be identified from speech waveforms: The prosodic, syllabic, and phonetic rhythms are represented in the amplitude modulation (AM) hierarchy at delta, theta, and beta/gamma bands, respectively. The AM hierarchy of speech sound also has a relatively straightforward neurophysiological interpretation. The delta, theta, and beta/gamma oscillators in the auditory cortex couple with the prosodic, syllabic, and phonetic phases respectively, underpinning each of phonological intelligibility. A body of previous studies has shown evidence that individuals with autism spectrum disorder (ASD) have specific characteristics of their speech rhythm, particularly in the prosodic domain. However, the characteristics of speech rhythm hierarchy in ASD remained unclear.

Objectives: The present study aimed to reveal the phonological characteristics of the speech rhythm hierarchy in adult individuals with ASD and typical development (TD). We examined the slow (<40 Hz) temporal modulation structure (prosody: 1-4 Hz, syllable: 4-12 Hz, phoneme: 12-30 Hz), using two complementary modeling approaches (i.e., filtering vs. probabilistic).

Methods: Adult speech sounds in ASD (N = 8, 87 samples in total) and TD (N = 6, 72 samples in total) were applied for this study. During speech recording, the participants were asked to tell their recent experience (episodic memory) about 12 topics (sweet, gloomy, etc.). The first modeling approach utilized a low-dimensional representation of the speech signal based on the cochlear filterbank in the human brain. The second utilized probabilistic amplitude demodulation based on Bayesian inference, a signal-driven modeling approach that makes no adjustments for the brain.

Results: Both models revealed a very similar hierarchical structure of the speech rhythm. As suggested by previous studies, a weaker prosodic rhythm was found in ASD compared to TD ( $p < .001$ ), while no significant group difference was detected in the syllabic and phonetic rhythms ( $p = 1.00$ ) (Fig 1). A transfer entropy analysis was also applied to estimate “dynamical” interdependencies between the hierarchies of speech rhythm. The results indicated that the transfer entropy from a higher hierarchical rhythm to a lower hierarchical rhythm (e.g., from the prosody to syllable) was smaller in ASD than TD ( $p = .028$ ), whereas no group difference was detected in the transfer entropy from a lower to a higher hierarchical rhythms ( $p = .283$ ) (Fig 2). This may imply that the top-down controls are weaker in ASD than TD.

Conclusions: This study revealed that the weak prosodic rhythm is a robust phonological characteristic of ASD. Further, the dynamical interdependencies between the hierarchies of speech rhythm discriminate ASD from TD. A closer analysis is, however, necessary to examine how the characteristics of speech rhythm hierarchy are involved in a hierarchy of neural oscillation.

**401.090 (Poster)** Successful Employment Experiences of a Large Sample of Adults with Autism

**Background:** Extant research in the field of employment for adults with autism describes bleak outcomes—high rates of unemployment and less time employed as compared to their neurotypical peers (Scott et al., 2015). However, research has also elucidated a number of desirable workplace traits that individuals with autism possess (Baldwin et al., 2014; Hillier et al., 2007). Often, it is assumed that individuals with autism would find success in STEM-related fields of employment. However, there is little research to validate this, or to identify other employment fields where individuals with autism may flourish.

**Objectives:** The current study aimed to: (1) describe a large sample of employed adults with autism in terms of age, gender, comorbid diagnoses, and duration of employment; (2) further analyze aspects of their employment experiences.

**Methods:** The current study utilized a previously collected sample of adults with and without autism who responded to an online survey (Schwartzman et al., 2015). From this sample, a smaller sample of adults with autism who had reported being employed at the time of initial data collection was selected (N = 131). Survey questions included self-reported autism diagnoses, comorbid diagnoses, highest level of education achieved, current employment status, duration of employment, and employment satisfaction, as well as other demographic categories such as age, gender, and ethnicity. Current employment entries were then coded into fields of employment using the US Department of Labor's Standardized Occupational Classification (SOC) system (e.g., Roux et al., 2013). Overemployment, underemployment, or appropriate employment were determined by matching an individual's level of education (e.g., participants who reported having a college degree) to their level of employment (e.g., jobs that require a college degree).

**Results:** Participant demographics, education levels, comorbid diagnoses, average duration of employment, and average employment satisfaction are displayed in Table 1 (image attached). Of the Department of Labor SOC categories, the most common job types were "Arts, Design, Entertainment, Sports, and Media" (N = 19), "Computer and Mathematical" (N = 19), "Life, Physical, and Social Science" (N = 13), "Educational Instruction and Library" (N = 13), and "Office and Administrative Support" (N = 11). 22 of the 23 Department of Labor SOC categories had at least one individual coded in that category. Data for each of these categories and corresponding average job satisfaction for each category is displayed in Table 2 (image attached). Ninety-six individuals were determined to be appropriately employed, 25 underemployed, and 7 overemployed.

**Conclusions:** Results from the current study indicate that individuals with autism are capable of experiencing employment success across a wide variety of job fields. Current literature on employment of individuals with autism often lumps this diverse population into a cohort of individuals who experience employment challenges. While this may be true of a majority of individuals with autism, to better inform future employment-related interventions for those experiencing unemployment and underemployment, it is essential to further develop an evidence base which describes the wide range of job experiences of individuals with autism who have found employment success.

**401.091 (Poster) Systematic Review of Evidence-Based Practices for Improving Daily Living Skills in Young Adults with Autism Spectrum Disorders**

**R. Schaaf<sup>1</sup> and R. L. Dumont<sup>2</sup>, (1)Occupational Therapy, Thomas Jefferson University, Philadelphia, PA, (2)Occupational Therapy, Thomas Jefferson University, Collegeville, PA**

---

**Background:** Independent living skills are an integral component in the transition to adulthood (Bal et al., 2015). However, many young adults with ASD have difficulty in these skills (Roux et al., 2017). According to a survey of 3520 adults with ASD, only 10% of adults with ASD live independently, and 43% of respondents also indicated that they do not independently manage or make choices in their daily routines such as when to sleep or eat meals (Roux et al., 2017). Thus, there is a need to address independent living skills in youth with autism but there is a paucity in the literature to guide practice.

**Objectives:** The purpose of this systematic review is to address the following question: "What are the evidence-based strategies for increasing Independent living skills for young adults with ASD?"

**Methods:** A systematic review using the Cochrane guidelines was conducted on literature published from January 2009 to May 2019 (Higgins et al., 2019). Two reviewers independently screened titles, abstracts, and full articles for inclusion and exclusion criteria, and convened for a consensus meeting at each stage. Risk of Bias was independently performed in duplicate using the Cochrane guidelines (Higgins et al., 2019), and using the single case design risk of bias tool (Reichow et al., 2018). Results were synthesized.

Results: Twenty-four articles met the inclusion criteria. Seven evidence-based strategies that improved Independent living skills were identified in the literature: video prompting, video modeling, reinforcement, roleplay/rehearsal strategies, prompt hierarchy, group engagement/training strategies and social story strategies. All had high risk of bias indicating an overall low quality of evidence.

Conclusions: While all of the strategies demonstrated improvements in Independent living skills, the findings are impacted by the risk of bias in the studies. Future research with high rigor is needed to evaluate strategies used to improve independent living skills in youth with ASD. This research should include the use of blinded evaluators to assess outcomes; blinded participants; and use of performance-based outcome measures.

**401.092** (Poster) The Association of Sleep Quality and Loneliness with Perceived Physical and Mental Health Status in Autistic Adults

N. C. Russell<sup>1</sup>, D. B. Kay<sup>1</sup>, D. Cimmino<sup>1</sup>, Z. Simmons<sup>2</sup> and M. South<sup>3</sup>, (1)Psychology, Brigham Young University, Provo, UT, (2)Brigham Young University, Provo, UT, (3)Psychology & Neuroscience, Brigham Young University, Provo, UT

---

Background: Individuals with autism experience significantly greater rates of physical (e.g., epilepsy) and mental health (e.g., depression and anxiety) challenges than the general population. These secondary challenges lead to increased mortality rates and greater healthcare burden on families and healthcare systems. However, little is known about those primary factors that impact the physical and mental health of these individuals. In the general population, factors such as loneliness and sleep quality have substantial impacts on physical and mental health in the general population but little research has investigated their impact in adults with autism.

Objectives: We examined the association of self-reported sleep quality and loneliness on the self-reported physical and mental health in adults with autism. Multiple regressions were employed to predict associations within each group.

Methods: Data were collected from neurotypical controls ( $n = 21$ ), individuals with insomnia ( $n = 23$ ), and individuals with autism ( $n = 22$ ). All measures were completed by the individuals at a single time point. Sleep quality was measured using the Patient-Reported Outcomes Measurement Information System Sleep Disturbance Questionnaire – Short Form 8a (PROMIS-SD-8a), loneliness was measured using the UCLA Loneliness Scale, and physical and mental health were measured using the 36-Item Short Form Survey (SF-36).

Results: The autism group scored worse than the neurotypical group across all variables. The autism group had comparable sleep quality to the insomnia group. As expected, reduced sleep quality was significantly associated with reduced perceived physical health in the insomnia group ( $p = .002$ ) and with increased loneliness in the neurotypical control group ( $p = .049$ ), accounting for 38.4% and 31.8% of the variance, respectively. However, neither sleep quality nor loneliness were significant predictors of physical health in the autism group. The story was different for perceived mental health, which was significantly associated with both reduced sleep quality ( $p = .007$ ) and increased loneliness ( $p = .030$ ) in the autism group, together accounting for 40.7% of the variance. Increased loneliness was significantly associated with lower perceived mental health for both the insomnia group ( $p = .024$ ) and the neurotypical group ( $p = .012$ ), accounting for 19.7% and 43.3% of the variance, respectively.

Conclusions: Differences in association were observed for sleep quality and loneliness and their association with perceived physical and mental health for each group. Sleep quality and loneliness appear to be particularly important factors in the

perceived mental health, but not perceived physical health, of autistic adults. In many clinical settings, these factors are not routinely investigated or screened for. Given the high rates of mental health challenges in this population, these results suggest that closer attention to sleep quality and loneliness may be warranted. It is also notable that the autism group had comparable sleep quality to the insomnia group and emphasizes the need for further attention in this area.

**401.093 (Poster)** The Cognitive Profile of Older Adults with High Autistic Traits.

**G. R. Stewart<sup>1</sup>, R. A. Charlton<sup>2</sup> and F. Happé<sup>1</sup>,** (1)Social, Genetic and Developmental Psychiatry Centre, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (2)Psychology, Goldsmiths University of London, London, United Kingdom

---

**Background:** Research with autistic and high autistic trait children and younger adults has indicated performance differences in a wide range of memory and executive functioning tasks. However, despite memory and executive functioning being sensitive to age-related change, little is known about the cognitive profile of older adults with high autistic traits.

**Objectives:** This study will explore differences in performance on a variety of memory and executive functioning tasks in a large sample of older adults with/without high autistic traits.

**Methods:** Using baseline cross-sectional data from the ongoing online PROTECT study, a total of 22,285 adults aged 50 to 80 years reported whether they experience longstanding social communication difficulties characteristic of autism. Approximately 1%, 325 individuals, were identified as endorsing high autistic traits in childhood and currently, referred to henceforth as the Autism Spectrum Trait (AST) group. Differences between the AST and an age mean/range, sex ratio, and education history matched Comparison Older Adults (COA; n = 11,744) group were explored in performance on a variety of memory and executive functioning tasks administered through a well-validated online platform.

**Results:** The AST group had lower performance than COA on tasks measuring verbal working memory (digit span), visual episodic memory (paired associates learning), spatial working memory (self-ordered search), attention and information processing (choice reaction time), sustained attention (digit vigilance), and cued episodic secondary memory retrieval (picture recognition). However, no differences between AST and COA were observed in verbal fluency or simple reaction time. A similar pattern of results were observed when controlling for age, and symptoms of current depression and anxiety.

**Conclusions:** The findings from the current study of a large sample of older adults suggest that autistic traits are associated with cognitive functioning throughout middle and later life. Older adults with high autistic traits experienced more performance difficulties in a range of memory and executive functioning tasks when compared to the comparison group selected for low autistic traits. This pattern of results remained when controlling for age, and current symptoms of depression and anxiety. Further longitudinal work is needed to examine age-related change in both older autistic and autistic trait populations.

**401.094 (Poster)** The Effect of Aging on Prospective Memory in Autism Spectrum Condition

**A. P. Groenman<sup>1</sup>, C. Torenvliet<sup>1</sup>, T. A. Radhoe<sup>1</sup>, J. Agelink van Rentergem<sup>1</sup>, A. M. Altgassen<sup>2</sup> and H. M. Geurts<sup>1</sup>,** (1)University of Amsterdam, Amsterdam, Netherlands, (2)Johannes Gutenberg-Universität Mainz, Mainz, Germany

---

**Background:** Prospective memory is an essential cognitive function for independent daily living. As such, it becomes more and more important with increasing age. However, how age affects prospective memory, and which aspects of PM age influences in autism remains unknown.

**Objectives:** To investigate the effects of age on prospective memory in autism spectrum conditions (ASC).

**Methods:** In this preregistered study (Aspredicted#34249), 193 individuals, aged between 30 and 85 years (82 ASC, 111 comparison (COMP) performed the lab-based Amsterdam Breakfast task, containing both event and time based tasks, and several naturalistic prospective memory tasks.

**Results:** Preliminary results show that both ASC and COMP perform worse on time versus event based laboratory tasks. No difference in performance is found between ASC and COMP on either type of task. Older individuals (over 55 years) performed worse than younger (under 50 years) individuals on both time based and event based laboratory tasks, independent of group.

**Conclusions:** Our preliminary results show that age affects prospective memory, but it appears that both ASC and COMP are affected equally. We will perform Bayesian analyses to assess the robustness of this null finding. Furthermore, we will explore the differences between lab based and naturalistic tasks.

**401.095 (Poster)** The Employers' Perspective: From Qualification to Sustainable Employment of Persons with ASD  
*K. Reich, BBW Abensberg, Abensberg, Germany*

---

### **Background:**

Despite of good school leaving certificates and vocational training degrees, persons with autism are still disadvantaged in getting jobs in the general labour market. There is a lot of research about getting or maintaining a job with ASD by taking the perspective of professionals and persons with ASD, but very little research was conducted to investigate the perspectives and experiences of the employers.

### **Objectives:**

The main objective is to gain new insights of the transition process from qualification to sustainable employment with special consideration of the employers' perspective. Therefore, existing helpful and inhibitory attitudes and experiences were investigated.

### **Methods:**

A semi-structured questionnaire was sent to N=2844 employers (first labour market). The sample was gained from address files of Vocational Training Centers ('BBW' - training youth with different disabilities or autism in qualified jobs), support and transition agencies and social enterprises. The addresses included both: employers, who doubtless employ/have employed autistic persons (N=886) and employers of whom this information was not available.

### **Results:**

Response rate 8% (n=222)

123 companies employ/have employed persons with autism

### **Companies (n=123):**

- Companies responded pointed out an industry wide dispersion
- Persons with ASD are employed in companies of different sizes (1-9 employees=24%; 10-49 =31%; 50-249 =24%; over 250 = 15%)
- 66% employ persons with ASD at the moment (48% in the past)

### **Matching:**

- (n=123): 77% of the actual (65% past) employment status are equivalent or higher than the level of training; 26% actual (20% past) lower than the level of training
- Main reasons of recruiting persons with ASD (n=114): "social aspects" (33%) followed by "convinced in probationary period/internship" (23%)
- Workplace adjustment (n=118): 22% of the companies interviewed indicated that workplace adjustment isn't necessary, 14% indicated an adaption of the workplace was necessary

### **Support for Employers:**

- Support for employers during recruitment phase/at the beginning of the employment relationship (n=116): 76% have received support (financial or personal); 26% haven't received any support. There is a moderate correlation between permanent employment contracts and the receipt of consulting in the past ( $\phi=0,37$ )
- (n=111): 91% employers stated, that consulting to cope with arising difficulties is important/very important; employers value consulting (83%), contact to ASD specialised services (81%) and training (80%) as important/very important
- (n=94): Most important advantage of employing a person with ASD: positive effect on colleagues (36%)
- (n=99): Biggest challenge: create acceptance among the colleagues (34%); adaption of workplaces (27%)

### Conclusions:

There are many indications in the present study that the vocational qualification activities specialised for persons with ASD as well as the assistance given during the recruitment process lead to permanent contracts of employment. But the importance of awareness-raising actions in the companies relating to autism were underestimated as well as an ongoing assistance of the working relationship. The transition services have to deepen their performances especially in providing information and awareness to colleagues and in giving assistance to employers in the creation of autism friendly workplaces.

#### 401.096 (Poster) The Phenomenology of Gender Dysphoria in Autistic Adults

**K. Cooper<sup>1</sup>, W. Mandy<sup>2</sup>, C. Butler<sup>1</sup> and A. Russell<sup>3</sup>,** (1)University of Bath, Bath, United Kingdom, (2)University College London, London, United Kingdom of Great Britain and Northern Ireland, (3)Psychology/Centre for Applied Autism Research, University of Bath, Bath, United Kingdom

---

#### Background:

Gender dysphoria is distress relating to a discrepancy between one's gender identity and sex assigned at birth and is associated with poor mental health. A disproportionate number of attendees at gender clinics have an Autism Spectrum Disorder (ASD). Autistic people and those with gender dysphoria often receive inadequate care in health services, and there is little research on how autistic individuals experience gender dysphoria to guide service improvements for this group.

#### Objectives:

To understand the phenomenology of gender dysphoria in transgender autistic adults, with a particular focus on how and if the experience of being autistic and gender diverse intersect. This will help to inform clinical services of the particular needs of autistic people who experience gender dysphoria, and what adaptations may be needed for this group.

#### Methods:

Qualitative methods were employed due to the exploratory nature and experiential focus of the research question. Purposive sampling was used to recruit 21 autistic adults who had experienced gender related distress for interviews about the lived experience of gender dysphoria. All participants had received a formal diagnosis of autism, identified as transgender or non-binary and had experienced distress in relation to their gender identity. Semi-structured interviews adapted for autistic participants were analysed using Interpretative Phenomenological Analysis.

#### Results:

Preliminary analysis indicated that there were two overarching themes: 'uncomfortable in my skin' and 'wrong planet'. The 'uncomfortable in my skin' theme underlined the discomfort that individuals felt for a number of reasons. First, distress was experienced due to dissonance between their gender identity and body, which for some participants was difficult to describe or described in behavioural terms, but for others was described in detail and as overwhelming. Second, distress due to a need to understand the self, including gender and autism identity. Third, there were multiple causes of distress with numerous difficulties that individuals faced including conflict of autism and gender needs as well as previous traumatic experiences; for some individuals these factors amplified dysphoria and for others they existed alongside dysphoria.

The 'wrong planet' theme described the discrepancy between the individual's needs and societal structures and included the struggle of being different including being bullied and othered, gender as social behaviour and social expectations and the need to be acknowledged and supported as an individual (taking into account gender, autism and other aspects of the self).

#### Conclusions:

Being autistic can influence the experience of gender dysphoria, and there are multiple complexities for the autistic person experiencing gender dysphoria to navigate in relation to their embodied sense of self as well as in the social world.

**401.097 (Poster)** The Relationship between Repetitive Behaviours and Sensory Processing in Autistic and Non-Autistic Adults and Impact on Self-Efficacy

*G. Nwaordu and R. A. Charlton, Psychology, Goldsmiths University of London, London, United Kingdom*

---

**Background:** Repetitive behaviours (RB) are a core feature of autism. RBs are described as “stims” and many autistic individuals report pressure to hide or suppress “stims” due to social pressures. “Stims” are suggested to be a barrier to learning in childhood however recent studies suggest that “stimming” may have beneficial effects. In qualitative studies, “stimming” is often described as a way of coping with overwhelming sensory or emotional situations. Few studies have yet examined the relationship between RBs, sensory sensitivities and feeling able to cope (known as self-efficacy) among autistic adults.

**Objectives:** We examined (1) the relationship between RBs and sensory sensitivities, and whether there were group difference in the pattern of associations; (2) whether there were group difference in RBs, sensory sensitivities and self-efficacy; and whether self-efficacy was impacted by the ability to “stim”.

**Methods:** Adults recruited through social media completed a set of questionnaires online. Participants reported whether they had a formal diagnosis of an Autism Spectrum Condition (ASC, n=182), self-identified as autistic or were seeking an ASC diagnosis (Suspected ASC, n=165), or did not identify as autistic (Non-ASC, n=146). Participants were predominantly female (ASC, female=140; Suspected ASC, female=146; Non-ASC, female=125). Due to the method of recruitment and task demands, we expect all participants to have abilities in the normal range. Self-report questionnaires examined RBs (Adult Repetitive Behaviours Questionnaire-2) and sensory sensitivity (The Glasgow Sensory Questionnaire). If participants performed repetitive behaviours (“stims”) they also answered five self-efficacy questions for when able to or not able to “stim”.

**Results:** In the whole sample RBs correlated significantly with sensory sensitivities ( $r=.867, p<.001$ ). Similar patterns and magnitudes of results were observed for each group. ASC and Suspected ASC groups reported significantly higher rates of RBs and sensory sensitivities than the Non-ASC group (Table 1). The effect of ability to “stim” or not on self-efficacy was examined between groups. Results demonstrate a significant main effect of “stimming” ( $F=196.98, p<.001$ ) and significant interaction effect ( $F=5.39, p=.005$ ), but no effect of group ( $F=.757, p=.470$ ). In all groups, being able to “stim” significantly increased self-efficacy. Not being able to “stim” lead to significantly lower ratings of self-efficacy in the autistic groups compared to the Non-ASC group. A similar pattern of results is observed when analysing only females.

**Conclusions:** Results suggest that RBs may help manage sensory sensitivities. The same pattern of associations was found in all three groups, but the Non-ASC group reported lower rates of RBs and sensory sensitivities than autistic groups. The ability to “stim” (versus not “stim”) lead to higher self-efficacy in all groups. Although only 20% of the Non-ASC group reported “stimming”, results suggest this behaviour is beneficial to many individuals, increasing feelings of being able to cope with difficulties. The impact of not being able to “stim” was more detrimental to autistic groups compared to the Non-ASC group, suggesting that “stimming” may be particularly beneficial for autistic individuals. Results suggest that RBs may help people to manage sensory sensitivities and help them feel able to cope with everyday difficulties.

**401.098 (Poster)** Topics and Timing of Sexuality and Relationship Education for Autistic and Neurotypical Adults in the United States

*X. Yang<sup>1</sup>, E. T. Crehan<sup>2</sup> and A. Donaghue<sup>1</sup>, (1)Child Study and Human Development, Tufts University, Medford, MA, (2)Eliot-Pearson Department of Child Study & Human Development, Tufts University, Medford, MA*

---

**Background:**

The lack of sexuality and relationship education (SRE) has become particularly problematic in autistic population due to the negative impact on physical health outcomes, mood and self-esteem, as well as the increased risk of abuse (Holmes & Himle, 2014). As new programs are being developed, we are in need of important details to inform design of these programs, such as what to cover and when. In this study, we explored SRE gaps on topics that are more socially laden, such as gender identity, sexual orientation, and relationship building skills.

**Objectives:**

The purpose of this study is to identify differences in the topics, timeline and rated knowledge of SRE exist in learning and comfort outcomes for autistic and neurotypical (NT) adults for SRE.

#### Methods:

An online anonymous survey was distributed to adults in the United States and included questions about SRE, sexual and relationship experiences, and autistic traits. A total of 132 participants (44 with autism, 88 without; average age of 26.82 years ( $SD = 6.8$ ) were recruited, representing 23 states). Participants completed the Autism Quotient-10 (AQ-10), a brief self-report instrument designed to screen for autism in adults. Some SRE-related questions were developed specifically for the purposes of this study, including whether they were interested in more information on nine SRE topics, at what age they first engaged in various romantic, sexual, and identity experiences, and how they rated their SRE knowledge compared to their same-age peers. Chi-square and correlations were used to analyze diagnostic group differences (autistic and NT).

#### Results:

Comparisons by diagnostic group revealed significant differences in which topics each group wanted more information about. Autistic individuals were significantly more likely to indicate that they wanted to learn more about gender identity,  $\chi^2(131)=10.14, p < .005$ , sexual orientation,  $\chi^2(130)=7.32, p = .007$ , consent,  $\chi^2(130)=7.19, p = .007$ , and assertiveness than NT peers,  $\chi^2(129)=4.50, p = .03$ . There were no significant differences in timing of sexual experiences. Analyses of one's own knowledge relative to peers indicated that the higher someone rated themselves on the AQ-10, the lower they rated their knowledge relative to peers for kissing ( $r = -.26, p = .003$ ), flirting ( $r = -.32, p < .001$ ), consent ( $r = -.24, p = .007$ ), and assertiveness ( $r = -.27, p = .002$ ).

#### Conclusions:

Analyses revealed important differences in SRE needs for autistic adults, which likely reflects the increased diversity in identity and orientation reported by autistic adults and there is a need to adapt these topics in programming for autistic learners (Bleakley et al., 2009). Findings highlighting the lack of difference in timeline for first experiences are the first data to capture the timeline of identity development and exploration across NT or autistic individuals. We also need creative solutions to provide the peer-based learning experiences to individuals who may not have a peers group from which to draw, either by choice or by lack of social network. The importance of incorporating needs of autistic learners into program design is also highlighted for future work.

#### **401.099** (Poster) Trajectories of Major Health Issues throughout Adulthood in Autistic Individuals *K. Byrne, K. Sterrett and C. Lord, University of California, Los Angeles, Los Angeles, CA*

---

**Background:** Physical and psychiatric health conditions affect adults with autism. However, relatively little is known about individual trajectories in autistic individuals' physical health from adolescence to adulthood.

**Objectives:** The current study uses a longitudinal design to describe the prevalence of seizures, medication use, and obesity in adulthood, to examine how these physical health challenges changed within individuals from early adolescence into adulthood, and to explore how intellectual disability and meeting ASD diagnostic criteria impact these medical conditions.

**Methods:** The present study uses a well-characterized longitudinal sample ( $n = 253$ ) to investigate rates of seizures, medication use and obesity, from early adolescence (age 10) into adulthood (age 30) among individuals with autism and other neurodevelopmental disorders.

**Results:** Seizure onset continued well into adulthood. Seizures and neuropsychiatric medication use were both higher for those with lower IQs. Medication use increased over time for these individuals, while those with higher IQs saw a reduction in medication use with age. In contrast, BMI increased throughout adulthood, especially for those with higher IQs.

**Conclusions:** Overall, continued risk for developing seizures, high rates of neuropsychiatric medication use, and significant and increasing rates of obesity from adolescence to adulthood underscore the importance of monitoring health issues in individuals with autism or other neurodevelopmental disorders throughout the lifespan.

**401.100 (Poster)** Understanding How Young Adults with Autism Spectrum Disorder Are Coping with the COVID-19 Pandemic  
A. Cilluffo<sup>1</sup>, L. Fryfogle<sup>1</sup>, M. Gallagher<sup>1</sup>, N. Nugent<sup>1</sup>, K. Wilson<sup>1</sup> and A. R. Dallman<sup>2</sup>, (1)Towson University, Towson, MD,  
(2)Occupational Therapy & Occupational Science, Towson University, Towson, MD

---

**Background:** The COVID-19 pandemic has ignited an unprecedented time disrupting and altering individuals' with autism spectrum disorder's (ASD) participation in everyday routines, habits, roles, and meaningful activities. The suspension of in-person educational and therapeutic entities has caused disruptions in routines and social opportunities for adults on the spectrum. These sudden alterations in daily routines and meaningful activities may be especially challenging for adults with ASD due to the frequent co-occurrence of social isolation and depression in this vulnerable group.

**Objectives:** (1) To examine how young adults with ASD are coping with the COVID-19 pandemic (2) To understand how they have adapted to the prolonged disruption to their routines, as well as their participation in meaningful occupations.

**Methods:** This convergent parallel mixed-methods study was completed in two phases. During *Phase One* participants completed online surveys (Brief Demographic Survey, Depression Anxiety Stress Scale [DASS]-21, Friendship Questionnaire, Routine Disruptions Questionnaire [RDQ]) through Qualtrics. During *Phase Two* participants were invited to a semi-structured virtual interview about their social and emotional experiences during the COVID-19 pandemic. Participants included adults (ages 18-35 years) with a self-reported diagnosis of ASD (n=15, expected n=20) who were able to independently complete a survey, recruited through snowball sampling from local agencies serving adults on the autism spectrum. Quantitative data was analyzed through the statistical analysis software, R. A linear regression was used to analyze and evaluate connections between the COVID-19 pandemic and emotional disturbances (i.e. high anxiety, increased depression) associated with routine disruptions. Also, relevant mean responses were noted and interpreted in relation to research findings. Qualitative data was collected with interviews that were manually transcribed and coded line-by-line to identify themes. Quantitative and qualitative data were merged and connected by using quantitative results and qualitative themes together to explain findings.

**Results:** The majority of participants reported either severe or extremely severe anxiety (n=15, 100%), depression (n=9, 60%), or stress (n=15, 100%) as indicated by the DASS-21. During interviews, participants shared several sources of anxiety including: individuals in the community not following rules, uncertainty about what information in the news is true, and the uncomfortable sensory experiences of wearing a mask. Unsurprisingly, participants reported high degrees of routine disruptions as indicated by the RDQ ( $M = 3.6$ ) which was not related to anxiety ( $t[1, 13]=0.11, p=0.91$ ). During interviews, participants discussed how the routine disruptions associated with the COVID-19 pandemic actually reduced previous stresses. Participants shared how protective measures such as social distancing were preferred even for non-pandemic times. Additional findings and themes will be presented.

**Conclusions:** Study findings contribute a valuable perspective to the experience of the COVID-19 pandemic for adults with ASD. Because of the novelty of the COVID-19 pandemic, the evidence is limited and there is a need for further research regarding the impact of the pandemic on participation in everyday routines, habits, roles, and meaningful occupations for adults with autism spectrum disorder.

**401.101 (Poster)** Understanding the Relationship between Comorbid Psychopathology and Social Skills Gains for Young Adults with ASD Following the UCLA PEERS® Intervention

L. D. Solouki<sup>1,2</sup>, C. Moody<sup>1</sup>, Y. S. Lograsso<sup>1</sup>, J. E. Lerner<sup>1</sup>, H. R. Goodman<sup>1</sup>, E. Denluck<sup>3</sup> and E. A. Laugeson<sup>1</sup>, (1)UCLA Semel Institute for Neuroscience and Human Behavior, Los Angeles, CA, (2)Graduate School of Education and Psychology, Pepperdine University, Los Angeles, CA, (3)UCLA Department of Psychiatry, PEERS lab: UCLA PEERS Clinic, Los Angeles, CA

---

**Background:** Prior research suggests that adults with autism spectrum disorder (ASD) have higher levels of psychiatric comorbidity compared to clinical populations of adults without ASD (Joshi et al., 2013). Comorbid psychopathology has been found to have a negative effect on social skills for youth with ASD (Waters & Healy, 2012). Research suggests that psychiatric comorbidity may affect social skills treatment gains in children with ASD (Antshel et al., 2011); however, more research is needed to examine the effects of comorbid psychopathology on treatment outcomes for young adults with ASD following social skills treatment.

**Objectives:** The current study examines symptoms of social anxiety, depression, and ADHD as predictors of social skills outcomes and problem behaviors among young adults with ASD following the UCLA Program for the Education and Enrichment of Relational Skills (PEERS®; Laugeson, 2017), an evidence-based caregiver-assisted social skills intervention (Laugeson et al., 2015).

**Methods:** Fifty-one young adults (males=38; females=13) with ASD ranging from 17-35 years of age ( $M=23.18$ ;  $SD=4.208$ ) and their caregivers participated in the study. All participants had clinically elevated ASD symptoms, as indicated by a caregiver-reported total score  $\geq 60$  on the Social Responsiveness Scale-Second Edition (SRS-2; Constantino & Gruber, 2012). Participants presented for social skills treatment through UCLA PEERS<sup>®</sup> Clinic. Participants and their caregivers attended 90-minute group treatment sessions over 16-weeks to learn guidelines related to the development and maintenance of social relationships. To assess young adults' baseline social anxiety and ADHD symptoms, caregivers completed the Social Anxiety Scale (SAS; La Greca, 1999) and the Swanson, Nolan, and Pelham Questionnaire-4<sup>th</sup> edition (SNAP-IV; Bussing et al., 2008), respectively. To measure young adults' baseline depression, young adults completed the Major Depression Index (MDI; Olsen et al., 2003). Treatment outcome was assessed by examining caregiver-reported change in social skills and problem behaviors on the Social Skills Improvement System (SSIS; Gresham & Elliot, 2008) pre and post-intervention.

**Results:** Paired samples t-tests reveal significant improvement in caregiver-reported social skills ( $M=7.961$ ,  $SD=11.228$ ,  $t(50)=5.063$ ,  $p<.01$ ) and problem behaviors ( $M=-5.216$ ,  $SD=11.839$ ,  $t(50)=-3.146$ ,  $p<.01$ ) among young adults following treatment. Linear regressions were used to assess baseline social anxiety, depression, and ADHD symptoms as potential predictors of treatment outcome. Results reveal change in social skills was not related to baseline social anxiety ( $R^2=.013$ ,  $F(1,49)=.658$ ,  $p>.10$ ), depression ( $R^2=.036$ ,  $F(1,49)=1.807$ ,  $p>.10$ ), ADHD-inattentive ( $R^2=.00$ ,  $F(1,49)=.021$ ,  $p>.10$ ), or ADHD-hyperactive/impulsive ( $R^2=.041$ ,  $F(1,49)=2.103$ ,  $p>.10$ ). Similarly, change in problem behaviors was also not related to baseline social anxiety ( $R^2=.072$ ,  $F(1,49)=3.778$ ,  $p>.05$ ), depression ( $R^2=.000$ ,  $F(1,49)=.001$ ,  $p>.10$ ), ADHD-inattentive ( $R^2=.011$ ,  $F(1,49)=.529$ ,  $p>.10$ ), or ADHD-hyperactive/impulsive ( $R^2=.031$ ,  $F(1,49)=1.556$ ,  $p>.10$ ).

**Conclusions:** Findings reveal that baseline social anxiety, depression, and ADHD are not predictive of improvement in social skills or problem behaviors for young adults with ASD following the UCLA PEERS<sup>®</sup> intervention. These findings are important because they reveal that young adults with ASD and comorbid psychiatric conditions can still make significant treatment gains through the UCLA PEERS<sup>®</sup> program. Future studies might examine treatment outcome for young adults with comorbid psychopathology and ASD with regard to other social skills interventions.

**401.102 (Poster)** Verbal, Social and Motor Skills in Minimally-Speaking Autistic Children: Baseline Profiles and Intervention Effects on Observational Assessments and Movement Kinematics

**E. J. Weisblatt<sup>1</sup>**, A. Mckinney<sup>2</sup>, K. Hotson<sup>3</sup>, Z. B. Ahmed<sup>4</sup>, C. M. Dias<sup>4</sup>, D. Ben Shalom<sup>5</sup>, J. Foster<sup>6</sup>, S. Belmonte<sup>11</sup>, (1)Department of Psychology, University of Cambridge, Cambridge, United Kingdom, (2)SMC Research Centre for Learning Difficulties, University of Edinburgh, Edinburgh, United Kingdom, (3)Division of Psychology, Nottingham Trent University, Nottingham, United Kingdom, (4)Peterborough Neurodevelopmental Service, Cambridgeshire and Peterborough NHS Foundation Trust, Peterborough, United Kingdom, (5)Department of Foreign Literatures and Linguistics, Ben-Gurion University, Beer Sheva, Israel, (6)Institute of Psychiatry, Psychology, and Neuroscience, King's College London, London, United Kingdom, (7)MRC Biostatistics Unit, University of Cambridge, Cambridge, United Kingdom, (8)Institute for Health Research, University of Bedfordshire, Luton, United Kingdom, (9)Department of Psychology and Neuroscience, University of North Carolina, Chapel Hill, NC, (10)Division of Neuroscience & Experimental Psychology, University of Manchester, Manchester, United Kingdom, (11)Com DEALL Trust, Bangalore, India

**Background:** Point OutWords <<http://PointOutWords.online/>> is a caregiver-delivered, iPad-assisted intervention targeting motor and cognitive skills prerequisite to communication (doi:10.1186/s13063-019-3931-1), designed for and with those minimally verbal autistic children whose severe deficits in expressive language are coincident with impaired motor skills (doi:10.3389/fnint.2013.00047).

**Objectives:** Assess 1) Relationships amongst verbal and motor functioning using parent-report and direct observational measures 2) Motor functioning measured by interactions with the iPad touchscreen, within the intervention group 3) Any change in these measures during this short-term treatment.

**Methods:** Our parallel-groups randomised controlled design recruited 30 autistic children aged 3–15 years, speaking fewer than 100 words functionally. The intervention group used Point OutWords 5 times a week for 8 weeks; controls used other iPad apps. Communication (Vineland, Mullen), motor, oromotor (VMPAC) and daily living skills were tested at baseline and post-intervention. Data were analysed with mixed ANOVA for behavioural and questionnaire measures. Children's touchscreen interactions were separated from their caregivers' modelled movements by Gaussian mixture modelling, then each movement was assessed for mean jerk (3<sup>rd</sup> derivative of position), mean direction error, and time to completion. These derived measures were regressed against time in treatment. As a secondary analysis, because clients and caregivers were most distinguished in terms of jerk (see figure), jerk effects and jerk-by-time interactions in a mixed-effects model served to confirm baseline abnormalities and treatment effects, respectively, in the autistic clients' movements in contrast to their caregivers' models.

**Results:** With reference to age norms, language and social skills were more impaired than motor though these were still significantly impaired (all  $p < 0.001$ ). Gross motor skills were superior to fine ( $p = 0.03$ ). Only 2 children had stronger expressive than receptive language. All children had severe impairments of fine oromotor control. There were no consistent effects of treatment versus control, although Mullen motor and language scores improved across both groups ( $p = 0.027$ ). On the iPad measures which were available only within the treatment group, 8 of 12 children significantly lessened the time to complete movements (each  $p < 0.02$ ), and every child showed significant increase in jerk ( $t(11) = 5.81$ ,  $p = 0.000118$ ). In slight ( $r^2 = 0.045$ ,  $0.0115$ ) but significant ( $p < 0.0001$ ) effects, greater jerk at baseline was associated with greater error in movement direction and longer movement paths, but the jerk-by-time interaction decreased both.

**Conclusions:** This study recruited a highly impaired group of children with minimal spoken language. Across a variety of assessments, the majority demonstrated better gross than fine motor skills, better motor than verbal skills, and better receptive than expressive verbal skills. For some, atypical motor interactions improved following intervention. Increased jerk for all subjects, alongside faster task performance for a majority, suggests that subjects were developing more frequent, finer-grained corrections for movements that are faster overall, yet still executed in an open-loop manner where error accumulates and is corrected piecemeal. The secondary analysis suggests that autistic subjects began with high direction error and long paths, and reduced these slightly but meaningfully over this brief intervention. Future work will investigate predictors of such changes, and their implications for augmentative and alternative communication.

**401.103 (Poster)** What Is Autistic Burnout? a Thematic Analysis of Autistic Adults' Online Forum and Twitter Posts  
*J. Mantzalas<sup>1</sup>, A. L. Richdale<sup>2</sup>, A. Adikari<sup>3</sup>, J. Lowe<sup>3</sup> and C. Dissanayake<sup>1</sup>, (1)Olga Tennison Autism Research Centre, La Trobe University, Melbourne, VIC, Australia, (2)Centre for Data Analytics and Cognition, La Trobe University, Melbourne, VIC, Australia, (3)Public Health Palliative Care Unit and Olga Tennison Autism Research Centre, La Trobe University, Melbourne, VIC, Australia*

---

**Background:** Compared to adults in the general population, autistic adults are more likely to experience poor mental health leading to greater risk for suicidal ideation, self-harm and death by suicide (Cassidy et al., 2018; Hedley & Uljarević, 2018; Hirvikoski et al., 2016). The autistic community have long identified autistic burnout as a significant mental health risk, but despite the wealth of anecdotal reports, until recently, studies about autism-related burnout focused on the experiences of parents, teachers, and peers of autistic children (Boujut et al., 2017; Varghese & Venkatesan, 2013). Early research (Raymaker et al., 2020) has highlighted the harmful impact of autistic burnout among autistic adults and the urgent need to better understand this phenomenon.

**Objectives:** The aim in this qualitative study was to explore the lived experiences of autistic adults to identify the characteristics and underlying mechanisms of autistic burnout and, in so doing, to improve current knowledge about the aetiology, symptoms, and impact of autistic burnout, as well as prevention and recovery strategies.

**Methods:** Data scraping was conducted using a computer algorithm that extracted publicly shared posts from Twitter and WrongPlanet containing one or more of the terms, 'Autistic Burnout', 'Burnout' or '#AutisticBurnout'. The participant sample comprised 683 adults (559 from Twitter; 124 from WrongPlanet) aged 18 years and above. Each post and user profile were examined and excluded if ineligibility was indicated. Privacy regulations prevented collection of demographic data for Twitter participants. The average age of WrongPlanet users was  $M = 41.4$  years ( $N = 80$ ; range 21-76). A total of  $N = 121$  participants from WrongPlanet disclosed their gender, with 60 users identifying as male, and 61 users identifying as female. Autistic status was presumed through the individual's self-reference as autistic or use of the #ActuallyAutistic hashtag.

**Results:** A total of 1,127 posts (955 tweets; 172 forum posts) were analysed using reflexive thematic analysis. An inductive, 'bottom-up' approach was used to understand the lived experiences of autistic burnout, with seven primary themes and three subthemes identified. 1. Systemic, pervasive lack of awareness. 1.1. Discrimination and stigma. 2. A chronic or recurrent condition. 3. Direct impact on health and wellbeing. 4. A life un-lived, or a blessing in disguise? 5. Self-awareness and personal control influence risk. 5.1. "You need enough balloons to manage the weight of the rocks". 6. Masking: Damned if you do, damned if you don't. 7. Autistic people are the experts. 7.1. Stronger together. The overarching theme was that a pervasive lack of awareness and stigma about autism belies autistic burnout.

**Conclusions:** This study contributes to the scant knowledge about autistic burnout. We identified a set of distinct, yet interrelated factors that characterise autistic burnout as a recurring condition that can, directly and indirectly, impact a person's functioning, mental health, quality of life and wellbeing. The findings suggest that increased awareness and acceptance of autism could be key to burnout prevention and recovery.

**401.104 (Poster)** Why Should I Disclose? Providing Clear Information for Autistic Individuals to Consider

*A. M. Love<sup>1</sup>, R. Y. Cai<sup>2</sup> and V. Gibbs<sup>3</sup>, (1)Aspect Research Centre for Autism Practice, Flemington, VIC, Australia, (2)Aspect Research Centre for Autism Practice, Autism Spectrum Australia, Melbourne, VIC, Australia, (3)Aspect Research Centre for Autism Practice, Autism Spectrum Australia, Sydney, NSW, Australia*

---

**Background:** Disclosure is an important topic which can influence the nature of an individual's daily activities and relationships. Whether or not to disclose is an individual decision, this is clear from the literature. What has not yet been established, however, is what exactly the outcomes in a natural environment are when one does choose to disclose. Providing this type of evidence can help individuals make informed decisions in their own lives. While there is a wealth of research on disclosure for autistic individuals, making sense of the literature and finding objective or consistent results that can guide one's decision on whether or not to disclose is difficult. This is partly due to a substantial discrepancy between research that is informed by autistic perspectives and research that is informed by the opinions of those who autistic people may disclose to. Research that focuses on the autistic perspective often indicates negative outcomes related to disclosure, while research that focuses on others' perspectives (mainly research that uses vignettes) indicates positive outcomes.

**Objectives:** Two research questions guided two phases of study:

Research question phase 1: What is the association between an individual's intersecting identities (e.g., cultural, sexual, autistic) and their decisions around disclosure?

Research question phase 2: What are the real life outcomes related to disclosure as reported by autistic people? Does this vary by age, gender or context?

The findings from this research will yield important information about how intersecting identities may or may not influence an individual's decision to disclose, and what exactly happens when individuals do disclose. The study aims to fill the gap of current disclosure literature, which has focused mostly on vignette and qualitative research.

**Methods:** Participants for this study were autistic adults. For Phase 1, participants completed a questionnaire about their personal identity and disclosure habits. For Phase 2, we used Experience Sampling Methodology and asked participants to keep a diary of their disclosure experiences. Their diary entries were prompted by answering a short survey every time they have a disclosure opportunity. We used SEMA<sup>3</sup> to collect data, which is a suite of software and a platform designed at the University of Melbourne for longitudinal survey research (Koval, 2019). This research was co-produced with autistic collaborators in all phases of the project.

**Results:** Data collection for this project is ongoing, but results will be completed by the INSAR 2021 conference. Quantitative analyses will be conducted for both phases of the study. Regression analyses will be used to determine which predictors lead to disclosure of autism, among other things.

**Conclusions:** This project directly answers the call for new research following two recent reviews (Lindsay et al., 2019; Thompson-Hodgetts et al., 2020), and in response to an increase in research on this topic in the last 10 years. The results will provide objective data for autistic individuals to make an informed decision about disclosure in their lives.

**401.106 (Poster) 'Autistic Burnout': Exploring Experiences of Stress and Burnout in Autistic and Non-Autistic Adults**  
*D. Ali<sup>1</sup>, G. R. Stewart<sup>1</sup>, W. Mandy<sup>2</sup> and F. Happé<sup>1</sup>, (1)Social, Genetic and Developmental Psychiatry Centre, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (2)University College London, London, United Kingdom of Great Britain and Northern Ireland*

---

**Background:** Despite many first-person accounts and clinical anecdotes of stress and 'autistic burnout', only one (autistic-led) study has been published to date. 'Autistic burnout' has been described as exhaustion, loss of skills and decreased tolerance to sensory stimuli (Raymaker et al., 2020). Unlike occupational burnout, autistic burnout may occur in any context where expectations outweigh abilities and support is insufficient.

**Objectives:** This study explored differences in self-reported perceived stress and burnout in autistic and non-autistic adults. Sex differences, current mental health difficulties (depression and anxiety), current age, and the influence of early vs. late ASD diagnosis/self-identification were also explored.

**Methods:** Using a cross-sectional online survey, a total of 462 adults (autistic n = 373; non-autistic = 89) aged 18-75 (mean age = 31.77 years) completed standardised questionnaires related to their experiences of perceived stress, (personal, work

and social) burnout, current symptoms of depression and anxiety, and autistic traits. Participants also completed a bespoke stress and burnout questionnaire. Group differences were examined.

**Results:** Those in the autistic group reported significantly higher scores of personal, work and social burnout, as well as perceived stress. These significant differences remained when adjusted for age, depression and anxiety. Sex differences were also found in the autistic group, with autistic females reporting significantly higher levels of personal burnout than autistic males. No sex differences were found in work or social burn out, nor perceived stress. Additionally, no group differences were found between autistic adults diagnosed in childhood vs. those diagnosed in adulthood.

**Conclusions:** The findings from the current study suggest that autistic adults may experience higher levels of perceived stress and burnout than non-autistic adults, as has been previously highlighted in personal accounts and Raymaker et al. (2020). Autistic females were found to experience elevated rates of personal burnout, compared to autistic males. Therefore, this study highlights the need for further exploration of reasons for high stress levels and burnout in autistic people, and future environmental adaptations and supports to address these. Additionally, longitudinal studies may elucidate the mechanisms which underpin the experience of stress and burnout in autistic people.

**401.107 (Poster)** “It’s Nice to Connect to People without the Pressure of in-Person Meetings”: Autistic Women’s Experiences during the COVID-19 Pandemic and Attending a Virtual Peer Support Group

*A. Tint<sup>1</sup>, D. Share-Strom<sup>1,2</sup>, D. Zener<sup>3</sup>, B. Shemovski Thomas<sup>2</sup>, Y. Hamdani<sup>1,3</sup>, C. Kasse<sup>1,5</sup>, Y. Lunsby<sup>1</sup> and M. C. Lai<sup>1,4,6,7,8,9</sup>, (1)Azrieli Adult Neurodevelopmental Centre, Centre for Addiction and Mental Health, Toronto, ON, Canada, (2)Dori Zener & Associates, Toronto, ON, Canada, (3)Department of Occupational Science and Occupational Therapy, University of Toronto, Toronto, ON, Canada, (4)The Margaret and Wallace McCain Centre for Child, Youth and Family Mental Health, Centre for Addiction and Mental Health, Toronto, ON, Canada, (5)Dalla Lana School of Public Health, University of Toronto, Toronto, ON, Canada, (6)Autism Research Centre, Department of Psychiatry, University of Cambridge, Cambridge, United Kingdom, (7)Department of Psychiatry, National Taiwan University Hospital and College of Medicine, Taipei, Taiwan, (8)Department of Psychiatry, University of Toronto, Toronto, ON, Canada, (9)The Hospital for Sick Children, Toronto, ON, Canada*

---

**Background:** The unpredictability of the COVID-19 pandemic, the social isolation associated with physical distancing measures, and the ensuing economic instability, could increase the risk of mental health problems and exacerbate health inequities experienced by autistic women. There is a timely need to adapt supports and this period of uncertainty highlights opportunities for sustainable improvements to care delivery. Important first steps are to identify the challenges and opportunities that the COVID-19 pandemic poses for autistic women, from their own perspectives, and seek their input as services and supports evolve to meet their needs.

Asperfemme Toronto offers a monthly peer support group for autistic women, which provides a forum for members to support each other in areas of mutual interest. The group is co-facilitated by a therapist who specializes in autism, and an autistic graphic designer/technical illustrator who supports other autistic individuals. In response to the COVID-19 pandemic, Asperfemme Toronto transitioned their monthly face-to-face meetings to virtual meetings.

**Objectives:** This exploratory, co-production research study aimed to describe the experiences of autistic women during the COVID-19 pandemic, including their experiences of attending virtual peer support group meetings.

**Methods:** Participants were recruited from postings on Asperfemme Toronto’s Facebook group and an associated email list. Interested participants were directed to an online survey and provided with open-ended questions about their experiences during the COVID-19 pandemic and attending virtual peer support group meetings. Data were analysed using a summative content analysis approach (Hsieh & Shannon, 2005). An autistic self-advocate and an academic researcher independently read the participants’ responses to identify key words and subsequently sorted the data into like categories and sub-categories. Identified categories were compared and discussed until a consensus on the final conceptualization was reached.

**Results:** The sample consisted of 35 autistic women, ranging in age from 21 to 63 years (M= 39.29 years, SD=11.16). Key categories pertaining to participants’ experiences during the COVID-19 pandemic included: 1) Less Means More; and 2) Change is Difficult. Participants noted that they experienced fewer social and sensory demands as a result of public health restrictions during the pandemic, which enabled them to focus more on activities of personal importance, and helped them to live more authentically. However, participants also acknowledged difficulties adapting to changes to their routines, and the quickness and urgency in which changes were enacted during the pandemic. Overall, participants largely appreciated having the opportunity to attend virtual peer group support meetings with other autistic women during the pandemic. Responses regarding their likes and dislikes of virtual peer support group meetings were categorized as: 1) (In)Convenience; 2) (Dis)Comfort; and 3) (Dis)Connection.

Conclusions: As the COVID-19 pandemic continues to bring about changes to service delivery models, the current study offers preliminary insights into promising areas for expanding virtual peer support programming for autistic adults.

**401.108 (Poster) “Just Invite Us”:** Autistic Adults’ Recommendations for Developing More Accessible Physical Activity Opportunities.

*A. M. Colombo-Dougovito<sup>1</sup>, J. Blagrove<sup>2</sup> and S. Healy<sup>3</sup>, (1)Kinesiology, Health Promotion, & Recreation, University of North Texas, Denton, TX, (2)Kinesiology, California State University, Chico, Chico, CA, (3)Behavioral Health and Nutrition, University of Delaware, Newark, DE*

---

Background:

Autistic adults engage in lower levels of physical activity (PA) than their non-autistic peers, and over sixty percent do not meet national guidelines for PA. Additionally, autistic adults face myriad barriers to PA participation that can make accessing physical activities challenging. As many of the cooccurring conditions that are associated with autism in adults can be moderated by PA, it’s vital that opportunities are accessible and meaningful for autistic individuals. Yet, research on PA participation in autistic adults is limited, with most studies focusing on the perspective of parents and other caregivers.

Objectives:

To support the inclusion of autistic adults in PA, the current study sought to explore first-hand recommendations for PA participation from autistic adults' perspective. In doing so, this study has sought to amplify the accounts of autistic adults so that practitioners have practical solutions to better include autistic individuals into PA experiences and make these opportunities more accessible.

Methods:

A qualitative descriptive design with a constructivist lens was used to examine autistic participants' recommendations for engaging in PA. Participants were recruited through online groups, university autism networks and a snowball sampling to leverage personal connections of autistic participants. Participants (n=23) ranged in age from 18 to 75 years (m=40.45, SD = 17.79); 12 participants identified as male and 11 identified as female. Twenty participants had a formal diagnosis of autism and three were self-diagnosed. The AQ-10 was used as a confirmatory measure of likelihood of an autistic diagnosis and all participants scores confirmed likelihood. Interview questions were developed to elicit participant perspectives of their PA experiences across their lifespan. Within a larger grounded theory study, the authors embedded questions that allowed participants to share recommendations on how to improve PA experiences for individuals "like themselves." The presented data form those recommendations.

Results:

Two themes were developed during the data analysis process: 1) It’s helpful to have someone there to support; and 2) It’s that sensory thing, it always is. Theme 1 encapsulates the importance of having vocal advocates willing to encourage and support the autistic persons in both individual and group activities. Theme 2 highlights the critical role that sensory factors play in the success of PA experiences for autistic adults across the lifespan, and how unique sensory needs may be met.

Conclusions:

Consistent with prior research, autistic adults in the present study faced a multitude of barriers to accessing PA. Yet, uniquely within this study, the authors asked adults to give recommendations for how they believe those barriers should be addressed. Though simple, the presented recommendations would show a radical balancing of the power dynamic between practitioners and autistic clients. Educators, service providers, and families should take these recommendations not only as direction from those who understand autistic adults best, but as a way to explore with those you work with and love how to provide PA programming and access best.

## POSTER SESSION — AFFECTIVE NEUROSCIENCE

### Poster 402 - Affective Neuroscience Posters

**402.001** (Poster) Brainstem Morphometric Differences in Children with Autism Spectrum Disorder, Developmental Coordination Disorder and Those Typically Developing

*P. Bosco<sup>1</sup>, L. A. Harrison<sup>2,3</sup>, A. Retico<sup>4</sup>, C. Butera<sup>2</sup>, S. Calderoni<sup>3</sup>, F. Muratori<sup>3</sup>, L. Aziz-Zadeh<sup>2,3</sup> and J. Delafeld-Butt<sup>6</sup>, (1)IRCCS Stella Maris Foundation, Pisa, Italy, (2)USC Mrs. T.H. Chan Division of Occupational Science and Occupational Therapy, University of Southern California, Los Angeles, CA, (3)Brain and Creativity Institute, Dornsife College of Letters, Arts and Sciences, University of Southern California, Los Angeles, CA, (4)Istituto Nazionale di Fisica Nucleare, Pisa, Pisa, Italy, (5)Department of Clinical and Experimental Medicine, University of Pisa, Pisa, Italy, (6)Laboratory for Innovation in Autism, University of Strathclyde, Glasgow, United Kingdom*

**Background:** The brainstem is a neglected topic in autism research, despite major lines of evidence indicating its active involvement in sensory, motor, affect, arousal, and social regulation (Dadalko & Travers, 2018). It is the substrate of what affective neuroscience identifies as the ‘Core Self’ (Alcaro, Carta, & Panksepp, 2017), and disruption to its growth and function appears to disturb core conscious experience in autism (Delafeld-Butt & Trevarthen, 2017; Trevarthen & Delafeld-Butt, 2013). Yet, although evidence indicates brainstem growth is disrupted in early childhood (Bosco et al., 2018), how these growth differences compare to closely related neurodevelopmental disorders, such as a Developmental Coordination Disorder (DCD), is not yet understood.

**Objectives:** To determine brainstem morphometric differences between children with ASD, DCD, and those typically developing (TD).

**Methods:** Study participants were 87 youths ages 8 to 17 assigned to the ASD ( $n = 30$ , 7 female), DCD ( $n = 24$ , 12 female) or TD ( $n = 33$ , 12 female) group. Exclusion criteria for all groups included IQ <80. TD were excluded if they had any neuropsychological or psychopathological disorder. DCD eligibility additionally included performance 16<sup>th</sup> percentile on the MABC-2 and no concern about an ASD diagnosis. ASD participants had a previous clinical diagnosis confirmed by ADOS-2 and ADI-R. Individuals were excluded if they had another neuropsychological disorder, except attention deficit or anxiety disorder. T1-weighted MPRAGE (1mm isotropic resolution) MRI data were acquired on a 3T MAGNETOM Prisma (Siemens). Brainstem morphology was analysed using SPHARM-MAT (<http://lisenlab.com/spharm/>), a 3D Fourier surface representation method. A typical surface was calculated for the TD group, and distances from this norm computed for each vertex. Mean distances at each vertex were computed for each group (ASD, DCD, TD) and compared, taking into account age, gender and supratentorial volume as covariates.

**Results:** Significant brainstem morphological differences were identified between all three (TD, ASD and DCD; Figure 1). Significant differences between TD and ASD ( $p < 0.01$ ) were identified in a large region of the anterior-most surface, extending caudally along the right posterior surface. Differences between TD and DCD groups were similar with reduced significance ( $p \gg 0.01$ ), and the pattern diverged with more inclusion of the anterior ventricular surface and less pronouncement at the right anterior border. Finally, significant differences were found between ASD and DCD groups ( $p < 0.01$ ), specifically at the anterior midline either side of the ventricular surface, and especially in two long anteroposterior columns on the left side adjacent and parallel to the fourth ventricle.

**Conclusions:** Surface morphology differences indicate alterations in local nuclei and/or tract growth within the brainstem, especially approaching the anterior surface in ASD and DCD children, and differentially between them at the ventricular surface. The former may relate to specific nerve growth of the pons, and the latter to cerebellar peduncle connectivity differences, superficial nuclei growth such as the hypoglossal, intercalatus, or vagus and associated tracts, or deeper nuclei such as the inferior olivary nucleus. Brainstem structural differences likely disturbs the integrative function of the Core Self. Higher resolution 7T MRI is required to resolve the underlying differential composition.

**402.002** (Poster) Frontal Alpha Asymmetry As a Predictor of Emotion Regulation and Strategy Use in Toddlers with ASD and TD

**S. R. Edmunds<sup>1,2</sup>, R. Iqbal<sup>1</sup>, A. Sagon<sup>1,3</sup>, V. E. Sanchez<sup>4</sup> and S. Faja<sup>1</sup>,** (1)Boston Children's Hospital, Boston, MA, (2)Psychiatry, Harvard School of Medicine, Boston, MA, (3)Suffolk University, Boston, MA, (4)Division of Developmental Medicine, Boston Children's Hospital, Boston, MA

---

**Background:** Children with ASD have difficulties with emotion regulation. The extent to which this difficulty is specific to core symptoms (e.g., changes in routine), or is more global in nature, differs for each child. In adults and older children, the relative difference between resting left and right frontal alpha EEG power (i.e., asymmetry) may be related to approach and avoidance behaviors and, subsequently, challenges with emotion regulation. There is little evidence as to the relation between asymmetry and affective regulation in typically developing preschoolers, and less still for young children with ASD.

**Objectives:** (1) To characterize frontal alpha asymmetry in preschoolers with ASD and typical development (TD); and (2) to explore whether asymmetry is related to behaviorally coded and parent-report measures of emotion regulation.

**Methods:** Children with ASD (n=18) and TD (n=30) completed 4 minutes of alternating eyes open/closed resting EEG data collection at 2 or 4 years of age. Concurrently, emotion regulation strategy use was coded from a 5-minute parent-child play interaction into five behavioral categories, following the Process Model of Emotion Regulation (Gross, 1998). Of relevance to this project is the Situation Modification scale, which captures attempted changes in the environmental context to modulate emotional response. Parent-report BASC-3 Aggression and Withdrawal scales (T-scores) assessed approach- and avoidance-related emotional and behavioral functioning. EEG power was derived from the BEAPP EEG processing pipeline as the natural log of mean power per hertz within the alpha (8-13 Hz) frequency band (Levin et al., 2018). Unique frontal activation relative to each hemisphere (i.e., asymmetry) was calculated by generating residual values, which are more sensitive than traditional difference scores (Meyer et al., 2017). Left relative activation was derived from a model of right power (F4) predicting left power (F3) (i.e., left power, controlling for right). Right relative activation was the inverse. Nonverbal IQ differed by group and was controlled for in all analyses. Data collection is ongoing.

**Results:** While there was no diagnostic group difference in degree of asymmetry,  $b=.11$ ,  $p>.05$ , and direction of asymmetry was not different by group,  $X^2(2)=3.00$ ,  $p>.05$ , qualitative observations suggested wide variability. Situation Modification scores did not differ by group,  $b=.05$ ,  $p=.60$ . Children with ASD had higher Withdrawal T-scores than TD children,  $b=.26$ ,  $p=.04$ . When split by diagnostic group, there were no significant relations between frontal asymmetry and emotion regulation. For all children, greater relative right frontal activation was correlated with less frequent use of situation modification strategies for emotion regulation,  $r=-.33$ ,  $p=.03$ . Greater relative left frontal activation was correlated with lower (i.e., more adaptive) Withdrawal T-scores on the BASC,  $r=-.39$ ,  $p=.02$ .

**Conclusions:** For children with and without ASD, greater right asymmetry, which may relate to avoidant or inhibited behavioral styles, related to less adaptive emotion regulation strategy use. Greater left asymmetry, which may relate to increased approach behaviors and impulsivity, here appears adaptive, in that these children have less clinically impairing withdrawn or inhibited presentations. Future work should examine the predictive power of frontal asymmetry in longitudinal designs and examine whether ASD diagnosis moderates these brain-behavior relations.

#### **402.003 (Poster) Intervention Engagement and Social Motivation Predict Increased Social Reward Response in ASD**

**E. Baker<sup>1</sup>, E. Veytsman<sup>2</sup>, A. M. Martin<sup>2</sup>, T. Choy<sup>3</sup> and K. K. Stavropoulos<sup>2</sup>,** (1)University of California Riverside, Riverside, CA, (2)Graduate School of Education, University of California Riverside, Riverside, CA, (3)University of California, Riverside, Riverside, CA

---

**Background:** The PEERS social skills intervention has been shown to improve social behaviors in adolescents with ASD (Laugeson et al., 2012); however, factors impacting intervention outcomes are relatively unknown. In broader therapeutic settings, participant engagement, measured through active participation in intervention, is associated with better outcomes (Chu et al., 2010). Quantifiable measures of treatment outcome, including brain-based measures, along with objective measures of participant engagement, and standardized measures of social functioning may illuminate factors influencing individual outcome.

**Objectives:** We sought to answer the following questions: (1) Do neural correlates of social reward responsivity change from pre- to post- PEERS intervention when compared to brain activity of neurotypical (TD) adolescents who did not participate in PEERS? (2) For ASD participants, do parent-report measures of social motivation (SM) and engagement during PEERS sessions predict individual changes in neural correlates of social reward from pre- to post-intervention?

**Methods:** Electroencephalographic (EEG) recordings were conducted to measure event-related potentials in ASD adolescents (n=12, mean age=14.2) before and after the 16-week PEERS intervention. TD teens (n=14, mean age=13.2) were age and gender-

matched to teens with ASD, and had brain activity measured at two time points—16 weeks apart, but did not partake in the intervention. The reward positivity (RewP) was utilized to measure reward processing. Adolescents were presented with rewards accompanied by incidental face (social) or arrow (nonsocial) stimuli. To measure change in the RewP from pre- to post-intervention, a difference score was created by subtracting pre-intervention from post-intervention RewP mean amplitudes. The SM subscale from the Social Responsiveness Scale, Second Edition (Constantino, 2012), was collected at pre- and post-intervention. Participant engagement was quantified as the number of times adolescents raised their hands to answer/ask questions, provide suggestions, or comment on lesson-related material across all 16 sessions.

Results: (1) A 2(group)x2(condition)x2(time) repeated-measures ANOVA revealed no significant main effects or interactions for RewP mean amplitude. (2) Two separate linear regressions were conducted in the ASD group to test if pre-intervention SM or in-session participation predicted change in RewP mean amplitude from pre- to post-intervention. 44.9% of the variance of the change in social reward responsivity (RewP mean amplitude in response to faces) was accounted for by SM pre-intervention scores,  $\beta=-0.7; F(1,10)=8.14, p=0.01$ . 43.9% of the variance of the change in social reward responsivity was accounted for by participant engagement,  $\beta=0.7; F(1,10)=9.60, p=0.01$ .

Conclusions: This is one of the few investigations to include objective (EEG) and observable (participant engagement) measures of outcome and/or prediction measures of intervention. Our findings underscore the importance of SM and active engagement during intervention, as ASD adolescents who had better SM skills before intervention and those who participated more during PEERS sessions displayed increased social reward responsivity after intervention completion. This indicates that engagement during intervention and baseline levels of social motivation may distinguish teens who make mild improvements from those who make more considerable improvements. This is particularly relevant when determining nuanced effects of intervention on an individual basis, which may not be detectable when examining average group differences.

#### **402.004** (Poster) Oxytocin Modulates Visual Attention Depending on the Social Context: A MEG Study in Adolescents with ASD

**A. Korisky<sup>1</sup>, A. Goldstein<sup>1,2</sup> and I. Gordon<sup>1,2</sup>, (1)Gonda Brain Research Center, Bar-Ilan University, Ramat Gan, Israel, (2)Department of Psychology, Bar-Ilan University, Ramat Gan, Israel**

---

#### Background:

Autism spectrum disorders (ASD) are neurodevelopmental conditions characterized mainly by social dysfunction and deficits in social perception. It has been shown that in this population, intranasal administration of Oxytocin (OT) can enhance attention toward social cues and modulates social perception in both behavioral and neural level. However, there is a gap in the literature regarding the effects of OT on oscillatory brain activity in ASD compared to typically developing (TD) individuals.

#### Objectives:

This study aims to explore the impact of OT on temporal dynamics in ASD using magnetoencephalography (MEG) during a well-validated social perception paradigm. We focused on: M100, M170, and M250, social perception related components, which tend to show atypical patterns in ASD. We hypothesize that OT will modulate these components' amplitudes to resemble an aged-matched TD group.

#### Methods:

Twenty-eight adolescents with ASD and 25 TD adolescents participated in this study. All participants were scanned using magnetoencephalography (MEG) and were asked to identify pictures of emotional facial expressions and pictures of vehicles. In two experimental sessions, approximately one week apart, individuals with ASD received a single dose of intranasal OT or placebo in a double-blind controlled study.

#### Results:

We first established that OT enhances accuracy in individuals with ASD in social and non-social conditions. Our results show that such individuals with ASD differed from the TD group in the PL sessions only. Next, Cluster-based nonparametric analysis using beamforming revealed differences between the ASD and TD groups in the 140-220 ms window (M170, a face processing related component). While TD individuals presented higher occipito-temporal activations for faces than vehicles, individuals with ASD presented elevated neural activation in the same regions for both faces and vehicles equally. Administration of OT reduced the observed activity for vehicles only, creating a neural differentiation that was closer to that of the TD group. In addition, we show that individuals with higher IQ benefited more from OT administration.

## Conclusions:

Our results show that OT administration modulates the neural balance between social and non-social stimuli making occipito-temporal regions more attuned to social cues. For the first time, we show an optional mechanism for OT's influence on adolescents' early social perception stages with ASD. Studies like this allow a better understanding of OT's influences on social perception in individuals with ASD and enhance our ability to improve their social difficulties.

### **402.005** (Poster) Predicting Electrophysiological Indices of Change in a RCT of a Group-Based Social Skills Intervention for Youth with ASD

**E. Kang<sup>1</sup>** and **M. D. Lerner<sup>2</sup>**, (1)Department of Psychology, Montclair State University, Montclair, NJ, (2)Department of Psychology, Stony Brook University, Stony Brook, NY

---

Background: Group-based social skills interventions are the most widely-used treatment approach for social deficits among youth with autism spectrum disorder (ASD) and have evinced moderate effects overall (Gates et al., 2017). One such intervention, socio-dramatic affective-relational intervention (SDARI), is designed to offer an “enriched social environment,” whereby changes in social information processing (SIP) and behavior are driven by repeated opportunities for motivated engagement within social contexts. Results from a recent trial demonstrated SDARI's effects on target neural mechanisms (EEG-indexed markers of early-stage SIP), N170 event-related potential [ERP] latency to faces (Kang et al., 2018) and N100 ERP amplitude to voices (Lerner et al., 2013). While SIP in ASD is thought to vary as a function of demographics (age, sex), social motivation, and social cognition (Mendelson et al., 2016), it is unknown whether such variables predict intervention-related *change* in SIP, thereby indicating prospective treatment responders.

Objectives: We assessed key demographic factors, ASD symptoms, social motivation, and Theory of mind (ToM) as putative moderators of electrophysiological changes following a randomized-controlled trial of SDARI.

Methods: 53 teens ( $M_{age}=11.7$ ,  $SD_{age}=3.1$ ; 39 male), with  $IQ \geq 70$  and ADOS-2-confirmed ASD diagnoses were randomly assigned to 10-week SDARI or an active control (AC) for 1.5 hours/week. AC was identical to SDARI in structure, minus SDARI-specific content. N170 and N100 ERPs were measured at baseline, endpoint, and 10-week follow-up during an emotion recognition task (DANVA-2; Nowicki, 2004). Parents completed measures of youth's social motivation (DMQ; Morgan et al., 2009) and ToM (ToMI; Hutchins et al. 2012) at baseline. Generalized estimating equations (accounting for group nesting) were used to examine moderators of change trajectories (across all 3 time points), with independent correlation matrix providing the best model fit.

Results: SDARI group showed accelerated N170 latency and increase in N100 amplitude relative to the AC group (Figure 1), with effects only present in boys (all  $ps < .05$ ). The N170 latency effect was greater in participants who were older or had fewer ASD symptoms (all  $ps < .005$ ), and present only in those with low or high social motivation ( $p < .028$ ; Figure 2), or poorer ToM ( $p = .031$ ). The N100 amplitude effect was driven by participants who had more ASD symptoms ( $p < .001$ ), and present only in those with medium social motivation or ToM ( $p < .019$ ).

Conclusions: SDARI led to specific improvements in EEG-based metrics of early-stage SIP, which have themselves been implicated as potential biomarkers of ASD. These effects vary by key correlates of SIP (age, sex, ASD symptoms, social motivation and cognition), suggesting directions for a precision medicine approach to impacting neural mechanisms of social deficits in ASD. For instance, SDARI may confer specific and durable improvements in face-related SIP in participants who have fewer ASD symptoms, or are highly motivated as they successfully engage in SDARI's enriched social contexts, but findings also suggest perhaps a distinct group of responders who have poorer ToM or low social motivation. Moreover, results provide further insights into the complex and often inconsistent relationship of SIP with social motivation and ToM (Garman et al., 2016; Jaswal & Akhtar, 2020).

### **402.006** (Poster) Vocal Emotion Recognition in Adolescents with and without ASD in Response to Child Versus Adult Voices

**S. Boateng<sup>1</sup>**, **T. C. Day<sup>1</sup>** and **M. D. Lerner<sup>2</sup>**, (1)Psychology, Stony Brook University, Stony Brook, NY, (2)Department of Psychology, Stony Brook University, Stony Brook, NY

---

Background: Autism Spectrum Disorder (ASD) is characterized by social communication impairments including difficulty recognizing other people's emotions (Uljarevic & Hamilton, 2013). These emotion recognition impairments are present across modalities (i.e., faces, body movements, and voices; Phillip et al., 2010), with most work focused on facial emotional recognition (FER; Harms et al., 2010). Recent research examining individual differences in FER in ASD has demonstrated that, similar to peers without ASD, adolescents with ASD exhibit “own-age bias,” or better performance recognizing same-age peers due to

frequent interaction with faces of similar age (Hauschild et al., 2020). While some studies have considered whether FER deficits extend into other modalities (e.g., vocal emotion recognition; VER; Jones et al., 2010), few have examined whether individual difference predictors (like own-age bias) do so as well. Such individual differences implicate variation in neural mechanisms during VER processing which can be measured using event-related potentials (ERPs). For instance, the N100 indexes intensity of and attention to early auditory information (Schirmer et al., 2011; Wang et al., 2017), while the P200 differentiates vocal emotions from neutral expressions and may differ based on the specific emotion and speaker (Paulmann & Kotz, 2008). Past studies have found differences in these components associated with ASD and VER performance (Korpilathi et al., 2007; Lerner et al., 2013), yet it is unknown if they relate to factors such as VER own-age bias.

**Objectives:** This study examined VER abilities and processing (N100, P200) in response to child versus adult voices in adolescents with and without ASD.

**Methods:** 122 adolescents with and without ASD participated in a standard voice emotion recognition task (Table 1) while electroencephalography (EEG) was collected (Table 1; Figure 1). Two-way ANOVAs were used to examine whether VER abilities and ERPs differed between groups or by (adult/child) condition.

**Results:** Participants made more VER errors in response to adult, compared to child, voices ( $p < .001$ ). Participants with ASD, compared to peers without ASD, made more VER errors ( $p = .001$ ). Compared to child voices, adult voices elicited larger P200 amplitudes across groups ( $p = .012$ ). No differences in N100 amplitude, N100 latency, or P200 latency emerged.

**Conclusions:** Own-age bias was present in VER in adolescents with and without ASD, consistent with prior work in FER (Hauschild et al., 2020). Compared to adolescents without ASD, adolescents with ASD made more errors identifying vocal emotions, supporting findings of multimodal emotion recognition difficulties in ASD (e.g., Phillip et al., 2010, Lerner et al., 2013). Across groups, the P200 amplitude was enhanced in response to adult, compared to child, voices. Given own-age bias was present across groups, an enhanced P200 in response to adult voices may reflect more effortful processing of adult emotional voices. Yet differences in ERPs between adolescents with and without ASD did not emerge, suggesting similar early processing of VER in ASD, despite behavioral differences. This diverges from the FER literature in which behavioral performance is intact while neural response is atypical (Harms et al., 2010), highlighting the importance of examining emotion recognition abilities across modalities and levels of analysis.

## Animal Models

### ORAL SESSION — ANIMAL MODELS

#### Oral 302 - Modeling Autism Mutations from Fish to Human Cells

##### 302.001 (Oral) Altered Brain-Wide Auditory Networks in a Zebrafish Models of Autism

R. Poulsen, L. Constantin, G. Vanwalleghem and E. Scott, Queensland Brain Institute, University of Queensland, Brisbane, QLD, Australia

**Background:** Individuals with autism usually present with hyper or hypo responsivity to auditory stimuli, however the neurological underpinnings behind these differences remain unclear.

**Objectives:** We looked at sub-cortical auditory processing *in vivo* in an autism model of zebrafish, to determine if there are any differences in auditory sensitivity or processing between the *fmr1* zebrafish and their wildtype siblings. We are also carrying out similar experiments on other genetic models of autism.

**Methods:** We use selective plane illumination microscopy with GCaMP6 calcium indicators to record the entire brain at cellular resolution, looking at whole-brain and regional auditory networks and neural responses to acoustic stimuli in larval zebrafish *in vivo*.

**Results:** Auditory responses in the *fmr1* fish were more plentiful, compared to their wildtype siblings, at a brain-wide level. The primary auditory region, the octavolateralis nucleus (homologous to the cochlear nuclei), was significantly better at decoding auditory at lower volumes in the *fmr1* fish. Three brain regions—the thalamus, torus semicircularis and tegmentum—had clusters of neurons that more strongly responded to auditory stimuli, indicating filtering is reduced. Inter-regional functional connectivity networks in the *fmr1* fish responded to sound intensities of half the amplitude (a -3 to -6 decibel shift) as wild type larvae.

**Conclusions:** Using larval zebrafish we can look at whole brain processes in *fmr1* and other genetic models of autism to determine if there are any differences in sensitivity and auditory processing. The *fmr1* results reflect the hypersensitivities documented in humans with FXS and autism, thereby providing possible network-level mechanisms by which sensory processes are altered at the sub-cortical level.

##### 302.002 (Oral) Germline Nuclear-Predominant Pten Murine Model Exhibits Impaired Social and Perseverative Behavior, Microglial Activation, and Increased Oxytocinergic Activity

N. B. Sarn<sup>1,2</sup>, S. T. Thacker<sup>3</sup>, H. Lee<sup>4</sup> and C. Eng<sup>5,6,7,8</sup>, (1)Department of Genetics and Genome Sciences, Case Western University, Cleveland, OH, (2)Genomic Medicine Institute, Cleveland Clinic Foundation, Cleveland, OH, (3)Genomic Medicine Institute, Lerner Research Institute of Cleveland Clinic, Cleveland, OH, (4)Genomic Medicine Institute, Lerner Research Institute, Cleveland, OH, (5)Genomic Medicine, Cleveland Clinic, Cleveland, OH, (6)Department of Genetics and Genome Sciences, Case Western Reserve University, Cleveland, OH, (7)Genomic Medicine, Cleveland Clinic Lerner Research Institute, Cleveland, OH, (8)Case Comprehensive Cancer Center, Case Western Reserve University, Cleveland, OH

**Background:** Germline mutations in the gene encoding Phosphatase and Tensin homolog deleted on chromosome TEN (*PTEN*) account for ~17% of all cases of autism spectrum disorder (ASD) with coincident macrocephaly. Animal modeling of cell-specific *Pten* loss or mutation has provided insight into how disruptions to the function of PTEN affect neurodevelopment, neurobiology, and social behavior. As such, there is a growing need to understand more about how various aspects of PTEN activity, cell-compartment-specific functions, contribute to certain neurological or behavior phenotypes. To explore the importance of cytoplasmic PTEN in the development of ASD and macrocephaly, we generated a mouse model with predominantly nuclear localization of Pten (*Pten*<sup>Y68H</sup> model).

**Objectives:** To further understand the relationship between Pten subcellular-localization and downstream effects on neurodevelopment and behavior.

**Methods:** We subjected the *Pten*<sup>Y68H/+</sup> mouse to morphological and behavioral phenotyping, including the 3-chamber sociability and marble burying tests. We subsequently performed *in vivo* and *in vitro* cellular phenotyping and concluded the work with a transcriptomic survey of the *Pten*<sup>Y68H/+</sup> cortex to profile gene expression in adult (P40) male mice (N<sub>+/+</sub> = 6; N<sub>Y68H/+</sub> = 5).

Results: Nuclear-cytoplasmic fractionation of *Pten*<sup>Y68H/+</sup> cortical tissue confirms Pten subcellular-localization is predominantly nuclear (Median $\Delta$ N/CRatio=0.20; 97%CI 0.15-0.34;  $P=0.029$ ). Additionally, we find *Pten*<sup>Y68H/+</sup> mice presents with macrocephaly (Median $\Delta$ BrainMass=0.15; 97%CI 0.090–0.21;  $P<0.0001$ ), decreased sociability using 3-chamber (Mean $\Delta$ Seconds=162; 95%CI 121-203;  $P<0.0001$ ), decreased preference for novel social stimuli (Mean $\Delta$ DSeconds=101; 95% CI 56.5-145;  $P<0.0001$ ), and increased perseverative activity using marble burying (Median $\Delta$ Marbles=4.68; 97%CI 2.12–7.23;  $P=0.002$ ). Cellular characterization of *Pten*<sup>Y68H/+</sup> cortex reveals significant microglial activation (Mean $\Delta$ MicrogliaArea=0.29; 95%CI 0.12–0.46;  $P=0.002$ ), and *in vitro* analysis of primary microglial cultures isolated from *Pten*<sup>Y68H/+</sup> mice reveal enhanced phagocytosis of latex beads compared to *Pten*<sup>+/+</sup> controls (Mean $\Delta$ BeadsEngulfed=3.2; 95%CI 2.5-4.0;  $P=0.005$ ). Subsequent Western blot analysis of *Pten*<sup>Y68H/+</sup> cortical lysate shows increased expression of Iba1 ( $P=0.029$ ) and C1q ( $P=0.029$ ). Finally, we characterized the neural transcriptome which revealed 332 differentially expressed genes [threshold:  $P<0.05$ ; Log<sub>2</sub>(Fold Change) $\geq 1.0$  or Log<sub>2</sub>(Fold Change) $\leq -1.0$ ], the majority of which are overexpressed and involved in neuroinflammation and neuronal function. Oxytocin transcript was 5-fold overexpressed ( $P=0.0018$ ) and confirmed by immune-fluorescent staining of oxytocin in para-ventricular neurons in the hypothalamus which shows significant increase in oxytocin intensity (Mean $\Delta$ IntDensity=6630; 95%CI 4860-8400;  $P<0.0001$ ).

Conclusions: The nuclear-predominant *Pten*<sup>Y68H/+</sup> model demonstrates that Pten dysfunction is linked to microglial activation and phagocytosis. Notably, we demonstrate that Pten dysfunction associates with changes in the oxytocin system, an important connection between a prominent ASD risk gene and a potent neuroendocrine regulator of social behavior. Ultimately, the findings from this work may reveal important biomarkers and/or novel therapeutic modalities that could be explored in individuals with germline mutations in *PTEN* with ASD.

### 302.003 (Oral) Behavioral and Cellular Characterization of a New Mouse Model for DDX3X Syndrome

**M. Garcia-Forn**<sup>1,2,3,4</sup>, **A. Boitnott**<sup>1,2,3,4</sup>, **D. C. Ung**<sup>1,2,3,4</sup>, **K. Niblo**<sup>1,2,3,4</sup>, **D. Mendonca**<sup>1,2,3,4</sup>, **M. Flores**<sup>1,2,3,4</sup>, **S. Maxwell**<sup>1,2,3,4</sup>, **Y. Park**<sup>1,2,3,4</sup>, **J. Ellegood**<sup>5</sup>, **D. Grice**<sup>1,2</sup>, **J. P. Lerch**<sup>3,6,7</sup>, **R. M. Rasin**<sup>8</sup>, **J. D. Buxbaum**<sup>1,2,3,4,9</sup>, **E. Drapeau**<sup>1,2</sup> and **S. De Rubeis**<sup>1,2,3,4</sup>, (1)Department of Psychiatry, Icahn School of Medicine at Mount Sinai, New York, NY, (2)Seaver Autism Center for Research and Treatment, Icahn School of Medicine at Mount Sinai, New York, NY, (3)Friedman Brain Institute, Icahn School of Medicine at Mount Sinai, New York, NY, (4)The Mindich Child Health and Development Institute, Icahn School of Medicine at Mount Sinai, New York, NY, (5)Mouse Imaging Centre, Hospital for Sick Children, Toronto, ON, Canada, (6)Department of Medical Biophysics, University of Toronto, Toronto, ON, Canada, (7)Wellcome Centre for Integrative Neuroimaging, University of Oxford, Oxford, United Kingdom, (8)Department of Neuroscience and Cell Biology, Rutgers University, RWJ Medical School, Piscataway, NJ, (9)Department of Neuroscience, Icahn School of Medicine at Mount Sinai, New York, NY

Background: DDX3X syndrome accounts for 1-3% of unexplained intellectual disability (ID) in females, presenting also behavioral problems and motor impairments. This syndrome is mostly caused by de novo mutations in DDX3X, an X-linked gene that regulates mRNA translation and has emerging functions in corticogenesis and synaptogenesis. Even though the genetic cause of the syndrome is known, the cellular and molecular mechanisms driving it remain elusive.

Objectives: The objective of this study is to elucidate the cellular and molecular mechanisms driving DDX3X syndrome during development, particularly during corticogenesis, and link them to the symptoms observed in DDX3X patients.

Methods: We generated the first Ddx3x haploinsufficient mouse (Ddx3x<sup>+/-</sup>) model with construct validity for loss-of-function mutations found in females with DDX3X syndrome. To study the impact of Ddx3x haploinsufficiency on development and behavior we followed a standardized battery for assessing developmental milestones during early postnatal life and cognition, social and motor functions in adults. To study the impact of Ddx3x haploinsufficiency on corticogenesis, we performed MRI studies and assessed cortical lamination using layer-specific markers and retrograde tracing to reconstruct sub-cortical connectivity.

Results: Ddx3x<sup>+/-</sup> mice show physical, sensory, and motor delays that evolve into behavioral anomalies in adulthood, including hyperactivity, anxiety-like behaviors, cognitive impairments, and motor deficits. Motor function further declines with ageing. This phenotype is reminiscent of the symptoms observed in DDX3X patients. The behavioral changes are preceded by reduction in brain volume postnatally, with some regions (e.g., cortex and amygdala) disproportionately affected. Cortical thinning is accompanied by defective cortical lamination, indicating that Ddx3x regulates the balance of glutamatergic neurons in the developing cortex.

Conclusions: While supporting face validity for a novel pre-clinical mouse model, our data shed new light on the developmental mechanisms driving DDX3X syndrome.

### 302.004 (Oral) Modeling Brain Overgrowth in Autism Using Human Pluripotent Stem Cells

**S. Chetty<sup>1</sup>**, J. F. Hallmayer<sup>2</sup>, R. O'Hara<sup>3</sup>, C. W. Nordahl<sup>4</sup>, M. Solomon<sup>4</sup>, S. M. Rivera<sup>5</sup> and D. G. Amaral<sup>1</sup>, (1)Psychiatry and Behavioral Sciences, Institute for Stem Cell Biology and Regenerative Medicine, Stanford University, Stanford, CA, (2)Psychiatry & Behavioral Sciences, Stanford University, Stanford, CA, (3)Psychiatry and Behavioral Sciences, Stanford University, Stanford, CA, (4)Department of Psychiatry and Behavioral Sciences, The Medical Investigation of Neurodevelopmental Disorders (MIND) Institute, UC Davis School of Medicine, University of California Davis, Sacramento, CA, (5)Department of Psychology, University of California, Davis, Davis, CA

---

#### Background:

Approximately 15-20% of individuals with Autism Spectrum Disorder (ASD) have disproportionate megalencephaly (ASD-DM), with enlargement in both gray and white matter volume. Individuals with ASD-DM have more severe behavioral and cognitive problems and are less responsive to standard therapeutic interventions, leading to very poor prognoses relative to individuals with ASD and normal head circumferences. Increases in brain size often precede clinical symptoms, suggesting that understanding the underlying mechanisms regulating brain overgrowth could provide a window of opportunity for intervention or mitigation of symptoms.

#### Objectives:

Here, we use human induced pluripotent stem cell (hiPSC) technology to model brain overgrowth in ASD-DM and investigate the underlying cellular and molecular mechanisms involved. The overarching goals are: 1) to investigate whether gray and white matter enlargement are due to an increase in cell proliferation, increase in cell survival, improper elimination of damaged cells, and/or a combination of all; and 2) to identify therapeutic targets by understanding the underlying cellular and signaling mechanisms involved.

#### Methods:

As part of the UC Davis MIND Institute Autism Phenome Project (APP) and Autism Centers of Excellence (ACE), we generated ~30 human iPSCs from cohorts of children (2-4 years old) with complete clinical and phenotypic data, including A) ASD subjects with megalencephaly, ASD-DM; B) ASD subjects with normal sized brains, ASD-N; C) Typically developing (TD) subjects with megalencephaly, TD-DM; and and D) TD subjects with normal sized brains, TD-N. We differentiated each of the iPSC lines into neural progenitor cells (NPCs) and oligodendrocyte progenitor cells (OPCs) and investigated changes at the molecular and cellular levels and alterations in phagocytosis in *in vitro* and *in vivo* models.

#### Results:

In the differentiated neural and glial progenitor cells, we observe increased proliferation and suppressed phagocytosis of NPCs/OPCs by macrophages in ASD-DM. RNA-sequencing of the differentiated progenitor cells reveals important signaling mechanisms related to the neuroimmune system in regulating cellular phagocytosis. Similarly, in genetic models of autism associated with brain enlargement, we show that CD47 (a 'don't eat me' signal) is overexpressed in both NPCs and OPCs in 16p11.2 deletion carriers with macrocephaly contributing to reduced phagocytosis *in vitro* and *in vivo*. Treatment of 16p11.2 deletion NPCs and OPCs with an anti-CD47 antibody to block CD47 restores phagocytosis to control levels. Furthermore, 16p11.2 deletion NPCs and OPCs upregulate cell surface expression of calreticulin (a pro-phagocytic 'eat me' signal), indicating that these cells should be phagocytosed but fail to be eliminated due to elevations in CD47.

#### Conclusions:

While the CD47 pathway is commonly implicated in cancer progression, we document a novel role for CD47 in regulating brain overgrowth in psychiatric disorders and identify new targets for therapeutic intervention. We demonstrate that anti-CD47 treatment can act as a therapeutic agent for clearing unhealthy cells in cellular and mouse models, potentially indicating that these forms of therapy could be translated to selected autistic individuals with brain overgrowth early in the disease. Furthermore, our study highlights that the balance between 'eat me' and 'don't eat me' signals may be more broadly playing critical roles during early neurodevelopment.

## ORAL SESSION — ANIMAL MODELS

### Oral 316 - Perturbing Genetic and Environmental Autism Risk Factors in Mouse Models

**316.002** (Oral) Generating a New ASD/ID Mouse Model By Deleting Epigenetic Factor ASH1L in Developing Brains  
**J. He<sup>1</sup>, Y. Gao<sup>2</sup>, N. Duque-Wilckens<sup>2</sup>, M. B. Aljazi<sup>2</sup>, G. I. Mias<sup>2</sup> and A. J. Robison<sup>2</sup>, (1)Biochemistry and Molecular Biology, Michigan State University, East Lansing, MI, (2)Michigan State University, East Lansing, MI**

#### Background:

ASH1L is an epigenetic factor that facilitates gene expression through modifying chromatin. Recent genetic studies reported that mutations of *ASH1L* are highly associated with human ASD/ID. The genetic findings are supported by multiple clinical reports that some children diagnosed with ASD and/or ID acquire various mutations of *Ash1L*. In addition to ASD/ID, patients also display a variety of developmental and behavioral abnormalities including delayed myelination, craniofacial deformity, skeletal abnormality, and feeding difficulties, suggesting critical roles of *Ash1L* in normal embryonic and postnatal development. However, the causal link between *ASH1L* mutations and clinical ASD/ID remains undetermined.

#### Objectives:

In this study we set out to use mice to address: (i) is loss of *Ash1L* in developing brains sufficient to induce ASD/ID-like phenotypes; and (ii) what are the possible molecular mechanisms linking *Ash1L* mutations to the pathogenesis of ASD/ID?

#### Methods:

Global *Ash1L* knockout (*Ash1L*-KO) and conditional *Ash1L* knockout in developing brains (*Ash1L*-nes-cKO) mice were generated to study the function of *Ash1L* in embryonic and postnatal development. Three-chamber tests, novel object recognition (NOR) tests, and open field assays were used to examine the sociability, social novelty, recognition memory, and anxiety-like behaviors of *Ash1L*-nes-cKO mice. RNA-seq analyses were used to examine the gene expression changes in the *Ash1L*-deleted neural progenitor cells (NPCs) during induced differentiation.

#### Results:

The three-chamber tests revealed that the deletion of *Ash1L* in developing mouse brains (*Ash1L*-nes-cKO) caused core autistic-like behaviors including impaired social interaction, repetitive and compulsive behaviors. The NOR and open field tests revealed that the *Ash1L*-nes-cKO mice displayed impaired cognitive memory and increased anxiety-like behaviors. In addition to the core ASD/ID-like defects, the deletion of *Ash1L* caused multiple developmental defects observed in human patients, which included early postnatal lethality, postnatal growth retardation, craniofacial deformity, and skeletal deformity. At the microscopic level, *Ash1L* deletion in developing brains resulted in delayed lamination during embryonic cortical formation and delayed myelination during early postnatal brain development. RNA-seq analysis revealed the deletion of *Ash1L* in neural progenitor cells impaired the expression of multiple genes critical for synapse formation and normal brain development.

#### Conclusions:

In this study, we generated a new ASD/ID mouse model by deleting an epigenetic factor ASH1L in developing brains. The loss of *Ash1L* gene alone in developing mouse brains is sufficient to cause autistic-like behaviors and ID-like deficits in adult mice, as well as multiple developmental defects that are observed in human patients, suggesting *ASH1L* gene mutations found in patients are likely to be the causative drivers leading to clinical ASD/ID. Gene expression analyses revealed that ASH1L plays an important role in activating the genes critical for normal brain development, providing a potential molecular mechanism linking *ASH1L* mutations to genesis of ASD/ID. As the new ASD/ID mouse model generated in this study recapitulates most clinical ASD/ID manifestations found in human patients, it provides an invaluable tool for further exploring the biological mechanisms underlying the pathogenesis of *ASH1L* mutations-induced ASD/ID, developing and testing new therapeutic approaches based on the functions of ASH1L and its regulated genetic pathways revealed by this study.

**316.003** (Oral) Influence of Maternal Genetics on Fetal Neurodevelopment in a Murine Model for PTEN-Associated Autism Spectrum Disorder

**R. Jaini<sup>1,2</sup>, M. R. Wolf<sup>1</sup>, Q. Yu<sup>1</sup>, T. W. Frazier<sup>3</sup> and C. Eng<sup>1,4,5</sup>, (1)Genomic Medicine, Cleveland Clinic Lerner Research Institute, Cleveland, OH, (2)Comprehensive Cancer Center, Case Western Reserve University School of Medicine, Cleveland, OH,**

**Background:** The genetic etiology of Autism Spectrum Disorder (ASD) is well established but complex. Most genetic studies in ASD have been focused on the proband, with little understanding of parental genetic contributions. Among parental factors, maternal inflammation due to autoimmunity, infections and toxins is recognized as a significant mediator of ASD. Associations between pregnancy loss/ASD risk and maternal autoimmune-susceptibility genes suggest a role for maternal genetics in *in-utero* inflammation mediated ASD. Murine studies on maternal inflammation in ASD have relied on experimental injection of strong inflammatory insults that elicit ASD-like behavior in the offspring. Therefore, the inherent impact of maternal genetics on ASD pathogenesis during *in-utero* neurodevelopment, without strong pro-inflammatory insults or ongoing inflammation has not been demonstrated. Moreover, the processes through which maternal genetics may modulate the penetrance of high-risk monogenic ASD genes in genetically predisposed offspring have not been investigated. *PTEN* is ranked as a category-1 ASD-associated gene, accounting for approximately 2% of all ASD and 17% of macrocephalic-ASD. With about 23% penetrance for driving ASD pathogenesis, *PTEN* mutations provide a good genetic model system to study additional impacts of environmental and genetic modifiers that help overcome the required threshold for disease development.

**Objectives:** In this study, we interrogated the inherent impact of maternal genetics predisposing to inflammation on fetal neurodevelopment under physiological conditions and in the absence of external inflammatory insults.

**Methods:** We used our *Pten<sup>m3m4</sup>* murine model to demonstrate the impact of maternal genotype on the penetrance of *Pten*-mutation-associated ASD-like phenotypes in the offspring. *Pten<sup>WT/m3m4</sup>* females were bred to *Pten<sup>WT/WT</sup>* males or *Pten<sup>WT/WT</sup>* females were bred to *Pten<sup>WT/m3m4</sup>* males to interrogate the offspring of a heterozygous mutant mother (Mom<sup>m3m4</sup>) versus of a wildtype mother (Mom<sup>WT</sup>). Maternal, placental, fetal liver and fetal brain were analyzed for inflammatory markers and nervous system cellular markers by multiplex ELISA (n=6 per group), immunohistochemistry (n=3 per group), nanostring RNA transcript analysis and bulk-RNA-sequencing (n=6 per group). Marble burying and three chamber sociability behavior tests were conducted on pups derived from mothers with different genotypes (n=10 per group).

**Results:** We show that maternal genetic predisposition to inflammation can alter immune responses to pregnancy leading to inadequate IL-10 mediated immunosuppression (< 4 pg/ml in 71.4% Moms<sup>m3m4</sup> vs 9% Moms<sup>WT</sup>, range 0-6.6pg/ml vs 0-16.2pg/ml, p=0.002). Lack of IL-10 induction in the mother was directly correlated with complement expression in the fetal liver indicating an impact on fetal physiology. Fetuses from mothers with a genotype predisposing to inflammation, had increased breakdown of the blood-brain-barrier, neuron loss and lack of glial maturation. This impact of maternal genotype was also evident postnatally on increased risk of newborn mortality (Chi<sup>2</sup>=66.66, p=0.001), visible macrocephaly (16% vs 0%, p=0.01) and ASD-like repetitive (p=0.0003) and social behaviors (p=0.04). Severity of post-natal ASD-like phenotypes was reflective of both maternal and offspring genotypes. Interestingly, non-predisposed (wildtype) offspring were also affected and disease penetrance was decreased in predisposed pups depending on the mother's genotype.

**Conclusions:** Our study highlights the importance of maternal genetics in fetal neurodevelopment merely via altering the immunosuppressive state during pregnancy.

## POSTER SESSION — ANIMAL MODELS

### Poster 403 - Animal Models Posters

**403.001 (Poster)** A Multifactorial Model for Autism Spectrum Disorder: Studying Gene-Environment Interactions between Genetic CNTNAP2 Deletion and Exposure to Maternal Immune Activation during Pregnancy

**F. L. Haddad<sup>1</sup>, C. DeOliveira<sup>1</sup>, M. Maroon<sup>1</sup> and S. Schmid<sup>2</sup>,** (1)University of Western Ontario, London, ON, Canada, (2)Anatomy and Cell Biology, University of Western Ontario, London, ON, Canada

**Background:** Currently, there is a lack of experimental approaches that attempt to target the complexity of causes of neurodevelopmental disorders such as Autism Spectrum Disorder (ASD). The epidemiology of ASD tells us that individual risk factors can only account for a small percentage of cases, and it is likely that multiple risk factors exhibit synergistic effects that lead to the manifestation of ASD.

Two prominent ASD risk factors are a genetic variation in contactin-associated protein like-2 (CNTNAP2) and exposure to maternal immune activation (MIA) during pregnancy. CNTNAP2 is a protein that plays a crucial role in brain development, and genetic variants of CNTNAP2 are linked with ASD. MIA occurs as a result of a viral or bacterial infection during pregnancy. MIA is known to impact the developing fetal brain, particularly when it occurs during early pregnancy. Rodent studies have

shown that either knock-out of the *cntnap2* gene or MIA at gestation day (GD) 9.5 lead to changes in sensory processing and cognitive ability as well as changes in synaptic structure, which potentially underlies the behavioural deficits seen in both rodent models.

**Objectives:** The goal of this study is to examine the interaction of the genetic and environmental impact by investigating whether MIA induces brain and behavioural changes in rats with a partial (heterozygous) *cntnap2* deletion and if it exacerbates phenotypes of rats with a complete *cntnap2* deletion (homozygous knockout).

**Methods:** Heterozygous (het) female *cntnap2* Ko Sprague Dawley rats were mated with het males and exposed to either saline or the immune stimulant polyinosinic polycytidylic acid (poly I:C) at GD9.5. Wildtype (WT), het or *cntnap2* ko animals born from 7 saline or 8 poly I:C dams were tested for changes in sensory reactivity, sensory filtering and sensorimotor gating using habituation and prepulse inhibition (PPI) of the acoustic startle response (ASR) at 6 weeks and 3 months of age. Additionally, attention and impulsivity were assessed in young adult offspring using the touch screen 5-choice serial reach time task (5-CSRTT).

**Results:** *Cntnap2* ko rats exhibited increased sensory reactivity at 6 weeks of age, as measured by amplitude of the ASR to sound intensities of 80 decibels or higher. On the other hand, 6-week poly I:C offspring, regardless of genotype, exhibit decreased long-term habituation (LTH) of startle, as measured by the change in startle reactivity across 4 days of testing. Neither poly I:C nor *cntnap2* deficiency impacted PPI or short-term habituation of startle. Testing of adult offspring is ongoing.

**Conclusions:** Our results indicate that the effects of poly I:C MIA may not synergize with those of *cntnap2* deficiency in our rat model at 6 weeks of age as measured by reactivity and habituation phenotypes of the ASR. Ongoing experiments are investigating these phenotypes as well as impulsivity and attention in the 5-CSRTT in adulthood, which is when more severe behavioural changes are seen in both rodent poly I:C and *cntnap2*<sup>-/-</sup> studies.

#### 403.002 (Poster) Altered Developmental Trajectory in Prenatal Valproate Rat Model of Autism Spectrum Disorder

**K. Anshu**<sup>1</sup>, **S. Srinath**<sup>2</sup> and **L. T. Rao**<sup>1</sup>, (1)Neurophysiology, NIMHANS, Bengaluru, India, (2)Child and Adolescent Psychiatry, NIMHANS, Bengaluru, India

---

**Background:** Converging evidence suggests that intervention programs for children with Autism Spectrum Disorder (ASD) are more effective when provided early in development. Prospective studies in children with high risk for ASD (younger siblings of children diagnosed with ASD) have demonstrated delayed acquisition of developmental milestones in social communication, motor, and sensory domains. This suggests that studying how ASD unfolds over the developmental trajectory from birth until the appearance of core symptoms, is a fundamental requirement for ASD research. Therefore, examining the developmental trajectory in animal models of ASD is crucial for understanding the mechanisms underlying the evolution of this complex developmental disorder and to explore early time windows for effective intervention.

**Objectives:** 1. Comprehensive assessment of the early developmental trajectory in a prenatal valproate (VPA) exposure rat model of ASD. 2. Creation of a composite developmental score integrating physical, sensory, and motor milestones.

**Methods:** Adult female and male rats were kept for overnight mating. Pregnancy was determined by the presence of a vaginal plug on the following morning (designated as embryonic day E1). On E12.5, prenatal VPA exposure (450 mg/kg sodium salt of valproic acid NaVPA, Sigma, dissolved in 0.9% saline solution at a concentration of 100 mg/ml) was administered using a single intraperitoneal (IP) injection while control dams received a single IP injection of 0.9% normal saline solution. Experiments were carried out on male and female offspring of the dams described above. Overall, 8 dams were used in the study resulting in 4 vehicle control (SAL) and 4 valproate (VPA) exposed litters with a total of 51 offspring (11 SAL male, 14 SAL female, 18 VPA male, and 8 VPA female). An extensive test battery encompassing physical, sensory, and motor developmental milestones during postnatal day 4 to postnatal day 21 was used to characterize early development in SAL and VPA pups. Standardized z-scores of all 15 readouts (higher values representing greater developmental delay) were combined to form a developmental composite score with high internal consistency (Cronbach alpha 0.76).

**Results:** VPA rats had significantly delayed milestones for physical (onset of incisor eruption and pinnae detachment), sensory (vibrissae placing, Limb placing, negative geotaxis) and motor (grasping reflex, level screen test, bar holding test) domains. Male and female VPA rats were almost similarly affected. Remarkably, the developmental composite score of individual rats effectively discriminated between VPA and SAL rats, and this contrast was particularly striking in males.

**Conclusions:** Prenatal VPA rats showed significantly altered developmental trajectory in male as well as female rats. Delay in early milestones indicates altered developmental programming of the central nervous system that might precipitate as core features of ASD later in childhood. Our results support clinical findings of altered early development in ASD. Considering the large heterogeneity in ASD phenotype, the developmental composite score provides a robust outcome measure to characterize overall early development in animal models of ASD and can be used to assess improvements after early intervention.

**403.003 (Poster)** Altered Maternal-Pup Behaviours in Developmental Vitamin D-Deficient Rats

**M. K. Tamang<sup>1</sup>, S. Alexander<sup>1,2</sup>, A. Ali<sup>1</sup> and D. Eyles<sup>1,2</sup>,** (1)Queensland Brain Institute, The University of Queensland, Brisbane, QLD, Australia, (2)Queensland Centre for Mental Health Research, Wacol, QLD, Australia

---

**Background:** Gestational or developmental vitamin D (DVD)-deficiency is an epidemiologically recognized risk factor for autism (Lee et al. 2019). Our lab has established a rat model of DVD-deficiency to investigate the neurobiological mechanisms implicated in DVD-deficiency (Eyles et al. 2003). Previous findings in DVD-deficient animals have pointed out the possible alterations in maternal stress response as a potential mechanism for altered behaviours in adult offspring (Eyles et al. 2006). Indeed, studies show that postpartum maternal care, primarily the frequency of licking/ grooming and arched-back nursing, influence several neural systems involved in offspring development (Meaney 2001).

**Objectives:** This study aims to examine maternal care and pup behaviours in DVD-deficient animals.

**Methods:** DVD-deficient rats were produced by methods already established in our lab (Ali et al. 2019). Postpartum maternal behaviours were video-recorded daily from postnatal day 2 (P2) to P6 in the home cages. Ultrasonic vocalizations (USVs) were recorded from each pup at P7 and P9 in a sound-attenuated chamber. Pup retrieval task was conducted in the home cage for each litter immediately after measuring their USVs at P7 and P9. Statistical significance was measured by multivariate analysis of variance (maternal behaviour and USVs) and student's t-test (pup retrieval).

**Results:** A total of 21 dams ( DVD n=12, Control n=9) were used for the maternal behavioural analysis. We found significantly increased licking and grooming ( $F_{1, 105}=9.918, p<0.05$ ) and blanket nursing ( $F_{1, 105}=4.716, p<0.05$ ) in DVD-deficient dams compared to controls. Similarly, USVs measurement showed that DVD-deficient pups emitted significantly increased number of calls ( $F_{1, 305}=6.194, p<0.05$ ) and longer duration of calls ( $F_{1, 305}=5.692, p<0.05$ ) compared to controls at P9 but not at P7. Call frequency and call amplitude were not different between control and DVD-deficient pups. The latencies to retrieve the pups were also not different between the control and DVD-deficient dams at both postnatal days.

**Conclusions:** Our current results show that maternal-pup interactions are altered in DVD-deficient animals. Studies have highlighted the implication of maternal care on several mechanisms affecting brain development, including altered hypothalamus-pituitary-adrenal function, oxytocin receptor expression, and synaptic plasticity in the offspring that might lead to long term effect on offspring brain development and behaviour. However, there is also a possibility that altered maternal behaviour observed in our DVD-deficient dams might have been driven by the pup's behaviour, such as increased USVs. This latter possibility remains to be explored.

**403.004 (Poster)** Assessment of Autism-Relevant Behaviors in C57BKS/J Leptin Receptor Deficient (db/+)Mice

**G. G. Gould<sup>1</sup>, S. M. Greene<sup>1</sup>, Y. R. Sanchez<sup>2</sup>, N. Pathapati<sup>1</sup> and G. N. Davis<sup>1</sup>,** (1)Cellular & Integrative Physiology, University of Texas Health Science Center at San Antonio, San Antonio, TX, (2)School of Nursing, University of Texas Health Science Center at San Antonio, San Antonio, TX

---

**Background:** Gestational diabetes mellitus (GDM), diagnosed by hyperglycemia arising in pregnancy, is a life threatening condition. Associations between GDM and increased risk of autism, either independently or with other risk factors such as maternal obesity or hypertension, have been uncovered. Leptin resistance and high plasma leptin are common in obese pregnancies. Disrupted leptin signaling may contribute to their coincidence, as it is found in both disorders. Given this we examined constitutive leptin receptor (Lepr) deficient (BKS.Cg-Dock7m +/+ Lepr db/J diabetic (db) heterozygous (db/+)) mice for autism-relevant behaviors. The mutation arose in the C57BKS/J (BKS) strain. BKS db/+ females are lean with normal blood glucose, but they develop GDM while pregnant. We hypothesized BKS db/+ offspring might exhibit physiological and behavior traits consistent with autism.

**Objectives:** Our primary goal was to screen db/+, BKS relative to C57BL6/J (BL6) mice for behaviors relevant to autism. An ancillary goal was to compare corticosterone, the mouse equivalent of human cortisol, for which disrupted diurnal cycles and stress responses are adolescent biomarkers shared by autism and fetal GDM exposure.

**Methods:** We compared behavioral and physiological traits of male and female BKS db/+ to less well-characterized BKS mice, and also BL6 mice commonly used as controls for other strains in autism research. Adolescent body weight, fasting blood glucose, and serum corticosterone were measured. Three chamber tests for social interaction and social novelty preference were performed. Self-grooming was measured during these tests, and marble burying was measured afterward. Social dominance was compared using a tube test in which each mouse was matched against 6 different 129S1/SvImJ mice. Mice pushing the other mouse out of the tube are winners, and mice backing out of the tube lose the match. After 3 min if no mouse exits it is considered a draw. Finally cognitive flexibility was compared using a water-T maze test for mice. A pre-training trial determined the preferred arm. A platform was put in the opposite arm from the preferred arm for 10 subsequent training trials. After each trial, mice were dried with towels to rest between trials while other mice were tested. There were 5 acquisition days, and 4 reversal days. Criteria for acquisition was met when mice correctly find the platform 80% of the time for 3 consecutive days.

**Results:** Male db/+ weighed more and had higher blood glucose and corticosterone relative to BKS or BL6 mice. Also, male db/+ had lower social interaction preference, explored arenas less, and buried more marbles than BL6 but not BKS males. Male and female db/+ were more dominant and made more mistakes in water T-mazes locating a sunken platform after its position was reversed than BL6, but not BKS mice. Overall BKS db/+, particularly males, exhibited some autism-like social deficits and restrictive-repetitive behaviors relative to BL6, but BKS strain contributions to BKS db/+ behaviors were also evident.

**Conclusions:** Genetic differences between BKS and BL6 strains are prominent contributing factors to BKS db/+ behavior phenotypes that can potentially impair the ability to detect GDM induced, autism-relevant developmental changes.

**403.005 (Poster) Attention to the Eyes Is Related to Maturation of the Visual Object Pathway in Infant Rhesus Macaques**  
**A. L. Ford**<sup>1,2</sup>, A. Wang<sup>2</sup>, J. Steele<sup>2</sup>, C. Payne<sup>1</sup>, S. Moss<sup>1</sup>, T. Jonesteller<sup>3</sup>, J. Wesson<sup>3</sup>, E. Feczko<sup>5</sup>, E. Earl<sup>6</sup>, L. Li<sup>7</sup>, M. Styner<sup>8</sup>, D. Fair<sup>9</sup>, W. Jones<sup>10</sup>, J. Bachevalier<sup>2</sup>, M. Sanchez<sup>2</sup> and Z. Kovacs Balint<sup>3</sup>, (1)Marcus Autism Center, Atlanta, CT, (2)Emory University, Atlanta, GA, (3)Yerkes National Primate Research Center, Emory University, Atlanta, GA, (4)Atlanta Speech School, Atlanta, GA, (5)Pediatrics, University of Minnesota, Medical School, Minneapolis, MN, (6)Oregon Health & Science University, Portland, OR, (7)Marcus Autism Center, Children's Healthcare of Atlanta, Emory University, Atlanta, GA, (8)Psychiatry and Computer Science, University of North Carolina, Chapel Hill, NC, (9)Masonic Institute for the Developing Brain, Minneapolis, MN, (10)Pediatrics, Emory University, Atlanta, GA

---

**Background:** Disrupted attention to the eyes of others in infancy is one of the earliest behavioral risk markers for Autism Spectrum Disorder. Typically, attention to the eyes increases during the first months of life as an adaptive means of scaffolding social development. However, the neural systems associated with this basic mechanism of social attention are currently unknown. Leveraging longitudinal data from rhesus macaque infants, an important model of human social development, we investigate functional connectivity (FC) within the visual ventral object pathway as a potential neural substrate. Connectivity in this pathway ultimately facilitates complex social cognition in rhesus macaques. Minimally developed at birth, this pathway matures in a caudal-rostral direction through the first months of life (Kovacs-Balint et al. 2019). During this period, infant macaques also show intense social development, yet how early visuosocial experiences relate to strengthening connectivity between regions along the ventral pathway is unknown.

**Objectives:** We use two bodies of densely sampled longitudinal data, eye-tracking and resting-state functional magnetic resonance imaging (rs-fMRI), to determine whether patterns of attention to the eyes of others are associated with FC changes in the maturing visual system

**Methods:** Eye-tracking data were collected from 31 male rhesus macaques (13 time-points), whereas rs-fMRI data were collected from a subsample of 21 animals (7 time-points) before 6 months of age. Attention to the eyes was measured as percent fixation while infants watched naturalistic videos of conspecifics (Wang et al. 2020). FC was calculated between regions of the ventral object pathway for the left and right hemispheres: primary visual cortex (V1), extrastriate visual cortex (V3), inferior temporal areas (TEO and TEp), and amygdala (AMY). Group mean and individual developmental trajectories were fit for both datasets using Functional Principal Components Analysis (FPCA) (Yao, Müller, Wang, 2005). Features of the individual trajectories for the 14 subjects with both eye-tracking and rs-fMRI data were extracted to test for relationships between social visual attention and FC development. Social rank for these 14 subjects was normalized to a percentile.

**Results:** Curve-fitting using FPCA reveals the primary component of variance across individual trajectories of FC captures magnitude. The secondary component of variance across individual trajectories of eye-looking captures the developmental timing of local maxima and minima. Linear regression between these components shows that infants with greater increases in FC between left V1 to V3, and left V3 to TEp have an earlier increase in eye-looking before 2 months and a more pronounced decrease in eye-looking at 2-3 months of age ( $p < .08$ ,  $p < .05$ ). Low ranking infants show accelerated trajectories of attention to eyes ( $p < .05$ ; Figure 1).

Conclusions: This is the first study to test associations between trajectories of functional brain development and social visual attention in rhesus macaques during the first 6 months of life. Data show that an infant's early social experiences are associated with earlier developing FC along the visual object pathway. This maturation in FC between areas of the visual object pathway may provide an important neural substrate supporting adaptive transitions in social visual attention during infancy.

**403.006 (Poster)** Bench to Bedside and Back: A Longitudinal Translational Study of Motor Outcome Measures in Individuals and Preclinical Models of Angelman Syndrome

**S. P. Petkova<sup>1</sup>, J. Duis<sup>2</sup> and J. L. Silverman<sup>1</sup>,** (1)Department of Psychiatry and Behavioral Sciences, MIND Institute University of California Davis School of Medicine, Sacramento, CA, (2)Pediatrics - Clinical Genetics and Metabolism, Children's Hospital Colorado Anschutz, Aurora, CO

---

Background: Angelman Syndrome (AS) is a genetic neurodevelopmental disorder characterized by developmental delay, lack of speech, seizures, intellectual disability, and walking and balance disorders. We have focused on motor ability as an outcome measure as movement disorders affect nearly every individual with AS. In AS, motor outcomes include ataxia, hypotonia, delayed walking, and posture anomalies and motor ability is highly correlated with more sophisticated behaviors such as cognition and communication. Motor outcomes present an outstanding yet understudied opportunity for direct translational studies to investigate pharmacological, dietary, behavioral, physical, and genetic therapies. Clear phenotypes have been widely published on these phenotypes clinically (Wheeler et al., 2017) and preclinically (Born et al., 2017; Berg et al., 2020). One pilot study in children with AS showed abnormal and stunted walking compared to an age matched typical developing group (Grieco et al. 2018).

Objectives: To date, gait studies have not been reported in any preclinical model of AS. Moreover, gait studies in AS patients are not extensive or definitive. The objective of this study was to investigate and precisely define motor abnormalities in AS individuals in parallel with translational behavioral methods in an AS mouse model to assess analogous motor outcomes. Additionally, development of abnormal gait was tracked longitudinally in the AS mouse model and cross-sectionally in AS patients.

Methods: Motor behaviors were assessed with multiple methods in AS patients aged 4-11 years including novel and innovative instrumented gait analysis, alongside more commonly used Zeno Walkway, and EMG recordings in a clinical setting as well as the Actimyo activity monitoring system in patients' home environment. In an AS mouse model, traditional motor behavior assays were used including gold standards of open field and the accelerating rotarod, and nuanced gait was studied using the digital and automated DigiGait treadmill system.

Results: For the first time, we demonstrated marked global motoric deficits in AS individuals and AS model mice on similar metrics. Many nuanced and pertinent differences were identified in quantitative spatial and temporal components and indices of gait between AS and typically developing individuals as well as between AS mice versus wildtype controls, elucidating and highlighting the predictive value of gait. These metrics were followed cross-sectionally in humans and longitudinally in mice to observe the progression of maladaptive gait in AS, clinically and preclinically. Finally, we observed specific kinematic and EMG findings in AS individuals that may underlie these specific motor difficulties.

Conclusions: Taken together, these findings demonstrate the robust translational value in the study of nuanced motor outcomes for AS, as well as other neurodevelopmental disorders that lack rigorous outcome measures, with the broad goal of improving bench-to-bedside successes.

**403.007 (Poster)** C58/J Mice with Autistic-like Phenotype Display Dendritic Spines' Abnormalities in the Prefrontal Cortex and Hippocampus

**I. Barón-Mendoza, E. Maqueda-Martínez, M. De la Fuente-Granada, M. Martínez-Marcial and A. González-Arenas,** Instituto de Investigaciones Biomédicas, UNAM, Mexico City, Mexico

---

#### **Background:**

ASD has a broad range of neurobiological characteristics, including structural plasticity-associated abnormalities, as alterations in dendritic spines. Due to dendritic spines represent approximately 90 percent of excitatory synapses, changes in their number or morphology would be related to the atypical brain communication that people with autism display.

There is evidence of ASD-related-dendritic spines alterations in monogenic mouse models of the disorder, but it is still missing data from spine changes associated with idiopathic autism. The C58/J mice is an inbred strain with autistic-like behavior, and it is considered a potential model for non-syndromic ASD.

### **Objectives:**

We aimed to analyze the changes in the number and morphology of dendritic spines in the pyramidal neurons from the prefrontal cortex and the hippocampus of C58/J autistic-like strain.

### **Methods:**

Brains of four male mice from C58/J (autistic-like) and C57 BL6/J (control) strains were stained through the Golgi-Cox technique. Data from the number, length, and width of approximately 6000 spines from the apical and basal dendrites of pyramidal neurons from layer II/III of the prefrontal cortex and CA1 region of the hippocampus were collected and analyzed. Spines were classified according to their morphological characteristics.

### **Results:**

We observed increased spine density in the apical dendrites of hippocampal neurons and decreased density in both apical and basal dendrites of the prefrontal cortex neurons of C58/J mice compared to control strain. According to length and width measurements, neurons of C58/J mice display longer dendritic spines with narrower heads. The shaped-based classification showed a higher number of long-thin and thin spines in the apical dendrites, along with an increased number of filopodia-like spines and lower mushroom spines with wide head in the basal dendrites of hippocampal neurons from autistic-like mice. In contrast, in the prefrontal cortex, we only observed fewer thin spines in the C58/J strain compared to the control mice.

### **Conclusions:**

There is a strong correlation between the morphology, function, and maturation state of dendritic spines; our results suggest a higher frequency of immature dendritic spines in the pyramidal neurons of the hippocampus and the prefrontal cortex of C58/J mice. These changes in the morphology of dendritic spines could be involved with atypical neuronal connectivity in both brain areas.

**403.008 (Poster)** Characterization of Behavior and Neurochemistry Following Social Stimulation in Oxytocin-Receptor-Mutants: Zebrafish Autism Model

*S. Shams<sup>1</sup> and L. Westberg<sup>2</sup>, (1)Pharmacology, University of Gothenburg, Gothenburg, Sweden, (2)Department of Pharmacology, University of Gothenburg, Gothenburg, Sweden*

---

**Background:** Intranasal administration of oxytocin has been recently reported to improve socialization in autistic patients and has shown promise as a potential treatment of social impairments seen in autism. Oxytocin is a neuropeptide that regulates a wide range of mammalian social and non-social behaviors that are relevant to autism, such as bonding, social recognition, and anxiety. As the mechanisms underlying social deficits seen in autism and oxytocin's role in improving social functions in autistic patients are not well-understood, animal models with capacity for sophisticated genetic manipulation and fast throughput screening are necessary. Zebrafish (*Danio rerio*) is a highly social vertebrate with phylogenetic conservation in oxytocin and relevant neurotransmitter systems, and relies more heavily on visual social information (not olfactory) and we exploit these features to improve animal modeling of social deficits present in autism.

**Objectives:** Involvement of the oxytocin system in mammalian social behavior is well-established, but the homologous system in zebrafish remains less discovered. Our aim is to build behavioral and neurochemical profiles of zebrafish with genetically manipulated oxytocin receptors to characterize the zebrafish oxytocin system and further establish a zebrafish model of social impairments relevant for autism.

**Methods:** We used adult (both males and females) CRISPR-Cas9-mutants lacking either of the two zebrafish oxytocin receptor genes, *oxtr* and *oxtrl*, and studied them in two different social behavioral tasks. We observed socialization between four fish (same-genotype,  $n \geq 20$  for each group) in a large open-field (40x body length) and measured shoaling, schooling, group excursions, general activity, and specific motor patterns of mutant and sibling control fish. We also measured responses of the mutant fish to automated visual-only social stimulus when individually placed in a separate tank and compared them with wild-type control fish. Following automated social stimulation, we also measured the levels of neurotransmitters and amino acids

(dopamine, serotonin, norepinephrine, glutamate, GABA, and glycine) in multiple brain regions using high precision liquid chromatography for these mutant fish and their wild-type control fish.

Results: Our data show that in the large ethologically-relevant open-field, zebrafish lacking oxytocin receptors display subtle differences in locomotion and anxiety-related behaviors, and significant deficits in social behavior. Group social behavior was affected by both *oxtr* and *oxtrl* mutation in a similar fashion. In contrast, we found that individual responses to automated visual-only stimulus was affected in *oxtr* mutant fish but not in *oxtrl* mutant fish. We also found differences in neurotransmitter levels in the measured brain regions (olfactory bulbs and telencephalon, mesencephalon, diencephalon, cerebellum & hindbrain), indicating a role of oxytocin in regulation of neurotransmitters associated with social and emotional behavior.

Conclusions: These results suggest that the two oxytocin receptor may play important but distinct roles in zebrafish social behavior. Further, these findings advance our understanding of neural mechanisms underlying oxytocin-regulated social interaction in zebrafish and highlight the potential of future investigation of zebrafish oxytocin system towards generating better therapeutic treatments for autism and related disorders.

**403.009 (Poster)** Characterization of KMT5B Haploinsufficiency in Mice Recapitulates Neurodevelopmental Disorder Phenotypes

**H. F. Stessman<sup>1</sup>**, R. Wickramasekara<sup>1</sup>, B. Robertson<sup>2</sup>, J. Hallgren<sup>1</sup> and J. Hulen<sup>1</sup>, (1)Pharmacology & Neuroscience, Creighton University School of Medicine, Omaha, NE, (2)Creighton University School of Medicine, Omaha, NE

---

Background: Recent sequencing efforts have highlighted lysine methyl transferase 5B (KMT5B) as a high-confidence neurodevelopmental disorder (NDD) risk gene associated with autism spectrum disorder (ASD) and intellectual disability (ID). KMT5B is the primary enzyme that di-methylates the lysine 20 residue of histone 4 (H4K20me2). It has been implicated in several cell processes including chromatin compaction, cell proliferation, cell cycle progression (G1-S phase transition), maintenance of quiescent stem cells pools, and double stranded DNA break repair. However, the role KMT5B plays in the developing brain is largely unknown.

Objectives: The goal of this work was to neurodevelopmentally characterize the effect(s) of KMT5B haploinsufficiency using a mouse model.

Methods: A *Kmt5b* gene-trap (+/gt) mouse line was obtained from the knockout mouse project (KOMP) repository at UC Davis. Wild-type (WT; +/+) and heterozygous (HET; +/-) progeny from WT x HET matings were subjected to a comprehensive neurodevelopmental test battery to assess reflexes, motor movement, learning/memory, social behavior, repetitive movement, and common ASD comorbidities (obsessive compulsion, depression, and anxiety). Given the strong sex bias observed in the ASD patient population, we tested both a male and female cohort of animals (>8 animals per genotype and sex) and compared differences between genotypes and sexes using 2-way ANOVA testing and post-hoc analyses.

Results: Initial HET x HET progeny showed sub-mendelian ratios of knockout (KO; gt/gt) pups starting after E18.5 ( $p=0.035$ ;  $\chi^2$  test) suggesting late-term or perinatal lethality. This was consistent with the absence of human patients carrying homozygous null *KMT5B* variation. Both WT and HET mice appeared healthy and were fertile; however, HET mice were significantly lower weight than WTs (males  $p<0.001$ ; females  $p=0.0001$ ) starting at P10 through young adulthood. This was more severe in males than females. HET neonates showed significantly weaker reflexes than WT littermates ( $p<0.01$ ; grasp strength and surface righting). Again, this was more severe in males. While no significant differences were seen based on genotype in the open field, elevated balance beam, rotarod, buried food, social approach, olfactory habituation/dishabituation, light↔dark, forced swim, and marble burying tests, there were significant differences between genotypes in the foot shock test ( $p<0.0001$ ) and extinction of conditioned fear ( $p=0.0058$ ). We also noted significant differences between sexes (but not genotypes) in the time to fall from the rotarod ( $p=0.0403$ ), first dark entry in the light↔dark test ( $p=0.0077$ ), speed in the elevated plus maze ( $p=0.0086$ ), escape in the Barnes maze ( $p=0.0003$ ), and the social preference test ( $p=0.0163$ ). Interestingly, several sexually dimorphic differences were noted including increased repetitive grooming behavior in HET females (Tukey's  $p=0.0042$ ), an increased latency to hot plate response in HET females versus a decreased latency in HET males ( $p=0.0029$ ), slower reversal learning in males in the Barnes maze (Sidak's  $p=0.0270$ ), and increased brain size in HET females (Sidak's  $p=0.0056$ ).

Conclusions: Our results identified several relevant behaviors impacted by KMT5B loss that may be probed by future studies to better understand the pathophysiology of this putative genetic subtype of NDD. We are specifically interested in the differences identified between sexes that suggest a female protective effect.

**403.011 (Poster)** Enriched Housing Alters the Trajectory of Pup Brain Early Development Via Maternal Behaviour

**C. Ligneul<sup>1</sup>**, R. Allemang-Grand<sup>2</sup>, M. Kaller<sup>1</sup>, J. Ellegood<sup>3</sup> and J. P. Lerch<sup>1</sup>, (1)WIN, University of Oxford, Oxford, United Kingdom, (2)The Hospital for Sick Children, Toronto, ON, Canada, (3)Mouse Imaging Centre, Hospital for Sick Children,

### **Background:**

During early life, the brain is particularly sensitive to environmental stimuli during key windows of development and early neurodevelopment is of particular importance in ASD mouse models. Environmental enrichment (EE) regulates adult ASD mouse behaviour and plasticity (Delorme et al, 2013) and induces rapid neuroanatomical changes in adult mice (Scholz et al, 2015). Impact of very early exposure to EE on neuroanatomical development remains unknown.

### **Objectives:**

The aim is to evaluate the impact of EE on early brain development when pups cannot explore their surroundings yet, and when maternal behaviour is the likely means whereby the environment is reflected on the developing brain.

### **Methods:**

Five primiparous pregnant CD1 dams were housed individually in standard housing (SH) or in EE cages (rat sized cage, containing a dome, a running wheel and a multilevel maze) at E13. Maternal behaviour was assessed at P3/P4 in 5 daytime sessions of (35+4x30)min. Pups were perfused at P7. 6 weeks later, dams were mated with their previous sire, and at E13 were housed in the same environment (SH - SH, 2 dams, or EE - EE, 1 dam), or switched (SH - EE, 1 dam, or EE - SH, 1 dam). Maternal behaviour was assessed and pups were perfused likewise. Pups' brains were scanned with a diffusion-weighted ( $b=1917\text{ms}/\mu\text{m}^2$ , 30 directions) 3D fast spin-echo MRI sequence ( $78\times 78\times 78\mu\text{m}^3$  resolution). The images were aligned using a series of iterative linear and nonlinear registrations steps (Avants et al, 2011; Friedel et al, 2014). A voxel-wise analysis was conducted, and multiple comparisons were corrected for using a 10% false discovery rate.

### **Results:**

One dam (SH-SH) delivered a highly disproportionated number of males, and was therefore discarded, as maternal behaviour has been suggested to be dependent on pups' sex. Pups born in EE notably display a volumic decrease in the nucleus accumbens and a volumic increase in the septohippocampal nucleus, the habenula and the periaqueductal grey (Figure 1A). The interaction between housing and litter (Figure 1B) reveals a consistent volume cross-over in these ROIs in the pups of dams who switched environments (from EE to SH or from SH to EE) between their two litters. Although dams' behaviour has to be interpreted cautiously due to the small number of dams, dams housed in EE spend on average more time in contact with their pups and are more engaged in nursing behaviours (Figure 1C). Interestingly, a cross-over matching neuroanatomical changes is observed: attention to pups is increased when switched to EE and decreased when switched to SH. It also seems generally increased for the 2<sup>nd</sup> litter, except for the EE-SH switch.

### **Conclusions:**

EE impacts pups' brain development, even before they can explore their environment (P7). At this stage, and as the behaviour data suggest, the sensitivity of pups' neuroanatomy to the environment likely reflects the different maternal care provided in different environments. Further analyses will explore the litter order effect on neuroanatomy. Exposure to different early environments might have an important and underappreciated impact in ASD mouse models.

### **403.012 (Poster) GABA<sub>B</sub> Receptor Agonist R-Baclofen Reverses Altered Auditory Reactivity and Filtering in the Cntnap2 Knock-out Rat Model for Neurodevelopmental Disorders**

**D. Moehrl<sup>1</sup>, W. Wang<sup>1</sup>, S. Whitehead<sup>2</sup> and S. Schmid<sup>3</sup>, (1)University of Western Ontario, London, ON, Canada, (2)Anatomy & Cell Biology, University of Western Ontario, London, ON, Canada, (3)Anatomy and Cell Biology, University of Western Ontario, London, ON, Canada**

---

**Background:** Altered sensory information processing, and auditory processing in particular, is a common impairment in individuals with autism spectrum disorder (ASD). One prominent hypothesis for the etiology of ASD is an imbalance between neuronal excitation and inhibition. The selective GABA<sub>B</sub> agonist R-Baclofen previously improved social deficits and repetitive behaviors in several mouse models for neurodevelopmental disorders including ASD, and R-Baclofen has shown to ameliorate social avoidance symptoms in some individuals with ASD.

**Objectives:** The present study investigated whether selective activation of GABA<sub>B</sub> receptors can remediate ASD-related altered sensory processing reliant on excitation/inhibition imbalance in the auditory brainstem.

**Methods:** We tested auditory reactivity, filtering and sensorimotor gating in form of acoustic startle reactivity, habituation and prepulse inhibition after acute administration of R-Baclofen (0.75, 1.5, and 3 mg/kg) in the *Cntnap2* knock-out (KO) rat model. In order to assess a possible excitation/inhibition imbalance in brainstem circuits mediating sensorimotor gating, we also detected and quantified GABA and glutamate neurotransmitter levels in the startle mediating PnC (nucleus reticularis pontis caudalis) as well as in the auditory cortex of *Cntnap2* wild-type (WT) and KO rats using Matrix-Assisted Laser Desorption Ionization Mass Spectrometry (MALDI MS).

**Results:** R-Baclofen treatment suppressed exaggerated auditory startle responses and improved disruptions in habituation in *Cntnap2* KO rats in a dose-dependent fashion, with the highest doses bringing animals close to control animals. Prepulse inhibition of the acoustic startle response (PPI) – an evaluation of sensorimotor gating – increased across various acoustic prepulse conditions after administration of R-Baclofen in *Cntnap2* KO, but it did not affect PPI in WT rats. MALDI MS analysis indicated differences in GABA and glutamate signal intensity between the PnC from *Cntnap2* WT and KO rats.

**Conclusions:** Our findings suggest that GABA<sub>B</sub> receptor agonists may be useful for pharmacologically targeting sensory processing disruptions involving neuronal excitation/inhibition imbalance in ASD.

We thank SFARI for providing R-Baclofen. This study was supported by CIHR and the Deutsche Forschungsgemeinschaft (MO 3857/2-1)

**403.013 (Poster)** Phenotyping Mouse Models of Angelman Syndrome Using Multidimensional Behavioral Clustering  
**J. K. Tanas<sup>1</sup>**, Y. Elgersma<sup>2,3</sup> and M. S. Sidorov<sup>4</sup>, (1)Children's National Hospital, Washington, DC, (2)Department of Neuroscience, Erasmus Medical Center, Rotterdam, Netherlands, (3)ENCORE Expertise Center for Neurodevelopmental Disorders, Erasmus Medical Center, Rotterdam, Netherlands, (4)Center for Neuroscience Research, Children's National Hospital, Washington, DC

---

**Background:** Angelman syndrome (AS) is a single-gene neurodevelopmental disorder with a multifaceted behavioral phenotype: deficits in motor function, epilepsy, cognitive impairment, impaired sleep, and other co-morbidities. Effectively modeling this behavioral profile and measuring behavioral improvement will be crucial for the success of ongoing and future clinical trials. Foundational studies have defined a suite of robust and reliable behavioral phenotypes in the AS mouse model. However, no single behavioral test is able to fully capture the complex nature of AS -- in mice, or in children.

**Objectives:** We seek to comprehensively quantify the behavioral profile of AS model mice.

**Methods:** Here, we use multidimensional analyses (principal component analysis + k-means clustering) to quantify combined performance across behavioral domains in a mouse model of AS.

**Results:** This approach successfully predicts the genotype of mice based on their behavioral profile using 2 principal components with >95% accuracy. >90% accuracy could be achieved using a single principle component.

**Conclusions:** Multidimensional analysis provides a platform to ask whether preclinical treatments for AS can improve the behavior of individual mice such that they can no longer be distinguished from their wild-type littermates based on behavior.

**403.014 (Poster)** Prenatal Exposure to Maternal Immune Activation Leads to Altered Dendritic Morphology in Dorsolateral Prefrontal Cortex in a Non-Human Primate Model  
**K. L. Hanson<sup>1</sup>**, R. K. Weir<sup>2</sup>, A. M. Iosif<sup>3</sup>, J. Van de Water<sup>4</sup>, C. S. Carter<sup>5</sup>, A. K. McAllister<sup>6</sup>, M. D. Bauman<sup>7</sup> and C. M. Schumann<sup>8</sup>, (1)Psychiatry, University of California Davis MIND Institute, Sacramento, CA, (2)Innovation & Enterprise Department, University College London, London, United Kingdom, (3)Public Health Sciences, University of California Davis, Davis, CA, (4)MIND Institute, University of California, Davis, Davis, CA, (5)Department of Psychiatry and Behavioral Sciences, University of California Davis, Sacramento, CA, (6)Center for Neuroscience, University of California Davis, Davis, CA, (7)UC Davis MIND Institute, Sacramento, CA, (8)MIND Institute, UC Davis, Sacramento, CA

---

**Background:** Women exposed to viral or bacterial infections during pregnancy are at an increased risk for having a child with autism, schizophrenia, or other neuropsychiatric disorders. Alongside genetic and environmental factors, maternal infection

during pregnancy, such as during the current COVID-19 pandemic, may represent a significant risk factor for the development of autism and related disorders by affecting brain development and morphology. Animal models of maternal immune activation (MIA) provide powerful translational tools for understanding the mechanisms that underlie deviations from typical development that lead to differences in behavior and cognition. Our previous studies demonstrated aberrant social behavior and attention in non-human primate offspring born to immune-challenged mothers. Preliminary findings suggest differences in dendritic morphology in the prefrontal cortex in offspring of PolyIC-treated rhesus macaque mothers.

**Objectives:** The present study analyzed the morphology of neurons in the brains of an extended cohort of MIA offspring to determine how maternal immune response during pregnancy may affect offspring brain development.

**Methods:** Pregnant dams were treated with a modified form of the viral mimic PolyIC in the first trimester (on gestational days 43-46, n=5) or second trimester (gestational days 100-103, n=4) or injected with saline (n=4) as a control. Treated dams showed immune responses characterized by increase in IL-6 levels and temperature and sickness behaviors as previously reported. At 3.5-4 years of age, brains of offspring (all male) were perfused with saline, and frontal lobe blocks were stained using the Golgi-Cox method. After 12 weeks, blocks were sectioned and mounted on slides for microscopic analysis. We identified pyramidal cells in the supragranular (II/III) and infragranular (V/VI) layers of Brodmann Area 9/46 in the dorsolateral prefrontal cortex (dlPFC) that met previously published inclusion criteria. Apical and basilar dendrites were traced in their entirety, and morphological measures were taken including cell soma size, total dendritic length, number of dendritic segments (an indicator of dendritic branching), and spine density and type.

**Results:** We found evidence for an increase in dendritic branching in pyramidal cells in both infra- ( $F_{2,10}=11.38$ ,  $P=0.026$ ) and supragranular ( $F_{2,10}=8.698$ ,  $P=0.007$ ) layers in the dlPFC in MIA-offspring brains as compared to controls, but no significant differences between first and second trimester MIA groups. We additionally found a significant effect of MIA on apical dendrite diameter in the infragranular layers of the dlPFC ( $F_{2,10}=7.675$ ,  $P=0.001$ ) in both MIA groups as compared to control, with no significant differences between first and second trimester MIA groups.

**Conclusions:** These results suggest that maternal immune challenge during pregnancy can affect cellular morphology at different timepoints of infection during pregnancy in specific regions of the brain important for executive and social function, with important implications for understanding the etiology of aberrant social behavior in neuropsychiatric disorders.

**403.015 (Poster)** Sex-Dependent Influence of Post-Weaning Environmental Enrichment in Angelman Syndrome Model Mice  
*A. D. Kloth, J. A. Cosgrove, L. K. Kelly and E. A. Kiffmeyer, Department of Biology, Augustana University, Sioux Falls, SD*

---

**Background:** Angelman Syndrome (AS) is a rare neurodevelopmental disorder caused by mutations or deletions of the maternal allele of UBE3A. AS in humans is marked by intellectual disability, ataxia, autism-like behaviors, and a happy, excitable demeanor. Considerable preclinical work has characterized the pathophysiology of AS in mouse models and examined possible therapeutic approaches, but so far there is no successful treatment in patients. One route to treatment may lie in the role the environment plays early in postnatal life, when the brain is highly plastic. Environmental enrichment (EE)—in which mice are provided with cognitive and physical enrichment—is one manipulation that has shown therapeutic potential in preclinical models of many brain disorders, including some neurodevelopmental disorders. Here, we examined whether postweaning environmental enrichment can rescue disease-relevant behavioral phenotypes in mice carrying maternal deletion of *Ube3a<sup>m-p/+</sup>* (AS mice), and whether any phenotypic improvements are sex-dependent.

**Objectives:** We investigated the degree to which chronic post-weaning environmental enrichment rescued the most penetrant behavioral phenotypes in AS mice on the C57BL6/J background. We performed these experiments separately in male and female mice to determine whether the response to enrichment was sex-dependent.

**Methods:** Mice (AS mice and *Ube3a<sup>m-p/+</sup>* controls) were randomly weaned with sex-matched littermates into standard shoebox housing (SH) or EE housing at P21. The enriched housing had a larger footprint, a running wheel, toys of different sizes, shapes, and colors and promoted foraging, burrowing, and climbing; toys were rotated twice weekly to add novelty to the environment. Following 6 weeks of enrichment, mice were submitted to a battery of tests that reliably demonstrate behavioral deficits in AS mice (Sonzogni *et al.*, 2018), including rotarod (motor coordination), open field (exploration and anxiety), marble burying (repetitive behaviors); weights were also monitored. These experiments were performed for both male and female mice; in total, there were 8 experimental groups with at least 12 mice per group. Experimenters and behavioral scorers were blind to genotype.

**Results:** We were able to replicate well-established sex-independent deficits in all of the aforementioned behaviors in SH-AS mice. In male AS-EE mice, we found complete restoration of motor coordination to the level of SH-control mice, a partial and statistically significant enhancement of marble burying behavior, and complete rescue of exploratory distance traveled and center

time in the open field, but we found no rescue of vertical behavior in the open field. EE-control mice showed small-to-modest enhancements of these behaviors. AS-EE also had weights comparable to SH-control mice. Intriguingly, in the female AS-EE, we found a complete failure to rescue any of the behavioral deficits relative to female SH-control mice, but weights were at SH-control levels.

**Conclusions:** Environmental enrichment over a relatively short period of time is an effective route to correcting the most penetrant, disease-related phenotypes seen in AS male mice. Future study will examine other highly reproducible cellular and electrophysiological defects to determine if they, too, are rescued in male mice. In addition, we will examine whether altering the parameters of environmental enrichment may lead to similar changes in female mice.

**403.016 (Poster)** The Mitochondrial Transporter Aralar: A New Target for Treatment of Social Behavior Deficits  
*A. K. Kanellopoulos<sup>1</sup>, V. Mariano<sup>1</sup>, T. Achsel<sup>1</sup> and C. Bagni<sup>1,2</sup>, (1)Department of Fundamental Neurosciences, University of Lausanne, Lausanne, Switzerland, (2)Biomedicine and Prevention, University of Rome Tor Vergata, Rome, Italy*

---

**Background:** Social impairment is frequently associated with mitochondrial dysfunctions and altered neurotransmission.

**Objectives:** While mitochondrial function is crucial for brain homeostasis, it remains unknown whether mitochondrial disruption contributes to social behavioral deficits.

Our laboratory has recently shown that fly mutants in the homolog of the human *CYFIP1*, a gene linked to autism and schizophrenia, exhibit mitochondrial hyperactivity and altered group behavior (Kanellopoulos et al. *Cell*, 2020).

**Methods:** Here, we used *Drosophila melanogaster* and performed behavioral, genetic, pharmacological and metabolic assays.

**Results:** Our study provides causal evidence linking mitochondrial energy production through the TCA cycle to alterations in GABA metabolism and further uncovers a mechanistic link between these molecular processes and alterations in behavior in social groups. Specifically, increased mitochondrial activity causes GABA sequestration in the mitochondria, reducing GABAergic signaling and resulting in social deficits. We identify Aralar as the mitochondrial transporter that sequesters GABA upon increased mitochondrial activity and identified, through different types of screenings, molecules that modulate Aralar activity.

**Conclusions:** This study greatly increases our understanding of the molecular mechanisms underlying aberrant mitochondrial functions and its impact on brain pathophysiology and social behavior.

*Reference : Kanellopoulos, A. K. et al. Aralar sequesters GABA into hyperactive mitochondria, causing social behavior deficits. Cell 180, 1178–1197 (2020).*

## POSTER SESSION — BEHAVIORAL GENETICS

### Poster 404 - Behavioral Genetics Posters

**404.001** (Poster) A Preliminary Investigation into Childhood Autism and Attention Deficit Hyperactivity Phenotypes in PAX6 Confirmed Aniridia

*N. Oluonye<sup>1,2</sup>, M. Moosajee<sup>3,4,5,6</sup> and N. Dale<sup>7,8</sup>, (1)Neurodisability Service, Great Ormond Street Hospital for Children NHS Foundation Trust, London, United Kingdom, (2)Paediatrics, Moorfields Eye Hospital NHS Foundation Trust, London, United Kingdom, (3)The Francis Crick Institute, London, United Kingdom, (4)Ophthalmology, Great Ormond Street Hospital for Children, London, United Kingdom, (5)Molecular Ophthalmology, UCL Institute of Ophthalmology, London, United Kingdom, (6)Genetics, Moorfields Eye Hospital, London, United Kingdom, (7)Psychological Services / Neurodisability service, Great Ormond Street Hospital for Children NHS Foundation Trust, London, United Kingdom, (8)UCL Great Ormond Street Hospital Institute of Child Health, London, United Kingdom*

#### Background:

Children with visual impairment are at increased risk of neurodevelopmental disorders with attentional difficulties (ADHD) present in up to 15.6% and autism diagnosed in up to 33% of children with profound visual impairment. Inheritance of autism and ADHD is multifactorial, with familial evidence of neurobiological basis in twin to twin studies and only a small number of genes identified as being causative.

Neurodevelopmental disorders have been linked to intragenic mutations of the *PAX6* gene on Chromosome 11p13, which encodes a transcription factor expressed in the early development of the eye, brain and other tissues. These mutations, of which 500 variants have been registered, cause loss of function of one of the genes, resulting in congenital aniridia, a rare sight threatening disorder with a prevalence rate of 1:40,000- 1:100,000. 2/3 of cases occur sporadically with the rest (familial aniridia) inherited in an autosomal dominant fashion.

#### Objectives:

To explore the neurodevelopmental phenotypes of children with isolated familial and sporadic aniridia.

#### Methods:

A retrospective case note review was carried out and screening questionnaires completed by parents of children with complete or partial aniridia. Children with additional genetic mutations or chromosomal rearrangements were excluded. All children had molecularly confirmed *PAX6* variants. Parents completed the Goodman's Strengths and Difficulties Questionnaires (SDQs) and Social Responsiveness Questionnaires - 2<sup>nd</sup> Edition (SRS-2). Verbal subtests of the Wechsler Preschool and Primary Scale of Intelligence or Wechsler Intelligence Scale for Children were administered to children who had undergone a full neurodevelopmental assessment at the time of the study.

Additional tests of attention (TEA-Ch), executive functioning (BRIEF) and direct and indirect observations were made of social communication skills.

#### Results:

23 children were identified, 18 of whom met the inclusion criteria. 6 families were either uncontactable or did not return questionnaires yielding a final cohort of 12 children. Participants were aged between 4.5 -15.5 years, with male: female ratio of 2:1. Best corrected visual acuity was within the moderate-severe range (LogMAR 0.6-1.1). All children but two (siblings) had different intragenic mutations.

66% of the children were of average to above average intellect.

SDQ's-Clinically significant scores:

- 54% of parents reported high levels of stress.
- 50% of the children had emotional difficulties.
- 58% had conduct problems.
- 58% reported peer relationship difficulties.
- 67% had hyperactivity.
- 75% had prosocial difficulties.

SRS-2: 75% scored within the clinically significant range for consideration of autism spectrum with 83% of parents reporting repetitive behaviours.

Co-morbidities: 36% of the children were on medication for ADHD, 24% had mental health concerns such as depression, anxiety or suicidal ideation, with intellectual disability, dyslexia or specific learning disability in 33%.

Conclusions:

Children with molecularly proven *PAX6* gene mutations appear to be at increased risk of hyperactivity, ADHD and autism than their similarly sighted peers. This may in part be due to the effects of visual impairment, but correlation with the *PAX6* gene mutation seems to be a risk factor. Additional mental health co morbidities are present, with reported anxiety, depression and suicidal ideation. Larger studies are required to further quantify genotype-phenotype correlation.

**404.002** (Poster) Binocular Rivalry Dynamic Discriminates Autism Genetic Subgroups

**Y. B. Choi<sup>1</sup>**, **J. Mentch<sup>1,2</sup>**, **C. Van Wicklin<sup>2</sup>** and **C. Robertson<sup>1</sup>**, (1)Psychological and Brain Sciences, Dartmouth College, Hanover, NH, (2)Massachusetts Institute of Technology, Cambridge, MA

---

Background:

Given the striking variability in genetic and phenotypic profiles associated with autism, identifying robust behavioral endophenotypes remains a crucial next step to improve diagnosis and individualized treatment. Close characterization of the neural and behavioral phenotypes caused by rare single-gene alterations with high penetrance for autism provides a promising approach as they may have a relatively more focused effect on neurobiology. Recently, our lab has identified one sensory paradigm as a compelling candidate for objective and non-invasive endophenotype: binocular rivalry. Binocular rivalry is a simple visual task during which two different images, presented separately to each eye, lead to alternations in perceptual awareness over time and has been linked to the balance of inhibition and excitation (E/I) in the visual cortex. Its dynamics are also under substantial genetic control and most importantly have been shown to be altered in individuals with autism and predictive of symptom severity.

Objectives:

The current study aimed to characterize binocular rivalry dynamics – a behavioral index of E/I balance in visual cortex - in individuals with two rare genetic events that are highly penetrant for autism: fMR1 and 16p11.2 deletions.

Methods:

Seventy-three adolescents and adults (28 with 16p; 17 Fragile X; 28 controls) were recruited, 65 of whom were able to complete the rivalry experiment (26 16p; 11 Fragile X) and matched for age. All participants had normal or corrected-to-normal vision.

Participants completed the non-verbal subtest of Kaufman Brief Intelligence Test (KBIT), and the participants or their parents completed the Autism Spectrum Quotient survey. Rivalry experiments were completed in lab or at remote locations at various conferences with portable head-mounted virtual reality (VR) headset to assure standardized testing conditions across locations.

After thorough instruction and practice with the task, participants completed a binocular rivalry paradigm. On each trial (5 trials, 45sec each), two (red/green) images were presented to an individual's left/right eyes and participants continuously reported whether they perceived the red, green or a mixture of the two images by button press. We compared individuals' performance on the binocular rivalry paradigm, as well as control paradigms assessing motor latency (2 trials, 45sec each) and perceptual decision thresholds (2 trials, 45sec each) across genetic groups.

## Results:

We compared rivalry transitions and switch rates in all three populations: fMRI, 16p11.2, and control individuals. On average, controls switched 10.5 times per trial, (14 times per minute). Switch rates for the 16p11.2 group were significantly slower than controls, at 7.8 times per trial (10.4 times per minute;  $p=0.04$ ). In contrast, switch rates for the fMRI group were comparable to controls 10 times per trial (13.3 times per minute;  $p=0.47$ ). We also compared performance on rivalry replay conditions assessing motor latency and perceptual decision thresholds.

## Conclusions:

Here, we find that rivalry dynamics stratify genetic populations with high penetrance for autism. These results suggest that visual functions like binocular rivalry may effectively identify more homogeneous subgroups of the autism spectrum on the basis of on common genetic and neurobiological alterations. Future studies seek to understand the neural basis of these effects.

### **404.003** (Poster) Developmental Milestone Attainment in Genetic Conditions from SFARI Registries

**J. Wickstrom<sup>1</sup>, S. Bishop<sup>2</sup>, C. Farmer<sup>1</sup>, L. Green Snyder<sup>3</sup>, A. R. Mitz<sup>1</sup>, S. J. Sanders<sup>4</sup> and A. Thurm<sup>1</sup>,** (1)National Institute of Mental Health, Bethesda, MD, (2)University of California San Francisco, San Francisco, CA, (3)Simons Foundation, New York, NY, (4)Department of Psychiatry, Weill Institute for Neuroscience, UCSF School of Medicine, San Francisco, CA

---

**Background:** Behavioral phenotyping allows us to understand differences among individuals with specific genetic conditions. While there is scant data on newly identified genetic conditions associated with neurodevelopmental conditions, there is extant literature on more common behaviorally-defined conditions, such as Autism Spectrum Disorder (ASD). Expected ages of milestone attainment are readily available for children with typical development, providing a normative standard by which to compare children with recognizable delays. Charting early milestone attainment in neurodevelopmental conditions, including those with specific genetic etiologies, may allow for the early identification of developmental phenotypes and ultimately inform intervention (Bishop et al., 2017; Vorstman et al., 2017).

**Objectives:** The purpose of this study was to: 1) determine ages of attainment of motor and language skills in genetic conditions associated with ASD and other neurodevelopmental disorders, and 2) determine which genetic conditions, in comparison to idiopathic ASD, exhibit pronounced delays in the attainment of motor and language milestones. Given existing data, we expected that genetic groups would exhibit a greater percentage of delays in motor milestones compared to the idiopathic ASD group. In addition, we expected that groups with genetic conditions would experience a greater percentage of delays and failure to attain skills across all milestones, in comparison to the idiopathic ASD group.

**Methods:** Participants in this study included individuals who consented and completed target measures in one of two Simons Foundation Autism Research Initiative (SFARI)-funded registries: Simons Searchlight and SPARK (refer to Table 1 for participant demographics). For Searchlight, we used data from 14 conditions (i.e., 4 CNVs: 1q21.1 deletion, 1q21.2 duplication, 16p11.2 deletion, 16p11.2 duplication; 10 Single Genes: *ADNP*, *ASXL3*, *CSNK2A1*, *DYRK1A*, *GRIN2B*, *PPP2R5D*, *SCN2A*, *SLC6A1*, *STXBPI*, *SYNGAP1*). Data from SPARK were used as an idiopathic ASD control group. Across both registries, inclusion criteria for analyses were: 1) minimum age of 36 months, 2) confirmed genetic testing results, and 3) availability of milestone data. Implausible ages to attain a milestone were converted to missing data.

**Results:** As shown in Figure 1, the majority of genetically-defined groups exhibited greater motor delays and several showed more language delays than the idiopathic ASD group. Delay and failure to attain language skills were more prominent than motor delays across all conditions. Groups with single gene mutations had the greatest percentage of delays across all milestones, followed by groups with CNVs, in comparison to the idiopathic ASD group.

**Conclusions:** These results increase our understanding of early developmental milestone trajectories in genetically-defined subgroups and idiopathic ASD. It is important to contextualize these results by noting that ascertainment bias is likely at play here, given these samples were enrolled based on genetic testing. Discovering early developmental phenotypes may have important implications for clinical identification as well as treatment targets and outcome measures. Ultimately, this work may be critical for identifying neurobiological mechanisms involved in the manifestation of neurodevelopmental disorder phenotypes.

### **404.004** (Poster) Genetic Risk Profiling of Insomnia in Autism

**M. Niarchou<sup>1</sup>, E. V. Singer<sup>1</sup>, B. A. Malow<sup>2</sup> and L. Davis<sup>1</sup>,** (1)Vanderbilt University Medical Center, Nashville, TN, (2)Sleep Disorders Division, Department of Neurology, Vanderbilt University Medical Center, Nashville, TN

---

**Background:** Sleep problems, particularly insomnia, are common in individuals with autism, and affect their quality of life and daytime behaviour. Insomnia in the general population is heritable and influenced by many genetic risk factors. Studies have indicated that the autism polygenic risk scores (PRS) (i.e., composite measure of genetic risk) can distinguish autism cases from controls and predict autism. Insomnia PRS similarly distinguishes those with insomnia from controls in the general population. However, there is no research to date examining whether insomnia PRS could be used to predict insomnia in individuals with ASD.

**Objectives:** We aimed to characterize sleep problems in the Vanderbilt Electronic Health Records and examine the genetic contribution of insomnia PRS established in the typically developing population, to risk of insomnia in individuals with autism.

**Methods:** We identified 349 individuals with autism and genetic data and confirmed their autism diagnosis through expert curation of their medical charts. We further characterized the sleep problems of these individuals, and constructed PRS of insomnia using the largest Genome Wide Association Study (GWAS) to date. We examined whether the PRS of insomnia predicts insomnia while also adjusting for sex, age at the time of the chart review, and the 10 principal components of genetic ancestry.

**Results:** Sixty-three percent of the individuals with autism had insomnia. The association between the insomnia PRS and insomnia in individuals with autism was not significant ( $b=0.02$ ,  $p=0.48$ ). To examine whether this result is due to low power or whether this is due to different genetic architecture of insomnia in individuals with autism compared to individuals in the general population, we examined whether the insomnia PRS are associated with sleep disorders (as defined using the corresponding ICD9 and ICD-10 codes for sleep disorders) in individuals in BioVU, regardless of whether they have autism. In a sample of 3,097 cases and 42,456 controls, we found that the insomnia PRS were higher in cases than controls ( $b=0.004$ ,  $p=0.0002$ ). We then downsampled this analysis, by randomly selecting 228 individuals with sleep disorders and 121 controls without sleep disorders, to see if the association with the insomnia PRS remains. The results were not significant ( $b=0.03$ ,  $p=0.25$ ). These findings indicate that the reason why we did not see a significant association in the BioVU autism sample, is likely due to power. By the time of the conference, we will provide results using a larger sample of 903 individuals with autism and insomnia and 2,584 controls.

**Conclusions:** Our study is the first to derive genetic risk profiling of insomnia in autism, paving the way for precision medicine in sleep and autism. Our findings indicate the genetic architecture of sleep problems in individuals with autism is likely similar to this of the sleep problems in individuals without autism.

---

**Background:**

Autism has a strong genetic component and is characterised by early brain processing atypicalities (De La Torre-Ubieta et al., 2016). However, how polygenic liability for autism relates to differences in brain development is not yet clear and there is no consensus on whether general neurodevelopmental or condition-specific mechanisms underlie autism emergence. In this study we examined the link between polygenic liability for general psychiatric or autism-specific outcomes, and early neural signatures of atypical face processing. The latency of the N170 event-related potential (ERP) in response to faces has been consistently considered a biomarker of autism in adults (Kang et al., 2018). Reduced differentiation between face and control non-face stimuli for the latency of the N290, precursor of the N170, has been previously shown to be predictive of autism diagnosis in infants with a family history of autism (Tye, Bussu et al., in press), and might represent an early sign of emerging brain processing atypicality in infants with elevated genetic liability.

**Objectives:**

In a subset of the cohort studied by Tye et al., we investigated group differences in the N290 latency at 8 months in infants at Elevated Likelihood (EL) and at Typical Likelihood of autism (TL) with EL subgroups based on neurodevelopmental outcome at

3 years. Subsequently, we linked this neural marker to autism and cross-disorder (xDx) polygenic scores to investigate polygenic contributions to early neurocognitive profiles.

#### Methods:

Electroencephalography (EEG) data recorded during a face/non-face paradigm and genome-wide genotype data were available for 102 infants (50 females) who participated in the British Autism Study of Infant Siblings (BASIS). 21 were TL infants, 46 were EL infants with typical development (EL-TD), 14 received a diagnosis of autism (EL-Aut) and 21 did not meet criteria for autism but showed signs of other neurodevelopmental difficulties (EL-Other) at 3 years. N290 latency difference between face and non-face stimuli (F-N 290 latency) was compared between the four outcome groups. Polygenic scores for autism (Grove et al., 2019) and xDx (Schork et al., 2019) were computed ( $p_T \leq 1$ ) and regression analyses conducted to test the association with F-N 290 latency.

#### Results:

F-N 290 latency significantly differed by outcome group ( $F(3, 96)=3.361, p=0.022$ ), consistent with Tye et al. Planned contrasts revealed that longer N290 latency to faces was found in the TL compared to the EL groups (TL vs EL,  $p=0.010$ ), with no significant difference based on autism or general neurodevelopmental outcome. F-N 290 latency was significantly negatively associated with xDx polygenic score ( $p_T=0.5$ ;  $R^2=0.063, p=0.014, FDR=0.048$ , Figure 1A) but not robustly associated with the autism polygenic score ( $FDRs>0.213$ , Figure 1B).

#### Conclusions:

These findings suggest that reduced brain responses to faces in infancy might emerge in the presence of general genetic factors that increase the liability for neurodevelopmental and psychiatric conditions. Future studies will need to replicate these results in larger developmental samples and leverage longitudinal data to identify what factors interact with genetic background to shape developmental trajectories in individuals with autism.

#### **404.006 (Poster)** Relationships between Autism Risk Genes, Vascular Signaling, and Behavior in Autism Spectrum Disorder: A Pilot Study

**G. Barnes<sup>1</sup>, X. Qiu<sup>2</sup>, K. Ojha<sup>1</sup>, R. Jagadapillai<sup>3</sup>, E. Gozal<sup>4</sup> and S. Zou<sup>5</sup>,** (1)University of Louisville School of Medicine, Louisville, KY, (2)Jiangxi Provincial Children's Hospital, Jiangxi, China, (3)Departments of Pediatrics, PRI, University of Louisville, Louisville, KY, (4)Pediatrics, PRI, University of Louisville, Louisville, KY, (5)Child Healthcare, Jiangxi Provincial Children's Hospital, Jiangxi, China

#### Background:

Autism Spectrum Disorder (ASD) is the most common neurobiological disorder (2%) in pediatric populations. Emerging evidence suggest that genetic factors may constitute up to 80% etiologies in ASD. Physicians are increasingly faced with clinical populations who need a multidisciplinary approach for treatment, and yet lack the tools for precision medicine to personalize treatments. Recent systems biology approaches may provide an unprecedented opportunity to test novel therapeutic strategies targeting molecular pathways such as vascular signaling to alleviate ASD symptoms and behavioral deficits in an ASD.

#### Objectives:

The aims of this study were to: 1) identify gene variants of vascular signaling associated with autism behaviors in specific neural circuits; and 2) identify whether vascular signaling gene variants promote neuroinflammation and BBB dysfunction in an animal model of autism and epilepsy.

#### Methods:

A clinical database of autism subjects (N=775) was queried for individuals both with and without seizures who had a CNV on microarray, Vineland, and Parent Concern Questionnaire scores (N=117 subjects). Pathway analyses of genes from these CNVs ( $P=0.001$ ) yielded 659 genes whose protein-protein interactions (Pearson's coefficient=0.9) and mRNA expression (Pearson's

coefficient=0.7) mapped 121 genes with maximal antenatal expression (PCW12-40 PCW) in 12 brain regions. A map of the neural circuits derived from Research Domain Criteria (RDoC) revealed significant differences in anxiety, motor, and activities of daily living skills scores between CNV genes and normal microarray subjects.

#### Results:

The RDoC neural circuits involved include the Positive Valence (reward), Cognition (IQ), and Social Processes. Among these genes, we did identify that vascular signaling, as a biological process, may influence the function of these neural circuits. ASD pathogenesis may involve various mechanisms including chronic neuroinflammation, GABAergic imbalance, monoaminergic dysregulation and mitochondrial dysregulation. Several lines of evidence point to ongoing neuroinflammation with microglial activation in the brain of individuals with ASD, as well as increased levels of inflammatory mediators. Deletion of one such vascular pathway of the blood-brain barrier (BBB), Semaphorin 3F- Neuropilin 2 (Sema 3F-NRP2) signaling, results in brain weight loss, EEG changes, and autism-like behaviors. Substantial evidence of neuroinflammation, including activation of microglia, iNOS, and 3-nitrotyrosine expression increases are observed. Signs of platelet deposition, activation, and release of serotonin occur in multiple brain regions important in ASD. Finally, along with platelet products, albumin leakage and uptake and outlining of neurons in these regions suggest possible deficits in the blood brain barrier.

#### Conclusions:

Disruption of neurovascular signaling molecules, such as Sema 3F-NRP2, may mediate causative pathophysiology in some subgroups with ASD via neuroinflammation, oxidative stress, and compromised BBB integrity. Although preliminary, these data clearly point at a possible first step toward the development of potential novel therapeutic pathways using clinically derived data, genomics, and cognitive and basic neuroscience methods.

---

**Background:** Longitudinal studies have suggested that the development of adaptive behavior in children with Autism Spectrum Disorders (ASD) can follow multiple distinct trajectories, with some children showing improvement while others plateau or regress. While increased detection of specific genetic etiologies has been helpful for prognostication, we remain limited in our ability to predict trajectory for most children with ASD. One possibility is that common variants in genes that affect the brain's response to different environmental circumstances may play a role. For example, the short (S) allele of the promoter region of *SLC6A4*, encoding the serotonin transporter protein, has been associated with increased susceptibility to cognitive and behavioral stress.

**Objectives:** We sought to determine whether dosage of the *SLC6A4* S allele influences adaptive behavior in children with ASD using retrospective clinical data. As much of the adaptive behavior data was collected during the Covid-19 pandemic, this afforded a unique opportunity to assess the relationship between the S allele and neurobehavioral outcomes at a time of high environmental stress, when differential effects of this variant may be expected to be most pronounced.

**Methods:** We identified 26 children in our clinical population with two administrations of the Vineland Adaptive Behavior Scales (VABS3) at least 4 months apart (mean  $190 \pm 5.1$  days, range 147-271 days), who also had pharmacogenomic testing including *SLC6A4*. We constructed a multivariate regression model to estimate effects of *SLC6A4* variants on VABS3 outcomes. The dependent variables were differences in standard scores for VABS3 Adaptive Behavior Composite (ABC), Socialization (Soc), Communication (Com), and Daily Living Skills (DLS) between the two assessments. The predictor variable was number of copies of the *SLC6A4* S allele. Covariates included level of severity (based on initial ABC scores), sex, age, and epoch – i.e., whether the final assessment was conducted before or after shelter-in-place (SIP) orders were issued in California, where all children in this sample resided.

**Results:** The overall multivariate model accounted for a significant proportion of the variance in ABC ( $R^2 = 0.71$ ,  $p = 0.016$ ) and the subscales Com ( $R^2 = 0.83$ ,  $p = 0.005$ ) and DLS ( $R^2 = 0.70$ ,  $p = 0.019$ ), but not Soc. Dosage of the S allele was a significant negative predictor of improvement in overall ABC ( $p = 0.003$ ), Com ( $p < 0.001$ ), and DLS ( $p = 0.012$ ). Of covariates included in the model, male sex was associated with worse outcomes in ABC ( $p = 0.007$ ) and subdomains. Children assessed prior to Covid-19 SIP showed significantly greater improvements in DLS ( $p = 0.02$ ), but not in other subdomains.

Conclusions: In this sample of 27 children with moderate to severe ASD, number of copies of the S allele of *SLC6A4* was a significant predictor of worse outcomes over approximately 6 months, in most cases coinciding with the Covid-19 pandemic. This may indicate that susceptibility to environmental stress modulates developmental trajectories in children with ASD. Further research will be required to determine whether this association is more generalized, and whether it can be modified by targeted interventions.

**404.008 (Poster)** The Cumulative Load of Early Medical Adversities on the Causal Pathway for Autism - a Population-Based Twin Study

**T. Carlsson<sup>1</sup>, S. Bolte<sup>2</sup> and M. Taylor<sup>3</sup>,** (1)Department of Women's & Children's Health, Center for Neurodevelopment Disorders at Karolinska Institutet (KIND), Stockholm, Sweden, (2)Center of Neurodevelopmental Disorders (KIND), Centre for Psychiatry Research; Department of Women's and Children's Health, Karolinska Institutet, & Stockholm Health Care Services, Region Stockholm, Stockholm, Sweden, (3)Karolinska Institutet, Stockholm, Sweden

---

Background: Autism spectrum disorder (ASD) is largely genetically caused, although environmental factors play an important role. While many possible environmental factors behind ASD have been proposed they often stem from observational studies with little or no control for familial confounding, thus making them susceptible to bias from measured or unmeasured shared genetic and environmental factors. A recent systematic review of all twin and sibling studies investigating environmental factors of ASD, concluded an association, beyond familial confounding, for advanced paternal age, low birth weight, major malformations and perinatal hypoxic stress. Other studies have also suggested that the cumulative load of early environmental factors might contribute to ASD, beyond the contribution of each factor respectively.

Objectives: To assess the existence of an association between the cumulative load of early medical adversities and ASD (measured both categorically and dimensionally), beyond familial confounding.

Methods: Data from 3 nationwide Swedish twin cohorts was used: The Swedish Medical Birth Register (MBR) – founded in 1973 and including data on practically all deliveries in Sweden; the Swedish National Patient Register (NPR) includes all in-patient care in Sweden from 1987, and since 2001 all outpatient doctor visits; and the Child and Adolescent Twin Study in Sweden (CATSS; participants born between January 1992 and December 2008). ASD diagnoses were identified for twins in the NPR, with follow-up to 2018. Questionnaires assigned screening diagnoses of ASD to CATSS participants and assessed autistic traits. A cumulative load of the early medical adversities was calculated for each subject based on the presence of low birth weight, malformations and perinatal hypoxic stress as binary variables, identified from the MBR and the NPR. First, a conditional regression based on generalized estimation equations, adjusting for familial confounding, was used to assess the association of autism and the cumulative load, and with each factor leaved out, respectively. Second, a twin design with a univariate model was used to assess the heritability and the non-shared environmental contribution of the cumulative load, and a bivariate model was used to assess the heritability of the association between the cumulative load of early adversities and ASD. Analyses is ongoing and performed since November 1, 2020.

Results: Data were available for 15280 pairs (4880 female same-sex pairs [31.9%], 5092 male same-sex pairs [33.3%], and 5308 opposite-sex pairs [34.7%]) in CATSS, with linking to delivery related and diagnosis information from the MBR and the NPR. Information has been found for birth weight, perinatal hypoxic stress, and major malformations, enabling a reliable test of the hypothesis.

Conclusions: If confirmed, the presence of a cumulative load of environmental factors beyond familial confounding would point to an overlying mechanism, outside the separate mechanisms involved in the specific factors respectively. Such mechanisms could involve the hypothalamic-pituitary-adrenal axis or environmental endocrine disruptors. Our rigorous hypothesis driven approach using nationwide twin cohorts will enable causal inference.

Mechanisms associated with sex and gender play multiple roles influencing the biological mechanisms associated with the emergence of autism, the developmental trajectories and coping experiences of autistic individuals, and the diagnosis and clinical care for people on the autism spectrum across sexes and gender. New discovery and improved understanding of these multiple roles of sex and gender in autism is promising in guiding new research to better understand the etiology and neurobiology of autism, and clinical innovation of sex- and gender-informed support for autistic people. This panel will present overviews and cutting-edge new findings on the rapidly emerging research field of sex and gender impacts on autism, across the levels of genomics, neurobiology across species, neuroimaging, and behavior.

**208.001** (*Panel Discussion*) Transcriptomic Investigation of Intersections between Sex-Differential and ASD Neurobiology in Pre- and Postnatal Human Cortex

**D. M. Werling<sup>1</sup>**, L. T. Kisse<sup>2</sup>, S. Pochareddy<sup>3</sup>, N. Sestan<sup>4</sup>, K. Roeder<sup>5</sup>, B. Devlin<sup>6</sup> and S. J. Sanders<sup>7</sup>, (1)Laboratory of Genetics, University of Wisconsin-Madison, Madison, WI, (2)Neuroscience Training Program, University of Wisconsin-Madison, Madison, WI, (3)Yale University, New Haven, CT, (4)Yale School of Medicine, New Haven, CT, (5)Department of Statistics and Data Science, Carnegie Mellon University, Pittsburgh, PA, (6)Department of Psychiatry, University of Pittsburgh School of Medicine, Pittsburgh, PA, (7)Department of Psychiatry, Weill Institute for Neuroscience, UCSF School of Medicine, San Francisco, CA

Background: Autism spectrum disorder (ASD) is a neurodevelopmental condition with a four-fold male bias in diagnosis and a significant genetic risk component. Genetic studies find that autistic females have a higher incidence of high-impact risk variants than males, consistent with the existence of a female protective effect. Identifying and understanding the biological mechanisms

that protect females and/or increase risk in males may promote the development of therapeutic options that are broadly applicable across genetically heterogeneous individuals. Toward this end, prior transcriptomic work in small samples has reported that expression levels of ASD risk genes do not differ by sex in the human cortex, but that multiple gene sets that are elevated in the ASD brain also tend to have male-biased expression in neurotypical controls, suggesting that sex modulates ASD risk in pathways downstream from risk genes.

**Objectives:** The objectives of this study are to validate and extend prior findings by characterizing sex-differential gene expression in an expanded data set of *post mortem* brain tissue from prenatal and postnatal human donors, and by evaluating current sets of genes implicated in ASD risk and pathophysiology for evidence of sex-differential regulation. These efforts aim to update and further resolve points of intersection between biological processes impacted by sex and those impacted in ASD.

**Methods:** We analyzed RNA-sequencing data from neurotypical *post mortem* human dorsolateral prefrontal cortex tissue from the BrainVar data set separately in both prenatal (N=85, 46 females, 14-21 post-conception weeks) and postnatal (N=28, 9 females, 13-19 years) donors. We ran transcriptome-wide sex-differential expression analysis using limma-voom and applied Fisher's exact and Wilcoxon rank sum tests to evaluate ASD-associated gene sets for enrichment of sex-differential expression. Gene sets included 102 risk genes identified by exome sequencing, genes with altered expression in ASD brain, and cell type markers.

**Results:** We identify 56 prenatal and 35 postnatal sex-differentially expressed genes (DEGs) at a false discovery rate of 0.1, including 6 autosomal transcripts. Consistent with prior work, expanded sets of high-ranking DEGs selected by  $p \leq 0.05$  and fold difference magnitude of 1.2 are not enriched for known ASD risk genes. Here, ASD risk genes are more likely than expected to show female-skewed expression both prenatally and postnatally, though the magnitude of these shifts is minimal. Male-biased DEGs are enriched for ASD-up-regulated, immune function associated co-expression module CTX.M19 (prenatal) and for markers of endothelial cells (prenatal) and microglia (prenatal, postnatal). The absence of DEG enrichment for ASD risk genes and prenatal male-biased DEG enrichment for CTX.M19 and microglial markers remain consistent when previously tested samples are excluded.

**Conclusions:** These results support prior observations that sex effects on autosomal gene expression in both postnatal and prenatal human cortex are generally subtle. Using a larger sample and updated gene sets associated with ASD biology, these results are also consistent with prior findings suggesting that ASD risk genes may not be directly sex-differentially regulated in the cortex during mid-fetal development or adolescence, but that sex effects instead act on downstream or interacting pathways potentially involving glial and immune function.

**208.002 (Panel Discussion) Ube3a Duplication Results in Sex-Divergent Effects on the Connectome and Transcriptome**

---

**Background:** Autism is more prevalent in males, but the mechanisms underlying this sex-bias remains unclear. *UBE3A* is an autism risk gene duplicated in 15q11-q13 (dup15q) syndrome – a CNV that occurs in 1-3% of all autism cases. *UBE3A* has several functions, but may impact sex-bias as a transcriptional co-factor with steroid hormone receptors. Thus, *UBE3A* could serve as a key transcriptional hub underlying sex-specific bias in autism.

**Objective:** To test for sex-divergent effects in imaging, behavioral, and gene expression data in male and female mice harboring duplication of *Ube3a*.

**Methods:** Multiple approaches were used to investigate sex-by-genotype interactions in male and female mice whom overexpress *Ube3a* (Ube3a-dup). These included resting state fMRI (rsfMRI) to map functional connectivity, behavioral assays and post-mortem gene expression with RNA-seq sampled from prefrontal cortex (PFC) and hypothalamus.

**Results:** Consistent with our hypothesis, rsfMRI revealed robust sex-specific divergences in functional connectivity. Specifically, Ube3a-dup females show reduced connectivity in hypothalamic and somatosensory cortex, while Ube3a-dup males show increased connectivity in PFC. With RNA-seq, while no genes were differentially expressed (DE) in hypothalamus, we further discovered >2800 DE genes in PFC that show a significant sex-by-genotype interaction. The sex\*genotype interaction could be explained by some DE genes that show a WT>Ube3a-dup effect in males, but an opposite pattern (Ube3a-dup>WT) in females (e.g., *Fmr1*, *Pten*, *Gria2*, *Scn2a*). In contrast, a different set of DE genes show the opposite directionality of effect (Ube3a-dup>WT in males, but WT>Ube3a-dup in females; e.g., *Shank3*, *Tsc2*, *Deaf1*). The DE gene set was also enriched for autism-risk

genes (SFARI) and DE genes in human dup15q patients, and showed differential glutamatergic and GABAergic cell types enrichments, potentially indicating an effect on E:I balance. Behavioral testing in the same cohort of mice revealed significantly increased self-grooming in Ube3a-dup males, but not in females, pointing to a sex-divergent behavioral phenotype.

Conclusions: *UBE3A* may be key mechanisms for sex-bias in autism due to its downstream sex-specific effects on the functional connectome and transcriptome.

**208.003 (Panel Discussion) Sex Differences in Amygdala Development in Autism from Early to Middle Childhood**  
**C. W. Nordahl<sup>1</sup>, J. K. Lee<sup>2</sup>, D. S. Andrews<sup>2</sup>, B. Heath<sup>2</sup>, M. Solomon<sup>2</sup>, A. M. Iosif<sup>3</sup> and S. Ozonoff<sup>4</sup>,** (1)University of California at Davis School of Medicine, Sacramento, CA, (2)Department of Psychiatry and Behavioral Sciences, The Medical Investigation of Neurodevelopmental Disorders (MIND) Institute, UC Davis School of Medicine, University of California Davis, Sacramento, CA, (3)Public Health Sciences, University of California Davis, Davis, CA, (4)Psychiatry and Behavioral Sciences, University of California at Davis, MIND Institute, Sacramento, CA

---

Objective: Females have historically been under-represented in MRI studies of autism, and consequently, little is known about sex-specific trajectories of brain development in autism spectrum disorder (ASD). We evaluated sex differences in amygdala structure and function across early childhood in girls and boys with ASD and neurotypical controls.

Methods: Participants include 294 children with ASD (95 females) and 135 typically developing (TD) controls (61 females) enrolled between 2-4 years of age. Longitudinal imaging was conducted at up to four time points spanning 2-13 years of age. All images were acquired on a 3T Siemens Trio. Children of all developmental levels were imaged, including children with intellectual disability. Analyses included evaluation of sex differences in: 1) amygdala functional connectivity at study entry (mean age 3.5y), 2) amygdala volume and associations with symptoms of psychopathology at study entry, and 3) longitudinal growth of the amygdala and anatomically connected structures across early childhood (2-13 years).

Results: 1) Global patterns of amygdala functional connectivity revealed robust sex differences in TD participants, but these differences were attenuated in children with ASD. However, autistic females exhibited greater differences from TD than their male counterparts in localized regions such as medial prefrontal and posterior cingulate cortex. 2) Amygdala enlargement was observed only in a subgroup of autistic children with high levels of psychopathology, and amygdala volume was positively associated with internalizing behaviors in autistic girls, but not boys. 3) Growth trajectories of amygdala connected regions did not differ in magnitude by sex between ASD and TD groups, but the underlying set of brain regions contributing to diagnostic differences was quite dissimilar in boys and girls.

Conclusions: Given that there are sex differences in normative amygdala development, it is critical to parse out alterations related to normative sex differences versus autism-related differences. Our findings reveal sex-specific patterns of amygdala development in ASD which could be indicative of different underlying etiologies and potentially useful in predicting different outcomes, co-occurring conditions, and tailoring treatments.

**208.004 (Panel Discussion) Will Neuroimaging Research Unveil the Mechanistic Roles of Sex and Gender in Autism? Sex/Gender-Based Heterogeneity, “Female-Protection”, and Compensation in the Human Autistic Brains**  
**M. C. Lai,** The Margaret and Wallace McCain Centre for Child, Youth and Family Mental Health, Centre for Addiction and Mental Health, Toronto, ON, Canada; Azrieli Adult Neurodevelopmental Centre, Centre for Addiction and Mental Health, Toronto, ON, Canada; Department of Psychiatry, University of Toronto, Toronto, ON, Canada; The Hospital for Sick Children, Toronto, ON, Canada

---

Various neuroimaging methodologies have been used to investigate the brain characteristics associated with autism. They have great potential to inform the neurodevelopmental pathways and mechanisms associated with the emergence of autism, as well as plasticity of the autistic brains. However, not all neuroimaging studies are well equipped to delineate the influences of sex and gender on the autistic brains. In this integrative presentation I will first provide an overview of the current state of human neuroimaging research in autism in relation to understanding sex or gender influences, with a focus on the MRI literature in the past 20 years. I will then consider findings from these studies to summarize what we know so far about (1) sex-based or gender-based heterogeneity in the human autistic brains, (2) neuroimaging observations that can speak to the “female-protection” model and underlying mechanisms, and (3) compensatory mechanisms in the human autistic brains that may be associated with sex or gender. I will conclude by highlighting designs and methodologies that may further enhance our understanding of the mechanistic roles of sex and gender in the neurodevelopment of autism.

## POSTER SESSION — BEHAVIORAL NEUROSCIENCE

### Poster 405 - Behavioral Neuroscience Posters

**405.001** (Poster) Intrinsic Structural Connectivity of the Default Mode Network and Behavioral Correlates of Executive Function and Social Skills in Youth with ASD

**J. E. Blume<sup>1</sup>**, **C. N. Kahathuduwa<sup>1</sup>** and **A. Mastergeorge<sup>2</sup>**, (1)Department of Human Development and Family Studies, Texas Tech University, Lubbock, TX, (2)Texas Tech University, Lubbock, TX

**Background:** Brain connectivity of individuals with autism spectrum disorders (ASD) is heterogeneous, as are the behavioral manifestations of ASD including hallmark social difficulties (King et al., 2019). A strong relationship exists between executive function and social competencies in youth with ASD (Kouklari et al., 2018). As children with ASD transition to adolescence, executive deficits become more evident, contributing to additional adaptive and behavioral challenges (Gardiner & Iarocci, 2018). Our prior neuroimaging work substantiates the work of others to suggest an inverse association between the strength of functional connectivity between the anterior and posterior nodes of the brain default mode network (DMN) and symptom severity, executive dysfunction and socio-emotional impairments in ASD (Kahathuduwa et al., 2019; Lynch et al., 2017; Odriozola et al., 2019). However, the structural connectivity patterns associated with ASD and their executive, behavioral and social correlates remain to be explored.

**Objectives:** This study aims to characterize the structural connectivity between the anterior and posterior nodes of the DMN using probabilistic tractography and to explore the associations between anterior-posterior DMN structural connectivity strength and measures of executive function and social responsiveness, in order to inform the potential role of underlying cognitive processes in socio-behavioral patterns and trajectories observed in ASD.

**Methods:** This investigation utilized a subset of secondary phenotypic and brain diffusion tensor imaging (DTI) data shared through the Autism Brain Imaging Database Exchange (ABIDE) II ( $N=45$ , 39 male, age= $7.63 \pm 1.72$  years). We applied the following preprocessing algorithms in the FDT toolbox in FSL to the DTI data: distortion correction, brain extraction eddy current correction and motion correction. We calculated anterior-posterior, posterior-anterior, and total connectivity measures from DTI using Bayesian estimation (BEDPOSTX), and probabilistic tractography (PROBTRACX). Subsequently, we performed structural equation modeling by regressing three latent factors, yielded from an exploratory factor analysis with the *Behavior Rating Inventory of Executive Function* (BRIEF; Gioia et al., 2000) Clinical Scales and *Social Responsiveness Scale* (SRS; Constantino & Gruber, 2005) Treatment Subscales, onto total DMN connectivity.

**Results:** The behavioral measures of executive function and social responsiveness yielded three latent factors which uniquely represent three dimensions of mental processing: Social Regulation Processing, Goal-Directed Cognitive Processing, and Self-Directed Cognitive Processing (see Table 1). In the converged model, both Social Regulation Processing and Self-Directed Cognitive Processing factors moderately and negatively correlated with total DMN connectivity (respectively  $r=-.396$ ,  $p=.015$  and  $r=-.386$ ,  $p=.032$ ) while the correlation between Goal-Directed Cognitive Processing and connectivity was non-significant ( $r=-.298$ ,  $p=.069$ ). See Figure 1 for factor covariances and model fit indices.

**Conclusions:** To our knowledge, this is the first study to use probabilistic tractography with the ABIDE II dataset. Our findings support previously observed aberrant intrinsic DMN functional connectivity in individuals with ASD (Padmanabhan et al., 2017) and executive dysfunction (Ikuta et al., 2014). Our model indicates the processes underlying behavior regulation and social functioning are more strongly associated than metacognition and thereby warrant greater emphasis on skills like inhibition, shifting, and emotional control to bolster holistic developmental outcomes when compared to skills such as initiation, planning, organization, working memory, and monitoring.

**405.003** (Poster) Restricted and Repetitive Behaviors and Social Communication: Their Relationship and Underlying Functional Connectivity in Autistic Children

**G. J. Cardon<sup>1</sup>** and **D. Rojas<sup>2</sup>**, (1)Brigham Young University, Provo, UT, (2)Colorado State University, Fort Collins, CO

Background:

Symptoms common to persons on the autism spectrum include restricted and repetitive behaviors (RRBs) and social communication (SC) differences. While some have denied their shared origin, it is possible that these sets of behaviors have common neural mechanisms. Investigating such neural foundations could both increase our understanding of autism and inform support services. Atypical sensory processing is now recognized as central to autism and is functionally related to RRBs and SC

independently. As such, the neural underpinnings of aberrant sensory processing and common autistic traits could be linked. Unfortunately, relatively little is known about the mechanisms of atypical sensory processing in autism. It is plausible that irregular processing in and connectivity between sensory and motor cerebral cortices, as well as supramodal brain regions (e.g., the cerebellum), contributes to such atypical sensory function, and is related to core autistic features.

#### Objectives:

We examined the relationship between behavioral measures of RRBs and SC, and its with functional connectivity between sensory, motor, and supramodal brain regions. We hypothesized that behavioral measures of RRBs and SC would be positively correlated, and that this link would be correlated with decreased functional connectivity between sensory cortices, the cerebellum, and motor brain regions in autistic participants.

#### Methods:

Structural MRI, resting-state fMRI (rs-fMRI) and behavioral data were obtained from a large, open database (ABIDE II) of autistic (n=74; mean age=11.83 years), and nonautistic children (n=76; mean age=11.34 years). Analyses consisted of pre-processing, motion correction, normalization, and a priori selection of regions of interest (ROI) based on their contributions to sensory, motor, and cerebellar function. Then, FDR-corrected ROI-to-voxel functional connectivity was computed for each ROI, controlling for age, sex, and site. Each dataset also included the following phenotypic data: Social Responsiveness Scale (SRS-2)<sup>11</sup>, and Repetitive Behavior Scale-Revised (RBS-R). To evaluate the relationship between RRBs and SC, we performed partial correlations between the RBS-R and SRS-Communication Subtest (SRS-Comm) scores. Differences in the FDR-corrected functional connectivity for each ROI between the Autistic and neurotypical (NT) children were then calculated, controlling for age, sex, and site, via ANCOVA. The ROI-voxel combinations that exhibited significant between groups rs-FC differences were noted. Then, the relationships between the rs-FC of these combinations and the RBS-R and SRS-Comm were assessed using partial correlations.

#### Results:

Behavioral RBS-R and SRS-Comm scores were significantly correlated in the autism ( $r=0.52$ ;  $p=0.00$ ) and comparison ( $r=0.59$ ;  $p=0.00$ ) groups. Additionally, several functional connectivity differences were observed between the groups that were also related to both the RBS-R or SRS-Comm—connectivity in the ASD group between the right precentral gyrus and right and left lateral occipital cortices was significantly negatively correlated with RBS-R scores ( $r=-0.302$ ;  $p=0.01$ ). Connectivity between the right precentral gyrus and several sensory cortical sites was also associated with poorer SRS-Comm scores—i.e., left lateral occipital cortices ( $r=-0.293$ ;  $p=0.013$ ), right lateral occipital cortices ( $r=-0.329$ ;  $p=0.005$ ), and left planum temporale ( $r=-0.349$ ;  $p=0.003$ ).

#### Conclusions:

These results suggest that RRBs and SC in autism may be both functionally and neurologically linked, and that their connection could be related to sensorimotor brain processes.

**405.004 (Poster)** Reward Processing in Young Children with Autism Spectrum Disorder: Evidence of Expectation Violation  
**C. Harrop<sup>1</sup>, J. Wu<sup>2</sup>, K. A. Pelphrey<sup>3</sup>, P. E. Ventola<sup>4</sup> and M. Crowley<sup>2</sup>,** (1)Department of Allied Health Sciences, University of North Carolina at Chapel Hill, Chapel Hill, NC, (2)Yale Child Study Center, New Haven, CT, (3)University of Virginia, Charlottesville, VA, (4)Yale Child Study Center, Yale University School of Medicine, New Haven, CT

**Background:** Reward processing (RP) encompasses responses to rewarding stimuli, the ability to learn from and anticipate rewards, and engagement in goal-directed behavior towards rewards. RP has been studied extensively in ASD as a mechanism underlying behaviors characteristic of ASD. EEG studies have characterized the neural correlates of RP, focusing on the N1, P2 and Feedback Response Negativity (FRN), with mixed findings between ASD and TD (Larson et al., 2010; McPartland et al., 2012).

**Objectives:** Characterize reward processing during a well-validated monetary reward paradigm in young autistic children (4 to 9 years).

**Methods:** Twenty-nine children (4 to 9; Mean=6.5 years) participated in the study (15 ASD, 14 TD). Twenty-six (13 ASD, 13 TD) provided sufficient EEG data (mean “win” trials= 29.50 (SD=11.31), mean “draw” trials= 29.54 (SD=12.30)). Children completed a feedback-reward paradigm consisting of equiprobable “win” and “draw” outcomes across four blocks of 30 trials.

Children were shown four different colored balloons and were instructed to select one by pressing the corresponding response button (Crowley et al., 2014). If children chose the “correct” balloon, they saw a green dollar sign and would “win” 10 cents. If they chose one of the “unlucky” balloons, they would see an empty white box and not win any money (“draw”). Wins and draws occurred in a random order and a set number of times per block independent of child choice. After each 30-trial block, an image of a jar appeared filling with dimes with accompanying sound.

Electrodes, regions of interest, and ERP components were selected based on prior research: frontal P2 (positive peak, 100-300ms), FRN (negative peak, 200-400ms), slow wave (averaged amplitude, 500-900ms); posterior P1 (positive peak, 50-200ms), N2 (negative wave, 100-300ms), and P3 (averaged amplitude, 250-450ms). Repeated measures ANOVAs were conducted on each ERP component by group and condition.

**Results:** Condition differences were found in posterior P1 latency ( $F(1, 24) = 29.35, p < .001$ ) and posterior N2 amplitude ( $F(1, 24) = 4.64, p = .04$ ). Post-hoc t-tests indicated shorter latencies to “draws” (mean difference = -14.66,  $t(1, 25) = -5.23, p < .001$ ). A significant group difference was found in frontal P2 latency ( $F(1, 24) = 6.78, p = .02$ ). Post-hoc t-tests indicated that autistic children had a shorter frontal P2 latency than the TD group ( $t(1, 24) = -2.60, p = 0.02$ ). There was a significant group\*condition interaction in posterior P3 amplitude ( $F(1, 24) = 4.39, p < .05$ ). Post-hoc t-tests indicated that the ASD group had smaller amplitudes to “draws” ( $t(1, 12) = -2.22, p < 0.05$ ).

**Conclusions:** Our data suggests that young autistic children place greater significance on negative feedback. This findings differs to prior literature suggesting similar neural responses to positive and negative feedback in young TD children (Mai et al., 2011). Enhanced responses to negative feedback could represent a violation of expectation or an intolerance for uncertainty – mechanisms hypothesized to underlie anxiety in ASD (Boulter et al., 2014). Future work is required to characterize developmental changes in RP and associations with the ASD phenotype and common comorbidities.

#### **405.005 (Poster) Visual Processing of the Signatures of Human Movement in Autism**

**S. Ben-Ami<sup>1,2</sup>, Y. Meirovitch<sup>1,2</sup>, D. Israeli<sup>3,4</sup> and T. Flash<sup>2</sup>, (1)Massachusetts Institute of Technology, Cambridge, MA, (2)Faculty of Computer Science and Applied Mathematics, Weizmann Institute of Science, Rehovot, Israel, (3)Psychiatric array, Kaplan Medical Center, Rehovot, Israel, (4)Faculty of Medicine, Hebrew University of Jerusalem, Jerusalem, Israel**

---

#### Background:

Individuals with Autism Spectrum Disorder (ASD) do not readily extract information from observing other people’s actions and movements. This is contrary to neuro-typical observers, who exhibit superior processing of visual displays depicting human movement, a remarkably selective behavioral and neural response to such displays, and a heightened spontaneous preference towards them.

A prominent source of information embedded in naturalistic visual input of human action is the kinematic regularity of stereotypical human movement, found critical for decoding others' intentions and for inferring their emotions and goals, a prerequisite for efficient communication and interaction. Several mathematical descriptions have been developed in the field of motor control to describe the kinematic invariants of human movement (herein, Human Movement Signatures).

#### Objectives:

Investigating whether ASD involves a deficit in visual processing of Human Movement Signatures, independently from the documented difficulties with processing complex stimuli and with attending to human body-form and context.

#### Methods:

Stimuli consisted of a single dot moving along a prescribed path. The dot’s speed profile was manipulated (in each trial) to adhere with differing degrees of compliance with the human movement signature formulated by the Two-Thirds Power Law (2/3PL), which describes the spatiotemporal pattern of coupling between movement curvature and velocity typical of human movement.

We utilized a perceptual illusion known to be elicited by observation of the 2/3PL, in which visual motion adhering to this human movement signature elicits an illusion of motion uniformity; despite prominent variations in its speed, it is perceived to be uniform, even more than motions that actually have a constant (Euclidean) speed.

Since this effect is believed to stem from a bias of the neuro-typical visuomotor system toward human movement signatures, we tested if ASD subjects similarly exhibit this human movement uniformity bias.

14 adults with a diagnosis of ASD and 13 age-, gender-, and IQ-matched neurotypical subjects were presented with 1800 pairs of motions each (over eight one-hour sessions), and asked to judge which was moving more uniformly.

To account for ASD subjects' heterogeneity, we implemented a novel individual-focused model which decoupled the subjects' judgments from the contribution of unreliability (in other words, the "noise" inherent to the responses of each individual subject), thus assessing and discerning the relative contributions of decisional from sensory-perceptual processes.

Results:

The visual illusion of motion uniformity was not elicited in most ASD subjects, who, unlike neurotypical subjects, veridically judged motions with constant Euclidean speed as uniform. Subjects' motion-uniformity bias was correlated with their load of autistic traits.

The model closely captured individual response patterns. Subjects' noise parameter correlated with their non-verbal cognitive scores.

Conclusions:

Our results suggest deficient visual processing of human movement signatures in ASD.

We link individual levels of this sensory-motor atypicality to the broader autistic phenotype, implying its relevance to core ASD symptoms.

More broadly, our modelling approach for studying visual perception of individual subjects allowed the discovery of a linkage between modeled "noise" and non-verbal IQ, providing mechanistic insight. This approach is a step of clinical and translational importance towards decomposing heterogeneity in Autism.

## Biomarkers (molecular, phenotypic, neurophysiological, etc)

### PANEL DISCUSSION — BIOMARKERS (MOLECULAR, PHENOTYPIC, NEUROPHYSIOLOGICAL, ETC)

#### Panel 209 - EEG Biomarkers in Neurodevelopmental Disorders: From Mechanisms and Methods to Clinical Trial Readiness

**Panel Chair:** Shafali Jeste, *University of California, Los Angeles, Los Angeles, CA*

As early interventions and etiologically-specific therapies are developed in NDDs, we must be prepared for the design and implementation of successful clinical trials. Quantitative, developmentally sensitive, and mechanistically informed biomarkers are critical for early detection, patient stratification, selection for therapeutics and establishment of drug target engagement. Electroencephalography (EEG) is a functional brain imaging method that assays, with exquisite temporal and developmental sensitivity, neural circuit function and dysfunction in NDDs and holds promise as a robust method for biomarker discovery in NDDs. However, there exist methodological challenges in EEG studies that require robust standardization of methods, well powered sample sizes, replication, and cross disorder and species comparisons. In this panel, we share experiences by experts in EEG methodology across these areas of early detection (Dr. Abigail Dickinson), the process of EEG biomarker approval through the FDA (Dr. Sara Webb), EEG as a translational biomarker across genetic syndromes (Dr. Charles Nelson) and EEG studies in Angelman syndrome that will inform upcoming trials (Drs. Mike Sidorov and Rob Komorowski). Dr. Shafali Jeste (discussant) will share perspectives on next steps needed to ensure that these EEG biomarkers can be applied in clinically accessible and reliable ways to improve care of children with NDDs.

**209.001** (*Panel Discussion*) EEG Biomarkers of Early ASD Detection in Infancy: Signal Processing Considerations and Consortium Building

*A. H. Dickinson, University of California, Los Angeles, Los Angeles, CA*

**Background:** Biomarkers of atypical infant brain development hold promise for expediting detection efforts in neurodevelopmental disorders and are especially crucial in autism spectrum disorder (ASD), where they may create an opportunity for preemptive interventions before behavioral symptoms emerge. Electroencephalography (EEG) represents a powerful tool for identifying early biomarkers, given its sensitivity to functional changes in the developing brain and practical suitability for tracking the infant siblings of children with ASD, who have a 20% risk of developing ASD (Charman et al., 2017). However, specific challenges surround the identification of brain-based biomarkers in infancy that can undermine their clinical usefulness. Typical brain activity patterns change rapidly over the first year of life, necessitating markers that can identify atypical deviations against a background of normative developmental variation. Quantifying these multidimensional spatio-spectral changes introduces further complexities, as traditional dimensionality reduction techniques can obscure developmental trends (Patino et al., 2017). Carefully designed multi-site research must test the robustness of candidate biomarkers, given that clinical application depends upon the ability to detect neural disruptions, despite the sample or setting (Jeste et al., 2015).

**Objectives:** We have focused our efforts to enhance the clinical utility of infant biomarker identification. First, we took a data-driven approach to sensitively characterize oscillatory trajectories over the first year of life in ASD, and now we are testing these strategies in a multi-site prospective study of familial risk infants (IBIS: Infant Brain Imaging Study).

**Methods:** For the first aim, spontaneous EEG data were collected at 3, 6, 9, & 12 months of age from infants with (N=51) and without (N=37) familial risk for ASD. Clinical outcomes were assessed at 36 months of age, with 14 participants meeting diagnostic criteria for ASD. After calculating spectral power across the scalp, functional principal component analysis (FCPA) extracted dominant oscillatory trends over the first year. Generalized linear mixed-effects models then assessed whether these functional changes were expressed differently across the two groups (ASD and non-ASD).

**Results:** FCPA revealed three components which accounted for over 96% of oscillatory variation over the first year. Significant main effects of diagnostic group indicated divergent maturation patterns between ASD and non-ASD participants for eigenfunctions one ( $P<.001$ ) and three ( $P<.001$ ), which captured variation in the amplitude of the emerging alpha peak, and the general redistribution of spectral power from lower (<4Hz) to higher frequencies (>6Hz), respectively. Notably, the expression of these components did not differ according to familial risk status, indicating that deviations from normative oscillatory development are associated with ASD outcome rather than general disorder vulnerability.

**Conclusions:** Identifying neural disruptions during infancy represents a promising biomarker avenue in ASD but presents specific challenges. Oscillatory trajectories deviate in the first year of life in infants who later develop ASD. Specifically, the emergence of a clear alpha peak, and spectral power redistribution, occurs earlier in infants who develop ASD. Our results reinforce that EEG markers of functional dysmaturation may provide early, objective predictors of ASD. We will discuss strategies implemented to assess the reliability of these neural changes across multiple research sites.

**209.002 (Panel Discussion)** A Framework for EEG Biomarker Development: The Autism Biomarkers Consortium for Clinical Trials

*S. J. Webb<sup>1</sup>, J. McPartland<sup>2</sup> and C. Sugar<sup>3</sup>, (1)Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA, (2)Child Study Center, Yale University School of Medicine, New Haven, CT, (3)University of California, Los Angeles, Los Angeles, CA*

---

**Background:** Numerous candidate neural biomarkers have been put forward for use in ASD research, with the primary focus on discriminating between individuals with or without ASD or quantifying biomarkers in relation to the clinical phenotype. Advancing biomarkers into use in clinical trials has been hindered by inconsistent results across small studies, substantial overlap in distribution between ASD and non-ASD groups, limited understanding of biomarker psychometric properties, and variable methodology in terms of acquisition and processing. The CDER Biomarker Qualification Program offers a framework for conceptualizing biomarkers for specific contexts of use to address drug development needs. Adoption of this framework has been central to study design and analysis in the Autism Biomarkers Consortium for Clinical Trials (ABC-CT).

**Methods:** The first phase of the ABC-CT was a large multisite, naturalistic study of 6 to 11 year-old children with ASD (n=280) and TD (n=119) designed to investigate EEG biomarkers for use in clinical trials. To this end, the ABC-CT evaluated an EEG battery composed of well-studied assays of resting state activity (Resting), face perception (Faces), biological motion perception (BM), and visual evoked potentials (VEP) for potential use in clinical trials for ASD. The biomarker, the “N170 Latency to Upright Human Faces,” was submitted to the CDER Biomarker Qualification Program (BQP) and accepted into the program for continued evaluation.

**Results:** In keeping with the BQP process priorities, initial analytic goals for the “N170 Latency to Upright Human Faces” biomarker have focused on acquisition rates, construct validity, six-week stability, group discrimination, and association with individual characteristics (including age). For this biomarker, artifact free data was acquired from 76% of the ASD group, construct validity was demonstrated by the expected reduced latency and enhanced amplitude to faces (versus houses) in the TD group, stability was adequate in the ASD group (ICC=.66), the ASD group exhibited delayed N170 latency relative to the TD group (p<.01), and stronger behaviorally quantified face memory was related to shorter latency (p<.05).

**Discussion:** Most existing biomarker research in ASD has focused on identifying group differences or phenotypic relations with EEG signals in individuals with ASD. However, the FDA BQP targets drug development need, with specific attention to measurement interpretation (e.g., construct, precision, decision making, risk/benefit) and measurement quality assurance/control in the context of a specific clinical research objective (i.e., context of use). As demonstrated by the example of the ABC-CT, this process requires specific analytic considerations to support biomarker qualification that must be considered in study design and analytic plans. Critically, attention to these guidelines also benefits rigor and reproducibility.

**209.003 (Panel Discussion)** Using Biomarkers to Characterize Neurobiological Deficits in Neurodevelopmental Disorders: A Case Study in TSC, Rett Syndrome, 16P, and Fragile X Syndrome

*C. A. Nelson, Developmental Medicine, Boston Children's Hospital, Boston, MA*

---

**Introduction:** EEG biomarkers can provide (a) insight into the neurobiology of NDDs and (b) offer opportunities to predict, stratify, and monitor progression and treatment response over time.

Here, we focus on several disorders, co-morbid with ASD, that differ behaviorally and neurobiologically: Tuberous Sclerosis Complex (TSC), 16p11.2, Rett Syndrome, CDKL5, and Fragile X syndrome (FXS). We (1) present our EEG findings with Fragile X, (2) discuss a cross-disorder comparison using the visual evoked potential (VEP), and (3) summarize our recent translational work.

**Methods:**

**Fragile X:** Resting-state EEG was collected from FXS boys with full mutation of *Fmr1* (2.5-7 years old, n=11) and compared with age-matched (n=12) and cognitive-matched (n=12) typically developing (TD) boys. Power spectra were compared using non-parametric cluster-based permutation testing. Associations between 30-50Hz gamma power and behavioral outcomes were evaluated.

**Cross-Disorder Comparisons:** We compared the morphology of the VEP across the following disorders: Rett Syndrome (n = 38), Tuberous Sclerosis Complex (TSC; n = 17), 16p11.2 variants (deletions; n = 19 and duplications; n = 9), and CDKL5 (n = 4) to TD controls (n = 51).

**Translation:** In animals, VEP morphology can index a form of cortical plasticity (stimulus-selective response potentiation; SRP) when repeated grating stimuli are viewed across days. We have translated the SRP paradigm for use with human adults (n = 25) and children (n = 10).

**Results:**

**Fragile X:** FXS participants showed increased power in the beta/gamma range (~25-50Hz) across multiple brain regions. Both a reduction in the aperiodic (1/f) slope and increase in beta/gamma periodic activity contributed to increased high-frequency power. Greater gamma power, driven by the aperiodic component, was associated with better language ability in FXS. No association was observed between gamma power and behavioral challenges, sensory hypersensitivities, or adaptive behavior.

**Cross disorder comparisons:** The Rett and 16p variant groups had smaller N1 and P1 amplitudes relative to other genetic disorders and TD (all  $p < .05$ ). In addition, the Rett group showed smaller N2 amplitudes relative to all other groups (all  $p < .05$ ). Participants with 16p variants showed longer latency to later components (P1, N2), while those with Rett showed shorter latency to the early N1 component. Preliminary results for the CDKL5 group indicated longer latencies to negative components (N1, N2). In contrast, the TSC group had more negative N1 amplitudes than the Rett group ( $p < 0.005$ ) but did not differ significantly from TD for amplitude or latency of any component (all  $p > 0.05$ ).

**Translation:** Following 2-4 days of habituation to a particular stimulus orientation, VEP amplitude (N2) in both children and adults was larger in response to a novel compared to a familiarized stimulus orientation ( $p < 0.05$ ). Considerable stability in VEP latency and morphology was observed within individuals across days, supporting the use of the VEP as a biomarker to characterize neurodevelopmental disorders.

**Conclusions:** Our findings indicate the promise of EEG-based biomarkers that possess the sensitivity to distinguish among neurodevelopmental disorders and have translational potential, enhancing their utility for clinical trials.

**209.004 (Panel Discussion) Quantifying EEG Oscillations in Angelman Syndromes: Implications for Drug Development**  
*M. S. Sidorov, Center for Neuroscience Research, Children's National Hospital, Washington, DC*

---

**Background:** Recent advances in genetics, biology, and chemistry have revealed opportunities for disease-modifying therapies across an array of monogenic neurodevelopmental disorders. Translating therapies from rodent models to the clinic requires objective and translatable biomarkers that can detect early functional improvement in these diseases. EEG reflects a safe and cost-effective way to objectively measure brain function and thus has been proposed as a biomarker with clinical relevance in NDDs. One recent example of the utility of EEG in drug development is in the case of Angelman syndrome (AS). AS is a neurodevelopmental disorder caused by loss-of-function of the maternal allele of the ubiquitin ligase E3A (*UBE3A*) gene. Common features of AS include impaired motor function, lack of speech, developmental delay, seizures, and sleep disruptions. A functional paternal *UBE3A* allele exists but is silenced in neuronal cells by an endogenous anti-sense transcript (*UBE3A-ATS*). Multiple approaches to "unsilence" the dormant paternal copy of *UBE3A* have been successful preclinically, making this disorder especially tractable for treatment. Reliable, objective, and clinically relevant biomarkers are needed to enable the success of clinical trials for AS.

**Objectives:** (1) To evaluate the potential of quantitative EEG biomarkers in the context of AS clinical trials. (2) To highlight a framework for basic science and pharmaceutical collaboration in a pre-competitive space that can be used as a model for other disorders.

**Methods:** We will discuss multiple collaborative projects using quantitative methods to retrospectively analyze EEGs from individuals with AS.

**Results:** Delta rhythms are reliably increased in individuals with AS and in mouse models of AS. Increased delta rhythms can be corrected by interventions at the genetic and circuit levels in rodents. Delta rhythms correlate with cognitive performance in children with AS.

**Conclusions:** Delta rhythms represent an objective and clinically relevant biomarker of clinical severity in AS.

**209.005 (Panel Discussion) Quantifying EEG Oscillations in Angelman Syndromes: Implications for Drug Development - Part II**

POSTER SESSION — BIOMARKERS (MOLECULAR, PHENOTYPIC, NEUROPHYSIOLOGICAL, ETC)

Poster 406 - Biomarkers (molecular, phenotypic, neurophysiological, etc) Posters

**406.001** (Poster) Adversarial Machine Learning for Confound Disentangled Autism Biomarkers

**W. E. Carson<sup>1</sup>**, D. Y. Isaev<sup>2</sup>, S. Major<sup>3</sup>, G. Sapiro<sup>4</sup>, G. Dawson<sup>5</sup> and D. Carlson<sup>6</sup>, (1)Department of Biomedical Engineering, Duke University, Durham, NC, (2)Duke Center for Autism and Brain Development, Durham, NC, (3)Duke Center for Autism and Brain Development, Department of Psychiatry and Behavioral Sciences, Duke University, Durham, NC, (4)Department of Electrical and Computer Engineering, Duke University, Durham, NC, (5)Department of Psychiatry and Behavioral Sciences, Duke Center for Autism and Brain Development, Durham, NC, (6)Department of Civil and Environmental Engineering, Duke University, Durham, NC

**Background:** Biomarkers may contain confounds that obfuscate useful information, impairing our ability to discern underlying causes and characteristics of autism spectrum disorder (ASD). Intellectual disability (ID) is a common comorbidity in individuals with ASD. Due to the overlap between ASD and ID, it is often difficult to determine whether observed differences can be attributed to ASD or differences in cognitive ability. Thus, methods to extract ASD-specific features independent of information attributable to intellectual disability are needed. We used an adversarial machine learning model to create confound-disentangled biomarkers for ASD diagnosis.

**Objectives:** We used an adversarial machine learning model to disentangle information related to a common comorbid disorder, ID, from our biomarkers, ensuring that our biomarkers inform only on ASD.

**Methods:** The cohort consisted of 31 children with ASD and 31 age-matched typically developing (TD) children. Simultaneously recorded EEG and videotaped behavior were collected while participants watched three video stimuli. Behavior features were generated based on participant attention to video stimuli. Specifically, total time attending to a video was divided by the number of looks away from the video. Similar to Principal Component Analysis (PCA), our model is a linear factor model with an analytical solution. Our adversarial factor model (referred to as adversarial PCA or aPCA) balances fitting the observed data while making the factors unpredictable or orthogonal to the confounding information. The degree of this unpredictability is controlled through a tuning parameter. The mean IQ of TD and ASD groups within our cohort were 114.3 (SD = 13.5) and 80.4 (SD = 21.9), respectively. We used aPCA to remove this confounding information on participant intelligence from our behavior features. Representations transformed via aPCA were evaluated on the area under the receiver operating characteristic curve (AUC) achieved when using them to predict diagnosis. For comparison, we also evaluated features transformed via PCA and features not subjected to dimensionality reduction on their ability to predict diagnosis. We evaluated feature sets on performance when predicting IQ group (defined as above or below 100 IQ) to determine the extent to which information on intellectual ability remained in our features.

**Results:** Results of using aPCA to enforce IQ invariance in our features are displayed in Table 1. aPCA generates behavior features completely unpredictable of IQ (AUC = 0.500) while still retaining information pertinent to ASD diagnosis (AUC = 0.631). Conversely, both the raw features and features decomposed via PCA were predictive of IQ group, with AUCs of 0.701 and 0.692, respectively. The leftmost plot in Figure 1 shows the tradeoff between diagnosis predictability and IQ predictability as adversarial strength is increased. The rightmost plot in Figure 1 shows how the correlation between behavior aPCA components and IQ decreases monotonically as adversarial strength increases, thus demonstrating the effectiveness of the adversary.

**Conclusions:** We demonstrated that an adversarial machine learning model can disentangle information related to a common comorbidity, ID, thus ensuring our biomarkers inform on ASD alone. Our framework for creating confound disentangled biomarkers is flexible and provides a template for future biomarker methods.

**406.002** (Poster) Assessing Glutamate Concentration As a Predictor for Social Behavioral Changes in ASD Due to Memantine  
**N. Nair<sup>1</sup>**, C. Riecken<sup>1</sup>, **D. Q. Beversdorf<sup>2</sup>**, B. J. Ferguson<sup>3</sup>, J. P. Hegarty<sup>4</sup> and C. Cirstea<sup>1</sup>, (1)University of Missouri, Columbia, MO, (2)Department of Radiology, Neurology, and Psychological Sciences, University of Missouri, Columbia, MO, (3)Health Psychology, Radiology, & Thompson Center for Autism & Neurodevelopmental Disorders, University of Missouri, Columbia, MO, (4)Psychiatry & Behavioral Sciences, Stanford University, Stanford, CA

**Background:** Autism spectrum disorder (ASD) is characterized by repetitive behaviors and impaired social communication. Differences in neural excitability/inhibitory ratios have been previously reported in ASD. Magnetic Resonance Spectroscopy (MRS) has been shown as an effective technique to measure concentrations of the neurotransmitter glutamate, which in general

causes increases in neural excitability. It is therefore possible that this may be used as a predictor for the efficacy of pharmacological interventions in ASD. Pharmacological interventions targeting glutamate have been examined recently, with mixed results found for the NMDA-glutamatergic antagonist memantine.

**Objectives:** To assess glutamate concentrations in brain regions as a biomarker for treatment efficacy of memantine in improving social behavior. To better understand effects of memantine on changes to social behavior in ASD.

**Methods:** MRS data from adult participants with ASD was processed to determine differences in glutamate concentration in the cerebellum and dorso-lateral prefrontal cortex (DLPFC). Social behavior was assessed before and after a 12 week trial of Memantine (titrated to 10mg twice a day) using the Clinical Global Impression (CGI) improvement scale. Changes in social behavior were compared to concentrations of glutamate in both ROIs to determine if glutamate concentration may serve as a predictor of changes in social behavior due to Memantine.

**Results:** A positive correlation was discovered between glutamate concentration in left DLPFC and changes in CGI scores related to social interaction. There was no relationship between glutamate concentration in either cerebellum or DLPFC with regard to aberrant or abnormal behavior, repetitive behavior, verbal or nonverbal communication, hyperactivity, anxiety, hypo or hyper sensitivity, or restricted interests.

**Conclusions:** More work is needed to further assess the efficacy of biomarkers acquired using MRS in predicting treatment response to Memantine, but the current results indicate that it may be possible that these biomarkers can predict changes in social interaction by measuring baseline glutamate concentration.

**406.003 (Poster)** Assessment of Motor Skills VIA a Tablet-Based GAME in Young Children with Autism Spectrum Disorder

---

## **Background:**

Several studies have shown that children with autism spectrum disorder (ASD) exhibit motor skill deficits which are apparent in the first year of life and represent one of the earliest symptoms of ASD. Our goal was to develop a tool for assessing motor skills that leverages recent advances in machine learning and computer vision and could be deployed on ubiquitous devices such as tablets and smartphones, opening the door to scalable, objective, and robust methods for automatically analyzing children's motor abilities.

## **Objectives:**

Develop and deploy scalable ASD behavioral phenotyping tool for assessing children's motor control and exploration via interaction with a touchscreen, based on analyses of behavioral patterns and response to a developmentally-appropriate interactive game under natural conditions with minimal instructions.

## **Methods:**

A series of carefully-designed visual stimuli was shown on an iPhone or iPad while children's behavior is recorded by the camera in the device. During an interactive bubble-popping game, we recorded and analyzed children's motor responses (see Figure 1a). The game features colored bubbles rising to the top of the screen. After a bubble is popped, the same one reappears in the same track, allowing assessment of repetitive behavior. Study 1 involved 18-34 month-old toddlers with ASD (N = 24) versus typical development (TD; N = 115). Study 2 involved 44 older children with ASD (56-99 months of age), 24 of whom had comorbid attention deficit hyperactivity disorder (ADHD). These subsamples were matched on IQ and exposure to digital devices. Age and IQ were used as covariates. On-device high precision inertial and gyroscopic sensors record multimodal information was derived from screen-based features such as bubbles popping and screen touches. Machine learning algorithms were used to automatically reveal motor behavioral features including motor accuracy, prospective motor control, sensorimotor timing and integration, repetitive or exploratory behavior, and overall engagement with the game (Figure 1c).

## Results:

Study 1 revealed that ASD and TD participants had comparable compliance and ASD participants showed, on average, lower fine motor control and accuracy compared to those with TD (Figure 1b), as reflected in the median error - defined as the distance between the centered of the popped bubble and the child's touch - and in the accuracy variability - standard deviation of the accuracy evolution when touching the screen, across all touches. Results of Study 2 indicated that ASD participants with ADHD were more engaged in the game, but less accurate, with less coherent movement and higher variability in the force applied when touching the screen (Figure 1c).

## Conclusions:

We demonstrated that information about motor skills can be automatically extracted from a simple bubble-popping game. These features can be then combined with other features automatically detected from behavioral recordings collected during other parts of the app. Attractive on-tablet games, equipped with high precision sensors, could lead to novel scalable screening and monitoring methods.

**406.004 (Poster)** Biophysical Responses to Pain As Biomarkers for Pain-Induced Stress in Autistic Individuals  
**M. Elsayed<sup>1</sup>** and **E. Torres<sup>2</sup>**, (1)*Rutgers University, New Brunswick, NJ*, (2)*Rutgers University, Piscataway, NJ*

---

**Background:** Pain sensation often goes unnoticed in nonverbal individuals such as those with Autism Spectrum Disorder (ASD)[1,2]. Current pain assessments rely on surveys and questionnaires such as numerical and verbal rating scales. Such self-reports – which assume a capacity to understand and verbalize mental/emotional states – and behavioral observation from parents and clinicians are subject to limitations, misinterpretation, and inaccuracies [3]. This in turn influences quality of care and delays appropriate diagnosis and treatment in healthcare[2,3].

**Objectives:** The goal of this study is to uncover signatures in Nervous System (NS) signals of individuals with typical peripheral and autonomic NSs in relation to those with ASD. This study questions how biophysical signals from the NSs are influenced by the introduction of pressure pain on the arm and how this may influence biophysical responses and/or interfere with performance on instructed or prompted motor-cognitive tasks. Using physiological signals to assess how pain influences motor(deliberate) and cognitive(intended) functioning can provide unique insights on the neurobiological mechanisms of pain sensation and perception in general[5].

**Methods:** We target the neurotypical (NT) population to understand signature responses to pain in order to develop digital biometrics that can be used to objectively assess when those with physical pain and/or neurological disorders demonstrate such responses under normal conditions. NT subjects performed various motor and/or cognitive tasks such as resting, walking, pointing, and drawing under different conditions (Figure 1A). ASD subjects then performed the same tasks only under control conditions. Kinematic signals (obtained from wearable motion sensors) representing bodily movements (via the Peripheral NS) were objectively analyzed for deliberate and spontaneous modes[4]. Electrocardiographic (ECG) signals representing cardiac activity (via the Autonomic NS) were characterized via clinically relevant heart rate variability metrics (HRV) to assess sympathetic and parasympathetic NS activation along with additional measures (Figure 1B). Such physiological responses were also compared to subjective numerical ratings to assess their correspondence with common pain assessments.

**Results:** Preliminary findings suggest unique statistical patterns in biophysical responses during the pain condition that is comparable to the responses observed in ASD subjects at baseline. This study identifies several parameters that can be used to stratify subjects based on their NS biorhythms when experiencing pain and/or pain-induced stress and anxiety. In NT subjects, the pain condition elicits a unique cardiac response that is associated with elevated sympathetic activity (fight-or-flight response) and/or decreased parasympathetic tone. Results from Gamma parameterization under the SPIBA [4,5] framework followed consistent patterns with common time & frequency domain HRV metrics (Figure 1B). Pain also appears to influence performance on motor-cognitive tasks of low cognitive load, suggesting disrupted kinesthetic feedback that is commonly found in ASD subjects at baseline [5].

**Conclusions:** Biophysical signals from the PNS and ANS (via motion and ECG sensors, respectively) offer a wealth of data that is useful in characterizing states of pain and stress. This work has several implications in developing a clearer neurophysiological understanding of pain and can ultimately help in objectively detecting internal levels of pain and stress in autistic individuals and the general population.

**406.005** (Poster) Comparison of Blood 25 Hydroxy Vitamin D, Copper, Zinc and Copper Zinc Ratio between Children with Autism Spectrum Disorder and Typically Developing Children: Analytical Cross-Sectional Study  
**R. Dubey<sup>1</sup>, G. S. Toteja<sup>2</sup>, N. Gupta<sup>3</sup>, R. M. Pandey<sup>4</sup>, S. Sapra<sup>5</sup>, V. Jain<sup>6</sup> and S. Gulati<sup>6</sup>,** (1)Neurosciences, Medanta Superspeciality Hospital, Indore, India, (2)Ministry of Health and Family Welfare (GOI), Indian Council of Medical Research, New Delhi, India, (3)Department of Endocrinology and Metabolism, All India Institute of Medical Sciences, New Delhi, India, (4)Department of Biostatistics, All India Institute of Medical Sciences, New Delhi, India, (5)Pediatrics, All India Institute of Medical Sciences, New Delhi, India, (6)Centre of Excellence and Advanced Research for Childhood Neurodevelopmental Disorders, Child Neurology Division, Department of Pediatrics, All India Institute of Medical Sciences, New Delhi, India

---

Background:

Vitamin D insufficiency is widely prevalent in India across all ages and socioeconomic strata. There is no published data on Vitamin D Status in Indian children with Autism Spectrum Disorder (ASD). Many studies have shown that children with autism also have altered levels of other micronutrients. These vitamins and minerals play important role in handling environmental stress.

Objectives:

### Primary

To compare plasma 25 (OH) Vitamin D level in children with ASD aged 2-5 years with age and gender matched TDC attending pediatric OPD at AIIMS, New Delhi India

### Secondary

To compare following in children with ASD aged 2-5 years with age/ gender matched TDC

1. Serum copper level
2. Serum Zinc level
3. Copper- zinc ratio

Methods:

Study design: Analytical Cross sectional study

Fifty-one children with autism and thirty-three TDC were enrolled after applying inclusion and exclusion criteria as per study protocol. Clinical psychology assessment was done for both groups. ASD group children underwent assessment by Childhood Autism Rating Scale 2, and DQ assessment by Development Profile 3 was done in both groups. Fasting blood samples were collected for micronutrient analysis as per lab guidelines. Samples were analyzed and results were analyzed.

Results:

1. Both groups were comparable for their demographic characteristics ( age and gender matched). Maternal age and paternal age at the time of birth of child was significantly high in ASD group.
2. Perinatal history was significant in ASD group compared to control (p=0.01). ASD group had more vegetarian children (p= 0.006). Milk consumption was significantly high in ASD group (p=0.001). Children in ASD group had less defined outdoor timings compared to controls (17% vs 51%).
3. Mean Serum 25 (OH) vitamin D was 9.86±6.91 ng/ml in ASD group and in control group mean±SD was 18.63±10.87. Both were in insufficiency range and data was skewed with high SD so logarithmic transformation was done; unadjusted logarithmic values were significantly low in ASD group (p 0.0001).
4. Serum copper was within range in all subjects, there was no difference in two groups.
5. Serum zinc was below lower reference range in 92% cases in ASD group and 33% in control group, (p-0.004)
6. Copper to zinc ratio was significantly high in ASD group with mean of 2.45, control group mean value was 1.73 (p:0.0005).

Conclusions:

In this study serum 25 (OH) vitamin D level was significantly low in 2-5 year old children with ASD compared to age and gender matched typical group. Similarly serum zinc level was significantly low in ASD group. Serum Copper to zinc ratio was significantly high in ASD group compared to neurotypicals.

### Recommendations

- Serum vitamin D level and Zinc level should be monitored in children with ASD as they are at risk for deficiency.
- Controlled intervention studies with micronutrients and their effect on core symptoms of autism and behaviour.

**Strength:** Adequate sample size, Both the groups were appropriately age and gender matched, the study selected younger children to see the effect of micronutrients in early years of development.

**Limitation:** doesn't show enough evidence to establish reasons for results and cause and effect relationship

**406.006 (Poster)** Comparison of Levels of Oxidative Biomarkers between Children with Autism Spectrum Disorder Aged 2-18 Years and Typically Developing Children: A Case-Control Study

**C. Reddy<sup>1</sup> and S. Gulati<sup>2</sup>:** (1)Pediatrics, AIIMS, New Delhi, India, (2)Centre of Excellence and Advanced Research for Childhood Neurodevelopmental Disorders, Child Neurology Division, Department of Pediatrics, All India Institute of Medical Sciences, New Delhi, India

---

Background: Autism spectrum disorders (ASD) constitute one of the most common neurodevelopment disorders. As per the CDC 2019 report, the prevalence of ASD is 1 in 59. But the etiopathogenesis of ASD still remains enigmatic. Though multiple genetic, metabolic and environmental factors are implicated, exact mechanisms are yet to be elucidated.

Objectives:

The primary objective was to compare the levels of methylation pathway biomarkers (blood methionine, cysteine, homocysteine and MTHFR C677T polymorphism) between children with ASD and age and gender matched typically developing children. Secondary objectives were to compare the blood levels of advanced glycation end products (AGEs) [N Carboxymethyl Lysine (CML), N Carboxymethyl Arginine (CMA) and dityrosine], urine uric acid/ creatinine ratio, arterial blood lactate, blood vitamin E, vitamin B12 and folate levels and to correlate the levels of these biomarkers with severity of autism (CARS score), sensory issues (SP2 score), co-morbidities (CBCL score) and DQ/IQ (MISIC/VSMS/BKT)

Methods: In this case- control study, children with ASD between 2-18 years fulfilling DSM-5 criteria were selected as cases and age and sex matched typically developing children as controls. Subjects with any chronic illness or those on any anti-oxidant therapy or multivitamins or anti epileptic drugs were excluded. Sample size was calculated using an effect size of 0.6  $\mu\text{mol/L}$  (difference means of plasma homocysteine level in children with ASD and control) from existing literature,  $\alpha$  error of 0.05, power 80% and case to control ratio of 2:1.

Results:

100 cases (male= 82) and 50 controls (male= 41) were enrolled in the study. The frequency of CC, CT and TT genotypes in ASD group was 84%, 14% and 2% respectively and in control group was 86%, 12% and 2% respectively. The results showed that the C677T polymorphism was not associated with increased ASD risk in any of the comparison models predicted by Hardy Weinberg Equilibrium. The median level of serum homocysteine in ASD group was 9  $\mu\text{mol/L}$  (95% CI: 7-16  $\mu\text{mol/L}$ ) which was significantly higher than median level in the control group 7  $\mu\text{mol/L}$  (95% CI: 4-11  $\mu\text{mol/L}$ ) ( $p=0.01$ ). The prevalence of hyperhomocystinemia ( $\geq 15\mu\text{mol/L}$ ) was 13.4% in ASD group compared to 3.8% in control group with a statistically significant difference ( $p=0.04$ ). There was no statistically significant correlation found between prevalence of hyperhomocystinemia and severity of autism/ DQ/ presence or absence of sensory issues/ presence or absence of behavioral issues. Among AGEs only dityrosine was found to be significantly elevated in ASD group. There was no statistically significant difference between the median levels of plasma cysteine or methionine levels, urine uric acid to creatinine ratio, arterial lactate, serum vitamin E, vitamin B12 and folate levels between the cases and controls.

Conclusions:

Our study shows that MTHFR C677T polymorphism is neither a risk nor a protective factor for autism. The prevalence of hyperhomocysteinemia is significantly higher in ASD compared to controls and is independent of MTHFR polymorphism or vitamin B12 or folate levels. The evidence for the role of increased oxidative stress in the pathogenesis of ASD is also strengthened by the increased tyrosine levels.

**406.008 (Poster)** Development of a Plasma Metabotype-Based Biomarker Test Battery to Screen for Children at Risk of ASD  
**A. M. Smith<sup>1</sup>, M. Ludwig<sup>1</sup>, L. Feuling<sup>1</sup>, D. Ney<sup>2</sup>, E. Donley<sup>1</sup>, M. Natowicz<sup>3</sup>, D. G. Amaral<sup>1</sup> and R. Burrier<sup>4</sup>,** (1)Stemina Biomarker Discovery, Madison, WI, (2)Nutritional Sciences, University of Wisconsin, Madison, WI, (3)Pathology & Laboratory Medicine Institute, Cleveland Clinic, LL-3, Cleveland, OH, (4)Department of Psychiatry and Behavioral Sciences, The Medical Investigation of Neurodevelopmental Disorders (MIND) Institute, UC Davis School of Medicine, University of California Davis, Sacramento, CA

---

#### Background:

Discovery of biomarkers associated with autism spectrum disorder (ASD) can lead to the development of tests useful in the screening for ASD. ASD is a heterogeneous disorder with etiologic and clinical heterogeneity that hampers diagnosis, frequently delaying therapeutic interventions. Stratification of the ASD population based on biochemical phenotypes of metabolic dysregulation (metabotypes) can be used to identify biomarkers amenable for use in diagnostic tests. We previously reported on stratification of 53% of the ASD subjects enrolled in the Children's Autism Metabolome Project (CAMP, ClinicalTrials.gov Identifier: NCT02548442) based on ratios of plasma metabolites that identify dysregulation of metabolism. In this work, we increase the number of metabolites profiled and employ a cross validation approach to identify additional biomarkers that, in turn, identify novel metabotypes associated with ASD in CAMP. These biomarkers are then optimized into a test battery with increased sensitivity compared to our previous reports.

#### Objectives:

The study sought to use quantitative plasma metabolite analyses to identify alterations of amino acid and other amines, purine, and organic acid metabolism to stratify ASD subjects into distinct metabotypes that may be clinically actionable.

#### Methods:

A training set of plasma samples from 499 children with ASD and 209 typically developing (TYP) children, age 18-48 months, were analyzed from CAMP which enrolled children from 8 centers across the US. The Autism Diagnostic Observation Schedule, Second Edition (ADOS-2) was performed by research reliable clinicians to confirm ASD diagnoses. Quantitative mass spectrometry-based methods were used to measure the concentration of 42 metabolites in plasma samples. Metabotype tests were created by setting a diagnostic threshold to identify a subpopulation of CAMP subjects primarily composed of children with ASD. Four-fold cross validation stratified by age, sex, and diagnosis repeated 50 times was used to identify metabotypes tests with subpopulations that have a minimum average diagnostic performance of 5% sensitivity and 95% specificity. Metabotype tests meeting minimum diagnostic performance were optimized to create a test battery that increases sensitivity of the overall diagnostic approach while maintaining a minimum of 90% specificity.

#### Results:

The cross validation approach increased the metabotype tests from 34 previously reported to 125 metabotype tests comprised of metabolites and ratios of metabolites. The 125 metabotype tests fell into several metabolic clusters associated with citrate and 2-ketoglutarate, lactate and pyruvate, amino acids, taurine, carnitine, 4-hydroxyproline, and ethanolamine and urate. Within these clusters, ASD subjects are often identified by multiple metabotypes. The individual metabotype tests had average sensitivities of 5-11% and specificities of 97-100%. The 125 metabotype tests were optimized into a battery, based on subset of 27 tests, that identified CAMP ASD subjects with a sensitivity of 69% and specificity of 90%.

#### Conclusions:

Our ongoing analyses have increased the number of metabotypes associated with ASD in the CAMP cohort from 53% to 69%. This research holds the prospect of producing a system for identifying risk of autism in very young children. It also establishes a pathway for identifying metabolically characterized subtypes of autism that, in turn, may have implications for targeted treatments.

**406.009 (Poster)** Development of the Pupillary Light Reflex from 9 to 24 Months in Infants with Elevated Familial and Genetic Liability to Autism.

**L. Fish<sup>1</sup>, P. Nyström<sup>2</sup>, T. Gliga<sup>3</sup>, A. Gui<sup>4</sup>, J. Begum-Ali<sup>5</sup>, L. Mason<sup>6</sup>, M. Johnson<sup>6</sup>, T. Charman<sup>7</sup>, R. ---

**Background:** Although Autism Spectrum Disorder (ASD) is highly heritable, the mechanisms through which genetic alterations contribute to behavioural symptom emergence remains unclear. Using a prospective study design, investigating early intermediate phenotypes in infants with a family history of ASD may provide a tool to bridge genotype to behavioural phenotype prior to clinical diagnosis. A candidate early intermediate phenotype is the pupillary light reflex (PLR): the rapid automatic reduction in pupil diameter in response to increased optical luminance. Altered PLR during infancy has been associated with later ASD.

**Objectives:** We aimed to examine whether later ASD diagnosis and symptom severity was associated with developmental trajectory of PLR latency and constriction from 9- to 24-months in infants with and without a family history of ASD. We also aimed to determine whether ASD polygenic score (a weighted sum of ASD-associated common genetic variants) was associated with PLR development.

**Methods:** We collected pupil data longitudinally at 9-, 14- and 24-months from 256 infants; 206 had a family history of ASD. Pupillary light reflex was induced, and pupil diameter was measured using eye-tracking technology. DNA samples were taken and polygenic scores for ASD were calculated for each infant. At 36-months ASD symptom severity was measured using the Autism Diagnostic Observation Schedule; 28 infants received an ASD diagnosis.

**Results:** Separate linear multilevel models with random intercepts were conducted. We assessed the interaction of visit timepoint (9-, 14- and 24-month) with a) 36-month ASD outcome, b) 36-month symptom severity and c) ASD polygenic score, on PLR latency and constriction amplitude. Infants with an ASD diagnosis at 36-months had a larger reduction in constriction amplitude between 9- to 24-months compared to typically developing infants with no ASD family history ( $\beta = 8.10$ , *s.e.* = 2.07,  $p < 0.001$ ) and typically developing infants with ASD family history ( $\beta = 4.01$ , *s.e.* = 1.84,  $p = 0.03$ ; Figure 1a). Higher symptom severity at 36-months was associated with larger decreases in constriction amplitude between 9- and 14-months ( $\beta = -0.67$ , *s.e.* = 0.32,  $p = 0.03$ ). ASD polygenic scores did not associate with PLR constriction amplitude across time. Infants with a later ASD diagnosis showed a larger latency decrease between 9- to 24-months compared to the typically developing group with no ASD family history (Figure 1b;  $\beta = 24.26$ , *s.e.* = 9.23,  $p = 0.001$ ). Those with a later ASD diagnosis demonstrated a non-significant difference in latency across 9-14 months. Higher ASD polygenic scores associated with increased latency between 9-14 months ( $\beta = 8.27$ , *s.e.* = 3.05,  $p = 0.01$ ).

**Conclusions:** Taken together, the development of basic pupillary responses is altered in infants with later ASD. Pupil constriction in response to light became attenuated more quickly over time for infants with a later ASD diagnosis compared to their typically developing counterparts. Polygenic liability appeared to associate with stagnating latency changes between 9-14 months. Infants with a later ASD diagnosis showed greater decreases in latency from 14- to 24-months, indicating an apparent 'catching up' profile.

**406.010 (Poster)** Diagnostic, Developmental, and Health Effects on Parasympathetic Regulation and Reactivity in Youth with Autism Spectrum Disorder

**R. A. Muscatello<sup>1</sup>, A. Kim<sup>2</sup>, S. Vandekar<sup>2</sup> and B. A. Corbett<sup>1</sup>,** (1)Psychiatry and Behavioral Sciences, Vanderbilt University Medical Center, Nashville, TN, (2)Department of Biostatistics, Vanderbilt University Medical Center, Nashville, TN

---

**Background:** The Autonomic Nervous System (ANS) plays an important role in physiological regulation and response to stress. The parasympathetic branch of the ANS promotes calm visceral states, while also serving as a behavioral regulator. A dynamic, flexible parasympathetic system promotes adaptation to changing environmental demands, important for appropriate behavioral and emotional regulation and response. Increasing evidence suggests individuals with autism spectrum disorder (ASD) demonstrate atypical autonomic regulation; however, research remains inconsistent and likely dependent on a number of influential factors, such as developmental influences or physical health.

**Objectives:** The primary goal of the study was to examine parasympathetic regulation and response to the Trier Social Stress Test (TSST), a social evaluative threat paradigm, in a large, well-characterized sample of youth, ages 10-13 years, with and without ASD. The study aimed to identify hypothesized differences between the groups in the response to the TSST. Further, in an effort to address inconsistencies in previous research, additional factors expected to contribute to ANS response were explored.

**Methods:** The total sample included 241 youth with ASD (N=138) or TD (N=103), ages 10-13 years. The ASD group was comprised of 102 males and 36 females, while the TD group included 57 males and 46 females. Participants completed a physical examination, conducted by trained, licensed, study physicians to assess pubertal development, height, weight, and body mass index (BMI). Participants were exposed to the TSST paradigm while parasympathetic response was measured continuously, indexed by respiratory sinus arrhythmia (RSA). Linear mixed effects models examined the effects of baseline RSA, time, age, sex, pubertal stage, BMI, and diagnosis.

**Results:** Initial models demonstrated a significant effect for diagnosis ( $X^2(1)=5.01$ ,  $p=0.02$ ) and time ( $X^2(4)=303.79$ ,  $p<0.0001$ ), revealing youth with ASD had significantly lower RSA on average relative to those with TD. However, there was no interaction for diagnosis and time ( $p>0.05$ ), suggesting the change in RSA during the TSST did not differ between the two diagnostic groups. Further analyses showed a significant main effect for BMI ( $X^2(1)=25.29$ ,  $p<0.0001$ ) but not pubertal development stage (all  $p>0.05$ ), such that elevated BMI was associated with lower RSA on average. Notably, in follow-up models of diagnosis, time and a diagnosis\*time interaction, including BMI, there was no longer an effect for diagnosis ( $X^2(1)=1.54$ ,  $p=0.21$ ).

**Conclusions:** There is an emerging and alarming literature showing higher rates of overweight and obesity in youth with ASD, which may have serious physical and mental health consequences. As lower parasympathetic regulation may increase susceptibility for a number of conditions, such as anxiety or depression, it will be important to further elucidate the link between BMI and the ANS, especially in ASD. Moreover, given the lack of diagnostic effects when controlling for BMI, current findings emphasize the need to account for relevant covariates when examining autonomic response in ASD, as these related variables may be contributing to noted inconsistencies in the literature.

#### **406.011 (Poster) EEG Biomarkers of Social Interaction in Fmr1 Null Mice**

**S. P. Uysal<sup>1</sup>, S. Gurnani<sup>2</sup>, L. Lalani<sup>3</sup>, A. Rotenberg<sup>4</sup>, M. Sahin<sup>5</sup> and M. E. Modi<sup>6</sup>,** (1)Cleveland Clinic, Cleveland, OH, (2)Neurology, Boston University Medical Center, Boston, MA, (3)Boston Children's Hospital, Boston, MA, (4)Neurology, Harvard Medical School, Boston, MA, (5)Boston Children's Hospital/Harvard Medical School, Boston, MA, (6)Neurology, Boston Children's Hospital, Boston, MA

---

**Background:** Alterations in neural activity as measured by EEG have promise as biomarkers of neurodevelopmental impairment in both patients with Fragile X Syndrome and Fmr1 mutant mice. Abnormal neurophysiological responses to auditory stimuli in this mouse model correlate with behavioral hypersensitivity, suggesting EEG can reflect behavioral phenotypes.

**Objectives:** To test whether there are similar EEG correlates in the social behavioral domain associated with FXS symptomatology, we characterized the spectral power of cortical EEG in the Fmr1 mutant mouse during social interaction.

**Methods:** Hemizygous Fmr1 and wild-type control male mice (n=12) were implanted with wireless EEG transmitters coupled to a frontal active electrode and a cerebellar reference electrode. EEG was recorded during repeated social interaction sessions with either juvenile or adult conspecifics. The freely-movingly implanted mice engaged in the social recognition task in which they were exposed in a series to 1) a novel conspecific, 2) the same now familiar conspecific and 3) a new novel conspecific. The time spent in olfactory investigation of the conspecific was scored and the spectral power of the EEG was calculated for baseline, non-social and social epochs. The habituation index between the first and second exposure was calculated for both olfactory investigation and spectral power.

**Results:** Both Fmr1 and control mice engaged in high levels of olfactory investigation of both adult female and juvenile male conspecifics and demonstrated a reduction in gamma power during social interaction epochs relative to baseline epochs ( $p<0.0001$ ). However, Fmr1 mice spent more time investigating novel animals ( $p=0.004$ ) and had a corresponding increase in theta power during investigation relative to control mice ( $p=0.005$ ). The Fmr1 animals did not display the species typical behavioral habituation to repeated interactions with the same conspecific indicated by a reduction in olfactory investigation. Control mice, contrastingly, exhibited a reduction in both olfactory investigation ( $p=0.02$ ) and total EEG power across repeated social exposure ( $p=0.05$ ). Consistent with their failure to exhibit a behavioral response, Fmr1 animals also did not show a reduction in total spectral power.

**Conclusions:** A broad EEG signature of social interaction in the reduction in gamma power can be seen across genotypes and social stimuli. The behavioral differences between Fmr1 mutant and control mice, namely increased investigation of novel

stimuli and decreased habituation to repeated stimuli by the Fmr1 animals, correspond to differences in spectral EEG power during social/olfactory interaction. The identification of features within spectral power that correlate with both behavioral states and genotypic differences suggests that EEG could be used as a readout of social circuitry to support preclinical investigations of therapeutic interventions targeted at this domain of impairments.

**406.012 (Poster) EEG Theta Power and Behavioral Characteristics of Children with Autism with and without Co-Occurring ADHD**

---

**Background:**

Theta electroencephalography (EEG) band has been related to performance and cognitive control and is implicated in attention-deficit/hyperactivity disorder (ADHD) and autism spectrum disorder (ASD), two disorders which have a high comorbidity rate. Studies support a differential theta response between these groups (ADHD: higher theta, ASD: lower theta) when compared to typical development (TD). Two studies investigated comorbid *ASD+ADHD* and found lower theta power compared to *ADHD-only*. Thus, the underlying physiological mechanisms of *ADHD-only* and comorbid *ASD+ADHD* may be different, and more research is needed to understand the brain correlates of the two disorders.

**Objectives:**

The current study compared EEG absolute theta power measured across frontal-central scalp regions in 4 groups of 3-7 year old children: *ASD-only* (n=41), *ADHD-only* (n=32), co-morbid *ASD/ADHD* (n=30), and TD (n=18). We also explored associations between levels of theta power and levels of social and adaptive skills among children with a diagnosis of *ASD-only* versus those with a diagnosis of *ADHD*. The latter group included children with both *ASD+ADHD* and *ADHD-only*. Finally, we explored these relationships among children with *ADHD-only*.

**Methods:**

We used ANCOVAs to test for differences in absolute theta power (4-6 Hz) during a resting state EEG paradigm (cascading bubbles), averaged across 5 frontal-central channels (F3,F4,Fz,C3,C4). We used linear regression to test the associations between theta power and a standardized measure of adaptive skills, the Vineland Adaptive Behavior Scales-3 (VABS). This scale provides information on several subdomains of skills, including Communication, Socialization, Motor, and Daily Living Skills. 121 children provided artifact-free EEG and were included in the analysis (mean Full Scale IQ = 96 ± 25, mean age = 72 ± 16 months). All models accounted for age, IQ, and sex.

**Results:**

First, we investigated potential differences in theta power between groups, and results revealed no overall group differences. Next, we studied associations between theta and VABS within the *ASD-only* group but observed no associations. Second, in a combined group including *any-ASD* diagnosis (i.e. *ASD-only* and *ASD+ADHD* combined), no associations were observed. Third, in a combined group including *any-ADHD* diagnosis (i.e. *ADHD-only* and *ASD+ADHD* combined), we found increased VABS Personal Daily Living, Motor, and Gross Motor Skills were associated with higher theta power ( $\beta=9.442e-03-0.007$ ,  $p<0.05$  for all). Finally, a similar analysis conducted with the *ADHD-only* group did not yield significant relationships; however, the small sample size makes this finding inconclusive.

**Conclusions:**

Based on these preliminary analyses, we do not find significant differences in frontal-central theta power among children with *ASD-only*, *ASD+ADHD*, *ADHD-only*, and TD. However, our results suggest that, among children with *any-ADHD* diagnosis (i.e. *ADHD-only* and *ASD+ADHD* combined), higher levels of frontal-central theta are associated with higher levels of adaptive and motor behaviors. Theta power may be especially relevant for development of adaptive skills in children with ADHD, regardless of whether or not they have co-occurring autism. It is surprising that a similar relationship was not found when the children with

ADHD-only were examined separately. We are continuing to collect additional data and a larger sample will provide more definitive conclusions.

**406.013 (Poster)** Examining Heterogeneity in Children on the Autism and Broader Autism Spectrum through Latent Factors Underlying Social and Cognitive Variability

**S. Yuan<sup>1</sup>, S. Koirala<sup>2</sup>, D. Parmaksiz<sup>3</sup>, E. Kushner<sup>4</sup>, A. Klin<sup>5</sup>, W. Jones<sup>5</sup> and L. A. Edwards<sup>5</sup>,** (1)Emory University School of Medicine, Marcus Autism Center, Atlanta, GA, (2)Department of Pediatrics, Emory University School of Medicine, Marcus Autism Center, Atlanta, GA, (3)Marcus Autism Center, Atlanta, GA, (4)Emory University, Marcus Autism Center, Atlanta, GA, (5)Marcus Autism Center, Children's Healthcare of Atlanta and Emory University School of Medicine, Atlanta, GA

---

**Background:** Autism Spectrum Disorder (ASD) is a neurodevelopmental disorder with high heterogeneity (Waterhouse, 2013). Efforts to embrace a more bio- and neural-marker-driven framework for defining mental health disorders (Insel et al., 2010) and DSM-5's employment of more quantitative scoring systems when assessing autistic traits (Ijichi et al., 2013) highlight the goals of identifying quantifiable markers of disability and also underlying processes of both ability and disability that might otherwise be obscured by categorical diagnostic labels. In this study, our goal is to identify latent developmental profiles that may predispose children towards more or less improved outcomes.

**Objectives:** We use data-driven approaches to identify subgroups of children on the autism and broader autism spectrum with divergent profiles of social-cognitive functioning.

**Methods:** We studied 52 children (42 males) with confirmed ASD diagnoses and an additional 27 (21 males) diagnosed with Broader Autism Phenotype (BAP). Children were part of a high-risk-for-ASD, infant-siblings study design, followed from birth with diagnoses confirmed at 24 and 36 months. Eye-tracking data were collected at 1, 2, 3, 4, 5, 6, 9, 12, 15, 18, 24, and 36 months of age, while children watched videos featuring naturalistic caregivers. Toddlers were assessed via *Mullen Scales of Early Learning* (MSEL) and *Autism Diagnostic Observation Schedule* (ADOS-2) at 24 months. Age-equivalent scores from MSEL domains (visual reception (VR), fine motor (FM), gross motor (GM), expressive language (EL), receptive language (RL)) and ADOS-2 domains (social affect (SA), restricted and repetitive behaviors (RRB)) were subject to factor analysis and spectral clustering. A Friedman test was used to assess whether derived subgroups have distinct social-cognitive profiles. Eye-tracking data were quantified as percentage of time spent fixating on regions-of-interest (ROIs) within the stimuli, and repeated-measures ANOVA were used to examine group differences in visual fixation patterns.

**Results:** A 3-group solution was selected based on spectral clustering. A significant MSEL/ADOS Measure-by-Group interaction ( $F=25.88$ ;  $p<0.001$ ) indicates distinct social-cognitive profiles across groups. Group1 comprised toddlers with higher verbal ability (significantly higher EL than Group1 and Group3; both  $p<0.001$ ), Group2 comprised toddlers with increased social disability and decreased verbal and nonverbal cognitive measures (significantly higher SA ( $p_{\text{Group1}}=0.008$ ,  $p_{\text{Group3}}=0.004$ ) and RRB scores ( $p_{\text{Group1}}=0.043$ ,  $p_{\text{Group3}}=0.014$ ), and significantly lower EL (both  $p<0.001$ ), RL (both  $p<0.001$ ), GM ( $p_{\text{Group1}}=0.002$ ,  $p_{\text{Group3}}=0.007$ ), and VR abilities (both  $p<0.001$ ) than Groups1 and Group3), and Group3 comprised toddlers with higher nonverbal cognitive abilities (statistically higher FM and VR than Group2 (both  $p<0.001$ )). Significant ROI-by-Group interactions indicated that visual fixation patterns were divergent at 15 ( $F=2.394$ ;  $p=0.030$ ) and 36 months ( $F=2.87$ ;  $p=0.013$ ). Group2 looked significantly less at mouths at 15 months ( $p_{\text{Group1}}=0.022$ ,  $p_{\text{Group3}}=0.017$ ), and significantly more at body ( $p_{\text{Group1}}=0.035$ ,  $p_{\text{Group3}}=0.026$ ) and object regions ( $p_{\text{Group1}}=0.002$ ,  $p_{\text{Group3}}=0.005$ ) at 36 months compared to Group1 and Group3.

**Conclusions:** Data-driven approaches can derive meaningful subgroups among children with varying levels of social-cognitive ability. Differences in visual attention to social stimuli between groups reveal the relationship between social visual engagement and early social-cognitive development. Future research will investigate whether and how these empirically-derived subgroups diverge in visual attention profiles over the first 36 months of development.

**406.014 (Poster)** Examining Resting State Alpha Power and Social Motivation Among Carriers of CHD8 Mutations and CHD8-Target Genes

**T. M. Rutter<sup>1</sup>, H. Rea<sup>2</sup>, E. E. Eichler<sup>3</sup>, R. A. Bernier<sup>4</sup>, S. J. Webb<sup>4</sup>, R. K. Earl<sup>1</sup> and C. M. Hudac<sup>5</sup>,** (1)Seattle Pacific University, Seattle, WA, (2)Center for Human Development and Disability, University of Washington, Seattle, WA, (3)Department of Genome Sciences, University of Washington, Seattle, WA, (4)Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA, (5)Psychiatry and Behavioral Sciences, University of Washington, Seattle, AL

---

**Background:** Investigating shared biological pathways of ASD-risk genes may provide greater utility in efforts to parse ASD heterogeneity. One high confidence candidate risk gene for ASD is chromodomain helicase DNA-binding protein 8 (CHD8) (Bernier et al., 2014), which also regulates the expression of other ASD-risk genes (CHD8-targets; Cotney et al., 2015). Research suggests that individuals with ASD with CHD8 and CHD8-target mutations demonstrate greater social motivation challenges on

the Social Responsiveness Scale (SRS-2) compared to individuals with other genetic mutations or idiopathic ASD (Beighley et al., 2020). However, less is known about shared neurophysiological phenotypes among these children and relations with social phenotype. One candidate is alpha EEG frequencies (8-13 Hz), given that individuals with ASD show greater alpha frequency compared to neurotypical controls (Cornew et al., 2012, Wang et al., 2013) and positive associations between social deficits and resting state alpha power (Cornew et al., 2012; Edgar et al., 2015; but see Keehn et al., 2017).

**Objectives:** We examined whether individuals with mutations in shared genetic pathways (CHD8 and CHD8-targets) exhibited shared brain phenotypes that corresponded to atypical social behaviors. Specifically, we tested group differences in alpha power among children with ASD with mutations in CHD8, CHD8-target genes, non-targets, or idiopathic ASD and modulation by social motivation.

**Methods:** Participants were 120 children ( $M_{Age} = 10.93$  years; 29% female) with a CHD8 gene mutation ( $n = 8$ ), CHD8-target ( $n = 14$ ), a genetic mutation not targeted by CHD8 (non-target;  $n = 30$ ), or idiopathic ASD ( $n = 68$ ). Genetic mutations were ascertained via genetic testing; idiopathic participants were confirmed via genetic testing and had an existing ASD diagnosis. Social motivation was measured via primary caregiver report on the SRS-2 (Constantino & Gruber, 2012) social motivation subdomain. Alpha power was acquired during an eyes-open resting state EEG paradigm averaging 2 minutes in duration in which participants were instructed to passively attend to screensaver-like videos.

**Results:** Linear effects models examining alpha power indicated an effect of group,  $F(3,496)=7.51, p < .0001$ , though pairwise corrections did not survive Bonferroni correction for multiple comparisons. This effect was modulated by a significant interaction,  $F(3,496)=7.72, p < .001$ , that indicated increased social motivation challenges were related to higher alpha in the CHD8-target group (slope=.08), lower alpha in non-target group (slope=-.07), and no relationship in CHD8 and idiopathic ASD (slopes <.007) groups. Linear effects models examining SRS social motivation domain scores indicated an effect of group,  $F(3,500)=17.435, p < .001$ , with non-target groups demonstrating fewer social motivation problems relative to all other groups,  $p$ 's < .0125.

**Conclusions:** Our results demonstrated a common alpha phenotype for CHD8 and idiopathic ASD that was not related to social motivation challenges, unlike other pathogenic groups. A more nuanced examination of other frequency bands may illuminate other variability related to shared genetic pathways. Future research should include larger samples to test for interactions with social functioning, and should investigate the role of RRBs, which may drive alpha differences related to ASD.

**406.015 (Poster) Extending the Clinical Utility of Eye-Tracking Assays of Social Visual Engagement to Minority Populations: A Pilot Study of Toddlers with ASD from African American and Non-English-Speaking Families**

*A. I. Mendez<sup>1</sup>, M. Reid<sup>2</sup>, C. Klaiman<sup>3</sup>, A. Klin<sup>3</sup> and W. Jones<sup>3</sup>, (1)Marcus Autism Center, Children's Healthcare of Atlanta and Emory University Department of Psychology, Atlanta, GA, (2)Catholic University of America, Washington, DC, (3)Marcus Autism Center, Children's Healthcare of Atlanta and Emory University School of Medicine, Atlanta, GA*

---

**Background:**

Despite the consensus that early identification optimizes outcomes for individuals with ASD, the median age-of-diagnosis remains at 4-5 years and lags another 1.5 years for lower-income, minority families. These disparities result in adverse impacts on outcomes: African American (AA) children with ASD have an increased burden of intellectual disability than White children with ASD, whereas non-English-speaking Hispanic children with ASD are ascertained at lower rates and display elevated burden of ID relative to English-speaking, White counterparts. There is crucial need for tools that increase access to early diagnosis simultaneously addressing racial/ethnic disparities. A previous double-blinded study tested a standalone investigational device that uses eye-tracking technology to quantify social visual engagement(SVE) -how children look at and learn about their social environment. Tests compared eye-tracking to clinician-best-estimate diagnosis and assessment. Results showed that eye-tracking assays could yield ASD diagnostic sensitivity of 83.9%(77.8-88.6), specificity of 82.3%(76.1-87.2), and explained 78.4% of variance in ADOS total scores, 71.2% and 60.3% of Mullen verbal and nonverbal scores, respectively. Here we extend the utility of these methods to minority populations, aiming to increase access to early diagnosis.

**Objectives:**

To probe the utility of eye-tracking assays of SVE in a sample of AA and Non-E toddlers with ASD relative to their white and English-speaking counterparts, respectively.

**Methods:**

Sociodemographic, clinical, and eye-tracking data were collected from N=204 toddlers referred for an ASD evaluation. Parent-reported child race and home-language was used to assign toddlers with ASD to AA (n=38), W (n=104), English-speaking (n=29) and non-English-speaking (n=33) groups. Additional non-ASD AA (N=11) and non-E (N=6) toddlers completed procedures to pilot diagnostic accuracy. Higher ADOS total scores were observed in AA-ASD toddlers when compared to W-ASD toddlers ( $p < .03$ ). No other significant differences were observed across comparisons.

Eye-tracking data were analyzed by using moment-by-moment visual scanning of social scenes relative to normative data previously collected from typically-developing toddlers. We quantified visual scanning by making nonparametric estimates of the underlying probability density function for visual fixation and scanning at each moment-in-time using time-varying kernel density estimation. These performance-based metrics are used to quantify levels of social disability and verbal/nonverbal ability.

### Results:

There were no significant differences in valid eye-tracking data collection across comparison groups. Results on the eye-tracking-based indices of social disability, verbal and nonverbal ability revealed no significant differences across AA-ASD and W-ASD groups, or across Non-E-ASD vs. E-ASD groups. Diagnostic accuracy for the AA-ASD vs AA-non-ASD comparison was 85.7%(73.0%-93.2%) and 87.2%(72.8-94.9%) for the Non-E-ASD vs E-ASD comparison.

### Conclusions:

Results suggest that eye-tracking assays perform equivalently in AA and non-English-speaking toddlers with ASD relative to their White and English-speaking counterparts. These results bode well for deployment of this technology for traditionally underserved populations that have limited access to early identification services, which ultimately delays access to early intervention. A major limitation of this study is the small samples of non-ASD AA and Non-E toddlers contributing to our estimates of diagnostic accuracy. These estimates should be considered as directional, and not yet robust. To address this, our group continues to expand the samples.

#### 406.016 (Poster) Eye Tracking Entropy from Social and Nonsocial Stimuli As an Attention Dispersion Measure for Autism Spectrum Disorder

C. Carlos, A. Naples, J. M. Wolf, T. McAllister, E. Cummings, T. C. Parker and J. McPartland, Child Study Center, Yale University School of Medicine, New Haven, CT

Background: Recent work in the field of autism spectrum disorder (ASD) has highlighted the utility of eye tracking (ET) as a tool for investigating visual attentional differences in individuals with ASD and typically developing (TD) individuals. A typical ET experimental battery presents a subject with visual stimuli relevant to a particular construct (e.g., social information, such as human faces or scenes featuring people), and may also contrast the resulting ET data with ET data collected from presentation of stimuli unrelated to the construct of interest (e.g., non-social information, such as objects). Currently, most ET data analyses in ASD research rely on *a-priori* designation of relevant regions of interest (ROIs) in a stimulus (e.g. eyes, mouth, face) or irrelevant (e.g. image background, landscape features), requiring both the collected ET data and the specific researcher-labeled stimuli to reach analytic conclusions. Information-theoretic approaches, such as entropy, hold promise to successfully characterize the complexity of ET data without reliance on ex-ante ROIs.

Objectives: To characterize the manner in which entropy of looking patterns differs between ASD and TD individuals viewing both socially relevant (i.e., human face) and non-social (i.e., house) stimuli.

Methods: Data was collected from adults with ASD (N=11) and TD adults (N=23). Subjects were presented with a crosshair directing attention to the center of a screen, followed by either a human face image or a house image for one second. ET data was collected by an EyeLink-1000 eye tracking system (SR Research) at 500 Hz and then accumulated by stimulus image to create heatmap visual attention matrices for each face and house image per participant. Shannon entropy was calculated for each face and house image. These entropy values were then averaged by stimulus type (i.e., face or house), and the difference between house-specific entropy and face-specific entropy was used as the final derived variable for each participant.

Results: No significant differences were observed between groups for average face entropy or average house entropy alone. However, a significant group difference in means ( $p = 0.008$ ) was observed in house/face entropy difference values.

Conclusions: Although no significant difference was observed between diagnostic groups when looking at face or house entropy alone, contrast of entropy values for social and non-social stimuli within each participant resulted in a significant difference in

means across groups. These results indicate that Shannon entropy characterizes ASD-specific deviations in visual attention, but only when considered within the context of that individual's unique visual response to houses and faces. Ongoing work will explore whether Shannon entropy derived from visual attention when not contrasted between social and nonsocial stimuli reflects individual variation irrespective of diagnostic status.

**406.017 (Poster)** Infants with a First-Degree Relative with Autism or ADHD Show Altered Brain Activity during Live Social Experiences

*E. V. Throm<sup>1</sup>, J. Begum Ali<sup>1</sup>, C. Taylor<sup>1</sup>, L. Mason<sup>1</sup>, T. Charman<sup>2</sup>, M. Johnson<sup>3</sup>, E. J. Jones<sup>1</sup> and .. the BASIS-STAARS Team<sup>1</sup>, (1)Centre for Brain and Cognitive Development, Birkbeck, University of London, London, United Kingdom, (2)Department of Psychology, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (3)Department of Psychology, University of Cambridge, Cambridge, United Kingdom*

---

**Background:** While neurodevelopmental disorders like Autism Spectrum Disorder (ASD) and Attention Deficit Hyperactivity Disorder (ADHD) are not diagnosed until childhood, differences in neural responses to social and non-social stimuli measured with optical imaging presented on screen at 6 months predicted later ASD (Jones et al., 2016; Lloyd-Fox et al., 2018).

**Objectives:** Because neural differences between infant social and non-social attention appear stronger for live vs screen action (Jones et al., 2015), we investigated how ASD and ADHD likelihood and outcome affect neural activity during live social and non-social experiences at 5-6 months of age.

**Methods:** Eighty-eight five-months old infants with a first-degree relative with ASD, ADHD or typical development watched an experimenter singing nursery rhymes (social) or operating toys (non-social) while EEG was recorded. Theta power (3-5.9 Hz) was extracted from 1-second segments of social and non-social attention. Linear mixed-effects models tested whether relative theta power during social and non-social attention was modulated by ASD and/or ADHD likelihood ( $n = 88$ ; 49 males; mean age: 174.80 days), categorical ASD outcome ( $n = 67$ ; positive  $n = 9$ ) and continuous ADHD outcome ( $n = 59$ ). Further variables were brain region (frontal, parietal, posterior, temporal) and laterality (left, right). Covariates were gender and age.

**Results:** Relative theta power (normalised) was stronger during social vs non-social attention ( $F(1, 84) = 11.67, p < .001$ ). This difference interacted with ADHD likelihood ( $F(1, 84) = 4.58, p = .035$ ), being only present in infants with typical ( $F(1, 61) = 11.15, p = .001$ ), but not with elevated ADHD likelihood ( $p > .6$ ). Further mixed-effects models revealed no stimulus interactions with ASD outcome at 36 months ( $p > .4$ ). No stimulus interactions were observed for ADHD traits measured at 36 months, both in the full sample ( $p > .1$ ) and in a subgroup of infants with elevated likelihood only ( $n = 18, p > .1$ ), with Pearson correlations being  $r \pm < .3$ .

**Conclusions:** Results are consistent with research suggesting that young infants typically show stronger theta power during social vs non-social live action (Jones et al., 2015), and seem to hold across different paradigms. While theta power modulation was reduced in infants with elevated ADHD likelihood, visual data inspection indicates reduced modulation also in infants with elevated ASD. The least modulation in infants with combined elevated likelihood for both conditions highlights the importance of considering ADHD likelihood when investigating emerging ASD. The nonsignificant interaction of ASD likelihood might be explained by insufficient power, or by the young age (5-6 months), with theta modulation differences possibly just emerging. Alternatively, young infants with elevated ASD process social stimuli more typically when presented live, while showing reduced modulation during screen presentation (Jones et al., 2016; Lloyd-Fox, 2018). Future studies may directly compare live and screen contexts. Because theta power during live social vs non-social attention typically strengthens over the first year (Jones et al., 2015), we will analyse EEG data from these infants at 14 months to see whether this trajectory is modulated by ASD and/or ADHD likelihood/outcome.

**406.018 (Poster)** Initial Evidence of Clinical Utility of Optimized FMRP Analysis in Fragile X Syndrome

*L. M. Schmitt<sup>1,2</sup>, A. Boggs<sup>1</sup>, C. Gross<sup>1,2</sup>, E. Pedapati<sup>1,2</sup>, K. Dominick<sup>1,2</sup> and C. A. Erickson<sup>1,2</sup>, (1)Cincinnati Children's Hospital Medical Center, Cincinnati, OH, (2)University of Cincinnati College of Medicine, Cincinnati, OH*

---

**Background:** The Fragile X mental retardation 1 (FMR1) gene-specific protein product, Fragile X mental retardation protein (FMRP), is critical for brain development as it is involved in synaptogenesis and activity-dependent synaptic plasticity. An unstable trinucleotide repeat expansion (CGG repeats  $>200$ ) and subsequent abnormal methylation of *FMR1* located on the X chromosome results in Fragile X Syndrome (FXS) and markedly reduced FMRP levels. Despite being a single-gene disorder, phenotypic heterogeneity is readily apparent in FXS. There are few studies demonstrating relationships between FMRP levels and phenotypic expression. Identifying these relationships may be critical to planning clinical care and understanding development over time.

**Objectives:** In the current study, we optimized a method to reliably and reproducibly detect FMRP at extremely low values in whole blood samples to examine the relationship between FMRP levels and phenotypic features in FXS.

**Methods:** Individuals with FXS were recruited as part of several federally-, foundation-, and institution-funded studies, and were only included in the current study if they completed both blood collection for FMRP processing and resting state EEG. Forty individuals with full mutation FXS (27 males (FXS(M) and 13 females (FXS(F)) aged 13-45 years completed testing. Participants completed a battery of psychosocial, neurocognitive, and neurophysiological measures. Participant whole blood samples, obtained via venipuncture, were spotted onto Whatman Bloodstain cards. Dried blood spots were hole-punched from the cards and proteins were eluted. The eluate was analyzed in triplicate against a nine-point standard curve generated from a recombinant protein, via a Luminex-based immunoassay, to determine participants' FMRP concentration, as described previously.

**Results:** Higher FMRP levels related to higher non-verbal IQ scores in FXS(M) but to higher verbal IQ scores in FXS(F). There was no relationship with neurocognitive variables on KiTAP tests. Higher FMRP levels were associated with less severe stereotyped behaviors, hyperactivity, and speech abnormalities on the ABC. During a social preference eye tracking task, higher FMRP levels were associated with a greater percentage of time looking at social scenes in FXS(M), but at geometric scenes in FXS(F). On resting state EEG measures, higher FMRP levels corresponded to lower peak alpha frequency and increased relative alpha1 power among FXS(M). In addition, correlations between higher FMRP and increased alpha2 and decreased gamma1 power trended towards significance. In a subset of individuals who completed an investigational drug study (n=12), only FXS(M) with complete absence of FMRP demonstrated increased RBANS verbal memory and reduced ABC irritability.

**Conclusions:** Our optimized FMRP analysis which allowed us to reproducibly identify FMRP at extremely low values provides new evidence of the link between FMRP production and phenotypic expression in FXS. Absence of FMRP in full mutation males is associated with more severe cognitive, psychosocial, and neurophysiological phenotypes. Results among females demonstrate a more complicated picture likely due to one unaffected X chromosome. Of note, we identify a subset of patients—males without any FMRP—who demonstrated significant improvement on verbal memory and irritability following two-week course of an investigational, which suggests optimized FMRP analysis may be a highly useful tool in treatment planning and trial stratification.

**406.019 (Poster)** Longer Auditory Brainstem Response Latency before 6 Months Does Not Predict Subsequent Language Impairment in Infants at-Risk for Neurodevelopmental Disorders: A Preliminary Investigation

A. Yi<sup>1</sup>, L. Yu<sup>2,3</sup>, B. Lai<sup>2,3</sup>, J. Zhang<sup>2,3</sup>, N. Li<sup>2</sup>, L. Ban<sup>2,3</sup>, J. Xin<sup>1</sup> and S. Li<sup>1</sup>, (1)Department of Children Rehabilitation, Foshan Chancheng Central Hospital, Foshan, China, (2)School of Psychology, South China Normal University, Guangzhou, China, (3)Autism Research Center, South China Normal University, Guangzhou, China

**Background:** Abnormal brainstem development has been associated with autism, language delay and social-emotional disorders of at-risk infants. Research has shown that these infants exhibit prolonged auditory brainstem response (ABR) latencies particularly Wave V as early as 0~3 months of age (Cohen et al., 2013; Miron et al., 2016). The findings highlight ABRs as cost-effective presymptomatic markers for neurodevelopmental disorders and the necessity to examine low-level brain structures. Despite the proposed link between ABR abnormality and language delay in infancy, evidence of direct association between the two is still lacking. Given that the brainstem pathways develop rapidly in the first 6 postnatal months, and the neural generators of ABR Wave III-V including nuclei from the superior olive to the inferior colliculus continue to mature through end of first year (Moore et al., 1995), it is unclear whether there exists meaningful relationships between early brainstem function and subsequent linguistic competence in at-risk infants.

**Objectives:** The current study aimed to provide preliminary evidence for the relationship between brainstem integrity before 12 months and subsequent language ability in infants at-risk for neurodevelopmental disorders.

**Methods:** Click-ABRs were recorded prior to 12 months of age from 27 at-risk infants admitted to pediatric rehabilitation unit. Developmental outcomes were obtained 6~22 months later using the Gesell Developmental Schedule. The mean age of ABR testing was 5.2 month, and 18.5 months at the Gesell assessment. One infant was diagnosed with unilateral sensorineural hearing loss. The infants were divided into early-ABR group (tested between 0~6 months of age,  $N = 21$ ) late-ABR group (tested between 7~12 months age,  $N = 6$ ). Pearson correlation was conducted to describe the developmental trajectories cross-sectionally and brainstem-behavior relations.

**Results:** The Wave V latency (mean = 6.21 ms) did not differ from clinical norm, and shortened with increasing age ( $r = -0.518^{**}$ ). The language ( $r = -0.41^{*}$ ) and fine motor ( $r = -0.4^{*}$ ) degraded with increasing age. Language was the only measure on the Gesell that significantly correlated with Wave V latency at younger ages ( $r = .46^{*}$ ). This relationship was driven by the early-ABR group ( $r = 0.64^{**}$ ) whereas suggestively reversed for the late-ABR group ( $r = -0.77$ ).

**Conclusions:** The developmental trajectories indicated that language and fine motor were the most impacted overtime in these at-risk infants. Contrary to our expectations, longer Wave V latency did not predict poorer subsequent language but the opposite in the sample. Given that longer latency indicated earlier testing in our data, it is possible that infants who tested earlier received more extended intervention services, which in turn ameliorated language impairment. Alternatively, ABR before 6 months may not be a reliable and consistent marker for better or worse language outcomes due to the exuberant development of brainstem in this early time window. Our finding can only be considered preliminary due to small sample. Further research is required to investigate factors such as critical periods of subcortical maturation in the progression of neurodevelopmental disorders.

**406.020 (Poster)** Relevance of the Plasma Oxytocin Concentration and Neurodevelopmental Disorders in 5-Year-Old Children Considering Gender

**Y. Sakamoto<sup>1</sup>, M. Saito<sup>1</sup>, A. Osato<sup>2</sup>, A. Terui<sup>1</sup>, K. Yoshida<sup>1</sup>, T. Mikami<sup>2</sup> and K. Nakamura<sup>2</sup>,** (1)Department of Neuropsychiatry, Graduate School of Medicine, Hirosaki University, Hirosaki, Japan, (2)Research Center for Child Mental Development, Graduate School of Medicine, Hirosaki University, Hirosaki, Japan

---

**Background:**

Previous studies have reported that plasma oxytocin (OT) concentration associated with characteristics of Autism spectrum disorder (ASD). Recently many researchers have investigated the efficacy of intranasal oxytocin infusion. So far, few studies have analyzed plasma OT concentration considering age and gender.

**Objectives:**

This study aimed to investigate the relevance of the plasma oxytocin concentration considering gender differences and neurodevelopmental disorders (NDD) in 5-year-old children.

**Methods:**

Subjects were children who participated in a 5-year-old developmental checkup in a city. They were 119 children with ASD (boys: girls =88:31, mean months age=64.56), 107 children with Attention Deficit Hyperactivity Disorder (ADHD) (68:39, 64.71), 89 children with Other Developmental Disorder (DD) (56:33, 64.63) and 79 children with TD (32:47, 65.25). Psychiatrists diagnosed them according to DSM-5. ADOS was added to diagnose ASD. Their caregivers completed the Autism-Spectrum Quotient (AQ) and the Conners3 Japanese version. The AQ assesses 5 different areas: social skill (AQ-social), attention switching (AQ-switching), attention to details (AQ-details), communication, and imagination. Blood samples were taken in the morning with fasting and plasma OT concentration was assayed by EIA. Statistical analysis was performed using Kruskal-Wallis test, Mann-Whitney U test, and multiple regression analysis ( $p < 0.05$ ).

**Results:**

While there was no significant difference in plasma OT concentration between the gender-specific diagnosis groups, the mean OT of girls (conc.= 5.0983) was significantly higher than that of boys (conc.= 3.7175) in TD ( $p < 0.05$ ) (Fig.1). The OT of girls tended to be higher than that of boys in ADHD and TD. On the other hand, the OT of girls tended to be lower than that of boys in ASD. However, there was no significant gender difference in ASD and ADHD. Multiple regression (independent variable: AQ, dependent variable: OT) showed that negative correlations between OT and AQ-details in total boys ( $R^2 = .104$ ,  $\beta = -.329$ ,  $p < 0.05$ ); OT and total AQ in total girls ( $R^2 = .107$ ,  $\beta = -.336$ ,  $p < 0.05$ ); OT and AQ-details in boys with ASD ( $R^2 = .124$ ,  $\beta = -.369$ ,  $p < 0.05$ ); OT and AQ-social in boys with ADHD ( $R^2 = .099$ ,  $\beta = -.338$ ,  $p < 0.05$ ); OT and AQ-switching in boys with other DD ( $R^2 = .271$ ,  $\beta = -.539$ ,  $p < 0.05$ ); OT and total AQ in girls with TD ( $R^2 = .171$ ,  $\beta = -.437$ ,  $p < 0.05$ ). Multiple regression (independent variable: Conners3, dependent variable: OT) showed that a positive correlation between OT and Oppositional defiant disorder score of Conners3 in boys with TD ( $R^2 = .186$ ,  $\beta = .460$ ,  $p < 0.05$ ); a negative correlation between OT and Executive functioning score of Conners3 in boys with ADHD ( $R^2 = .054$ ,  $\beta = -.261$ ,  $p < 0.05$ ); a negative correlation between OT and Oppositional defiant disorder score of Conners3 in boys with other DD ( $R^2 = .074$ ,  $\beta = -.302$ ,  $p < 0.05$ ); a positive correlation between OT and Hyperactivity score of Conners3 in girls with ASD ( $R^2 = .227$ ,  $\beta = .504$ ,  $p < 0.05$ ) (Fig.2).

**Conclusions:**

This study showed that plasma OT concentration was associated with symptoms in each neurodevelopmental disorder depending on gender. Although the results do not mention the causal relationship between OT and developmental traits, the effects of OT on the developmental traits of preschool children may differ by gender.

**406.021 (Poster)** Serum Biomarkers Indicate Higher Estradiol Levels and Maternal Insulin Resistance during Pregnancies of Offspring Who Develop Autism

**W. Worsham<sup>1</sup>, A. V. Bakian<sup>2</sup>, S. Dalton<sup>3</sup>, M. S. Esplin<sup>4</sup>, P. Burghardt<sup>5</sup>, A. Fraser<sup>6</sup> and D. A. Bilder<sup>2</sup>,** (1)University of Utah, Salt Lake City, UT, (2)Psychiatry, University of Utah, Salt Lake City, UT, (3)Obstetrics and Gynecology, University of Utah, Salt Lake City, UT, (4)Obstetrics and Gynecology, Intermountain Healthcare, Salt Lake City, UT, (5)Wayne State University, Detroit, MI, (6)Huntsman Cancer Institute, University of Utah, Salt Lake City, UT

---

**Background:** Maternal diabetes and hypertension (i.e., prenatal metabolic syndrome, PNMS) are associated with increased autism spectrum disorder (ASD) risk, which may be attributable to inflammation and steroid dysregulation that characterize these conditions. Estrogen is an established serum marker for fetal viability, yet elevated estradiol levels have been identified during pregnancies of offspring who develop ASD. Low maternal sex hormone binding globulin (SHBG) levels indicate insulin resistance and precede clinical manifestations of gestational diabetes and hypertension. Interestingly, low maternal serum SHBG in early 2<sup>nd</sup> trimester has also been linked to ASD among offspring born at term.

**Objectives:** (1) Identify the relationship between prenatal maternal serum sex steroid related biomarkers and ASD, and (2) Using maternal SHBG levels as a proxy for insulin sensitivity, compare insulin sensitivity during pregnancies that differ by diabetes/hypertension exposure, offspring ASD status, and pregnancy duration.

**Methods:** ASD case status was ascertained among index offspring of Utah's First and Second Trimester Evaluation of Risk of Aneuploidy (FASTER) Study participants (1998-2002) who consented to future use of banked early second trimester maternal serum. ASD case status was determined by the Utah Registry of Autism and Developmental Disabilities, which was enriched with cases identified through Utah's participation in CDC's Autism and Developmental Disabilities Monitoring Network. Birth certificate data identified either diabetes or hypertension exposure, gestational age, maternal age, pregnancy weight gain, and pre-pregnancy BMI. Commercially available ELISA kits measured estradiol (Abcam; Boston, MA) and SHBG (RayBiotech; Norcross, GA). A one-way Analysis of Covariance quantified the association between a four-level measure of ASD/PNMS exposure: ASD-/PNMS- (N=36), ASD-/PNMS+ (N=32), ASD+/PNMS- (N=38), and ASD+/PNMS+ (N=30). Analyses included covariates described above and were repeated following stratification by term/preterm status. Post hoc tests used the Sidak method to adjust for multiple comparisons.

**Results:** The overall model for serum SHBG concentrations was significant ( $F_{(6,135)}=11.7, p<.001$ ) as was the main effect of ASD/PNMS exposure on SHBG ( $F_{(3,135)}=16.2, p<.001$ ). A dose-response pattern emerged: increasing ASD/PNMS exposure was associated with decreasing SHBG concentrations. After multiple comparison adjustment, mean SHBG concentrations differed significantly between the ASD-/PNMS- and ASD+/PNMS- (lsmean difference = 200.5, 95% CI = 86.2-314.8,  $p < 0.001$ ) and ASD+/PNMS+ (lsmean difference = 266.6, 95% CI = 136.7-396.6,  $p < 0.001$ ); and between ASD-/PNMS+ and ASD+/PNMS- (lsmean difference = 181.5, 95% CI = 62.8-300.3,  $p < 0.001$ ) and ASD+/PNMS+ (lsmean difference = 247.7, 95% CI = 119.8-375.5,  $p < 0.001$ ; Figure 1). When stratified by term/preterm status, the results were similar. The overall model for estradiol was significant ( $F_{(6,134)}=2.5, p=0.03$ ), and ASD+/PNMS+ differed significantly from ASD-/PNMS- (lsmean difference = 410.0 (95% CI= 67.0-753.0,  $p=0.01$ )). Following stratification by term/preterm status, this finding appeared specific to term pregnancies.

**Conclusions:** Offspring who develop ASD experienced significantly higher maternal insulin resistance as indicated by lower SHBG levels irrespective of whether clinical manifestations of PNMS emerged or the infant was born preterm. This supports the presence of insulin resistance as a common metabolic milieu in early 2<sup>nd</sup> trimester in ASD+ pregnancies. Estradiol's significant relationship with ASD risk was limited to term pregnancies.

**406.022 (Poster)** The Neural Response to One's Own Name in Infants with Elevated Likelihood of Developing Autism Spectrum Disorder: An EEG-Study

**T. Van Lierde<sup>1</sup>, J. R. Wiersema<sup>2</sup>, P. Warreyn<sup>3</sup> and H. Roeyers<sup>3</sup>,** (1)Ghent University, Ghent, Belgium, (2)Department of Experimental Clinical and Health Psychology, Ghent University, Ghent, Belgium, (3)Department of Experimental-Clinical and Health Psychology, Ghent University, Ghent, Belgium

---

**Background:**

Children with autism spectrum disorder (ASD) often show diminished reaction to their own name compared to typically developing children. Previous research on how the infant brain reacts to hearing one's own name suggests that children who later develop ASD show a different neural response compared to typically developing children (Arslan et al., 2020).

### Objectives:

The current research project investigates reaction to one's own name (RtoN) in infants at 10 months ( $n = 35$ ) and 14 months ( $n = 32$ ) with elevated likelihood (EL) of developing ASD. They participate in an ongoing large-scale prospective longitudinal study. We aim to expand on previous work of Arslan et al. (2020) with a larger sample and by adding a condition to control for mere familiarity. We will investigate whether EL-infants show an enhanced neural RtoN (compared to an unfamiliar name) at 10 and 14 months of age, and whether this can be attributed to mere stimulus familiarity.

### Methods:

Using electro-encephalography (EEG), we investigated the neural RtoN in an auditory event-related potential task where infants are repeatedly exposed to three conditions: their own name, an unfamiliar name, and a familiar reference (e.g. "mama"). We calculated average waveforms within a time window of 300-600ms post-stimulus at three regions of interest (left-frontal, right-frontal, and parietal area).

### Results:

To investigate the frontal region, a 2x2 repeated measures ANOVA was conducted with condition (own vs unfamiliar vs familiar) and laterality (left vs right) as within-subject factors. This revealed a significant interaction effect of laterality and condition in 10-month old EL-infants ( $n = 35$ ,  $F(2,35) = 3.56$ ,  $p = .034$ ). No statistically significant results were observed in 14-month old EL-infants ( $n = 32$ , all  $ps > .084$ ). Closer inspection of the results (see *Figure 1*) in the 10-month old group indicate that, within the left frontal area, the own name evokes a stronger neural response in young EL-infants than in the other two conditions. The results of the right frontal area reveal a different pattern, where the familiar reference evokes a stronger response compared to the other conditions. When left and right frontal areas were analyzed separately, we only found a marginally significant main effect of condition in the right frontal area ( $n = 35$ ,  $F(2,35) = 2.76$ ,  $p = .07$ ). We found no statistically significant results in the parietal region in either of the age groups (all  $ps > .423$ ).

### Conclusions:

The data suggests that socially relevant information may be processed in a lateralized manner depending on the nature of the stimulus. While both the own name and the familiar reference condition are similar in terms of their familiarity to the infant, it appears that they are not processed in the same fashion, indicating that the EL-infant brain is sensitive to one's own name at 10 months of age. This pattern may start to differentiate in some individuals as the infant brain continues to develop, perhaps coinciding with the onset of early ASD-symptoms. While speculative, this could account for the null results in the 14-month old group.

#### 406.023 (Poster) Towards a Personalized Social Intervention for Autistic Adolescents: Utilization of MRI Biomarkers As Predictors of PEERS® Treatment Responders.

A. Arias<sup>1</sup>, W. L. Tseng<sup>2</sup>, B. Dolan<sup>3</sup>, A. D. Haendel<sup>1</sup>, A. J. McVey<sup>4</sup>, H. K. Schiltz<sup>5</sup>, M. Carlson<sup>1</sup>, W. Krueger<sup>6</sup>, B. Yund<sup>6</sup>, F. Mata-Greve<sup>10</sup> and A. V. Van Hecke<sup>8</sup>, (1)University of California, Santa Barbara, Santa Barbara, CA, (2)Child Study Center, Yale School of Medicine, New Haven, CT, (3)Medical College of Wisconsin, Milwaukee, WI, (4)Speech-Language Pathology, Concordia University Wisconsin, Mequon, WI, (5)University of British Columbia, Vancouver, BC, Canada, (6)Psychology, Marquette University, Milwaukee, WI, (7)Education, Marquette University, Milwaukee, WI, (8)Speech Pathology and Audiology, Marquette University, Milwaukee, WI, (9)Psychology, University of Wisconsin Milwaukee, Milwaukee, WI, (10)Marquette University, Shorewood, WI

Background: Electrophysiology (e.g., EEG) has previously been used to explore biomarkers of the *Program for Education and Enrichment of Relational Skills (PEERS®)*; Laugeson & Frankel, 2010, Van Hecke et al., 2015), a well-validated social skills intervention (Hill et al., 2017) as treatment outcomes. *PEER®* has shown efficacy for ameliorating social anxiety symptoms in adolescents (Schohl et al., 2014). Biomarkers to predict intervention responders for those whom undergo *PEERS®* has yet to be explored.

**Objectives:** The present study sought to examine social brain structure volume at baseline as a predictor of treatment responders following *PEERS*®.

**Methods:** The sample comprised of 37 male autistic adolescents randomized to the experimental group (EXP; n=20) and the waitlist group (WL; n=17). Data were collected at pre- and post-intervention time points. Data included adolescent self- and caregiver-reports of social skills, self-report social anxiety, and structural MRI data. Three responder types were defined in the EXP: 1) participants exhibiting a decrease in clinical level severity of social problems on the Child Behavior Checklist (CBCL); 2) participants showing a decrease of social problems in Youth Self-Report (YSR; Achenbach & Rescorla, 2001); 3) Participants exhibiting a decrease in their scores by at least one standard deviation on the Social Anxiety Scale for Adolescents (SAS-A; LaGreca, 1999). Receiver Operating Characteristic (ROC) curves were used to determine significant baseline structural MRI biomarkers and the best cut-off values for discriminating treatment responders vs. non-responders. Structural regions of interests were nominated due to prior function and structural associations with social behavior (e.g., McPartland & Pelphrey, 2012).

**Results:** ROC-Social Domain indexed by adolescent self-report (Figure 1): Left rostral Anterior Cingulate Cortex (rACC) volume at baseline significantly discriminated treatment responders (n = 8) from non-responders (n =12), with 75.0% sensitivity and 83.3% specificity at a cut-off value of 3.382 cm<sup>3</sup>. Baseline YSR social problem scores also significantly predicted treatment responders (n=3) vs. non-responders, (n=17) demonstrating 100% Sensitivity and 91.7% Specificity.

**ROC-Social Anxiety (Fear of Negative Evaluation) Domain (Figure 2):** Left and Right Amygdalae and the Left Insula volumes at baseline significantly predicted treatment responders vs. non-responders, with 100.0% sensitivity and 82.4% specificity at a cut-off value of 2.102 cm<sup>3</sup>, 100.0% sensitivity and 76.5% specificity at a cut-off value of 2.123 cm<sup>3</sup>, and 100.0% sensitivity and 94.1% specificity at a cut-off value of 7.950 cm<sup>3</sup>, respectively. Baseline social anxiety scores were not significantly predictive of treatment responder status. Refer to Table 1 for ROC statistics.

**Conclusions:** Baseline severity of social problems appeared to predict responder status with better sensitivity and specificity than baseline Left rACC volumes did. In contrast, bilateral amygdalae and left insula volumes significantly predicted treatment responder status indexed by social anxiety improvement, while baseline severity of social anxiety did not. These findings are in line with previous work suggesting a link between these two structures with social anxiety (Kawaguchi et al., 2016). Findings hold potential clinical implications for developing personalized social interventions for autistic adolescents (i.e., brain structural markers may be useful in identifying who may be more likely to respond to treatment).

#### **406.024 (Poster) Validating an EEG-Based Biomarker of Socio-Communicative Impairments in ASD**

**M. Moerkerke<sup>1</sup>, N. Daniels<sup>2</sup>, S. Van der Donck<sup>3</sup>, A. Bamps<sup>4</sup>, J. Steyaert<sup>1</sup>, K. Alaerts<sup>1</sup> and B. Boets<sup>5</sup>,** (1)Leuven Autism Research Consortium (LAuRes), Leuven, Belgium, (2)Rehabilitation Sciences, KU Leuven, Leuven, Belgium, (3)Center for Developmental Psychiatry, KU Leuven, Leuven, Belgium, (4)UZ Leuven, Leuven, Belgium, (5)Leuven Autism Research Consortium (LAuRes), KU Leuven, Leuven, Belgium

**Background:** Processing facial emotional expressions plays an important role in non-verbal communication and may be impaired in individuals with autism spectrum disorders (ASD). Using a novel Fast Periodic Visual Stimulation EEG approach (FPVS-EEG), Van der Donck et al. (2020) showed that school-aged boys with ASD are dramatically less sensitive than matched controls, on a neural level, to implicitly detect emotional faces. Accordingly, this fast and robust technique offers new perspectives for supporting clinical diagnosis.

**Objectives:** The current – ongoing – research is a replication study of the work by Van der Donck et al. (2020), in an independent and larger population, including both boys and girls. Similarly, we expect to find reduced neural sensitivity in the ASD group towards emotional faces.

**Methods:** FPVS-EEG is used to implicitly assess the neural response for emotional (happy, fearful) faces that are presented rapidly among a stream of neutral faces, to children (8-12 y/o) with ASD and neurotypical controls. Neutral faces, with different identities, are presented at 6 Hz, periodically interleaved with emotional faces every fifth image (i.e. 1.2 Hz). The periodicity adds a distinguishable frequency tag to the neutral and emotional stimuli allowing an objective quantification of the emotional face processing responses in only four recordings of 60s per condition.

**Results:** Preliminary analysis indicate that individuals with ASD show a reduced rightward lateralisation for the processing of fearful faces.

Conclusions: These results, combined with the previous findings of Van der Donck et al. (2020), show the ability of the FPVS-EEG technique to detect differences in the emotional face processing mechanism in ASD children on an implicit, fast and straightforward manner and can contribute to the delineation of an objective biomarker for socio-communicative sensitivity in ASD.

**406.026 (Poster)** Visual Evoked Pupillary Response to Distinguish Children with ASD and Children with TD: The Effect of Stimulus Frequency on Classification Results

*Q. Liu, X. He, B. Zhou, H. Wu, C. Zhang, Y. Qin, L. Shen and X. Gao, School of Medicine, Tsinghua University, Beijing, China*

---

### **Background:**

Eye tracking technology is widely used in autism research due to its non-invasive and comfortable characteristic. Pupillogram of eye tracking is an effective technique that can describe changes in pupil diameter. Previous research has demonstrated that visual evoked pupillary response is a powerful biomarker for distinguishing children with autism spectrum disorder (ASD) and children with typical development (TD). But no study tells whether the frequency of stimulus is an influential factor. Our study focus on **Tremendously Low Frequency Steady-State Visual Evoked Pupillary Response** (TLF-SSVEPR), trying to find a better experiment for classification of ASD and TD.

### **Objectives:**

Comparing TLF-SSVEPR evoked by **Tremendously Low Frequency Black and White Flicker Stimulus** (TLF-BWFS) of two different frequencies of 0.1Hz and 0.167Hz in ASD and TD children, find out which frequency is better in evoking effective pupillary response and distinguishing ASD and TD.

### **Methods:**

Two groups of 3-6 years old children were recruited, with 53 ASD and 51 TD in group 1 and 47 ASD and 35 TD in group 2.

Different experiment design was applied to the groups. Group 1 with 0.1Hz TLF-BWFS experiment provided valid data from 27 ASD and 50 TD, while group 2 with 0.167Hz TLF-BWFS experiment provided valid data from 14 ASD and 25 TD.

The experiments used SMI RED500 desktop eye tracking system with sample frequency 120Hz. The basic TLF-BWFS experiment is a series of 12 pictures of same size and luminance with 6 black pictures and 6 white pictures. The interval between one black picture and one white picture is corresponding to the TLF-BWFS experiment frequency, i.e. 5s for 0.1Hz in group 1 and 3s for 0.167Hz in group 2.

Subject's pupillogram data in the two experiments were collected. 100 features were extracted from minimum, middle, maximum, average and standard deviation on amplitude, time, velocity and latency of pupillary responses, with 2 additional features of valid counts on different pictures. Further statistical analysis and modeling classification was done by Python. The data of the two experiments were processed in the same way.

### **Results:**

Two experiments both showed significant difference on some features, but the 0.1Hz TLF-BWFS experiment had more features shown significant difference than 0.167Hz TLF-BWFS experiment, refer to attached table 1.

The performance of the classification models from two experiments were compared by their metrics of precision, recall, F1, accuracy and area under curve (AUC). Results showed that model of 0.1Hz TLF-BWFS experiment achieves a better performance on every metrics than model of 0.167Hz TLF-BWFS experiment, refer to attached table 2.

### **Conclusions:**

Lower frequency of 0.1 Hz TLF-BWFS experiment performs better than higher frequency of 0.167Hz TLF-BWFS experiment, which provide us a better and practical TLF-BWFS experimental design in distinguishing children with ASD and children with TD.

**406.027** (Poster) Voice Acoustics As a Biomarker for Autism

**M. Latinus<sup>1</sup>**, C. David<sup>1</sup>, S. Silleresi<sup>1,2</sup>, J. Malvy<sup>1,3</sup>, S. Ferre<sup>1</sup> and F. Briend<sup>1</sup>, (1)UMR 1253, iBrain, Université de Tours, Inserm, Tours, France, (2)Department of Psychology, University of Milano-Bicocca, Milan, Italy, (3)CHRU Tours, Tours, France

---

Background:

Autism spectrum disorder (ASD) is a multifaceted disorder that affects social communication. Atypical voice prosody is one of the earliest markers of ASD; yet, genuine acoustic features of the voice are also altered in autism.

Objectives:

We aimed to determine whether acoustic features of the voice could be used as a diagnostic biomarker specific for autism by classifying ASD against a heterogeneous control population: deaf children with a cochlear implant (CI), children with a developmental language disorder (DLD), and typically-developing children (TD).

Methods:

Acoustics data of 108 children (6-12 years) were included in the study: 38 with ASD (1 girl; 8.5 years), 25 with CI (8 girls; 8 years), 21 with DLD (9 girls; 7.9 years), and 24 TD children (12 girls; 8.2 years). Children partook in a nonword repetition task in which they repeated 50 or 70 non-words of varying phonological complexity. Among these, the 20 with less phonological errors were chosen for acoustic analysis (Praat). For each non-word, we extracted 9 acoustics parameters: mean fundamental frequency, mean formant frequencies (F1 to F4), mean formant dispersion, mean harmonic-to-noise ratio, mean jitter and mean shimmer; they were then averaged across logatomes. Data were analyzed two ways with unsupervised and supervised K-means clustering (KC). ROC (Receiving Operator Curve) supervision allows determining the most discriminating acoustic variables in our sample. We used percent of variation (PV) as quality criteria of KC. A first analysis was realized on a sample of 90 participants with good-quality data (Test1). First, we selected randomly 20 children with ASD and 40 other children as train data (this was repeated 100 times); selectivity, sensitivity and PV were measured from unsupervised and ROC-supervised KC (Test1). Cross-validation was run on the remaining 30 participants: percent of correct classification was measured (Test2). Finally, our model was tested with low-quality data (Test3; n=18).

Results:

Unsupervised KC with all acoustics variables had a PV of 78%, a sensitivity of 0.88 and a specificity of 0.56, and correctly classified 51 % of DLD, 38% of CI and 79% of TD children in the non-ASD group (Test1). The unsupervised KC classified the remaining children with an accuracy of 89% for ASD and 58% for controls (Test2). In Test3, classification accuracy was 57% for ASD children and 44 % for non-ASD children.

The ROC analysis determined F1, jitter and shimmer as the most discriminant parameters. The ROC-supervised KC had a PV of 58%, a sensitivity of 0.76 and a specificity of 0.77; it classified correctly 74% of DLD, 81% of CI and 76% of TD in the non-ASD group (Test1). 77% of ASD and 76% of the control population were correctly classified (Test2). With our low-quality data (Test3), the ROC-supervised KC classified children in both groups with a 70% accuracy.

Conclusions:

Here, we showed that an acoustic-based ROC-supervised clustering algorithm successfully discriminated ASD children from a range of non-ASD children including children with other sensory or developmental disorders. Mean f1 frequency, jitter and shimmer can be used as a diagnostic biomarker to help ASD diagnosis.

## Cellular Models/Stem Cells

### PANEL DISCUSSION — CELLULAR MODELS/STEM CELLS

#### Panel 223 - Harnessing the Potential of Induced Pluripotent Stem Cells to Model Autism Spectrum Disorders

**Panel Chair:** Nael Nadif Kasri, *Human Genetics, Radboudumc, Nijmegen, Netherlands*

**Discussant:** Joseph Buxbaum, *Department of Psychiatry, Icahn School of Medicine at Mount Sinai, New York, NY*

Genetic analyses of large cohorts of individuals with autism spectrum disorders (ASD) have enabled the identification of numerous de novo and inherited rare DNA variants linked to ASD. Despite this considerable progress in elucidating the genetic architecture of ASD, a major gap exists between the genetic findings and deciphering the cellular and molecular pathobiology of ASD. Capitalizing on new developments in induced pluripotent stem cell technology (iPSCs) we can finally study the cells of interest outside of the patient, capturing features of the human condition in vitro, thereby allowing the pathobiology to be studied in the context of the human genome. Over the past years, significant progress has been made to differentiate iPSCs into robust 2D and 3D neuronal models that recapitulate the main features of human brain development. Much effort has been put in to the establishment of relevant phenotypic assays for mechanistic understanding and drug screening. These include brain-on-a-chip technologies to link genetic deficits observed in patients to neuronal network measurements. Finally, developments in genome engineering and genomic technologies can be leveraged in large screening assays to identify points of convergence between ASD genes. This panel will discuss recent advances and opportunities in this exciting field of research.

**223.001 (Panel Discussion)** High-Throughput Single-Cell Functional Elucidation of Neurodevelopmental Disease-Associated Genes Reveals Convergent Mechanisms Altering Neuronal Differentiation

**M. A. Lalli<sup>1</sup>, D. Avey<sup>2</sup>, J. Dougherty<sup>3</sup>, J. Milbrandt<sup>4</sup> and R. Mitra<sup>1</sup>,** (1)*Icahn School of Medicine at Mount Sinai, New York, NY*, (2)*Washington University in St Louis, St Louis, MO*, (3)*Genetics, Washington University School of Medicine, St. Louis, MO*, (4)*Genetics, Washington University in St. Louis, St. Louis, MO*

**Background:** Genetic studies of autism spectrum disorder (ASD) have been hugely successful and have now discovered over 100 genes harboring mutations conferring large effects on ASD risk. We can leverage these large-effect ASD risk genes to elucidate molecular mechanisms of ASD, but studying each gene one at a time in animal or patient-derived models is a nearly insurmountable task and challenges the comparison of results across studies. As mutations in each ASD gene are individually rare, identifying convergent mechanisms shared between subsets of these genes is critical to understanding and treating ASD. To do so, novel methods are needed for high-throughput functional elucidation of risk genes.

**Objectives:** We sought to establish a scalable functional genomics approach to study large-effect genes linked to ASD and other neurodevelopmental disorders in a human, disease-relevant context and to enable direct comparison of findings across ASD genes.

**Methods:** We used catalytically inactive Cas9-based transcriptional repression (CRISPRi) to knockdown the expression of 13 ASD-related genes in a simple human cellular model of neuronal differentiation using LUHMES human neuronal progenitor cells. We captured the resulting transcriptional consequences of ASD gene knockdown using single-cell RNA-sequencing (scRNA-seq). We performed differential expression and pseudotime analysis to identify individual transcriptional signatures for each ASD gene knockdown and their effects on the trajectory of neuronal differentiation. We then compared results across genes to identify potential shared mechanisms. We used live-cell imaging to confirm our predictions, and validated the results in induced pluripotent stem cell derived neural progenitor cells.

**Results:** We established and validated LUHMES as a tractable human model of neuronal differentiation suitable for high-throughput disease gene perturbation. CRISPRi efficiently knocked down candidate ASD genes and elicited transcriptional dysregulation and changes in neuronal differentiation that could be recovered using scRNA-seq. Pseudotime and differential expression analysis discovered two functionally convergent modules of ASD genes: one that delays neuron differentiation and one that accelerates it. Five genes that delay neuron differentiation (ADNP, ARID1B, ASH1L, CHD2, and DYRK1A) mechanistically converge, as they all dysregulate genes involved in cell-cycle control and progenitor cell proliferation. Live-cell imaging after individual ASD-gene repression validated this functional module, confirming that these genes reduce neural progenitor cell proliferation and neurite growth.

Conclusions: By coupling pooled CRISRPi to scRNA-seq in a simple and highly tractable human model of neuron differentiation, we have established a rapid, scalable, and disease-relevant system in which tens to hundreds of genes can be modulated in parallel and their effects measured in a robust manner. This approach should facilitate the discovery of convergent mechanisms across the numerous and diverse genes implicated in neurodevelopmental disorders.

**223.002** (*Panel Discussion*) Neurons-on-a-Chip to Model ASD  
*N. Nadif Kasri, Human Genetics, Radboudumc, Nijmegen, Netherlands*

---

Background:

Recent progress in human genetics has led to the identification of hundreds of genes associated with ASD, including a growing number of genes encoding epigenetic regulators of gene expression. These regulators exert their function through genome-wide posttranslational modification of histones or by mediating and/or recognizing DNA methylation. Several of these ASD-linked epigenetic factors directly interact with one another in complexes that regulate chromatin structure at genes important for neurodevelopment and/or neuroplasticity. Despite considerable progress in elucidating the genetic architecture of ASD, a major gap exists between the genetic findings and deciphering the cellular or molecular pathobiology of ASD. In particular, understanding which transcriptional changes have the most relevant functional consequences, and whether or not those consequences overlap in different patients.

Objectives:

Functional analysis of syndromic ASD genes. More specifically, we aim at generating a phenotypic landscape for ASD genes by combining neuronal network measurements on microelectrode arrays (MEAs) with transcriptomics, i.e. MEASeq.

Methods:

Interrogation of neuronal network activity by growing patient-derived neurons on MEAs offers a robust, efficient and physiologically relevant readout to probe for phenotypes at the neuronal network level. We take advantage of direct differentiation methods toward specific neuronal lineages of excitatory and inhibitory neurons grown on MEAs. Using MEAs, we can repeatedly and passively record the same cultures as they traverse distinct neurodevelopmental transitions without disturbing their development. In addition, since changes in neuronal morphology, intrinsic properties or synaptic connectivity are reflected at the network level, MEA recordings provide a sensitive and unbiased assessment of the neuronal properties. We have benchmarked the robustness and sensitivity of MEA-derived neuronal activity patterns, with patterns derived from multiple different healthy individuals functionally clustering together.

Results:

We generated neuronal networks from multiple patient-derived neurons with mutations in different ASD genes, including *ARID1B*, *EHMT1*, *CHD8*, *CHD2*, *KANSL1*, *KMT2D* and *ANK2*. In addition, we generated genome-edited isogenic lines with heterozygous loss-of-function for each of these genes. We monitored the electrophysiological activity of neuronal networks coupled to MEAs over time and compared their activity to healthy controls and between ASD syndromes. Using independent clustering analysis, encompassing 15 independent MEA parameters, we show that all patient lines deviated from healthy control lines and their respective isogenic lines. Furthermore, we show that neuronal networks with mutations in the same gene, including the isogenic lines, functionally clustered together. At the same time, we show that subtypes of ASD sharply segregated from each other with distinguishable network patterns. The most pronounced differences between ASD subtypes were observed at the level of network activity, either at the level of network burst frequency, or network burst length. Finally, by combining MEA recordings with transcriptomics we identified molecular pathways that underlie specific neuronal network phenotypes observed in ASD subtypes.

Conclusion:

Our data indicate that MEASeq is a robust and sensitive method to perform genotype-phenotype analyses, which can serve as a powerful platform to identify functional points of convergence between ASD genes and be used for high-throughput drug screening assays.

**223.003** (*Panel Discussion*) In Vivo Perturb-Seq Reveals Neuronal and Glial Abnormalities Associated with Autism Risk Genes  
*X. Jin, Society of Fellows, Harvard University, Cambridge, MA*

---

## Background:

Human genetic studies have revealed long lists of genes and loci associated with risk for many diseases and disorders, but it remains challenging to systematically evaluate their phenotypic effects. Without any a priori knowledge, these risk genes could affect any cellular processes in any cell type or tissue, which creates an enormous search space for identifying possible downstream effects. New high-throughput approaches are needed to functionally dissect these large gene sets across a spectrum of cell types in vivo.

## Objectives:

Analysis of trio-based whole-exome sequencing has implicated a large number of de novo loss of function variants contributing to Autism Spectrum Disorder and developmental delay (ASD/ND) risk. Such de novo variants often have large effect sizes, thus providing a key entry point for mechanistic studies. We have developed in vivo Perturb-Seq to allow simultaneous assessment of the individual phenotypes of a panel of such risk genes in the context of the developing mouse brain.

## Methods:

Using CRISPR-Cas9, we introduced frameshift mutations in 35 ASD/ND risk genes in pools, within the developing mouse neocortex in utero, followed by single-cell transcriptomic analysis of perturbed cells from the early postnatal brain. We analyzed five broad cell classes: cortical projection neurons, cortical inhibitory neurons, astrocytes, oligodendrocytes, and microglia/macrophages, selecting cells that had received only single perturbations. Using Weighted Gene Correlation Network Analysis, we identified 14 co-varying gene modules representing transcriptional programs expressed in different classes of cortical cells.

## Results:

These modules included both those affecting common biological processes across multiple cell subsets, and others representing cell type-specific features restricted to certain subsets. We estimated the effect size of each perturbation on each of the 14 gene modules by fitting a joint linear regression model, estimating how module gene expression in cells from each perturbation group deviated from their expression level in internal control cells. Perturbations in 9 ASD/ND genes had significant effects across 5 modules across 4 cell classes, including cortical projection neurons, cortical inhibitory neurons, astrocytes, and oligodendrocytes. These results were validated using a single-perturbation model as well as a germline modified mutant mouse model.

To establish whether the perturbation-associated gene modules identified in the mouse cerebral cortex are relevant to human biology and ASD/ND pathology, we performed co-analyses of data from human ASD and control brain and human cerebral organoids. Both gene expression and gene co-variation ("modularity") of several of the gene modules identified in the mouse Perturb-Seq analysis are conserved in human brain tissue. Comparison to single-cell data from ASD patients showed overlap in both affected cell types and transcriptomic phenotypes. These findings suggest that Perturb-Seq can uncover potential shared effects across species.

## Conclusions:

In vivo Perturb-Seq can serve as a scalable tool for systems genetic studies of large gene panels to reveal their cell-intrinsic functions at single-cell resolution in complex tissues. In this work, we demonstrated the application of in vivo Perturb-Seq to ASD/ND risk genes in the developing brain. This method can be applied across diverse diseases and tissues in the intact organism.

### **223.004** (Panel Discussion) Brain Organoids and Next-Generation Assembloid Models to Study Human Development and Disease

*S. Pasca, Department of Psychiatry and Behavioral Sciences., Stanford University., Stanford, CA*

---

A critical challenge in understanding the programs underlying the development, assembly and dysfunction of the human brain is the lack of direct access to intact, functioning human brain tissue for direct investigation and manipulation. In this talk, I will describe efforts in my laboratory to build functional cellular models and to capture previously inaccessible aspects of human brain development and disease. To achieve this, we have been using instructive signals to derive, from pluripotent stem cells, self-organizing 3D tissue structures called regionalized brain organoids or neural spheroids that resembles domains of the

developing central nervous system. We have shown that these cultures, such as the ones resembling the cerebral cortex, recapitulate many features of neural development, can be derived with high reliability across dozens of cell lines and experiments, and can be maintained for years in vitro to capture advanced stages of neural and glial maturation and function. Moreover, we demonstrated that regionalized brain organoids can be put together to form integrated structures we named brain assembloids, which can be subsequently applied to investigate cell migration and formation of neural circuits. Lastly, I will illustrate how our modular, stem-cell derived 3D system can be used to study the cellular and molecular consequences of mutations or copy number variants associated with neuropsychiatric disorders, including autism spectrum disorder.

## POSTER SESSION — CELLULAR MODELS/STEM CELLS

**407.001 (Poster)** Elucidating Molecular Mechanisms of Genetic Interaction and Oligogenicity in Autism Spectrum Disorder  
A. L. Sertie<sup>1</sup>, A. L. Teles e Silva<sup>1</sup>, T. Glaser<sup>2</sup>, K. Griesi-Oliveira<sup>1</sup>, J. Corrêa<sup>2</sup>, G. Campos<sup>3</sup>, H. Ulrich<sup>2</sup>, A. Balan<sup>4</sup> and M. R. Passos-Bueno<sup>5</sup>, (1)Centro de Pesquisa Experimental, Hospital Israelita Albert Einstein, Sao Paulo, Brazil, (2)Department of Biochemistry, University of Sao Paulo, Sao Paulo, Brazil, (3)Centro de Estudos do Genoma Humano e Células Tronco, University of Sao Paulo, Sao Paulo, Brazil, (4)Department of Microbiology, University of Sao Paulo, Sao Paulo, Brazil, (5)Centro de Pesquisas Sobre o Genoma Humano e Células-Tronco, Instituto de Biociências, Universidade de São Paulo, Sao Paulo, Brazil

**Background:** Analyses of rare genetic variants in autism spectrum disorder (ASD) cohorts have found in a fraction of patients evidence of an oligogenic mode of inheritance, in which two or more mutated genes, individually not sufficient to cause ASD, may act additively or synergistically to produce the clinical phenotype. However, currently little is known about how these ASD-risk variants interact with each other and converge on specific neurobiological pathways underlying ASD. Through whole-exome sequencing (WES) of 280 proband-parent trios of ASD, we identified in one proband compound heterozygous missense variants in the Reelin gene (*RELN*), which we have previously characterized as harmful, and a de novo splice site variant in the Cav3.2 calcium channel gene (*CACNA1H*).

**Objectives:** To investigate whether the variant in *CACNA1H* is functional and interact with mutated *RELN* causing abnormal neuronal phenotypes.

**Methods:** We used induced pluripotent stem cells-derived neural progenitor cells (NPCs) from this proband with ASD and from neurotypical controls as well as a heterologous expression system; we examined calcium influx, the activity of Reelin, Cav3.2 and mTORC1 pathways, and the behaviour of NPCs. Also, we reanalyzed our WES data looking for an increased burden of co-occurring rare and impactful variants in Reelin pathway and Ca<sup>2+</sup> channel genes in ASD individuals.

**Results:** We found that the variant in *CACNA1H* leads to increased Ca<sup>2+</sup> influx into the cells, which overactivates mTORC1 signaling pathway and, consequently, further exacerbates the impairment of Reelin signaling. Also, we showed that mutant Cav3.2-mediated overactivation of mTORC1 pathway acts individually to induce enhanced proliferation of NPCs from the proband and in concert with impaired Reelin signaling to cause abnormal migration of these cells. Finally, reanalysis of our WES data revealed that the co-occurrence of rare and potentially damaging variants in one allele of Ca<sup>2+</sup> channels genes and in both alleles of Reelin pathway genes is significantly enriched in ASD individuals (3/280 probands).

**Conclusions:** Our results suggest an abnormal functional connectivity between mutated *CACNA1H* and *RELN* genes, and also the nonrandom co-occurrence of rare and potentially damaging variants in genes for the Reelin pathway and Ca<sup>2+</sup> channels in ASD individuals, which provide additional evidence supporting the notion that genes with co-occurring deleterious variants tend to have interconnected signaling pathways and act additively to cause oligogenic forms of ASD.

**407.002 (Poster)** iPSC-Derived Innervated Gastrointestinal Organoids to Model the Enteric Nervous System in Autism Spectrum Disorder

S. J. Walker<sup>1</sup>, D. Leavitt<sup>2</sup> and D. Mack<sup>3</sup>, (1)Wake Forest Institute for Regenerative Medicine, Winston Salem, NC, (2)Wake Forest University, Winston Salem, NC, (3)University of Washington, Seattle, WA

**Background:** Children with autism spectrum disorder (ASD) are more likely to experience chronic gastrointestinal (GI) symptoms of uncertain etiology than their typically developing peers. Because chronic constipation is a common finding in this population, we hypothesized that in some ASD children an abnormally functioning enteric nervous system (ENS) may underlie colonic hypomotility. We chose to test this hypothesis using a model of Phelan McDermid Syndrome (PMDS) because: (1) ~80% of individuals with PMDS have an ASD diagnosis, (2) >50% of that subset are reported to have chronic GI symptoms and, (3) the

hallmark of PMDS is haploinsufficiency of a key neuronal protein, SHANK3. In the central nervous system (CNS), SHANK3 contributes to the formation and maintenance of postsynaptic density of excitatory synapses. The goal of our study using PMDS patient-specific iPSC-derived GI organoids is to determine the role of SHANK3 in the *ENS* and to identify potential therapeutic targets to correct gut hypomotility.

**Objectives:** To create an *in vitro* model, using iPSCs from PMDS patients, to study ENS function in individuals with ASD and chronic GI symptoms.

**Methods:** PMDS iPSC lines (proband and non-affected parent) were obtained from the NIMH Repository and Genomics Resource Project. Patient-derived iPSCs were used to create an innervated gut organoid through the combination of individually cultured GI spheroids and neural crest cells (NCCs). After the GI spheroids had been passaged 9 times and NCCs had been cultured for 20 days, the two cell types were mechanically aggregated and co-cultured for 5 days. Immunocytofluorescence was used to characterize the individual components (GI spheroids and NCC) and then the innervated gut organoids following co-culture.

**Results:** Immunocytofluorescence staining confirmed the presence of Sox9 demonstrating that the patient-derived iPSCs were successfully reprogrammed to GI spheroids (Fig 1A). NCC identity was confirmed by neuronal communication via axonal extensions of nearby NCCs (Fig 1B) and further supported via immunocytofluorescence staining with HNK1 (Fig 1C). Co-culture of mechanically aggregated GI spheroids and NCC for 5 days resulted in evidence of spheroid innervation (Fig 1D).

**Conclusions:** This pilot study describes the early stages of development of a novel model system to evaluate the contribution of a malfunctioning enteric nervous system in ASD by using iPSCs from a PMDS patient with co-occurring diagnoses of ASD and chronic GI symptoms. Next steps will entail a longer period of co-culture, followed by functional assays.

## POSTER SESSION — CLINICAL GENETICS

### Poster 408 - Clinical Genetics Posters

**408.002** (Poster) Autism Spectrum Disorder Is Burdened By Severely Pathogenic Variations within Core Domains of CHD8 and Its CHD7-Binding Motif

A. SNM, DoS in Genetics and Genomics, University of Mysore, Mysuru, India

Background: Several recurrently mutated genetic risk-factors have been implicated in ASD manifestation. *Chromodomain helicase remodeller (CHD8)* is one such master regulator mediating the expression of genes controlling neuron functions. To date, only one study by (An et al., 2020) described the mutational landscape of CHD8 with respect to its domains across three different populations- ASD, cancer and general population. However, they relied on just one parameter, i.e. effect prediction score, for variant prioritisation.

Objectives: Considering the lack of holistic knowledge on the immense genetic burden appended by *CHD8* on ASD manifestation, we aimed to perform a comprehensive mutational burden analysis with emphasis on deciphering the specific roles of ASD-associated CHD8 variations in disease manifestation.

Methods: We collected 8,124 exonic SNPs in *CHD8* from 4 databases representing the general and ASD populations; subjected them to multi-layered function predictions on >25 different computational tools- including SNP effect and stability prediction; protein intrinsic disorder measurement and Molecular Recognition site identification; protein interaction network analyses and molecular dynamics analysis.

Results: We observed that nsSNPs were common in the general population. Distinct hotspots for truncating and nsSNPs were identified within exons encoding the N and C terminals, respectively. Evolutionarily conserved regions involving CHD8 core domains: Helicase-C-terminal, Helicase-ATP-binding and SNF2\_N domains, recorded the lowest density but severely pathogenic SNPs. Conversely, evolutionarily variable regions- CHD7-binding and BRK domains- hosted the highest SNPs, but were benign. Post-Translational-Modifications (PTMS) occurred on residues outside domains (P<0.01) i.e., non-conserved regions of CHD8 including the N and C terminals that were determined to be Intrinsically-Disordered-Protein-Regions (IDPRs) with 9 Molecular-Recognition-Features sites. Contrastingly, ASD population recorded significantly higher incidences of truncating SNPs than general population (P<0.0001). ASD-SNPs frequently occurring within core domains were severely damaging and accounted for >30% of all ASD variations. The CHD7-DNA-binding motif, with most PTMs, recorded the highest recurring truncating ASD-SNPs. The CHD8 PPIs effortlessly recapitulated the phenotypes presented by children with CHD8 mutations like macrocephaly and anxiety (5 genes each), impaired social behaviour (2 genes), formation of the brain (4 genes), gastrointestinal tract (6 genes), body axis and long-term memory (2 genes each). 11/13 (84.6%) interacting molecules were IDPs. We identified 9 CHD8 nsSNPs that produced the strongest long-range disturbances, altering the modelled protein's global conformational dynamics.

Conclusions: *CHD8* is indeed a master regulator of neuronal and GI functions and hence a potent contributor of ASD. Our in-silico analysis provides a blueprint of the mutational landscape and pathogenicity patterns of CHD8. ASD is burdened by the variations occurring within core domains and frequently occurring truncating SNPs- especially within CHD7-binding site.

**408.003** (Poster) Quantitative 3D Analysis of Craniofacial Dysmorphia in DYRK1A Mutations

C. M. Miles<sup>1</sup>, E. C. Kurtz-Nelson<sup>1</sup>, C. M. Hudac<sup>2</sup>, E. E. Eichler<sup>3,4</sup>, R. A. Bernier<sup>1</sup> and R. K. Earl<sup>1</sup>, (1)Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA, (2)Center for Youth Development and Intervention, Department of Psychology, University of Alabama, Tuscaloosa, AL, (3)Department of Genome Sciences, University of Washington, Seattle, WA, (4)Howard Hughes Medical Institute, Seattle, WA

Background:

Disruptive mutations to *DYRK1A*, located in the Down Syndrome critical region of chromosome 21, are associated with autism spectrum disorder, intellectual disability, and medical comorbidities (Courcet et al., 2012; Earl et al., 2017; Guedj et al., 2012). Parents often seek genetic testing based on physiological traits observed in their children, and previous literature suggests facial anomalies in children with *DYRK1A* mutations, predominantly around the eyes, nose, and chin (Oegema et al., 2010; Van Bon et al., 2016). Studies of *DYRK1A*'s regulatory functions confirm its role in the expression of several genes, with *DCAF7*, *DYRK1A*'s

highest predicted functional partner, directly involved in craniofacial development (Park et al., 2009; String Consortium, 2020). However, past *DYRK1A* studies have not quantitatively assessed the nature and severity of dysmorphic facial features.

Objectives:

To determine if quantitative differences in facial features exist between children with *DYRK1A* mutations and the general population, including unaffected parents.

Methods:

From a sample of 28 children with de novo *DYRK1A* mutations, analyses focused on nine white non-Hispanic children ( $M$  age = 11.33 years, 77.78% male) and their unaffected biological parents due to the availability of facial norms. Data were collected using a 3dMDhead System as part of an ongoing genetics-first study. Three-dimensional (3D) imaging tools allow for measurement of craniofacial features while reducing measurement error, and 3dMD's tools in particular demonstrate quality and reliability (Aldridge et al., 2005). Facial landmarks of interest were registered in 3D and measurements between landmarks were calculated using 3dMDvultus software. FaceBase's 3D Facial Norms for European Caucasians were used as a control group, and Z-scores were calculated for all complete measures using FaceBase norms (Brinkley et al., 2016). Six measures—intercanthal width, outercanthal width, palpebral fissure lengths, cranial base width, and philtrum width—were selected for analysis based on Van Bon et al., (2011). Wilcoxon sign-rank tests were performed to compare Z-scores between probands and each biological parent, assessing familial influence on dysmorphologies (Earl et al., 2017).

Results:

Outercanthal width in probands was significantly different from both biological parents (subject-mother  $Z = -2.67$ ,  $p = .01$ ; subject-father  $Z = -2.55$ ,  $p = .01$ ) and significantly smaller than average. Additionally, palpebral fissure lengths significantly differed between probands and fathers (right  $Z = -2.43$ ,  $p = .02$ ; left  $Z = -2.07$ ,  $p = .04$ ); both measurements were below population averages for probands. All other Z-scores did not significantly differ between parents and probands.  $P$  values were not corrected for multiple comparisons due to small sample size.

Conclusions:

Facial morphology of individuals with *DYRK1A* mutations significantly differs from the general population and unaffected parents when examining eye regions. This bolsters the link between *DYRK1A* and genes coding for craniofacial development (e.g., *DCAF7*). The absence of other significant discrepancies between parent and proband measurements suggests the facial phenotype associated with *DYRK1A* mutations may be more nuanced than expected, presenting challenges for clinical assessment. Future analyses will extend to non-white participants. Additional research should examine how *DYRK1A* interacts with genes that code for eye regions and possible differences in dysmorphology between sexes.

---

**408.004** (Poster) Return of Individual Genetics Results in the Largest Recontactable Cohort of People with Autism  
**J. R. Wright<sup>1</sup>**, S. D. Barns<sup>2</sup>, J. B. Hall<sup>1</sup>, S. Ganesan<sup>1</sup>, B. Han<sup>3</sup>, C. Diggins<sup>1</sup>, T. Greene<sup>1</sup>, S. Consortium<sup>3</sup>, N. Volfovsky<sup>2</sup>, P. Feliciano<sup>1</sup> and W. K. Chung<sup>4</sup>, (1)SFARI, Simons Foundation, New York, NY, (2)Simons Foundation, New York, NY, (3)SPARKForAutism.org, New York, NY, (4)Department of Pediatrics, Columbia University, New York, NY

---

Background: SPARK — the largest recontactable cohort of people with autism spectrum disorder (ASD) — seeks to engage at least 50,000 individuals with autism and their family members in research. A tenet of the study is to form a partnership with participants and return research results to them — including any genetic variants believed to be a major contributing risk factor to their ASD.

Objectives: More than 250,000 individuals are currently enrolled in SPARK, making it the largest autism study to return genetic results to families. SPARK is rapidly increasing the number of families receiving genetic results and has identified several challenges in returning individual research results at this scale.

Methods: SPARK returns genetic findings associated with ASD that meet ACMG criteria for likely pathogenic (LP) and pathogenic (P) variants. Currently, SPARK is returning LP/P variants within a pre-defined list of 176 high-confidence ASD genes or copy number variants (CNVs). Starting in 2021, SPARK will also return secondary findings in a subset of genes on the ACMG SF v2.0 list. All variants are confirmed in a CLIA (Clinical Laboratory Improvement Amendments) laboratory. At the time of enrollment, each participant can set preferences to accept or decline to receive genetic results related to autism; a parent

consents for children and dependent adults. Participants may receive their result from a genetic counselor (at no cost to them) or from their own provider. SPARK provides gene-specific guidebooks that explain the features associated with the individual's genetic result.

Results: SPARK has identified more than 800 returnable genetic results in nearly 10,000 individuals with autism. Preliminary evidence suggests that the total yield will be roughly 10% of all SPARK participants with autism. Clinically significant results are roughly equally split between CNVs, single nucleotide variants, and small insertions/deletions. 53% are de novo; 17% are inherited and a quarter are of undefined inheritance.

Being a female with autism increases the odds of having a clinical genetic result by 2 times, compared with males. The odds of having a clinical genetic result goes up by 2 to 3 times if a participant has cognitive impairment, is non-verbal (and 5 years or older), reports a birth defect, or has seizures. However, nearly a third of the participants with clinical genetic results had none of these features. The odds of having a result are 0.28 times lower if the participant has above-average cognitive ability.

93 percent of participants with completed returns from genetic counselors said that result return was a positive or valuable experience; 6 percent seemed indifferent and 1 percent provided little to no feedback.

Challenges to result return include decreasing the time from sequencing to return, reaching all participants, and re-consenting independent adults who have aged out of the study. Iterative analysis adding additional samples identifies novel autism genes.

Conclusions: Large-scale return of genetic results is feasible and benefits from reanalysis. A commitment to the return of genetic results is an important goal for genetic research studies. SPARK's experiences can inform the process for other genomic research studies.

## POSTER SESSION — CLINICAL TRIAL DESIGN

### Poster 409 - Clinical trial design Posters

**409.001** (Poster) Autistic People's Views on the Acceptability of Participating in Randomised Controlled Trials  
*L. Beasant<sup>1</sup>, N. Mills<sup>1</sup>, A. X. Realpe<sup>1</sup>, S. Douglas<sup>2</sup>, L. Kenny<sup>3</sup> and D. Rai<sup>4</sup>; (1)Bristol Medical School, University of Bristol, Bristol, United Kingdom, (2)Bristol, United Kingdom, (3)Centre for Research in Autism and Education (CRAE), London, United Kingdom of Great Britain and Northern Ireland, (4)Population Health Sciences, Bristol Medical School, Centre for Academic Mental Health, Bristol, United Kingdom*

**Background:** Randomised controlled trials (RCTs) are the gold standard to understand the effectiveness of healthcare interventions, but few involving autistic adults have been conducted to date. There is minimal published research on how autistic adults perceive or engage with RCTs. Uncertainty is a central component of RCTs, but intolerance of uncertainty is common in the autistic population and may be a barrier to participation.

#### Objectives:

1. To explore autistic adults' views about health-related research, specifically RCTs.
2. To ascertain understanding and acceptability of key components of RCTs; randomisation, blinding and placebo.
3. To identify potential barriers and facilitators to recruiting autistic people to RCTs.

**Methods:** Participants were purposefully sampled from those who responded to an advert to ensure a spread of clinical and socio-demographic factors. Sampled individuals were sent an information leaflet explaining the study, accompanied by an example of a double blinded RCT of treatment for anxiety in autistic adults. Participants were invited to interview using their preferred method (e.g. face-to-face, video, phone, email). Interviews were audio-recorded with consent, transcribed verbatim, anonymised, and analysed thematically from an inductive perspective. Sampling, data collection and analysis occurred until the point of data saturation. Two authors analysed data, drawing on a contextualist framework of critical realism.

**Results:** Approximately 150 individuals expressed an interest in the study following advertising via Twitter and the UK charity Autistica. The final sample included 49 autistic adults aged 21-67 years (24 male, 22 female, 3 non-binary). Half were employed (49%) and over two-thirds had degree-level education (69%). Four themes were identified:

1. Understanding and acceptability of RCT processes

RCT concepts were understood as being utilised to reduce or avoid bias, and to ensure research findings were trustworthy. Participants reported varied levels of tolerance for uncertainty and some had concerns about side-effects in medication RCTs. There was an assumption that an active drug would be more beneficial than a placebo.

2. RCT design: Issues unique to autism

RCT processes were viewed as acceptable because they maintained fairness, not just for participants, but also to achieve a fair and valid study outcome. Randomisation and blinding were viewed as a means of facilitating equality between clinicians and participants.

3. Trust and health inequalities

Potential barriers to RCT engagement included health inequalities and a lack of accessible healthcare. Some participants discussed negative experiences of past healthcare interactions which resulted in a lack of trust in the medical community.

4. Altruism

Participants were altruistic and mindful about helping others in society, progressing medical research in the autistic community, and highlighted the importance of including autistic people in all stages of the research process.

**Conclusions:** The concept of RCTs and its processes was well understood and acceptable to the adult autistic population interviewed herein, although some concerns and barriers were also identified. These findings have informed the design of an RCT for the treatment of anxiety in autistic adults, and it is hoped will contribute more broadly to develop future RCTs to improve the evidence base and reduce health inequalities in this population.

**409.002 (Poster)** Concomitant Medication Use in Children with ASD: Data from the Autism Biomarkers Consortium for Clinical Trials (ABC-CT)

**L. Shurtz<sup>1</sup>, C. DiStefano<sup>2</sup>, S. Jeste<sup>3</sup>, J. McPartland<sup>4</sup>, C. A. Nelson<sup>5</sup>, G. Dawson<sup>6</sup>, N. M. Kleinhans<sup>7</sup>, S. Faja<sup>8</sup>, S. J. Webb<sup>9</sup>, F. Shic<sup>10</sup>, A. Naples<sup>1</sup>, K. Chawarska<sup>1</sup>, C. Sugar<sup>3</sup>, J. Dziura<sup>11</sup> and M. Santhosh<sup>10</sup>,** (1)Semel Institute for Neuroscience and Human Behavior, UCLA, Los Angeles, CA, (2)University of California Los Angeles, Los Angeles, CA, (3)University of California, Los Angeles, Los Angeles, CA, (4)Child Study Center, Yale University School of Medicine, New Haven, CT, (5)Developmental Medicine, Boston Children's Hospital, Boston, MA, (6)Department of Psychiatry and Behavioral Sciences, Duke Center for Autism and Brain Development, Durham, NC, (7)University of Washington, Seattle, WA, (8)Boston Children's Hospital, Boston, MA, (9)Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA, (10)Center for Child Health, Behavior and Development, Seattle Children's Research Institute, Seattle, WA, (11)Yale University, New Haven, CT

**Background:** Children with ASD are prescribed a variety of medications to address complex behavioral issues, with targets such as irritability, anxiety, insomnia, inattention, and hyperactivity. In clinical trials, concomitant medications often are excluded in order to maintain homogeneity of the sample and to prevent contamination of biomarkers or clinical endpoints. However, this choice may significantly diminish the clinical representativeness of the sample. In a recent multisite study designed to identify biomarkers and behavioral endpoints for clinical trials (ABC-CT), children with ASD and typically developing (TD) controls were enrolled without excluding for medications, thus providing a unique opportunity to examine characteristics of medication use in a research cohort and supplying data to guide future decisions on medication-related inclusion criteria.

**Objectives:** (1) Quantify the frequency and type of medications reported in school-age children enrolled in the ABC-CT and (2) Examine behavioral features of children with ASD based on medication classes.

**Methods:** Data regarding medication use were gathered via caregiver interview (ASD n=280 ASD; TD n=119 TD; 6-11 years). Groups were sex-matched (ASD 77% male; TD 70% male). Medications were classified based on whether they have a known effect on the central nervous system (CNS), and then further classified into 16 categories (see Figure 1). Behavioral measures of interest included the Aberrant Behavior Checklist (ABC), Vineland Adaptive Behavior Scales (VABS), and the Social Responsiveness Scale (SRS). For objective 1, rates of medication use in each group were described. For objective 2, behavioral characteristics were compared between ASD participants on CNS medications and those that were not.

**Results:** 66% (185/280) of children with ASD and 30% (36/119) of TD children endorsed some type of medication use. 43% (119/280) of children with ASD and 2.5% (3/119) of TD children reported taking CNS medications. Within the ASD group, the following medication classes were most commonly endorsed (percent of total ASD sample provided): Melatonin (28%), Stimulants (24%), SSRIs (21%), Alpha agonists (19%), and antipsychotics (11%). Children taking CNS medications were significantly older (9.2 years vs 8.13 years,  $p<.001$ ), had higher verbal IQ (99 vs 94,  $p=.04$ ), lower VABS socialization scores (67 vs 72,  $p=.01$ ), higher ABC hyperactivity (0.52 vs 0.21,  $p=.006$ ), higher ABC irritability (0.74 vs 0.22,  $p<.001$ ), and higher SRS scores (76 vs 72,  $p=.002$ ). Mean scores across assessments for the top five medication classes are provided in table 1. As some participants were taking multiple medications, medication groups were not mutually exclusive and, therefore, not compared statistically.

**Conclusions:** A considerable number of school age children with ASD report use of CNS medications that may have an impact on both behavior and biomarkers. The most commonly reported CNS medications included melatonin, stimulants, SSRIs, alpha agonists, and antipsychotics, each of which may reflect common comorbidities in ASD (e.g. insomnia, inattention/hyperactivity, anxiety). In order to optimize the clinical representativeness of clinical trial cohorts, future studies may consider stratification based on medication class and the potential comorbid conditions that may underlie medication use. Next steps in this consortium study include comparing electrophysiological and eye tracking biomarkers between medication classes.

**409.003 (Poster)** Feasibility of a Randomized Clinical Trial for Children with Autism Spectrum Disorder and Co-Occurring Attention-Deficit/Hyperactivity Disorder: Addressing Enrollment and Retention Challenges

**M. Spanos<sup>1</sup>, T. Chandrasekhar<sup>2</sup>, L. Reinhart-Mercer<sup>3</sup>, G. Dawson<sup>1</sup>, S. H. Kollins<sup>4</sup>, S. Compton<sup>1</sup>, N. O. Davis<sup>4</sup>, M. Sabatos-DeVito<sup>5</sup>, L. Franz<sup>5</sup>, J. Howard<sup>5</sup>, R. E. Aiello<sup>1</sup>, L. Lee<sup>5</sup>, A. Teoh<sup>5</sup> and L. Sikich<sup>1</sup>,** (1)Department of Psychiatry and Behavioral Sciences, Duke Center for Autism and Brain Development, Durham, NC, (2)Duke University Medical Center, Durham, NC, (3)Duke Center for Autism and Brain Development, Durham, NC, (4)Department of Psychiatry and Behavioral Sciences, Duke ADHD Program, Duke University Medical Center, Durham, NC, (5)Psychiatry and Behavioral Sciences, Duke Center for Autism and Brain

**Background:** Approximately half of children with autism spectrum disorder (ASD) have co-occurring attention-deficit/hyperactivity disorder (ADHD). Unfortunately, long-term outcomes of individuals with both conditions are significantly worse than for either condition alone. We hypothesize that ADHD compromises an individual's ability to benefit from autism specific behavioral interventions and that combining ADHD treatment with ASD behavioral intervention may improve functional outcomes for children.

**Objectives:** We designed a randomized double-blind placebo-controlled study of flexibly dosed Adzenys-XR-ODT or matched placebo and Early Start Denver Model (ESDM) informed caregiver coaching, in order to evaluate the benefit of optimized ADHD medication treatment and behavioral intervention on social-communication skills in children with both ASD and ADHD. The initial trial (design 1) failed to enroll an adequate sample size, necessitating modifications and implementation of a second trial (design 2). This analysis compares recruitment, enrollment, and retention for two different study designs in order to identify factors that will improve success of enrollment in future trials.

**Methods:** Design 1 included children between ages 36 and < 96 months of age with both ASD and ADHD who received medication management for 10 weeks prior to behavioral intervention. Participants received combination treatment for 14 weeks and follow-up assessments at 52 weeks. To address challenges in enrollment/retention for design 1, we expanded the upper age limit to 11 years, reduced the period of medication optimization prior to behavioral intervention and total study length. These adjustments occurred due to difficulties with diagnosis of co-occurring ADHD and ASD in young preschool age children. Caregivers also reported that the study length was too burdensome and that attention difficulties were less impairing prior to the onset of school. As a result, design 2 is a 24-week study, which includes 2 weeks of medication optimization prior to 8 sessions of ESDM informed caregiver coaching.

**Results:** Trial design 1: 138 participants completed a telephone screening, 28 were diagnosed with both ASD and ADHD, 3 enrolled for the treatment study, and 0 participants were retained until week 52. Trial design 2: 112 participants completed a telephone screening, 30 were diagnosed with both ASD and ADHD, 16 enrolled in the study, and 13 participants were retained until week 24.

**Conclusions:** Clinical trials of combined medication and behavioral interventions in young children with ASD and ADHD are vitally important, given the prevalence of these co-occurring conditions and the lack of a sufficient evidence base to guide early treatment. The most common reasons that potential participants declined study enrollment were hesitancy about medication treatment in young children with a new diagnosis of ASD and/or ADHD, concern about medication side effects, study length, and number of sessions. Enrollment was also enhanced by early and frequent contact with the study team during the diagnostic portion of the study. Our experiences illustrate the challenges in enrollment of participants and suggest important considerations for future studies, including the importance of including a broader age range of participants, less burdensome length of study, and discussion of a treatment study early and often during the diagnostic evaluations.

**409.004 (Poster)** Multicentre, Randomized Controlled Trial of the Frankfurt Early Intervention Program for Toddlers and Preschool Children with Autism Spectrum Disorder – a-Fip

**Z. Kim, J. Kitzerow, K. Teufel and C. M. Freitag, Autism Research and Intervention Center of Excellence Frankfurt, Department of Child and Adolescent Psychiatry, Psychosomatics and Psychotherapy, University Hospital Frankfurt, Goethe University, Frankfurt, Germany**

---

**Background:**

Naturalistic developmental behavioral interventions (NDBI) have been shown to improve autism specific symptoms in toddlers and preschool aged children with ASD. Studies on early and longitudinal development in children with ASD point to many impaired core domains, which need to be targeted by complex, individualized NDBI approaches focusing on the child's individual strengths and weaknesses. Cost-effective interventions which can easily be implemented in the local health care / social welfare system are necessary. A-FFIP is such a complex, low-intensity, manualized approach. It has shown medium effects in a small clinically controlled study on autism symptom improvement measured by the ADOS severity score after one year (Kitzerow, J., Teufel, K., Jensen, K., Wilker, C., & Freitag, C. M., 2019). Therefore, an adequately powered, randomized-controlled, multi-centre efficacy study is currently performed. Here, we present essentials of the study design of the multicentre, randomized-controlled A-FFIP trial.

**Objectives:**

(1) To establish one-year efficacy of the low intensity, manualized early intervention program A-FFIP in toddlers and preschool children aged 2;0 to 5;6 years old with ASD compared to early intervention as usual (EIAU). It is hypothesized that A-FFIP will result in improved autism specific symptoms compared to EIAU; (2) To assess A-FFIP effects on the child's cognition, language and behavior; on parent's competences, anxiety, depression and stress, and family quality of life; (3) To study the child's and parents' characteristics as predictors and moderators of outcome; (4) To explore treatment mechanisms (mediators) related to parents' and child's competences.

#### Methods:

The trial is designed as a confirmatory phase III, prospective, randomized, multi-centre, controlled, parallel-group study with two treatment groups (134 subjects, i.e. 67 subjects per treatment group) and six measurement time points. Study participants are recruited at four study centres in Germany. Experimental intervention is the manualized Frankfurt Early Intervention program for children with Autism Spectrum Disorder (A-FFIP; Teufel, K., Wilker, C., Valerian, J., & Freitag, C. M., 2017). Two hours of intervention/week with two therapists working with the child are provided. Control intervention is early intervention as usual (EIAU). For EIAU, individual or group therapy intensity of 1-10 hours/week as well as waiting time prior to intervention onset is allowed.

#### Results:

The data collection is currently in process (descriptive data of the current sample will be presented at the conference). The primary endpoint is the absolute change in the total score of the Brief Observation of Social Communication Change (BOSCC-AT) between baseline and 12 months after the first intervention session. The secondary endpoints include measures on the child's and parent's characteristics and competences.

#### Conclusions:

If efficacy of A-FFIP is established, the current study will change clinical practice strongly towards implementation of evidence based methods in ASD early intervention in Germany. Additional positive effects by the trial will be: (1) Improvement of care including diagnosis as well as treatment in underserved areas in Germany; (2) Alerting many different professionals working in early intervention to effective methods; (3) Establishing an effective method and setting of training professionals to high treatment fidelity of evidence based early intervention.

# Clinical Trial Endpoints

## PANEL DISCUSSION — CLINICAL TRIAL ENDPOINTS

### Panel 230 - Digital Outcome Measures

**Panel Chairs: Christopher Chatham**, *Neuroscience and Rare Diseases (NRD), Roche Pharma Research and Early Development, Roche Innovation Center, New York, CA*

**Gahan Pandina**, *Janssen Research & Development, Titusville, NJ*

To better help individuals with autism lead healthy & happy lives, we must first find more efficient ways to learn from them: with higher resolution, at a larger scale, and across a broader scope of behaviors than classical approaches have afforded so far. This paradigmatic shift will require innovation to be coordinated across traditional divides between basic and applied work, and to align emerging insights from autism screening with the analysis of scalable assessments deployed in the context of interventional trials. For robust insights to emerge, this shift will also require a careful marriage of new and old - incorporating new digital biosensors, machine learning approaches, and sensor/modality fusion with older and irreplaceable traditions of gathering meaningful feedback from qualitative interviews; of rigorous work at the intersection of psychometrics, psychophysics and physiology; and of regulatory-grade trial design & inference. We will showcase the many facets of this shift, as it is already occurring today, by bringing together cutting-edge academic insights with new industrial efforts and regulatory perspectives on this evolving space.

**230.001** (*Panel Discussion*) A New Digital Biomarker Platform Tracking Core & Associated Symptoms in Two Clinical Trials **D. Nobbs**<sup>1</sup> and **C. H. Chatham**<sup>2</sup>, (1)Roche Pharma Research and Early Development, Roche Innovation Center Basel, Hoffmann-La Roche, Basel, Switzerland, (2)Neuroscience and Rare Diseases (NRD), Roche Pharma Research and Early Development, Roche Innovation Center, New York, CA

#### Background

Historical approaches to characterizing autism and associated interventions typically involved the laborious collection of subjective data (often second- or third-hand) or complex research-grade technology (e.g., eye-trackers). These assessments often take alternate forms for different ages and intellectual abilities, requiring in-person expert administration, challenging their use across demographically- and geographically-diverse populations. These assessments nonetheless continue to represent a gold-standard in clinical practice, clinical trials, and fundamental research alike.

Newly-tractable computational techniques and the emerging ubiquity of computing hardware (including smartphones and wearables) create new opportunities here. For example, these technologies naturally enable remote administration, increasing access and feasibility for the intensive longitudinal characterization of time-evolving individual experience. However, key challenges remain: many new approaches were adapted *ex post facto* from traditional test modalities without design input from individuals on the spectrum and without rigorous theory-driven mathematical foundations for analysis; further, these technologies are not always appropriate across a wide range of ages and cognitive abilities, and hence for the long-term intensive longitudinal assessments that would ideally accompany next-generation interventions.

#### Objectives

To develop a platform of computationally-enhanced assessments (a) through participatory design with autistic individuals which is (b) appropriate for diverse ages and cognitive abilities, (c) scalable to enhance global deployment & access, (d) well-characterized through rigorous validation & formal modeling, and (e) sensitive to individual differences & longitudinal change.

#### Methods

Respectively for the objectives above, we will provide the first empirical overview of the “Wavelength” digital biomarker platform for autism, including 5 active tests and multiple passive monitoring modalities, (a) collaboratively designed in two international focus groups (n=55) including males and females with autism (b) stratified by age & intellectual ability and (c) deployed transatlantically. We will then introduce the (d) formal computational models used to refine the assessments & quantify key results (e) both in terms of practice effects as well as correlations with gold-standard assessments used to motivate subsequent confirmatory tests.

## Results

Participatory design critically informed specific changes to difficulty, stimulus selection, and termination rules for several assessments within the “Wavelength” suite, including our assessments of spatial working memory, cooperative behavior/theory of mind, emotion recognition, and interpersonal interaction. In response, computational techniques were employed at both acquisition and analysis (including psychometrically-normed staircasing for emotion recognition, Bayesian non-player characters for cooperation, and both agent-based and neural network models of spatial working memory) to drive an evaluation of Wavelength’s potential, both in terms of its convergent validity and reliability. Finally, we demonstrate how this set of computational models and exploratory analyses enables us to prioritize “Wavelength” endpoints for confirmatory test in two (ongoing) double-blind, placebo controlled interventional trials evaluating the effects of different GABA modulators in autism.

## Conclusion

We demonstrate how a combination of modelling and participatory design enables the creation of next-generation markers that are meaningful, powerful and feasible for high-frequency, remote testing in intensive longitudinal designs. Ultimately, we plan to make “Wavelength” available to the field at large.

### 230.002 (Panel Discussion) Scalable Computational Behavioral Phenotyping for the Assessment of Attention and Gaze in Autism

*G. Sapiro<sup>1</sup>, Z. Chang<sup>1</sup>, J. M. Di Martino<sup>1</sup> and G. Dawson<sup>2</sup>, (1)Department of Electrical and Computer Engineering, Duke University, Durham, NC, (2)Department of Psychiatry and Behavioral Sciences, Duke Center for Autism and Brain Development, Durham, NC*

---

**Background:** Early detection of autism spectrum disorder (ASD) is a critical first step toward access to intervention which can influence long term outcome. ASD screening questionnaires are useful, but they require literacy and have lower performance with families from minority racial/ethnic backgrounds and lower education. Based on computer vision and machine learning, we have developed a scalable digital assessment tool for ASD symptom detection and monitoring. This computational behavioral phenotyping tool is delivered on ubiquitous mobile devices by designing an application (app) consisting of several brief movies shown on an iPhone or iPad screen while the child’s behavior is recorded via the device’s front-facing camera. This presentation will discuss how this computational approach assess attention and gaze patterns in toddlers with ASD.

**Objectives:** Describe a computational behavioral phenotyping approach to the assessment of attention and gaze behaviors in toddlers with typical development (TD) and toddlers with ASD.

**Methods:** The sample included 993 children 17–37 months, 40 of whom were subsequently diagnosed with ASD. Gaze information was extracted from the video of the child captured with the device’s frontal camera while the children were watching the carefully-designed movies presented on the device’s screen. Movies consisted of an engaging person shown on one side of the screen who was blowing either bubbles or a pinwheel located on the opposite side of the screen. Another movie showed two women standing on opposite sides of the screen engaged in a back-and-forth conversation. We first automatically computed attention to the stimuli, exploiting both pre-defined filters and machine learning techniques. For the attending frames, gaze information was then extracted; specifically, the percent of frames attending the right versus left side of the screen (social vs. non-social; percent right), strength of the left and right clusters (silhouette score), and the time correlation of the gaze with the conversational flow between the two women.

**Results:** A trained attention network achieved 89% accuracy (preliminary result), sufficient for the subsequent gaze analysis. The percent right and silhouette scores revealed significant differences between the TD and ASD groups, with toddlers with ASD showing reduced attentional preference to the social stimuli (‘Spinning pinwheel’:  $P < .001$  and effect size = .51 for percent right,  $P < .001$  and effect size = .52 for silhouette score; ‘Blowing bubbles’:  $P < .001$  and effect size = .47 for percent right,  $P < .001$  and effect size = .51 for silhouette score). We also observed significant differences between the ASD and TD groups for the gaze-speech time correlation ( $P < .001$ , effect size = .42). Whereas children with TD show a tight correlation between their gaze and the alternating speech of the two adults in a conversation, the children with ASD show a more variable pattern, less coordinated with speech.

**Conclusions:** We demonstrated for the first time that ubiquitous devices can be used to collect and quantify, in a scalable framework, attention and gaze information relevant to ASD. This is an important step toward developing computational behavioral phenotyping tools for advancing methods for early detection and reducing disparities in access to screening and diagnosis.

**230.003** *(Panel Discussion)* Digital Signals and Approaches to Drug Development in ASD  
**G. J. Pandina**, Janssen Research & Development, Titusville, NJ

---

The use of digital signals may improve clinical trial methodology for patient selection and outcome measurement in ASD. These range from novel outcome measures and sampling techniques, to task paradigms with biosensor signals designed to parse the brain's responses to social information. These methods will also benefit from translational efforts to link human clinical and animal models of disease neurobiology, and to consider the utility of the different types of signals across stages of drug development. Traditional measures and biosensors may provide independent information to better understand or predict drug response, and combinatorial approaches should be explored, particularly in early development. Areas of overlap and divergence in biosignatures for ASD as compared with typically developing and other clinical populations may also be informative, given the challenges in classifying subgroups of individuals with ASD. Efforts must also be made to establish measures that can be informative across nonspecific factors such as age, IQ, communication ability, and severity. Illustrative examples will be provided from eye-tracking, facial affect recognition, and novel clinical measures.

**230.004** *(Panel Discussion)* Regulatory Considerations on the Use of Digital Health Technologies to Aid Drug Development for Autism Spectrum Disorder  
**V. Mantua<sup>1</sup>**, **M. Davis<sup>1</sup>** and **T. R. Farchione<sup>2</sup>**, (1)FDA, Silver Spring, MD, (2)Office of Neuroscience - Division of Psychiatry, FDA, Silver Spring, MD

---

Drug development for autism spectrum disorder (ASD) faces several challenges, including phenotypic and biological heterogeneity and lack of consensus on novel targets and outcome measures. Digital health technologies (DHTs), in combination with existing clinical assessments, could help overcome some of these challenges by enabling drugs to be tested for their impact on new digital phenotypes or symptom clusters, enriching patient populations, and allowing continuous and objective measurements of highly variable outcomes.

DHTs can meet the definition of biomarkers or clinical outcome assessments (COAs), depending on whether they measure defined biological characteristics or how patients feel, function, or survive.

DHTs that measure biomarkers may have different roles, depending on how their use impacts the clinical trial or drug development program. The FDA Center for Drug Evaluation and Research (CDER) has a drug development tool (DDT) qualification program through which DHTs can be qualified for use in drug development programs for a specific context of use.

COAs using DHTs necessitate clinical and patient input from the target patient population to ensure the parameter(s) assessed using the DHT are important to patients and relevant to the disease or condition under study. Validation and implementation of DHT measures requires a multidisciplinary approach, which includes evaluating relationships with other outcomes (e.g., patient-reported outcomes) as well as characterizing changes that would be clinically meaningful to patients.

Despite the fact that some of the steps to develop a DHT for use in drug development are similar to those needed for a traditional measure, DHTs have some unique characteristics that involve software and hardware development in conjunction with clinical development. This uniqueness necessitates early discussion with regulatory agencies to ensure that the DHTs will be suitable for use in clinical trials intended to support marketing applications.

The FDA is developing guidance on the use of DHTs for remote data acquisition in clinical investigations, as well as guidance on the conduct of decentralized trials, which frequently use DHTs to engage and assess remote study participants. CDER has also recently launched the Innovative Science and Technology Approaches for New Drugs (ISTAND) pilot program to encourage development of DDTs that may be out of scope for existing DDT qualification programs, including tools that leverage DHTs.

Overall, DHTs have the potential to overcome hurdles in drug development for ASD, but their use requires additional considerations from a clinical development and regulatory perspective.

## POSTER SESSION — CLINICAL TRIAL ENDPOINTS

### Poster 410 - Clinical trial endpoints Posters

**410.001** (Poster) Analysis of the Childhood Autism Rating Scale 2 (CARS-2) in Two Item Sets Aligned on DSM-5 Core Symptoms of ASD. Application to a Bumetanide Oral Liquid Formulation Clinical Trial  
*V. Crutel<sup>1</sup>, E. Lemonnier<sup>2</sup>, E. Lambert<sup>1</sup>, S. Kyaga<sup>1</sup>, D. M. Ravel<sup>3</sup> and S. Serret<sup>4</sup>, (1)Servier, Suresnes, France, (2)centre expert autisme du limousin, CHU de limoges, Limoges, France, (3)R&D, Neurochlore, Marseille, France, (4)Child and Adolescent Psychiatry Department, CHU Children Hospital of Nice, Nice, France*

#### Background:

The Childhood Autism Rating Scale revised in 2010 (CARS-2) and the Social Responsiveness Scale (SRS-2) have been recommended as a primary efficacy measure in the 2017 EMA guideline for the clinical development of medicinal products in ASD. The guideline states that a treatment effect must be demonstrated on at least one out of two core symptoms. The SRS-2, in alignment with DSM-5 criteria provides two sub-scales corresponding to the two symptom domains: Social Communication and Interaction (criterion A) and Restricted Interests and Repetitive Behavior (criterion B).

The objective of this study is to propose a similar approach on the CARS-2, using data from a phase 2 dose-ranging study of bumetanide in a pediatric population with ASD, where CARS-2 was the primary endpoint. In this study, 88 patients were randomised to bumetanide oral liquid formulation twice daily (bid) 0.5mg (n=20), 1.0mg (n=23), 2.0mg (n=22), or placebo (n=23). Bumetanide safety in children and adolescents was consistent with earlier adults studies and the dosage considered to provide the best benefit/risk was 0.5mg bid.

Objectives: N/A

#### Methods:

In the CARS-2 manual, all items (except item 15 omitted because it is a summary and subjective impression score) are grouped by similarity of feature that address broad domains of behavior and apply for main intervention strategies, the so called 5 areas of interventions. The items of Social interactions and Communication related to DSM-5 criterion A were grouped. The same was done for the items of Restrictive patterns and Sensory issues related to DSM-5 criterion B. The categorization of items according to the areas of intervention and their correspondence with DSM-5 criteria A and B are shown in Table 1.

This grouping leaves item 14 (intellectual response) not considered but this can be consistent with the DSM-5 approach clarifying between Autism and Intellectual Disability as separate diagnoses implying that their co-presence will require different levels of individual support.

The categorization of CARS-2 into two subscales was applied to the bumetanide trial using data from 20 patients included in the bumetanide 0.5 mg group and 23 patients included in the placebo group. The change between baseline and Day 90 in CARS-2, expressed as two subscales, was analysed using a general linear model with baseline value as covariate. Dunnett's multiple comparison procedure was used to take into account the multiplicity of doses.

#### Results:

The difference between bumetanide 0.5 mg versus placebo on the change from baseline for DSM-5 criterion A was: -2.55 [-4.30; -0.81] p=0.002 and for DSM-5 criterion B was: -2.34 [-4.34; -0.35] p=0.017, both statistically significant.

#### Conclusions:

To our knowledge, this is the first report assessing change in CARS-2 items in relation to the two core symptoms defined in DSM-5. Although further investigation and validation is required, the approach allows for the assessment of treatment efficacy on each of the two core symptoms. Applying this new analysis of CARS-2 to a phase 2 study suggests that bumetanide improves both Social Communication and Interaction (criterion A) and Restricted Interests and Repetitive Behavior (criterion B) in ASD.

**410.002 (Poster) Feasibility and Acceptability of the Parent Mediated Group Intervention Coping with Uncertainty in Everyday Situations (CUES)**

**J. Rodgers<sup>1</sup>, M. Freeston<sup>2</sup>, D. Garland<sup>3</sup>, V. Grahame<sup>3</sup>, J. Goodwin<sup>4</sup>, A. Kernohan<sup>4</sup>, M. Labus<sup>5</sup>, M. R. Osborne<sup>6</sup>, J. R. Parr<sup>1</sup> and C. Wright<sup>7</sup>,** (1)Population Health Sciences Institute, Newcastle University, Newcastle upon Tyne, United Kingdom, (2)Newcastle University, Newcastle Upon Tyne, United Kingdom, (3)Cumbria, Northumberland, Tyne and Wear NHS Foundation Trust, Newcastle upon Tyne, United Kingdom, (4)Population Health Sciences Institute, Newcastle University, Newcastle Upon Tyne, United Kingdom, (5)Research and Enterprise Services, Faculty of Medical Sciences, Newcastle University, Newcastle Upon Tyne, United Kingdom, (6)South Tyneside's Kids And Young Adults Klub - Special needs support group (KAYAKS), South Shields, United Kingdom, (7)Child and Adolescent Mental Health Service, Northumbria Healthcare NHS Foundation Trust, North Shields, United Kingdom

---

**Background:**

Anxiety is common in autistic children. One key mechanism underlying anxiety is intolerance of uncertainty, a tendency to react negatively on an emotional, cognitive, and behavioural level to uncertain situations. We have worked with clinicians and parents to develop a parent-based programme to assist autistic children to manage uncertain situations more effectively: Coping with Uncertainty in Everyday Situations (CUES<sup>®</sup>). We conducted a pilot randomised controlled trial of this programme.

**Objectives:**

We aimed to ascertain whether CUES<sup>®</sup> helped to increase tolerance to uncertainty. Also, we aimed to determine whether it was feasible and acceptable for families.

**Methods:**

Fifty families were recruited to the study through clinical services. The children were aged 6 – 16 years, had a diagnosis of autism, and were experiencing anxiety related to uncertainty. At baseline, parents were asked to identify two target real-life situations that caused their child significant intolerance of uncertainty. Parents were allocated by chance to either receive CUES<sup>®</sup> or attend a psychoeducation group in a small group setting.

The target uncertain situations at baseline were compared to a 6-month follow up. They were rated on a nine-point scale of improvement/deterioration independently by a panel of experienced clinicians. The top 3 points defines a 'responder'.

Four months after the programme, parents completed a semi-structured interview about their experiences of the intervention. The data from the interviews were then analysed thematically.

**Results:**

Six months post-programme, the CUES<sup>®</sup> group had significant improvement in terms of the impact of the uncertain situation on the child (n = 12 'responders') and family (n = 11 'responders') compared to the group that received psychoeducation (n = 2 'responders' for child and family impact),  $p = .028$  and  $.051$  respectively.

In terms of feasibility, sixty percent of the CUES<sup>®</sup> group attended at least 80% of the sessions, and 86% completed primary outcome data.

Parents reported that taking part in the CUES<sup>®</sup> group was useful: it allowed them to understand their child's anxiety, identify uncertain situations and apply the strategies they learned during the programme. In addition, taking part in the study helped parents to feel less isolated. All parents reported that the programme highlighted the role of uncertainty in their child's anxiety and they felt better equipped to manage it.

**Conclusions:**

Our data support the value of CUES<sup>®</sup> in reducing the impact of uncertainty on the child and family, as well as its acceptability and feasibility. The findings indicate that parents valued a range of aspects of the programme, including the content and pace of the programme, the small group setting which was beneficial for peer support, repetition of concepts to consolidate learning, and the focus on uncertainty, which had face validity for parents. Our pilot trial has established parents were willing to be recruited

and randomised, the format and content of the groups were feasible and acceptable, and the outcome measures were appropriate for use in a future definitive trial.

**410.003 (Poster)** Person-Ability Scores As an Outcome Measure Alternative to Norm-Referenced Scores in ASD Clinical Trials: A Simulation Study

*C. Farmer<sup>1</sup>, A. J. Kaat<sup>2</sup> and A. Thurm<sup>1</sup>, (1)National Institute of Mental Health, Bethesda, MD, (2)Department of Medical Social Sciences, Northwestern University, Chicago, IL*

---

**Background:** It is well-established that clinical trials in autism spectrum disorder (ASD) suffer from a dearth of adequate outcome measures. Norm-referenced scores, often used as outcomes in clinical trials, represent the comparison of an individual's level of ability to that of their chronological age-peers. However, these scores are often not sensitive to within-person change, and the reliability of norm-referenced scores is compromised at the extremes of the distribution. Item-response theory-based person ability scores are a direct index of ability, and are designed to assess within-person change. However, ability scores are unfamiliar to many users and have unknown distributional properties in the population.

**Objectives:** We used simulation to explore and compare the statistical power and accuracy of norm-referenced and ability scores as outcome measures in ASD clinical trials.

**Methods:** The Vineland Adaptive Behavior Scales, Third Edition provides ability scores (growth scale values, GSV) at the subdomain level, where the norm-referenced scores are called V-scale scores. We focused on the Socialization subscale, which comprises three subdomains: Interpersonal Relationships, Play and Leisure, and Coping Skills. We simulated a series of randomized controlled trials, varying the following factors: subdomain, age range of participants, baseline level of functioning, sample size, and treatment effect size. For each factorial combination of conditions, 2,500 datasets were constructed. The outcomes of interest were the efficiency with which the GSV and V-scale scores recover the true effect size (i.e., normalized root mean square deviation, nRMSD, smaller values are better) and the power of the studies to detect the true effect (i.e., the proportion of simulated studies in which the null hypothesis is rejected at  $p < .05$ , higher values are better when the true effect is non-zero).

**Results:** Selected results for the Interpersonal domain are shown in Table 1. The GSV and V-scales performed similarly when the true effect size was zero. Regardless of sample size, both maintained the Type I error rate around 5%, and the nRMSD was similar between the scores. However, in the presence of a moderate effect on the GSV scale, the GSV outperformed the V-scale scores. The power advantage of the GSV was slight: 65% versus 62% for  $N = 50$ ; 95% versus 94% for  $N = 100$ . However, the nRMSD was much smaller for the GSV, reflecting a more accurate estimate of the true effect size, whereas the V-scale tended to underestimate the effect size. The results from all parameterizations of study conditions will be presented.

**Conclusions:** The results of this simulation study provide initial empirical support for the argument that ability scores may offer statistical and methodological advantages over norm-referenced scores when used as outcomes in clinical trials of ASD. In the next stages of this work, we will explore the extent to which this is true under other sets of conditions commonly encountered in ASD research.

**410.004 (Poster)** Predictors of Treatment Response Using the Brief Observation of Social Communication Change (BOSCC).

*R. Grzadzinski<sup>1</sup>, K. Donovan<sup>2</sup>, K. Truong<sup>3</sup>, A. Holbrook<sup>3</sup>, C. Lord<sup>3</sup> and S. H. Kim<sup>4</sup>, (1)Carolina Institute for Developmental Disabilities, University of North Carolina, Chapel Hill, NC, (2)Gillings School of Global Public Health, University of North Carolina, Chapel Hill, NC, (3)University of California, Los Angeles, Los Angeles, CA, (4)Psychiatry, Center for Autism and the Developing Brain, White Plains, NY*

---

**Background:** The BOSCC is a coding scheme of ASD symptoms that is used as a treatment response measure. The BOSCC coding scheme has been validated in a study of toddlers who participated in early interventions ( $n=56$ ) over the course of about 6 months (Grzadzinski et al., 2016). In this work, the coding scheme was applied to 10-minute videos of parent-child free-play sessions (Standard-BOSCC). Subsequent work validated the coding scheme when applied to standardized segments of ADOS videos (ADOS-BOSCC; Kim, Martinez, Grzadzinski, & Lord, 2019). These works confirmed the utility of the BOSCC as a treatment outcome measure when applied to parent-child and clinician-child interactions. Though these projects used an overlapping sample of children participating in early intervention trials, whether the children who show improvements on the Standard-BOSCC are the same as those that show change on the ADOS-BOSCC is unknown. Further, the impact of child characteristics improvement on the Standard BOSCC vs. ADOS-BOSCC needs to be further explored.

**Objectives:** 1. To provide a data-driven definition of “improvers”, 2. To evaluate the overlap between ADOS-BOSCC and Standard BOSCC groups, and 3. To determine whether there are characteristics that predict group status.

**Methods:** The Standard-BOSCC and ADOS-BOSCC was gathered within three days (range=0-49 days) for toddlers participating in intervention trials (n=49; 39 males; age=25 months  $\pm$ 10 months) over the course of ~9 months ( $\pm$ 5 months). Two domains of the Standard-BOSCC and ADOS-BOSCC were assessed separately: Social Communication (SC) and Restricted, Repetitive Behaviors (RRBs). Children were administered the Mullen Scales of Early Learning (MSEL) to assess verbal and non-verbal developmental level (DL). An alpha value of 0.01 was used to account for multiple comparisons.

**Results:** Latent Growth Trajectory analyses revealed good model fit (Figure 1, Panel a) for a three-class result in SC (high, medium, and low improvers) as well as a three-class result in the RRBs (improving, stable, worsening) across both Standard-BOSCC and ADOS-BOSCC. There was observed consistency across ADOS-BOSCC and Standard-BOSCC class membership (Table 1, with 68% of cases remaining in the high or medium SC improvers group as well as 69% of cases remaining in the improving or stable RRB groups. Child baseline skills (intercept) for Standard-BOSCC SC and ADOS-BOSCC RRB as well as baseline symptom severity (ADOS-CSS-SA) for Standard BOSCC SC were significant predictors of group membership. Verbal and Non-Verbal DL at baseline were significant predictors of group membership for Standard-BOSCC and ADOS-BOSCC SC (Figure 1, panel b).

**Conclusions:** Standard-BOSCC and ADOS-BOSCC were relatively consistent in determining who is improving over the course of an intervention. Higher Verbal and Non-Verbal skills predicted more improvement over a relatively short intervention in SC across both Standard-BOSCC and ADOS-BOSCC. Higher ADOS-CSS-SA (more severe ASD SC symptoms) predicted less improvement in SC skills on the Standard-BOSCC, but not the ADOS-BOSCC. These results highlight that early intervention researchers should consider child verbal and non-verbal skills as well as ASD severity when assessing what a “meaningful” amount of improvement is over short periods of time.

#### **410.005 (Poster) Psychometric Properties of Restricted and Repetitive Behavior (RRB) Scales and Associations between Rrbs and Co-Occurring Symptoms and Behaviors**

**J. Tillmann<sup>1</sup>, E. Eule<sup>1</sup>, P. Schoenenberger<sup>1</sup>, D. Volz<sup>2</sup>, T. Ciobanu<sup>1</sup>, C. H. Chatham<sup>3</sup>, C. Goeldner<sup>4</sup>, M. del Valle Rubido<sup>1</sup>, D. Umbricht<sup>1</sup>, L. Murtagh<sup>1</sup>, F. Bolognani<sup>1</sup> and J. F. Hipp<sup>5</sup>,** (1)Neuroscience and Rare Diseases (NRD), Roche Pharma Research and Early Development, Roche Innovation Center, Basel, Switzerland, (2)Department of Biometrics, F. Hoffmann-La Roche AG, Basel, Switzerland, (3)Neuroscience and Rare Diseases (NRD), Roche Pharma Research and Early Development, Roche Innovation Center, New York, CA, (4)Axial Therapeutics, Inc., Basel, Switzerland, (5)Neuroscience and Rare Diseases (NRD), Pharma Research & Early Development, Roche Innovation Center Basel, F. Hoffmann-La Roche AG, Basel, Switzerland

**Background:** Restricted and repetitive behaviors (RRBs) span a broad range of behaviors including repetitive sensory motor behaviors (RSMB), ritualized and rigid behaviors, compulsions, and restricted interests, regrouped as insistence on sameness (IS) behaviors. There is a high need for accurate and reliable assessments of RRBs for the use in clinical practice, basic research and clinical trials. Yet, limited insight into the psychometric properties of existing RRB measures present a major obstacle to better understand underlying mechanism and develop effective treatments. Further, the relationship between RRBs and sensory symptoms, as well as other associated symptoms (anxiety, sleep disturbances) and executive functions is poorly understood, particularly in a longitudinal context.

**Objectives:** First, compare test-retest reliability, convergent validity and ability to detect change of commonly used caregiver-reported (RBS-R, CRI-R, RBQ-2) and self-reported (ARI, RBQ-2A) RRB questionnaire measures. Second, explore the relationships between RRBs and other associated symptoms and behaviors – specifically sensory symptoms, anxiety and sleep problems - within a deeply characterized cohort of individuals with Autism Spectrum Disorder (ASD).

**Methods:** 95 individuals with ASD from children to adults (aged 5-36) and varying levels of intellectual functioning (IQ 50-115) completed a comprehensive battery of assessments at three clinic visits (baseline, week 2, week 12). Test-retest reliability of RRB scales (caregiver-reported: RBS-R, CRI-R, RBQ-2; self-reported: ARI, RBQ-2) was assessed via Intraclass Correlation Coefficients (ICC) using baseline-week 2 data and estimates of the standard error of measurement (SEM) of each scale were derived. Convergent validity, ability to detect change, and the relationship between RRBs and other associated symptoms was assessed via correlational analyses both cross-sectionally and across the 12-week study period.

**Results:** All RRB measures demonstrated good-to-excellent test-retest reliability, being excellent for the RBS-R, CRI-R and ARI (ICCs  $\geq$ .90 for total scores), and good-to-very good for the RBQ-2A (ICC=.78) and RBQ-2 (ICC=.85) respectively. As expected, convergent validity was high for RRB measures completed by the same rater across total scores ( $r>0.8$ ) and subscale scores measuring similar RRB constructs (RSMB:  $r>0.6$ ; IS:  $r>0.7$ ). Change correlations demonstrated a significant moderate degree of

convergence between caregiver-reported measures for total scores ( $r$  range: 0.3-0.4,  $n=68$ ) and IS behaviors ( $r$  range: 0.24-0.46,  $n=68$ ), but less so for RSMB ( $r$  range: 0.09-0.32). Change correlations between self-reported measures (RBQ-2A and ARI) were small and not significantly related ( $r=.18$ ,  $p=.27$   $n=38$ ). Across caregiver-reported measures, more frequent/severe RRBs were associated with greater sensory and anxiety symptoms ( $r>.7$  and  $r>.5$  respectively,  $n=58$ ), as well as sleep problems and executive function deficits (all  $r$ 's  $>.3$ ,  $n=72$ ). More RRBs based on self-report were highly associated with greater anxiety symptoms ( $r>.6$ ,  $n=43$ ) and sleep problems ( $r>.44$ ,  $n=42$ ), but not with executive function deficits ( $r<.1$ ).

**Conclusions:** In this well characterized ASD sample, these results demonstrate the good-to-excellent psychometric properties of caregiver- and self-reported RRB questionnaire measures, including test-retest reliability and convergent validity, and further elucidate the complex relationships of RRBs with other associated symptoms and behaviors. The study design affords to evaluate performance of these scales over a 12-week period under conditions comparable with interventional studies.

**410.006 (Poster)** Social Networks As a Mediator for Transition Success: Building Better Bridges RCT

Drexel Autism Institute, Drexel University, Philadelphia, PA, (2)NORC at the University of Chicago, Chicago, IL, (3)University of California, Los Angeles, Los Angeles, CA, (4)Penn Center for Mental Health, University of Pennsylvania, Philadelphia, PA, (5)AJ Drexel Autism Institute, Drexel University, Philadelphia, PA, (6)California State University, Dominguez Hills, Carson, CA, (7)MIND Institute, UC Davis, Sacramento, CA, (8)University of Rochester Medical Center, Rochester, NY, (9)UC Davis MIND Institute, University of California, Davis, Sacramento, CA, (10)Healthy African American Families, Los Angeles, CA**

Background: Children with autism can experience difficulties navigating school transitions (Nuske et al., 2019). Parent advocacy is considered a key determinant of successful outcomes for children with disabilities (Turnbull & Turnbull, 2001), however under resourced, minoritized families experience formidable challenges advocating in school settings, due to lack of access to resources, little knowledge about their rights, lack of training, negative stereotypes (Burke et al., 2018; Coots, 2007) and social class status and power inequalities (Bourdieu, 2018; Lareau, 2011) leading to distrust and disconnection between home and school (Lareau, 1989). Research suggests that both parents and intervention providers value collaboration (Azad & Mandell, 2016), and preliminary evidence suggests that parent-school collaboration affects treatment quality (Ingersoll & Dvortcsak, 2006) and goal attainment (Ruble, Dalrymple, & McGrew, 2010) for children with ASD. We hypothesize that building parent-school networks during transition could positively impact transition outcomes for under-resourced children with autism.

Objectives: To test this hypothesis, we investigated the mediating role of network strength in a randomized control trial of *Building Better Bridges (BBB)*, a multiple-dimensional intervention for under resourced parents of children on the autism spectrum experiencing school transitions. Parents in the treatment group received a binder of transition resources and coaching support during six training modules, two of which focused on building connections with pre and post transition school teams. Control parents received the transition resource binder only.

Methods: Parent networks of family and school staff (Network Size) were collected at 3 timepoints from four sites, and parents rated their satisfaction with the transition. We used structural equation models to test the mediating effect of social networks on transition satisfaction. Mediation was tested at each step by calculating the indirect, direct, and total effect of the pathways ( $c = c' + a*b$ ).

Results: BBB increased parent-school network size and larger network size was associated with better transition outcomes. Overall, the indirect pathways accounted for 68% of the total effect of treatment. As shown in Table 1, in Model 1a, there was a significant, direct effect of treatment on the outcome. In Model 2, there was a significant direct effect of treatment on the outcome, as well as a significant pathway between Network Size at Time 3 and the outcome. There was also a significant effect of treatment on Network Size at Time 3. In this model, the total indirect effect (the mediation of Network Size) accounted for 18% of the treatment effect. In Model 3 there was a significant direct effect of treatment and Network size at Time 3 on the outcome. The pathway between treatment and Network Size at Time 3 was not statistically significant, but there was a large, positive association between treatment and Network Size at Time 2.

Conclusions: Interventions that target network building for under resourced parents with school staff can impact outcomes of children with autism, suggesting that social network support is a potentially powerful modifiable factor for addressing socioeconomic gaps for under resourced children on the autism spectrum.

---

## Background:

Autism spectrum disorder (ASD) is a neurodevelopmental condition, defined by impairments in social communication and the presence of restricted or repetitive behaviors. Today, no pharmacological treatments exist for this disorder. An oral liquid formulation of bumetanide, a NKCC1 chloride-importer inhibitor, is being evaluated as a potential treatment in children and adolescents with ASD. Two identical phase III trials including children 2 to <7 years old (yo) and children and adolescents 7 to <18 yo, respectively (SIGN trials), are ongoing to assess the efficacy and safety of bumetanide in ASD. Here, we report the baseline characteristics of patients included in one of these trials.

Objectives: N/A

## Methods:

This is an international, randomised, double-blind, placebo-controlled, ongoing phase III trial. Children and adolescents aged 7 to <18 yo, with moderate or severe ASD (Childhood Autism Rating Scale 2 (CARS-2)  $\geq 34$ ; Social responsiveness Scale (SRS-2) total score  $\geq 66$  T-Score; Clinical Global Impression (CGI)-S  $\geq 4$ ) were randomised (1:1 ratio) to one of two parallel treatment groups: bumetanide 0.5 mg oral liquid formulation twice daily (BID) or placebo BID, and entered a 6-month double-blind treatment period, followed by a 6-month open-label treatment period and a 6-week discontinuation period after treatment stop. Patient demographic, clinical data and efficacy parameters including CARS-2 (main efficacy criterion), SRS-2, CGI-S, quality of life parameters (PedsQL and WHOQOL) were collected at baseline.

## Results:

211 patients were enrolled in 10 countries (9 European countries and Brazil). Mean (SD) age of patients was 10.4 (3.0) years and 82.5% were male. Mean BMI was 19.5 (4.3) kg/m<sup>2</sup>, mean age at diagnosis was 4.7 (2.5) years, mean time since diagnosis was 6.4 (3.5) years and 68.7% reported at least one previous condition, mainly psychiatric disorders (22.7%). Among 155 patients evaluable for IQ mean IQ score was 71.2 (26.2), with 47.7% of patients scoring  $\geq 70$ . About 3/4 of patients (75.8%) were assessed according to CARS2-ST (for use with individuals < 6yo or with communication difficulties or below-average estimated IQs) and 24.2% according to CARS2-HF ( $\geq 6$  yo and verbally fluent individuals, with IQ scores above 80). Mean CARS-2 total raw score at baseline was 40.1 (4.9) and mean SRS-2 total score was 116.7 (23.4). The majority of patients (50.7%) were categorised as 5 (markedly ill) according CGI-S score. Mean PedsQL total score was 59.55 (14.49); According to WHOQOL, 50% of caregivers/parents reported a 'good' overall quality of life and 32.2 reported 'neither good nor poor'.

## Conclusions:

The profile of patients enrolled is consistent with the population targeted in the protocol. This trial offers a large and representative data set for children and adolescents with moderate to severe ASD. The population appears well characterized considering CARS and SRS baseline scores but also considering age, IQ and time since diagnosis. Study outcomes will inform the benefit and safety of bumetanide and, if positive, could contribute to the first available pharmacological treatment to enhance social reciprocity and adaptive behavior, thereby helping people and families living with ASD to improve their social integration and quality of life.

## PANEL SESSION — COGNITION: ATTENTION, LEARNING, MEMORY

### Panel 202 - Tracking Outside the Box: Moving Beyond Traditional Areas of Interest in ASD Eye Tracking Research

**Panel Chair:** Elena Tenenbaum, *Duke Center for Autism and Brain Development, Durham, NC*

**Discussant:** Frederick Shic, *Center for Child Health, Behavior and Development, Seattle Children's Research Institute, Seattle, WA*

Over the last two decades, eye tracking has become one of the most widely used tools for behavioral research in autism. Many important discoveries have been forged in this paradigm by selecting areas of interest (AOIs) within a scene and calculating the proportion of time an individual focuses their attention on that area. While this approach has been fruitful, it has also glossed over and left unstudied vast amounts of potentially rich data regarding attention allocation in autism. In this panel, we will discuss four ways to move beyond traditional AOIs to deepen our understanding of the importance of eye movements and attention in autism research. Our first speaker will address aspects of eye tracking that are rarely explored intentionally in research but provide their own windows into phenotypic heterogeneity in ASD. The second speaker focuses on the importance of time-course data in eye tracking. Our third speaker introduces a novel method for constructing AOIs for use with photographs, videos, and in wearable eye-tracking research. Our final speaker turns to virtual reality and semantic models to push the boundaries of what eye tracking can tell us about how individuals with and without autism attend to complex information in real-world environments.

#### Background:

Eye-tracking (ET) is an objective, easily acquired, and noninvasive measure of visual attention that is appropriate for individuals of any age or level of cognitive ability and widely used in autism research. However, despite the rich data generated by ET experiments, the quantity and quality of data collected can vary substantially among individuals, and it is unclear to what extent these metrics influence experimental findings or index meaningful individual differences.

#### Objectives:

We sought to assess: (1) The relationship between metrics of data quality and clinical characteristics; (2) The reliability of data quality metrics within a person over time; and (3) To what extent, different metrics of data quality are interrelated.

#### Methods:

Data were collected as part of the Autism Biomarkers Consortium for Clinical Trials (ABC-CT); a multisite, naturalistic study of 6-11 year-old children with ASD (n=280) and typical development (TD, n=119). ET data were collected while participants viewed static and dynamic social and non-social stimuli spanning six experiments. Children participated in three identical visits over six months, allowing assessment of reliability. The primary metrics of data quality included %ValidTrials, the percentage of valid trials obtained from a task; %ValidData, the percentage of eye-tracking data obtained relative to total experimental time; and ET calibration uncertainty/error. Clinical characterization included measures of cognitive ability (Differential Ability Scales — DAS-II), ASD symptomology (Autism Diagnostic Observation Schedule — ADOS-2) and adaptive behavior (Vineland Adaptive Behavior Scales—VABS3).

## Results:

Both groups exhibited high rates of data quality. Although rates were lower in ASD, with %ValidData ranging, across experiments, from 89—93% in ASD to 96—97% in TD (all  $ps < .005$ ). Among children with ASD, %ValidData was correlated with cognitive ability ( $rs$  ranging from .13—.38); ADOS-2 social affect (-.14—-.31); and VABS3 Social and Communication subscales (.14—.3), such that increased symptomology, was associated with reduced %ValidData (all  $ps < .005$ ). Test-retest reliability of %ValidData ranged from .47—.66 but fell to .001—.37 when including data from participants with high calibration error or few trials who would have been otherwise excluded from subsequent analyses, indicating interdependence among data quality metrics.

## Conclusions:

Our results demonstrate: (1) Data quality is associated with symptom heterogeneity above and beyond what is explained by relationships with age or cognitive ability; (2) Data quality metrics exhibited moderate levels of intraindividual stability, indicating that they index features of the participant, not random error; and (3) These metrics exhibited asymmetric interdependence, e.g., data metrics such as calibration error directly influence our ability to measure valid eye-tracking data.

These findings show that data metrics, including those used to establish diagnostic cutoffs or inclusion criteria, are inextricably tied to participant characteristics and must be carefully considered lest experimental designs introduce bias. These metrics may serve as a heretofore untapped tool for understanding heterogeneity in ASD. The ongoing ABC-CT work explores the extent to which these metrics associate with measures of social attention, and inform our understanding of social attention, and considerations for new measures that explicitly model data quantity as a quality unto itself.

**202.002 (Panel)** Distance from Typical Scan Path When Viewing Complex Stimuli in Children with Autism Spectrum Disorder and Its Association with Behavior

*E. Tenenbaum<sup>1</sup>, S. Major<sup>2</sup>, K. L. Carpenter<sup>3</sup>, J. Howard<sup>1</sup>, M. Murias<sup>2</sup> and G. Dawson<sup>3</sup>, (1)Duke Center for Autism and Brain Development, Durham, NC, (2)Duke Center for Autism and Brain Development, Department of Psychiatry and Behavioral Sciences, Duke University, Durham, NC, (3)Department of Psychiatry and Behavioral Sciences, Duke Center for Autism and Brain Development, Durham, NC*

---

Background: Eye-tracking has been used for decades to distinguish between the gaze patterns of individuals with autism spectrum disorder (ASD) and typically developing (TD) individuals. These studies have identified group differences in patterns of attention and correspondence between gaze patterns and behavioral measures. Many of the studies exploring group differences have relied on proportion of looking time to predefined areas of interest collapsed across the length of the stimuli presented. While overall looking time at specific areas is clearly important, this measure fails to capture one of the key features of the eye-tracking technology: time-course data.

Objectives: Here we capitalize on time-course data (1) to quantify the extent to which gaze paths among children with ASD differ from the scan paths of TD participants and (2) to determine whether symptoms of ASD are related to the distance from the average scan path.

Methods: Using video stimuli in which a woman engages in dyadic bids, sandwich-making, joint attention, and moving toy conditions, we calculated the mean fixations frame-by-frame in a group of TD children ( $n = 40$ ; 23 males, 17 females;  $M$  age = 49.95 months,  $SD = 10.51$ ). We then determined the mean distance from that typical fixation frame-by-frame for 155 children with ASD (122 males, 33 females;  $M$  age = 65.65 months,  $SD = 19.73$ ). This allowed us to identify critical periods in the 3-minute-long stimuli when the two groups were closest to and most divergent from each other. Finally, we used partial correlations (controlling for age and IQ) to assess the correspondence between mean distance from the TD path and symptoms of ASD as measured by Autism Diagnostic Observation Schedule (ADOS-2), Vineland Adaptive Behavior Scales (VABS-3), Pervasive Developmental Disorder Behavior Inventory (PDD-BI) and Aberrant Behavior Checklist (ABC).

Results: Results showed that context (i.e., dyadic bid, joint attention bid, sandwich-making, or moving toy condition) had a significant effect on the mean distance between ASD fixations to the typical scan path (Figure 1). Moments in which the groups were most divergent tended to involve social cues (e.g., dyadic bid, joint attention). Moments in which ASD fixations were closest tended to involve salient movement (e.g., sandwich making; see Figure 2). Significant correlations were identified for mean distance from ASD fixations to the TD scan path on multiple behavioral measures including VABS Communication ( $R^2 = .19, p = .02$ ), ADOS-2 Severity Score ( $R^2 = .20, p = .01$ ), PDD-BI Expressive Social Communication ( $R^2 = -.23, p = .005$ ), and ABC-C Lethargy/Social Withdrawal ( $R^2 = .33, p < .001$ ). In each case, greater distance from the typical scan path was associated with lower communication abilities and/or greater ASD symptomatology.

Conclusions: These results indicate that moment-by-moment changes in stimulus content can have significant effects on what constitutes typical fixation and the extent to which participants with ASD demonstrate divergent gaze patterns. This has important implications for our use of eye-tracking as a measure of atypical attention. Findings also support previous results demonstrating correlations between gaze and ASD symptomatology.

**202.003** (Panel) Automated and Flexible Area-of-Interest Construction for Eye-Tracking Research: With Applications to Autism Research

*R. S. Hessels and I. Hooge, Utrecht University, Utrecht, Netherlands*

---

**Background:** Areas of Interest (AOIs) are used to transform an eye-tracker signal that consists of timestamped spatial coordinates into more meaningful entities such as fixations on relevant objects in the world. AOIs have been widely used to characterize looking behavior to faces in Autism Spectrum Disorder (ASD). However, AOI construction can be problematic for researchers. First, AOIs are often constructed manually, which means subjective choices are made about AOI shape or size. As a result, AOIs differ tremendously even between studies using highly similar stimuli. Second, if the stimulus contains moving objects, AOI construction needs to be done manually for each video frame, which is laborious. The recent emphasis on investigating looking behavior in ASD across various social contexts – from observing photos or videos to live interaction – suggests a need for an automated and flexible AOI-construction method.

**Objectives:** To develop and validate an automated AOI-construction method that can be used to investigate looking behavior to human bodies and faces across various social contexts.

**Methods:** We developed an AOI-construction method based on Voronoi tessellation. It allows researchers to manually specify AOI centers, or to use computer-vision techniques to determine relevant AOI centers. AOI shape and size are then automatically determined by the method, optionally constrained in size by a radius-parameter.

Our AOI-construction method was validated in three studies. First, our method was compared against conventional AOI-construction methods in an eye-tracking study of 10-month-old infants (n=40), adults with ASD (n=13) and adult controls (n=16) observing photographs of faces. Second, an automated implementation was built for videos of faces using OpenFace facial landmark detection and validated in an eye-tracking study of video-mediated dyadic interaction (n=96). Third, an implementation using OpenPose body keypoint estimation was used in a wearable eye-tracking study on social encounters during locomotion (n=23).

**Results:** The outcomes of a study depend on the AOI-construction method used: Relevant measures such as total looking time and the time to first fixation of the eyes, nose, and mouth differed between the AOI methods. Crucially, AOI size affected the statistical comparison of looking time to the eyes between individuals with ASD and controls. The AOI-construction method based on Voronoi tessellation involves the least number of subjective choices, is most noise-robust, and is easiest to implement automatically using a computer.

Validation of the automated implementation for videos of faces revealed that total looking times to the eyes, nose, and mouth, were highly similar ( $\leq 2.6\%$  absolute difference) to an implementation where the researcher determined the AOI centers manually. Thus, the automated implementation is at least as good as manual AOI-construction methods. The implementation for eye-tracking glasses is a proof of concept that our AOI-construction method can be used in less constrained settings as well.

**Conclusions:** The AOI-construction method based on Voronoi tessellation is less subjective than the common manual AOI-construction method. It is easy to implement automatically using state-of-the-art computer-vision techniques and can thus be flexibly used across many different social settings relevant to Autism research.

**202.004** (Panel) Measuring Naturalistic Attention in Complex, Real-World Environments in Autism

*A. J. Haskins<sup>1</sup>, T. L. Botch<sup>1</sup>, B. D. Garcia<sup>1</sup>, J. L. McLaren<sup>2</sup> and C. Robertson<sup>3</sup>, (1)Dartmouth College, Hanover, NH, (2)Geisel School of Medicine, Dartmouth, Lebanon, NH, (3)Psychological and Brain Sciences, Dartmouth College, Hanover, NH*

---

Background: Eye-tracking studies provide substantial insight into cognition, revealing stable, heritable differences in patterns of information-seeking that often distinguish individuals with and without autism. Yet, traditional eye-tracking studies lack key features of the real-world environments in which individual differences in attention are most apparent. In traditional paradigms, images are viewed passively on a computer screen and segmented into a small number of discrete areas of interest (AOIs) for statistical analysis. In contrast, real-world environments are immersive and actively explored, containing a high-dimensional

space of semantic information vying for individuals' attention. A crucial next step for leveraging gaze behavior is to better approximate real-world environments in laboratory settings.

**Objectives:** 1) Develop a novel experimental paradigm using eye-tracking + headmounted virtual reality to measure gaze behavior while participants actively explore complex, real-world environments. 2) Characterize patterns of attention in individuals with and without autism using continuous and high-dimensional models of semantic information.

**Methods:** We showed 40 young adults (N = 21 TD; 19 ASC) a set of varied, real-world photospheres specifically curated to contain a balance of engaging social, object, and scene information. While actively exploring each photosphere (i.e., freely moving eyes, head, and body), participants' gaze was measured via in-headset eye-trackers. Each photosphere was decomposed into a set of smaller image tiles, and the content of each tile was verbally described by online participants (N = 3000). Using a computational language processing model, Bidirectional Encoder Representations from Transformers (BERT), we transformed the verbal descriptions of each tile into high-dimensional semantic embeddings. Sentence embeddings were then used to model continuous feature spaces of each photosphere. We validated this approach for modeling semantic features by comparing the computationally-derived and experimenter-derived (i.e., traditional AOIs) models of information in one specific domain: social information.

**Results:** We obtained high-quality eye-tracking data from participants with and without autism: we observed no group differences in the accuracy of pre-trial fixations ( $p = 0.12$ ) and retained over 90 percent of trials for participants in both groups after excluding trials with poor eye-tracking. Furthermore, we observed high correspondence between the continuous semantic maps generated via sentence embeddings ("social maps") and hand-drawn AOIs. Regions of an image labeled by an experimenter as social (i.e., faces) were ranked in the 90th percentile or higher ( $M = 97.25 \pm 1.75$ ) in semantic maps generated computationally. However, unlike AOIs, which represent binary information (e.g., "face", "not face"), social maps successfully capture the continuum of socially-relevant information present in real-world photospheres and explain a greater proportion of attention across all participants ( $p < 0.001$ ).

**Conclusions:** Here we demonstrate two methodological advances for eye-tracking studies: 1) an experimental approach to enable immersive, active viewing in real-world environments using VR, and 2) a computational approach for modeling rich information in real-world stimuli. This novel approach can be used to test classic hypotheses regarding attentional deployment in autism in more naturalistic contexts, and to generate new hypotheses about the semantic dimensions most relevant to attentional differences in autism.

## ORAL SESSION — COGNITION: ATTENTION, LEARNING, MEMORY

### Oral 322 - Behavior, Gaze, and Biomarkers

#### **322.001** (Oral) Altered Locus Coeruleus Activity during Reaction Time Performance in Autism

*N. Bast<sup>1</sup>, S. Boxhoorn<sup>2</sup>, L. Polzer<sup>3</sup>, B. Helfer<sup>4</sup>, H. Super<sup>5</sup>, C. Klein<sup>6</sup> and C. M. Freitag<sup>7</sup>. (1)Department of Child and Adolescent Psychiatry and Psychotherapy, University Hospital Frankfurt, Frankfurt, Germany, (2)Department of Child and Adolescent Psychiatry, Goethe University Frankfurt, Frankfurt, Germany, (3)Goethe University Frankfurt / Department of Child and Adolescent Psychiatry, Frankfurt, Germany, (4)Imperial College London, London, United Kingdom, (5)Catalan Institution for Research and Advanced Studies, Barcelona, Spain, (6)Department of Child and Adolescent Psychiatry, University of Freiburg, Freiburg, Germany, (7)Autism Research and Intervention Center of Excellence Frankfurt, Department of Child and Adolescent Psychiatry, Psychosomatics and Psychotherapy, University Hospital Frankfurt, Goethe University, Frankfurt, Germany*

**Background:** Arousal mediates our sensitivity to sensory input, amplifies perceptual acuity, and regulates behavioural performance. Atypical arousal regulation may thus explain slower mean reaction time (MRT) in visuospatial task performance in Autism Spectrum Disorder (ASD) and Attention-Deficit/Hyperactivity Disorder (ADHD) compared to typically developing controls (TD). The Locus Coeruleus – Norepinephrine system (LC-NE) underlies arousal regulation and adapts its activity to the utility of a task. LC-NE tonic and phasic activity are indexed by baseline pupil size (BPS) and stimulus-evoked pupillary response (SEPR).

**Objectives:** Investigate group difference in arousal regulation as index of LC-NE activity during visuospatial task performance of different task utility.

**Methods:** The present study assessed pupillometry in matched children (8-17y) with ASD (n=31), ADHD (n=28), or TD (n=31) during a visuospatial reaction time task. Participants were instructed to respond to the visuospatial location of a target with button

presses (up, down, left, right). The task manipulates arousal by varying task utility between conditions. A high-utility condition with slow event rates versus and a high-utility condition with fast event rates (1s.) that also rewarded intra-individually fast MRT. We estimated linear-mixed models of BPS, SEPR, and MRT in a per-trial analysis. Effect sizes were estimated by marginalized means (M) and coefficients ( $\beta$ ).

**Results:** Across groups, high utility was associated with faster MRT ( $\beta = -1.03$ , 95% CI [-1.09, -0.96]), lower BPS ( $\beta = -0.25$ , 95% CI [-0.33, -0.16]), and higher SEPR ( $\beta = 0.15$ , 95% CI [0.07, 0.24]) indicating manipulation of performance and arousal. In low utility, BPS and SEPR were inversely related ( $r = -.50$ , 95% CI [-.53, -.48]) and additively associated with faster MRT indicating an emphasized neuro-modulatory effect of arousal on performance when task utility is low (see figure A).

Three main group findings were observed: (1) Slower MRT was specific to ASD compared to TD during low utility ( $\Delta M = -0.48$ , 95% CI [-0.68, -0.28]). (2) Higher ASD symptoms across groups (Social Responsiveness Scale [SRS] total score) were associated with higher BPS during low utility ( $\beta = 0.20$ , 95% CI [0.06, 0.34]). (3) Changes in BPS and SEPR from low to high utility were smaller in ASD compared to ADHD and TD (see figure B).

**Conclusions:** We successfully manipulated arousal as indicator of LC-NE activity by task utility variation in a visuospatial task. In line with previous meta-analysis, slower visuospatial task performance in ASD might be specific to conditions of low task utility that lack exogenous salience.

Overall, arousal was associated with task performance and showed altered activity in ASD. Increased BPS during low task utility indicates increased LC-NE tonic activity, which might be applied as transdiagnostic ASD symptom marker in children. Smaller BPS and SEPR changes indicate attenuated LC-NE tonic down- and phasic up-regulation in response to high utility, which suggests reduced exploitative processing that impairs sensory selectivity to target stimuli. In ASD, attenuated visuospatial task performance and atypical arousal regulation are likely associated with attenuated LC-NE activity adaptation, which shall be investigated as biomarker in future research.

### **322.002 (Oral) Attention Allocation during Visual Exploration Tasks in School-Age Children with ASD: Autism Biomarkers Consortium for Clinical Trials**

*M. Xie<sup>1</sup>, A. Naples<sup>2</sup>, G. Hellemann<sup>3</sup>, D. Senturk<sup>3</sup>, C. Sugar<sup>4</sup>, S. J. Webb<sup>5</sup>, G. Dawson<sup>6</sup>, S. Jeste<sup>4</sup>, C. A. Nelson<sup>7</sup>, R. A. Bernier<sup>8</sup>, N. M. Kleinhans<sup>8</sup>, J. McPartland<sup>2</sup> and F. Shic<sup>1</sup>, (1)Center for Child Health, Behavior and Development, Seattle Children's Research Institute, Seattle, WA, (2)Child Study Center, Yale University School of Medicine, New Haven, CT, (3)UCLA, Los Angeles, CA, (4)University of California, Los Angeles, Los Angeles, CA, (5)Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA, (6)Department of Psychiatry and Behavioral Sciences, Duke Center for Autism and Brain Development, Durham, NC, (7)Developmental Medicine, Boston Children's Hospital, Boston, MA, (8)University of Washington, Seattle, WA*

#### **Background:**

Between-group differences in visual attention in response to social vs. non-social stimuli may reflect a potential class of biomarkers for ASD. In the Autism Biomarkers Consortium for Clinical Trials (ABC-CT), a visual exploration task was employed within the eye-tracking (ET) battery with children with ASD and typical development (TD). This task examined the detection of and preference for social images (faces) when they were in competition with non-social distractors. Previous studies have found ASD-TD differences in ET measures in visual exploration tasks [1]. However, it is still unclear as to what extent these differences methodologically or conceptually relate to more general attentional issues in ASD.

#### **Objectives:**

Assess (1) ASD-TD between-group differences in attention patterns during a visual exploration task, (2) the effects of controlling for overall data acquisition rates (associated with general attentiveness to presented stimuli) on results.

#### **Methods:**

The sample comprised 399 6-to-11-year-old participants (280 ASD and 119 TD). The task (from [2]) presented an array of five images: one social image (face) and four non-social distractors (e.g. face outlines, technology, birds, cars). Variables analyzed were adapted from [1]: latency for participants to look at the face image; exploration (number of images viewed); perseveration (fixation duration per image viewed); detail orientation (number of fixations per image viewed); and percentage of valid data. ANOVAs with follow-up contrasts were conducted to compare between-group differences with and without control for valid data.

## Results:

As expected, children with ASD had longer latency times to initially view the social image compared to TD children (mean difference=248ms;  $p=0.009$ ). Contrary to prior work, children with ASD showed less perseveration towards social images compared to TD children (mean difference=237ms;  $p=0.039$ ) and lower levels of exploration in non-social images (mean difference=.103 images;  $p=0.001$ ). There were no significant between-group differences in social exploration, non-social perseveration, and detail orientation.

However, there was a difference in percentage of valid data between ASD and TD children, with children with ASD having a lower percentage of valid data than TD (mean difference=5.1%;  $p<0.0001$ ). When the percentage of valid data was controlled for, all significant between-group differences were rendered non-significant, indicating that general attention differences between groups may share substantial variance with indices of social attention.

## Conclusions:

The results suggest that differences exist in visual exploration performance between ASD and TD participants. However, because these differences seem linked to the extent of lost ET data, they may reflect more general attention issues in ASD rather than specific constructs associated with atypical social attention or cognition. Further investigation will be needed to unpack the methodological or conceptual variance associated with atypical general versus exploratory social attentional processes in ASD. Future work should (1) consider methodological sources of variation (number of images in the array, heterogeneity in non-social images, etc.) that may exacerbate general attention issues in ASD and (2) explore possible links between lower percentages of valid data and atypical visual exploration in ASD to ASD and ADHD comorbidity.

### 322.003 (Oral) Increased Attention to the Mouth at 12 Months Predicts Language Outcomes in Infants at Low-Risk but Not Elevated-Risk for ASD

**H. Feiner<sup>1</sup>**, E. Diamond<sup>1</sup>, C. Banarjee<sup>2</sup>, D. M. Goncalves Fortes<sup>1</sup>, M. Butler<sup>1</sup>, R. Foster<sup>1</sup>, A. Boxberger<sup>1</sup>, F. Shic<sup>3</sup>, E. Brennan-Wydra<sup>1</sup>, A. Verneti<sup>1</sup>, S. Macari<sup>1</sup>, D. Lewkowicz<sup>1</sup> and K. Chawarska<sup>1</sup>, (1)Child Study Center, Yale University School of Medicine, New Haven, CT, (2)University of Miami, Coral Gables, FL, (3)Center for Child Health, Behavior and Development, Seattle Children's Research Institute, Seattle, WA

Background: Between six and twelve months, infants increase their attention to speakers' mouths, coinciding with their expanding speech production and understanding (Lewkowicz & Hansen-Tift, 2012). Attention to the mouth facilitates access to combined auditory and visual speech cues and is positively associated with later language development (Tenenbaum et al., 2015; Young et al., 2009). Due to familial liability, younger siblings of children with autism spectrum disorder (ASD) often exhibit language delays (Drumm et al., 2015). We prospectively followed 12-month-old infants with (high-risk, HR) and without (low-risk, LR) familial risk for ASD to examine if these delays are linked with limited ability to attend to the face and utilize redundant audiovisual information in speech. Evaluating links between infants' selective attention and language outcomes is fundamental to identifying factors contributing to typical and atypical early language development.

Objectives: Determine (1) whether attention to a speaker's face and mouth at 12 months differs between HR and LR siblings, and (2) whether risk status modulates the relationship between 12-month selective attention to the face and mouth and 18-month language skills.

Methods: Participants included 61 LR and 90 HR infants, none with ASD. At 12 months, infants participated in a free-viewing eye-tracking study depicting a female speaker (Chawarska et al., 2012). Their proportion of time looking at the scene (%Valid-Looking: scene-looking time/experiment duration), face (%Face: face-looking time/scene-looking time), and mouth (Mouth-Eye Index (MEI): mouth-looking time/mouth+eye-looking time) were computed. Expressive language (EL) and receptive language (RL) were evaluated with the Mullen Scales of Early Learning (MSEL) at 12 and 18 months. Two-sample t-tests assessed group differences in %Valid-Looking, %Face, MEI, and MSEL language t-scores. Multiple linear regressions tested the effects of 12-month predictors (%Valid-Looking, %Face, MEI, RL and EL t-scores) on RL and EL t-scores at 18 months in the HR and LR groups.

Results: At 12 months, groups did not significantly differ in %Valid-Looking, %Face, MEI, or MSEL language t-scores. RL at 18 months was significantly lower in HR siblings compared to LR peers (Table 1). Multiple linear regressions indicated that for LR infants, 18-month RL was predicted by MEI ( $p=.025$ ,  $\beta=.25$ ) and %Face ( $p=.022$ ,  $\beta=.27$ ); for HR infants the only predictor was %Valid-Looking ( $p=.047$ ,  $\beta=.20$ ). EL at 18 months was predicted by %Face ( $p=.005$ ,  $\beta=.35$ ) for LR but not HR siblings (Table 2).

Conclusions: At 12 months, LR and HR infants showed comparable language abilities and selective attention patterns, yet risk status modulated links between attention and language outcomes. Unlike LR peers, HR infants' ability to attend to the speaker's face in a complex social scene did not predict increased language understanding and production six months later. Furthermore, greater attention to the speaker's mouth contributed uniquely to RL outcomes for LR siblings only. These findings suggest that HR infants, despite attending to audiovisual social information similarly to LR peers at 12 months, may not process audiovisual information in a way that facilitates language development. It is imperative to develop language learning methods for HR siblings that target their combined attentional and language processing vulnerabilities.

### **322.004** (Oral) Episodic Memory Dysfunction in ASD – Is It Real?

*M. A. Alkan<sup>1</sup>, A. Easton<sup>1</sup>, D. M. Riby<sup>2</sup> and T. V. Smulders<sup>3</sup>, (1)Psychology, Durham University, Durham, United Kingdom, (2)Department of Psychology, Durham University, Durham, United Kingdom, (3)Bioscience Institute, Newcastle University, Newcastle upon Tyne, United Kingdom*

---

Background: Episodic memory (EM) is memory for past events in specific spatial-temporal contexts ('what-where-when' memory [WWWhen]) (Tulving, 1972). In typical development, EM emerges around 4-5 years of age (Tulving, 2003, 2005). Existing research suggests that individuals with autism spectrum conditions (ASC) display significantly poorer memory when recalling episodic events, compared to neurotypical controls (NT) - which might derive from diminished autoegetic (self-knowing) consciousness and impaired binding processes. However, often tests of EM use verbal material to be recalled, which can be problematic for young NT children and children with an ASC. Although highly variable, language delays and language impairments are documented in ASCs. Therefore, complying with the demands of traditional EM tasks which rely on the language capacity of the child may underestimate their EM ability. Here, we report the first experiments exploring EM in ASC using a behavioural and nonverbal content-based measure of EM which allows us to identify the integration and binding of different associations within an episodic representation.

Objectives: This study aimed to provide the first insights into EM in ASC using a behavioural and non-verbal measure of memory that allows us to disambiguate events in spatiotemporal context, with information about What happened, Where and in Which occasion.

Methods: We developed a hide-and-seek task combining elements of the "WWWhen" memory test by Holland and Smulders (2011) and the "What-Where-Which" memory test by Eacott and Norman (2004). Nineteen children with ASC (mean age = 8.02 years; SD = 1.38 [16 Male]) and 20 NT children (mean age = 6.15 years; SD = .45 [12 Male]) matched on mental age participated. Children completed two sessions to hide six coloured pens (what) at specific locations (where) in two different contexts (which). At retrieval, children retrieved six pens across two sessions yielding two trials each of What-where, What-Which and What-Where-Which. Cognitive functioning was assessed using the Wechsler Intelligence Scale (WPPSI-IV and WAIS-IV) and was used to match the groups (ASC and NT) on mental age.

Results: A Generalised Estimating Equation (GEE) analysis was performed on repeated measures binary data using accuracy as the dependent variable and group (ASC, NT), trial type (EM, what-where, what-which) and encoding order (first, second) as predictors. Results showed no effect of group on the EM task: Wald  $\chi^2 = 3.428$ ,  $N = 39$ ,  $p = .023$ . Bayes factor (B) calculations returned a BF of .064, suggesting substantial evidence of a genuine absence of a difference. Comparisons to chance revealed that both groups are performing above chance (ASC:  $X^2 = 5.158$ ,  $p = .023$ ,  $BF_{10} = 3.003$ ; NT:  $X^2 = 24.025$ ,  $p < 0.001$ ).

Conclusions: Findings suggest that contrary to existing research reporting poorer episodic skills among children with ASC, these children actually demonstrated a pattern of performance similar to TD children, with no evidence of atypicality. We propose that the absence of impairments found in this study may reflect the nonlinguistic methods used. This work suggests a new way to investigate and understand the memory profile in ASCs.

## POSTER SESSION — COGNITION: ATTENTION, LEARNING, MEMORY

### Poster 411 - Cognition: Attention, Learning, Memory Posters

**411.001** (Poster) A Model for Disruption and Heterogeneity of Attentional Processes in Autism: Role of Prefrontal Cortical and Thalamic Networks

A. Yazdanbakhsh<sup>1</sup> and B. (. Zikopoulos<sup>2,3</sup>, (1)Psychological & Brain Sciences, Boston University, Boston, MA, (2)Health Sciences, Boston University, Boston, MA, (3)Anatomy and Neurobiology, Boston University School of Medicine, Boston, MA

**Background:** The activity of lateral prefrontal cortices (LPFC) has been associated with a variety of executive functions including working memory, selective attention control, and regulation of emotional responses, processes that are affected in Autism Spectrum Disorders (ASD). LPFC has reciprocal short-range connections with the anterior cingulate cortex (ACC), an area that is involved in learning changing task rules: coordinated neuronal firing, first in ACC and then LPFC, has been shown to correlate with successful task-switching performance, attributed partially to changes in the regulation of attention.

**Objectives:** Attention and task-related performance are disrupted in ASD, with very heterogeneous behavioral outcomes. The mechanisms and processes underlying this disruption are not understood. We hypothesized that an imbalance in excitation/inhibition within LPFC circuits interacting with ACC and thalamic networks may be at the core of ASD pathology.

**Methods:** Our recent neuropathological findings suggest highly variable, increased connectivity in short-range ACC-LPFC networks that disproportionately affects the feedback output of ACC to superficial LPFC layers in ASD. We have also reported a decrease in the density of specialized inhibitory neurons that innervate other inhibitory neurons in the superficial layers of LPFC in ASD. These inhibitory neurons are likely targeted by diffuse thalamic pathways in mammals and are the predominant inhibitory neurons in the human cortex. Based on this evidence we created a computational model to simulate typical LPFC neural network function and its disruption in ASD during simultaneous processing of distinct inputs. We test the variability of cortical response after changes in the balance of excitation and inhibition, based on our neuropathological findings.

**Results:** Our simulations reveal mechanisms that raise base cortical tone in ASD and can spread this disruption widely in the extended cortical attentional network, through thalamocortical pathway involvement. These result in decreased signal to noise ratio and difficulty in the distinction of signals that can adversely affect attention. Variable changes in the balance of excitation/inhibition can also provide clues about compensatory mechanisms and processes underlying the observed ASD heterogeneity, through variability in cortical responses, accuracy, and reaction times in a simulated behavioral task.

**Conclusions:** Overall, our findings highlight the important role of feedback excitatory cortical communication and widespread thalamocortical inputs in attention networks and the imbalance of excitation/inhibition in these networks in ASD.

**411.002** (Poster) Altered Internal Concentration in Autism Spectrum Disorder

A. Ahmad<sup>1</sup>, S. Gulati<sup>2</sup>, R. Sharma<sup>3</sup>, S. Sharma<sup>4</sup>, S. Kaur<sup>5</sup>, P. Tayade<sup>6</sup> and B. Chakrabarty<sup>6</sup>, (1)Department of Physiology, All India Institute of Medical Sciences, New Delhi, New Delhi, India, (2)Centre of Excellence and Advanced Research for Childhood Neurodevelopmental Disorders, Child Neurology Division, Department of Pediatrics, All India Institute of Medical Sciences, New Delhi, India, (3)Department of Physiology, All India Institute of Medical Sciences, New Delhi, India, (4)Child Neurology Division, Department of Pediatrics, All India Institute of Medical Sciences, New Delhi, New Delhi, India, (5)Physiology, All India Institute of medical sciences, New Delhi, India, NEW DELHI, India, (6)Pediatrics, All India Institute of medical sciences, New Delhi, India, NEW DELHI, India

**Background:** Attentional incompetence are widely reported in children with Autism spectrum disorder (ASD). Children with ASD are atypically over-focused to be able to pay attention towards an external stimulus, over their motivational state. This phenomenon is referred as altered attentional modulation in which selection of desired information from infinite number of objects and events that are available in environment for further processing is difficult. We propose that distinct patterns of delta spectral power could be used to distinguish children with ASD from typically developing children (CTRL).

**Objectives:** To compare EEG delta power in children with ASD compared to typically developing children (CTRL) during attention task.

**Methods:** EEG was recorded during attention task i.e. digit span forward task, using 128 channel hydrocel geodesic sensor net in 61 children with ASD diagnosed by DSM 5 criteria and 48 age matched CTRL. Raw EEG was filtered (1-100 Hz band pass,

50Hz notch) followed by segmentation into 5 epochs of 1 second duration from each trial i.e. total of 15 epoch of 1 second duration. Artifacts such as eye movement, eye blink and bad channel were removed using Net-station software. EEGLAB was used to remove ECG and power line noise artifact using independent component analysis. Average re-referencing was computed. After exclusion of files with artifacts or corrupt files at some or preliminary analysis steps, EEG data of 19 children with ASD were analysed. For comparison EEG data of age matched 20 CTRL children were used for analysis. Mean  $\pm$  SD age of children with ASD ( $6.12 \pm 2.4$  years) and CTRL ( $7.24 \pm 2.3$  years) were not significantly different. Individual alpha frequency (IAF) was calculated using "Spectopo" EEGLAB function, with window size of 256 data points and overlapping windows of 50%, to classify the EEG frequency bands i.e. delta bands for spectral power analysis. Further, for spectral power analysis Fast Fourier Transform was performed in MATLAB using a custom made script. For plotting of power results, EEGLAB topoplot function was used.

Results: Delta power changes during digit span forward task was measured and compared between ASD and CTRL. Decreased spectral power ( $p < 0.0005$ ) in delta band was observed in children with ASD compared to CTRL

Conclusions: Reduced delta power during attention task suggests altered internal concentration in ASD children compared to CTRL. Previous studies also reported that resting state activity in delta band is inversely associated with higher cognitive functions such as self-reflection, working memory, and sustained attention. Additionally, EEG studies during arithmetic task showed increases in delta power in control subject. To the best of knowledge this is the first EEG study exploring delta power during attention task in ASD children, therefore further studies could be undertaken to explore the same in tasks involving attention as the predominant cognitive domain.

#### **411.003 (Poster) Assessing Event Knowledge in Relation to Autistic Traits and Social Ability**

**K. E. Hannah<sup>1,2</sup>, K. S. Brown<sup>3</sup>, M. Hall-Bruce<sup>2</sup>, R. A. Stevenson<sup>1,2</sup> and K. McRae<sup>1,2</sup>, (1)Psychology, University of Western Ontario, London, ON, Canada, (2)Brain and Mind Institute, University of Western Ontario, London, ON, Canada, (3)Pharmaceutical Sciences and Chemical, Biological, and Environmental Engineering, Oregon State University, Corvallis, OR**

**Background:** Event knowledge, a person's understanding of patterns of activities in the world, is crucial for everyday social interactions. Atypical event knowledge could contribute to the social communication issues prominent in autism spectrum disorder (ASD). Previous research indicates that event knowledge is atypical in autistic individuals, including knowledge of temporal order of event activities. However, research in this area is minimal, particularly concerning the relationship between event knowledge and social abilities.

**Objectives:** We aimed to investigate how event knowledge, measured through ordering of event activities, relates to traits associated with ASD, particularly lower social abilities.

**Methods:** Two studies were conducted. In Study 1, 140 participants ordered activity lists presented with commonplace events, such as "baking a cake". In Study 2, 123 participants listed their own steps for presented commonplace events. Events were categorized based on the level of social interaction (personal interaction, with others, non-social) involved in the event for Study 2 only. All participants completed self-report questionnaires assessing autistic traits, including measures of social abilities and repetitive behaviours: Autism-spectrum Quotient (AQ), Multidimensional Social Competence Scale (MSCS), and Repetitive Behaviour Questionnaire (RBQ-2A). In both studies, average deviation from consensus ordering of event activities (activity ordering deviation) was calculated per participant. In Study 1, correlational analyses were conducted between questionnaire scores and activity ordering deviation. In Study 2, composite scores were calculated for social ability (using applicable AQ and MSCS subscales) and repetitive behaviours (using applicable AQ and RBQ-2A subscales). Participants were categorized as having high or low levels of traits using a median split. ANOVAs were used to analyze differences in activity ordering deviation across the three event categories between high and low trait levels.

**Results:** In Study 1, more atypical activity ordering was associated with higher overall autistic traits ( $r(137)=.21, p=.01$ ). Lower social ability was also related to more atypical activity ordering ( $r(138)=.27, p=.01$ ). More atypical activity ordering was not associated with higher overall repetitive behaviours ( $r(138)=.10, p=.26$ ). In Study 2, a significant interaction between level of social ability and event category was found ( $F(2, 242)=3.82, p=.02$ ). For the low social ability group, activity ordering became more atypical as events became more social in nature (Figure 1). Repetitive behaviours were not found to relate to ordering of event activities.

**Conclusions:** Because event knowledge plays a central role in social interactions, atypical event knowledge may cascade into further issues, including social communication issues in ASD. Results suggest that individuals with higher autistic traits may have difficulties with predictability related to the temporal order of events. As activity ordering became more atypical as events became more social in nature for the low social ability group, social events may be even less predictable, such that it may be more difficult for these individuals to retain representative event knowledge of extremely social events. Future research could

consider investigating the interplay between event knowledge, autistic traits, and related areas such as inferencing ability.

**411.004 (Poster)** Assessing the Impact of Sensory Processing on Academic Achievement and Attention

**J. C. Bullen<sup>1</sup>** and **P. Mundy<sup>2</sup>**, (1)University of California, Davis, Davis, CA, (2)University of California at Davis, Sacramento, CA

---

**Background:** Atypical sensory processing is widely recognized as a feature of ASD (Tomcheck & Dunn, 2007), and it is hypothesized that difficulty with sensory processing may impact academic achievement (Ashburner et al., 2008). Additionally, it is also hypothesized that difficulty with auditory processing may be linked with attentional difficulties (Moore et al., 2010) which may also impact achievement in ASD. This study was designed to examine both hypotheses.

**Objectives:** To understand the impact of sensory processing difficulties on academic achievement and symptoms of attention deficit/hyperactivity disorder (ADHD) in children and adolescents with ASD without a comorbid intellectual disability (ASD-WoID).

**Methods:** Participants in this study included 81 children with ASD-WoID (FIQ > 74; M = 11.29 years, SD = 2.13). Parents completed the Sensory Profile 2 (SP2) to provide a measure of sensory processing and Conners-3 to provide a measure of their child's ADHD symptoms. An objective measure of children's auditory processing was obtained using the SCAN. Math ability was measured with Numerical Operations and Problem Solving measures from the WIAT-III and reading ability was measured with Reading Comprehension and Reading Fluency measures from GORT5. WASI2 was used to provide a measure of full-scale IQ (FIQ).

**Results:** Pearson correlations conducted between the academic, attention, and sensory variables are reported in Table 1. Parent and objective measures of auditory processing were not correlated, and there was little evidence of relations between ADHD symptoms and sensory measures. Regression analyses indicated that SP2 Auditory Processing predicted GORT Reading Fluency scores ( $b = -.11, p < .05$ ) above FIQ ( $b = 0.07, p < .01$ ), age and gender ( $ps > .05$ ),  $F(4, 50) = 6.85, p < .05, R^2 = .35$ . SP2 Auditory Processing also predicted reported Conners-3 Learning Problems ( $b = 0.61, p < .05$ ), above FIQ ( $b = -0.25, p < .05$ ), age ( $p > .05$ ), and gender ( $b = -8.24, p < .05$ ),  $F(4, 49) = 5.08, p < .01, R^2 = 0.29$ . SP2 Visual Processing significantly predicted Problem Solving scores ( $b = -0.80, p < .05$ ) above FIQ ( $b = 0.92, p < .001$ ), age and gender ( $ps > .05$ ),  $F(4, 50) = 13.73, p < .001, R^2 = 0.52$ . The SCAN, but not SP2 measures, was related to FIQ. The Scan also correlated with GORT Comprehension and WIAT Problem Solving, but regressions indicated these relations did not hold when FIQ was included in the model. All other models did not reach statistical significance.

**Conclusions:** The findings indicate that measures sensory processing may relate to some aspects of academic achievement and learning ability. However, this did not appear to be due to sensory associations with ADHD symptoms. The results also indicated that parent report and objective measures of sensory processing may measure different processes. While the former was related to academic achievement, the later appear to be related to domain general cognitive development. Additional studies are needed on the mechanisms by which sensory processing and cognitive development are related, academic achievement in ASD, and measurement issues in sensory processing research.

**411.005 (Poster)** Atypical Exogenous and Endogenous Orienting in People with ASD

**S. Li<sup>1</sup>**, **E. L. Burrows<sup>2</sup>** and **K. A. Johnson<sup>1</sup>**, (1)School of Psychological Sciences, University of Melbourne, Parkville, VIC, Australia, (2)Florey Institute of Neuroscience and Mental Health, University of Melbourne, Parkville, VIC, Australia

---

**Background:**

Attention orienting determines where we focus our concentration and is an essential contributor to all cognitive processes. It involves endogenous (goal-directed) and exogenous (stimulus-driven) systems. A deficit in attention orienting may be one of the earliest features in individuals with Autism Spectrum Disorder (ASD), but previous investigations into attention orienting in ASD have presented inconsistent results. Possible explanations are that the atypical attention orienting in individuals with ASD is related to abnormal alerting levels or appear during specific developmental periods. To date, it remains unclear what factors contribute to atypical attention orienting found in some individuals with ASD.

**Objectives:**

We aimed to examine whether individuals with ASD showed atypical attention orienting and whether the provision of an alerting tone and age affected attention orienting differently between the ASD and typically developing (TD) groups. Given limited

research on gender differences in ASD on attention, we also investigated whether males and females with ASD showed different patterns of attention orienting.

#### Methods:

Twenty-seven people with ASD (14 males; mean age = 21 years, SD = 9.21) and 22 TD people (13 males; mean age = 23 years, SD = 9.77) completed both the exogenous and endogenous Posner tasks. Participants were required to respond to a target on either the left or right side of the computer screen after presentation of a visual cue. The cues either validly or invalidly indicated the location of the target or they were non-informative neutral cues. An alerting tone was present before the visual cue in 50% of trials. Attention orienting was measured through the orienting effect (invalid trials RT – valid trials RT), benefit of valid cue effect (neutral trials RT – valid trials RT), and cost of invalid cue effect (invalid trials RT – neutral trials RT).

#### Results:

In the exogenous task, the ASD group showed a larger orienting effect and benefit effect compared to the TD group. No group difference was found in the cost effect. The alerting tone, age, and sex did not affect the outcome measures. In the endogenous task, the ASD group showed a larger cost effect compared to the TD group. No group difference was found in the orienting or benefit effect. The cost effect reduced with age in the ASD group but was stable across age in the TD group. The alerting tone and sex did not affect any outcome measures.

#### Conclusions:

The participants with ASD performed the Posner task with atypical exogenous and endogenous orienting. They were more efficient at orienting to valid exogenous cues but showed difficulties in disengaging from invalid endogenous cues. The provision of an alerting tone did not affect attention orienting for either group. Although attention orienting appeared to be stable after adolescence in the TD group, endogenous orienting continued to develop until middle adulthood in people with ASD.

#### **411.007 (Poster) Executive Function and Emotion Regulation As Predictors of Academic and Social Outcomes in Kindergarteners with ASD**

*A. P. Viggiano<sup>1</sup>, D. Swain<sup>2</sup>, H. R. Thomas<sup>3</sup> and S. H. Kim<sup>4</sup>, (1)Weill Cornell Medicine Center for Autism and the Developing Brain (CADB), White Plains, NY, (2)Virginia Polytechnic Institute and State University, Blacksburg, VA, (3)Psychological Sciences, University of Connecticut, Storrs, CT, (4)Psychiatry, Center for Autism and the Developing Brain, White Plains, NY*

**Background:** Executive function (EF) and emotion regulation (ER) are critical for academic and social development in typically developing (TD) children (e.g., McClelland et al., 2007). However, EF and ER vary in young children with ASD (Konstantareas et al., 2006; Venter, Lord, & Schopler, 1992). Thus, more in-depth examinations of how school-entry EF and ER predict academic and social outcomes have strong implications for early interventions for young children with ASD.

**Objectives:** To examine how kindergarten-entry EF and ER predict concurrent and kindergarten-exit academic and social outcomes while controlling for age, gender, autism symptom severity, and cognitive levels.

**Methods:** Participants included 64 cognitively-able children with ASD (13 females) assessed at kindergarten-entry (M=63.8 months; SD=5.1) and -exit (M=72.3 months; SD=4.4). EF was assessed based on innovative, tablet-based tasks, “EF-Touch”, targeting inhibitory control (“Spatial Conflict Arrows”; SCA), working memory (“Pick the Picture”; PTP), and attention shifting (“Something’s the Same”; STS; all % correct rates). ER was measured by caregiver report using the Child Behavior Checklist-Dysregulation Profile (CBCL-DP; sum of three Syndrome Scale T-scores: Attention Problems, Anxious/Depressed, Aggressive Behavior). The Woodcock-Johnson III tests of achievement (WJ) was used to measure academic achievement in reading (Passage Comprehension [PC]) and math (Applied Problems [AP]). Social outcomes in the areas of Peer Interaction (PInteract), Peer Disruption (PDisrupt), and Peer Disconnection (PDisconnect) were assessed using the Penn Interactive Peer Play Scale (PIPPS). Kindergarten-entry ASD symptom severity and cognitive skills (Full Scale IQ) were assessed with the Autism Diagnostic Observation Schedule-2 calibrated severity scores (ADOS-2 CSS) and the Differential Ability Scale (DAS). Regression analyses were conducted to examine whether EF and ER significantly predicted concurrent and future academic and social outcomes while controlling for age, gender, ADOS CSS, and FSIQ. Two separate sets of analyses were conducted with EF Touch scores first and then with CBCL-DP.

**Results:** For concurrent predictions with EF, kindergarten-entry attention shifting (STS) predicted math performance (WJ AP; B=44.670, p=0.004). For ER, kindergarten-entry dysregulation levels predicted math performance (WJ AP, B=0.268, p=0.003) and peer play (PIPPS PDisrupt, B=0.291, p<0.001; PDisconnect, B=0.261, p=0.016; PInteract, B=-0.184, p=0.024). For the

predictions of kindergarten-exit outcomes with EF, kindergarten-entry attention shifting (STS) predicted math performance (AP;  $B=57.196$ ,  $p=0.003$ ). For ER, kindergarten-entry dysregulation levels also predicted kindergarten-exit math performance (WJ AP,  $B=0.260$ ,  $p=0.02$ ) and peer play (PIPPS PDisrupt,  $B=0.321$ ,  $p<0.001$ ; PDisconnect,  $B=0.199$ ,  $p=0.005$ ; PInteract,  $B=-0.156$ ,  $p=0.039$ ). All predictors were significant after controlling for age, gender, FSIQ, and symptom severity.

**Conclusions:** Kindergarten-entry EF and ER may play a critical role in concurrent and future academic and social development at kindergarten-exit in children with ASD. Impairments in attention shifting and emotion dysregulation predicted poor math outcomes. Emotion dysregulation also predicted higher levels of peer play disruption and disconnection and lower levels of peer interaction. Results highlight the importance of targeting EF and ER even before school-entry to maximize academic and social outcomes in children with ASD (Jones et al., 2017).

**411.008 (Poster)** Inhibitory Difficulties in Autism Spectrum Condition: A Nuanced View on an Ongoing Debate  
*C. Torenvliet, A. G. Lever, A. P. Groenman, K. R. Ridderinkhof and H. M. Geurts, University of Amsterdam, Amsterdam, Netherlands*

---

**Background:** Difficulties in prepotent response inhibition (PRI) have been argued to explain the repetitive behavior, and social difficulties in autism spectrum conditions (ASC). However, the evidence in autistic adults is rather mixed. As PRI is a complex executive feature, we hypothesized that these mixed findings could be explained by the involvement of other executive features.

**Objectives:** We aimed to replicate the PRI difficulties of autistic individuals observed in previous research in a large adult sample. Furthermore, we investigated whether context monitoring and adaptation, two features hypothesized to be involved in PRI, were associated with these PRI difficulties.

**Methods:** We used a 3-stimulus Go-NoGo-task and a complementary 3-stimulus Oddball-task in a sample of 246 adults between 19 and 79 years (106 ASC and 146 non-ASC). Our pre-registered analysis plan ([osf.io/ayn7e](https://osf.io/ayn7e)) consists of three steps. 1) Group differences were analyzed on mean reaction time, standard deviation of reaction time, (c)omission errors, and post error slowing. 2) We investigated associations with age, and group\*age interactions on these measures. 3) We tested whether PRI (commission errors Go-NoGo) could be predicted by context monitoring (omission errors Oddball) and adaptation (post error slowing (PES) Go-NoGo) and their interactions with group, and age.

**Results:** Preliminary results showed 1) no significant group differences on any of the measures. 2) On the Go-NoGo task more (c)omission errors, more variable and slower responses, and more PES were associated with older age. On the Oddball task, older age was only related to slower responses, and more omission errors. No group\*age interactions were observed. 3) Commission errors were significantly associated with PES, but not with omission errors. No interactions with group, or age were observed.

**Conclusions:** We found no evidence for PRI difficulties in autistic adults. Also, no differences between groups in context monitoring and adaptation were observed. Nearly all measures showed a significant relation with age, highlighting the importance of age in explaining previous contrasting findings. Also, remarkably large standard deviations demonstrated the heterogeneous performance on these measures, and the caveats of using group-based statistics. Nonetheless, we carefully conclude that difficulties in PRI do not seem (dominantly) present in ASC.

**411.009 (Poster)** Investigating Executive Functioning in Preschool Children with Autism Spectrum Disorder  
*O. Zacharov<sup>1</sup>, R. Huster<sup>2</sup> and A. Kaale<sup>1,3</sup>, (1)Department of Special Needs Education, University of Oslo, Oslo, Norway, (2)Department of Psychology, University of Oslo, Oslo, Norway, (3)Norwegian Centre of Expertise for Neurodevelopmental Disorders and Hypersomnias, Oslo University Hospital, Oslo, Norway*

---

**Background:** Impairments in executive functions (EF), a group of complex inter-related cognitive processes that are essential for deliberate and goal-directed behaviour, have been reported in school-age children with Autism Spectrum Disorder (ASD). The results from studies on EF performance among preschool children with ASD are highly inconsistent and it therefore remains to be seen whether EF difficulties in preschool ASD children are linked to the disorder itself or other factors, including the nonverbal age (NVA).

**Objectives:** Compare the performance between ASD and typically developed (TD) preschool children on EF tasks and to investigate whether potential performance differences are independent of nonverbal age.

**Methods:** Fourteen children ( $M = 51.71$  months,  $SD = 6.32$ , range = 40 – 59, 85.7 % boys) with a confirmed ICD – 10 diagnosis of ASD and thirty-three TD children ( $M = 48.64$  months,  $SD = 6.92$ , range = 37 – 59, 57.6 % boys) performed two non-digital behavioral tasks, namely the Block Sorting Task (BST), consisting of 12 pre-switch and 12 post-switch trials, and the

Dimensional Card Sorting Task (DCST), consisting of 5 pre-switch and 5 post-switch trials. Both tasks are purported to measure cognitive flexibility and inhibitory control. Children's performance was video recorded and then coded. For each participant, the dependent variable was the composite score computed by adding the number of correctly sorted post-switch trials from both tasks. The composite score ranged from 0 to 17, with the latter indicating ceiling performance. The children were also assessed with the Mullen Scales of Early Learning from which the NVA was derived. At the day of this writing the process of participant recruitment is ongoing.

**Results:** There was a significant difference in performance ( $t(45) = -2.08, p = .043, 95\% \text{ CI} [-6.07 - -.10], \text{Hedges' } g = 0.67$ ) with ASD children performing worse ( $M = 9.21, SD = 5.19$ ) than TD children ( $M = 12.30, SD = 4.41$ ) on the sorting tasks. NVA was significantly different ( $t(45) = -5.89, p < 0.001, 95\% \text{ CI} [-22.66 - -11.11], \text{Hedges' } g = 1.87$ ) between the ASD ( $M = 32.25, SD = 8.38$ ) and TD groups ( $M = 49.13, SD = 9.22$ ). A multiple linear regression was conducted with group and NVA as predictor variables and composite scores as outcome. The results indicated that the model explained 22.8% of the variance of the composite scores ( $F(2,44) = 6.49, p = .003$ ). While NVA contributed significantly to the model ( $B = .202, p = .007$ ), the group variable did not ( $B = -.328, p = .859$ ).

**Conclusions:** The results suggest that factors other than ASD, in this case NVA, may be responsible for the difference in performance on the executive functioning task. It may be the case that factors that are not exclusive to ASD but highly associated with the disorder may be contributing to the impairment in EF in young children.

**411.010 (Poster) Long-Term Melodic and Pitch Memory in Children with Autism Spectrum Disorder.**

**S. T. S. Wong, S. Stanutz, S. Sivathasan, E. Stubbert, J. Burack and E. M. Quintin, Educational & Counselling Psychology, McGill University, Montreal, QC, Canada**

---

**Background:** Short and long-term memory for individual tones and melody are enhanced among some musically untrained persons with autism spectrum disorder (ASD) (Bonnell et al., 2003; Stanutz, Wapnick, & Burack, 2014). Particularly, absolute pitch (AP), the ability to identify pitch of a tone without a reference pitch, is enhanced among musical savants with autism (Hermelin, 2001). As the abilities to identify and distinguish pitches are not as outstanding in typically developing (TD) children (Cooper, 1995; Fancourt, Dick & Stewart, 2013), AP may offer a potential framework for understanding the musical memory strengths of persons with ASD.

As visual-spatial skills have been linked to musical learning among both TD persons (Rauscher & Zupane, 2000) and musical savants with ASD (Heaton 2012), they may be a potential mechanism for the enhanced musical memory among persons with ASD.

**Objectives:** Investigate the potential roles of pitch memory and visual-spatial skills in performance on a melodic memory task among high functioning children with ASD.

**Methods:** High functioning children with ASD aged 8-12 years and TD children matched on chronological (and mental) age learned 4 melodies and completed a melodic memory task one week later. In the first session, the participants learned melodies in a specific key that were each matched to a specific animal. One week later, the participants were presented each of the four melodies in the original key and two other transposed keys. They were then asked to identify 1) the key in which they originally learned each melody; and 2) the animal with which each melody was paired. The Wechsler Abbreviated Scale of Intelligence, 2<sup>nd</sup> edition (WASI-II), Digit Span of the Wechsler Intelligence Scale for Children, 5<sup>th</sup> edition (WISC-V, DS), Salk and McGill Music Inventory (SAMMI, Levitin et al. 2004), and Music Training and Experience Questionnaire (MTEQ, Quintin et al., 2011) were administered to account for intelligence and musical experience. The children with ASD were assessed with the Autism Diagnostic Observation Schedule, 2<sup>nd</sup> edition (ADOS-2) to confirm their diagnosis. One parent of each child completed the Social Responsiveness Scale, 2<sup>nd</sup> edition (SRS-2) and the Social Communications Questionnaire Lifetime version (SCQ-L) to ascertain autism symptomatology among the participants with ASD and to ensure that the TD children did not present with signs of ASD.

**Results:** In preliminary analyses, 7 children with ASD showed more accurate long-term melodic memory ( $p < .05$ ) than 16 TD children after accounting for intelligence and auditory working memory (measured with WISC-V, DS), but no group difference were found in distinguishing the target melody from the transposed version of the melody ( $p > .05$ ) (Figure 1). Correlational analyses revealed a positive relationship between accuracy in pitch memory task and all of the cognitive measures among the participants with ASD, but not among the TD participants (Table 1).

**Conclusions:** These tentative findings suggest that previously documented strengths in musical memory among children with ASD are attributable to melodic memory rather than pitch memory. They also suggest the potential cognitive overlap between visuo-spatial skills and pitch memory within children with ASD.

**411.011 (Poster)** Measuring the Impact of Bilingualism on Inhibitory Control Abilities in Autistic Children.

*R. V. Davis<sup>1</sup>, L. Montgomery<sup>2</sup>, V. Chondrogianni<sup>2</sup> and S. Fletcher-Watson<sup>3</sup>, (1)Department of Psychiatry, University of Edinburgh, Edinburgh, United Kingdom, (2)University of Edinburgh, Edinburgh, United Kingdom, (3)Salvesen Mindroom Research Centre, University of Edinburgh, Edinburgh, United Kingdom*

---

**Background:** There is a dearth of empirical literature addressing how bilingualism might impact upon those with autism. The limited literature that currently exists suggests that bilingual exposure is unlikely to lead to poorer development in children with ASD and could provide an advantage across a number of cognitive domains. However, many parents remain concerned about the potentially harmful effects of bilingualism on cognitive development.

**Objectives:** The overall aim of this research is to explore the impact of bilingualism on cognitive development in autistic children. Here we advance understanding of the relationship between bilingualism and inhibitory control; an area in which autistic people frequently exhibit difficulties.

**Methods:** Eighty-eight (43 autistic, 45 non-autistic) children aged 5-12 years were included in the analysis. In order to understand the potential cumulative effects of bilingualism, exposure was analysed as a continuous variable, with participants reporting varying levels of bilingual exposure. Participants completed two widely used measures of inhibitory control; The Psychomotor vigilance task (PVT) and the Flanker Task. In addition, IQ, expressive language and demographic information was collected.

**Results:** For each measure of inhibitory control, we fit a linear mixed effects models with fixed effects of Group (autistic / non-autistic), Bilingual Exposure, Age and IQ. For the PVT, a two-way interaction term between bilingualism and group was included, with Number of False Starts at the outcome variable. For the Flanker, Trial Type (congruent/ incongruent), and a three-way interaction between Group, Bilingualism and Trial Type were included, with Reaction Time as the outcome variable. The number of variables were reduced using a backwards stepwise selection procedure.

*PVT:*

Number of False Starts (error rate) was significantly associated with Bilingual Exposure across all participants (Odds Ratio = 0.19, CI = [0.11 – 0.34],  $p = 0.001$ ), when accounting for Age (Odds Ratio = 0.41, CI = [0.20 – 0.83],  $p = 0.014$ ) and IQ (Odds Ratio = 2.46, CI = [1.22 – 4.99],  $p = 0.012$ ). Model fit using conditional  $R^2 = 0.663$ . Higher levels of Bilingual Exposure were associated with fewer False Starts.

*Flanker:*

Reaction Time of correct responses was predicted by Age (Estimate = -0.08, CI = [-0.15 – 0.00],  $p = 0.040$ ), IQ (Estimate = -0.16, CI = [-0.24 – 0.09],  $p = <0.001$ ), and Bilingual Exposure (Estimate = 0.06, CI = [-0.00 – 0.12],  $p = 0.051$ ) across all participants. Although Bilingual Exposure did not reach significance as a predictor, it contributed significantly to the fit of the model,  $R^2 = 0.603$ .

**Conclusions:** The results provide preliminary evidence that increased bilingual exposure could positively impact on aspects of inhibitory control. This is the first study to analyse bilingual exposure as a continuous variable, showing the possible cumulative positive effects from greater exposure. The study proposes the possibility that bilingualism could provide a naturalistic opportunity to further develop specific executive function skills, and importantly, demonstrates that bilingualism is not harmful for these skills in autistic children. The work makes important contributions to an evidence base for parents to make an informed decision about bilingualism.

**411.012 (Poster)** Memory for Actions and Reality Monitoring in Adults with Autism Spectrum Disorder

*K. Yamamoto<sup>1</sup> and K. Masumoto<sup>2</sup>, (1)Graduate School of Human and Environmental Studies, Kyoto University, Kyoto, Japan, (2)Graduate School of Human Development and Environment, Kobe University, Kobe, Japan*

---

**Background:**

People with autism spectrum disorder (ASD) often have repetition errors. Previous studies in typically developing people (TD) have reported that reality monitoring errors are associated with repetition errors. Reality monitoring is defined as distinguishing between internally generated information sources, such as images, from externally generated information sources, such as perceived or performed actions. The results of previous studies on reality monitoring in people with ASD have been inconsistent,

and there are no studies that have used performance, including imagined or performed actions. Moreover, previous studies on reality monitoring in ASD have assessed memory performance. People with ASD are known to have reduced self-related memory. Therefore, we assessed the memory performance of people with ASD.

#### Objectives:

The purpose of this study was twofold: (1) to investigate reality monitoring regarding actions in people with ASD, and (2) to investigate the memory for actions and memory for action images in people with ASD.

#### Methods:

Twenty adults with ASD (18 men and 2 women) and twenty neurotypical adults (6 men and 14 women) participated in the study. Participants in the ASD group had received formal diagnoses of ASD, according to the criteria of the DSM-IV and ICD-10. The ASD group was recruited from a Career Transition Support Office in Hyogo Prefecture. All participants were fully informed about the study, and they gave their written consent for participation. The ethics committee of the author's institution approved the study protocol. All study procedures were conducted in accordance with the Helsinki Declaration.

Participants memorized action sentences, such as "wear a hat," under three conditions. In the imagined condition, participants imagined the action and memorized the sentences read by the experimenter. In the pantomime condition, the experimenter read each sentence aloud, and the participants memorized the sentences by performing them. In the enactment condition, after the experimenter read each sentence aloud, the participants performed the action using objects and memorized the sentences. After that, free recall, yes/no recognition, and reality monitoring tests were conducted immediately and one week later.

#### Results:

The results indicated that there was no difference between the ASD and TD groups in reality monitoring (Fig.1). The free recall performance of the ASD group was lower than that of the TD group, and both were ranked in the order of Enacted, Pantomime, and Imaged conditions (Fig.2). Moreover, there was no significant difference in recognition between the groups.

#### Conclusions:

People with ASD have intact reality monitoring. Reality monitoring does not affect repetition errors in people with ASD. However, free recall performance of those with ASD was lower than TD. It is possible that a decline in self-related memory is associated with repetitive errors in ASD.

#### **411.013 (Poster)** Mind the Gap: Does Executive Functioning Predict the Discrepancy between IQ and Adaptive Functioning in Children with ASD without ID?

*I. Hastedt, Y. Braverman, S. R. Edmunds and S. Faja, Boston Children's Hospital, Boston, MA*

---

**Background:** Autism spectrum disorder (ASD) is associated with poor adaptive functioning (AF), even in the absence of intellectual disability (ID). AF decreases with age relative to non-ASD peers, whereas the gap between IQ and age-expected AF increases with age (Pugliese et al., 2015). Executive functioning (EF) and AF are correlated in ASD (Pugliese et al., 2015; Pugliese et al., 2016), although results are mixed regarding which aspects of EF and AF are linked. No study has examined the association between EF and the gap between IQ and AF in children with ASD without ID.

**Objectives:** We aim to evaluate whether: (a) AF decreases with age relative to same-age peers, (b) the gap between IQ and AF increases with age, and (c) EF is associated with AF. We will also explore (d) which components of EF are associated with the gap between IQ and AF.

**Methods:** Parents of children with ASD without ID (N = 101, 89% boys) ages 84 - 144 months completed the Vineland Adaptive Behavior Scales (VABS) and the Behavior Rating Inventory of Executive Functioning (BRIEF). Multiple regressions examined whether age predicted (a) VABS domain scores beyond IQ, income, and parental education, and (b) the gap between IQ and VABS domain scores beyond income and parental education. Hierarchical regressions examined whether BRIEF Behavioral Regulation Index (BRI) or Metacognition Index (MCI) predicted (c) VABS domain scores beyond age and IQ and (d) the gap between IQ and VABS domain scores beyond age and income. When BRIEF index scores were significant, subsequent analyses explored which subscales predicted each outcome.

Results: Age negatively related to VABS Communication ( $\beta = -.380, p < .001$ ), Daily Living Skills ( $\beta = -.325, p = .001$ ) and Socialization ( $\beta = -.377, p < .001$ ). Age positively related to the gap between IQ and VABS Communication ( $\beta = .324, p = .001$ ), Daily Living Skills ( $\beta = .259, p = .01$ ), and Socialization ( $\beta = .280, p = .006$ ). MCI significantly predicted Communication ( $\beta = -.353, p = .002$ )—specifically Working Memory ( $\beta = -.375, p = .004$ ). Neither MCI ( $\beta = -.199, p = .10$ ) nor BRI ( $\beta = .082, p = .52$ ) predicted Daily Living Skills. BRI significantly predicted Socialization ( $\beta = -.316, p = .006$ )—particularly Emotional Control ( $\beta = -.299, p = .016$ ). Neither MCI nor BRI predicted the gaps between IQ and Communication or Daily Living Skills. Only BRI predicted the gap between IQ and Socialization ( $\beta = .435, p < .001$ )—particularly Emotional Control ( $\beta = .263, p = .04$ ).

Conclusions: Children with ASD without ID decline in AF compared to same-age peers and the gap between IQ and AF increases with age. Greater working memory deficits predicted lower communication skills and greater emotional control deficits predicted lower socialization skills. EF did not predict the gap between IQ and communication or daily living skills. However, greater emotional control deficits predicted a larger gap between IQ and socialization. These findings demonstrate the potential importance of EF interventions for this population.

**411.016 (Poster) Rhythm Perception: A Preserved Musical Ability of Children with Autism Spectrum Disorder**  
**H. Dahary<sup>1</sup>, M. Kaedbey<sup>2</sup>, C. Rimmer<sup>1</sup>, S. Sivathanan<sup>2</sup> and E. M. Quintin<sup>2</sup>, (1)McGill University, Montreal, QC, Canada, (2)McGill University, Montreal, QC, Canada, (3)Educational & Counselling Psychology, McGill University, Montreal, QC, Canada**

---

Background: There is growing evidence showing musical ability as a strength of people with autism spectrum disorder (ASD). Many studies demonstrate intact or superior musical pitch, melody, and memory perception in ASD (Heaton, 2009), but only a few studies explore musical rhythm perception abilities. The preliminary research on rhythm perception suggests that people with ASD can process and produce simple and complex rhythms and that these musical skills are positively linked to cognitive visuospatial skills in adolescence (DePape et al., 2012). Therefore, it is possible that rhythmic patterns in music can be used as temporal cues for synchronizing social interactions and facilitating impulse control in children and adolescents with ASD (Pellitteri, 2000). However, more research on the developmental trajectory of rhythm perception and its association with cognitive skills is necessary for future intervention planning.

Objectives: The purpose of this research is to 1) compare rhythm perception in typically developing (TD) children and children with ASD, as well as 2) compare rhythm perception and 3) its association with cognitive skills in younger and older children with ASD.

Methods: Eighteen TD children and 29 children with ASD (6-12 years of age) were recruited to examine objective #1. Nineteen older children with ASD (13-17 years of age) were also recruited to examine objective #2-3. All the participants completed a cognitive test (WISC-V/ WASI) and a rhythm perception task, which was an adapted version of the Beat Alignment Test (Iverson & Patel, 2008). The participants listened to short musical excerpts with overlaid beeps (on or off the musical beat) and identified whether the beeps matched the musical beat.

Results: One-sample t-tests revealed that TD children and children with ASD performed above chance level (two choices: 50%) on the rhythm perception task ( $p < .05$ ); however, further inspection revealed that children with ASD with cognitive difficulties (full scale IQ < 70) could not complete the task above chance level, ( $p > .05$ ) and thus, were removed from the sample ( $n = 8$ ). An independent t-test revealed no group differences in task performance ( $p > .05$ ). #2: There was also no difference in task performance between younger and older children with ASD ( $p < .05$ ). Pearson correlations was used to confirm that there was no significant relationship between task performance and the age of participants ( $p > .05$ ). #3: There was a strong positive correlation between visual-spatial abilities and rhythmic perception in older children with ASD ( $r = .52, p < .05$ ) but not in younger children with ASD ( $p > .05$ ).

Conclusions: Findings are consistent with previous research showing preserved rhythm perception for children with ASD across development, though this may not extend to children with ASD with cognitive difficulties. In harmony with the literature, we also found that rhythmic perception abilities are associated with visual-spatial abilities in adolescence. Findings could help guide the development of musical training programs that leverage preserved rhythm perception in ASD by using rhythmic patterns in music to facilitate behavioural (social skills, impulse control) and cognitive (visual-spatial abilities) functioning.

**411.017 (Poster)** Sensorimotor Flexibility in Autism Spectrum Disorders: The Contextual Interference Effect Facilitates the Retention and Transfer of Newly Acquired Sensorimotor Skills

**N. C. Foster<sup>1</sup>**, C. Ansuini<sup>1</sup>, N. Pretti<sup>1</sup>, F. Battaglia<sup>1,2</sup>, L. Nobili<sup>2,3</sup>, S. J. Hayes<sup>4</sup> and C. Becchio<sup>1</sup>, (1)Cognition, Motion and Neuroscience, Istituto Italiano di Tecnologia, Genova, Italy, (2)IRCCS Istituto Giannina Gaslini, Ospedale Pediatrico, Genova, Italy, (3)Department of Neurosciences, Rehabilitation, Ophthalmology, Genetics and Maternal and Children's Science, University of Genoa, Genova, Italy, (4)Department of Psychology and Human Development, Institute of Education, University College London, London, United Kingdom

---

**Background:** Acquiring sensorimotor skills via random practice (i.e., performing different actions) often facilitates retention and transfer compared to blocked practice (i.e., performing the same action). Random practice facilitates learning by inducing effortful and elaborative cognitive processing known as the contextual interference (CI) effect (Shea & Morgan, 1979). Although autistic individuals acquire sensorimotor skills via blocked (Foster et al., 2020) and random practice (Hayes et al., 2016), these studies did not measure performance in retention or transfer. Therefore, whilst these findings indicate sensorimotor adaptation across practice, it is unclear whether these processing effects underpin the CI effect in autistic individuals.

**Objectives:** (1) to examine CI in autistic children.

**Methods:** Thirty autistic (mean age: 11.3 (1.8) years.months; 6 female) and thirty matched neurotypical (mean age: 10.9 (1.6) years.months; 6 female) children volunteered for the study, which was approved by the local ethics committee. Children practised three different 3-segment motor sequences during an acquisition phase via blocked (low CI), or random (high CI), practice. Children then performed the practised sequences in two retention tests (random and blocked structures) and two transfer tests (novel 3-segment and 4-segment sequences). We quantified *reaction time (RT)*, *movement time (MT)* and *total time (TT)* from all children across the three phases. To examine the CI effect, a *retention/transfer index* [last 5 trials of acquisition – first 5 trials of test] was calculated for *RT/MT/TT* from the retention, and transfer, tests. Retention scores for *RT/MT/TT* were analysed using separate 2 *diagnosis* (autism, neurotypical) x 2 *practice* (blocked, random) x 2 *test* (blocked, random) mixed design ANOVAs. Transfer test scores were analysed using separate 2 *diagnosis* (autism, neurotypical) x 2 *practice* (blocked, random) mixed design ANOVAs.

**Results:** There were no diagnosis effects in retention ( $ps > 0.05$ ). *RT* and *TT* scores were superior ( $ps < 0.05$ ) in the retention test following random, compared to blocked, practice. Blocked practice specifically led to poorer ( $p < 0.05$ ) *MT* and *TT* scores in the random retention test. Transfer scores for *RT* and *TT* in the 3-segment transfer test were superior following random practice ( $ps < 0.05$ ), but autistic children had poorer *RT* scores ( $p < 0.05$ ). There was no effect of practice ( $p > 0.05$ ) between transfer scores in the 4-segment transfer test ( $p > 0.05$ ), but compared to the neurotypical children, the autistic children showed poorer *RT* and *TT* scores ( $ps < 0.05$ ).

**Conclusions:** Autistic and neurotypical children that learned via random practice showed superior *RT* and *TT* scores in retention, and transfer (novel 3-segment sequence). Whilst sensorimotor planning problems have often been reported (Rinehart et al., 2001) in autism, the present CI effect suggests that domain general elaborative cognitive planning processes are operational. Importantly by designing interventions and/or tasks that effectively engage these processes (i.e., via random practice) they can better support the development of internal action models that support sensorimotor flexibility to different task demands.

**411.018 (Poster)** The Relationship between Performance on a Musical Working Memory Task and Parent Reports of Working Memory: A Comparison between Typically Developing Children and Children with ASD.

**G. Philibert-Lignieres<sup>1</sup>**, C. Rimmer<sup>1</sup>, T. Q. Boucher<sup>2</sup>, B. Tillmann<sup>3</sup>, G. Iarocci<sup>2</sup>, A. Bertone<sup>1</sup> and E. M. Quintin<sup>4</sup>, (1)McGill University, Montreal, QC, Canada, (2)Psychology, Simon Fraser University, Burnaby, BC, Canada, (3)Université Claude-Bernard Lyon1, Lyon, France, (4)Educational & Counselling Psychology, McGill University, Montreal, QC, Canada

---

Background:

Autism Spectrum Disorder (ASD) is often associated with strengths in music perception, which requires auditory working memory, although parent reports often suggest difficulty with working memory in daily life.

Objectives:

We thus aim to **1**) compare the performance of typically developing (TD) children and children with ASD on a musical working memory task and **2**) investigate the relationship between the performance on a musical working memory task and (non-musical) day-to-day working memory skills.

## Methods:

Eighteen children with ASD (age= 6-12) and eighteen TD children (age= 7-11) participated in this study. To assess musical working memory, sequences of 3, 4, and 5 pitches were presented in pairs and participants were asked to identify whether sequence-pairs were similar or different. The 4 and 5 pitch sequences included two conditions: 1) the different sequence-pairs introduced a new pitch, or 2) the different sequence-pairs used already introduced pitch but inverted their position in the sequence. The goal of creating these two conditions (e.g., 4 pitch vs. 4 pitch with inversion) was to increase the task's complexity. Total performance was calculated as Hits minus False Alarms. The Working Memory Scale of the Behavior Rating Inventory of Executive Functions-2 (BRIEF-2) parent questionnaire was used as a potential correlate of the participants' task performance.

## Results:

1) Independent sample t-tests revealed that total performance on the musical working memory task did not differ between the ASD and TD groups, nor did it differ on the 3- 4- 5-pitch and 4- 5-pitch with inversion conditions (all  $p$ -values  $>.05$ ). However, when comparing the performance within groups, the TD group performed significantly lower on the 4-pitch with inversion vs. the 4-pitch condition ( $p=.001$ ), while the ASD group's performance did not differ between conditions ( $p=.110$ ). Both ASD and TD groups performed significantly lower on the 5-pitch with inversion vs 5-pitch condition ( $p=.01$ ) 2) Independent sample t-test revealed that there was significantly lower BRIEF-2 working memory skills in the ASD compared to TD group ( $p=.01$ ). However, BRIEF-2 working memory skills were not related to musical working memory task performance for either group.

## Conclusions:

Our findings reveal that children with ASD performed equally well on the musical working memory task in comparison to TD children. While the 5-pitch sequences were more difficult for both groups, the ASD group's performance on the 4-pitch sequences with and without inversion revealed that they were not as impacted by the complexity and difficulty of the task in comparison to TD children. This finding is in line with documented strengths of people with ASD in musical perception. Furthermore, parent reports of working memory were not related to task performance for either group. Results provide preliminary evidence for the use of music as a strength-based modality to assess the working memory abilities of children with ASD to complement traditional tests and questionnaires.

### 411.019 (Poster) Visual Perception in Autism: Autistic Adults Are More Accurate at Identifying Subtle Differences between Stimuli.

N. Jassim<sup>1</sup>, S. Baron-Cohen<sup>1</sup> and O. E. Parsons<sup>2</sup>, (1)Autism Research Centre, Department of Psychiatry, University of Cambridge, Cambridge, United Kingdom, (2)University of Cambridge, Cambridge, United Kingdom

---

**Background:** Autism is associated with superior attention to detail (Shah & Frith, 1983), heightened drive to “systemize” (i.e. to identify if-and-then rules in a system) (Baron-Cohen et al., 2003; 2009), and enhanced perceptual function (Motttron et al., 2006). Evidence of distinct autistic perception has been derived from decades of historical reports, first-hand accounts, and behavioural research. For example, autistic individuals have consistently shown superior performance on tasks related to visual search and identifying hidden figures in complex scenes.

**Objectives:** To examine visual perception in autistic vs non-autistic adults by means of web-based cognitive tasks.

**Methods:** 140 autistic (82 females) and 147 non-autistic (118 females) adults aged 18-60 years participated in this study. Participants completed a battery of cognitive tasks probing working memory and visual perception via *Cambridge Brain Sciences*, a web-based platform for cognitive assessments. Participants whose working memory performance fell below 2 standard deviations from each group mean were excluded from further analysis. The following 2 visual perception tasks were employed:

1. *Polygons:* A pair of overlapping polygons is displayed on one side of the screen. Participants indicate whether a polygon displayed on the other side of the screen is identical (“match”) or not identical (“mismatch”) to one of the interlocking polygons.
2. *Feature Match:* Two grids are displayed on the screen, each containing an array of abstract shapes. In half of the trials the grids differ by just one shape. Participants indicate whether or not the grid's contents are identical (“match”) or not identical (“mismatch”).

To investigate group differences in the visual perception tasks, we conducted a 2x2 Factorial ANOVA on accuracy rates with group (autistic vs non-autistic) and task condition (“match” vs “mismatch”) as factors. To account for the unbalanced sex ratio, an exploratory analysis was then conducted on the female only subgroups to ensure that the sex did not affect the direction of the results.

**Results:** Autistic individuals had higher mean accuracy rates in the “mismatch” condition of the *Polygons* task (Fig1a). The 2x2 ANOVA on *Polygons* accuracy rates showed a significant group-by-task condition interaction ( $F_{1,16}=7.0852, p=0.008013^*$ ) (Fig 1c). Meanwhile, *Feature Match* accuracy rates were high across both groups, with autistic individuals showing more ceiling effects on the “mismatch” condition (Fig1b). The 2x2 ANOVA on *Feature Match* accuracy rates revealed a significant group-by-task condition interaction ( $F_{1,16}=6.6305, p=0.0103^*$ ) (Fig 1d).

**Conclusions:** On average, autistic individuals, when compared to non-autistic controls, made significantly more correct responses in the “mismatch” conditions of visual perception tasks, i.e., autistic individuals were found to be better at identifying subtle differences between stimuli. These findings lend support to a large body of evidence of distinct autistic perception.

## POSTER SESSION — COGNITIVE NEUROSCIENCE

### Poster 412 - Cognitive Neuroscience Posters

**412.001** (Poster) Associative Learning Under Uncertainty in ASD: Intact Learning of Cue-Outcome Contingencies but Slower Updating of Predictions after a Change in Contingency

*L. A. Sapey-Triomphe<sup>1,2</sup> and J. Wagemans<sup>1</sup>, (1)Laboratory of Experimental Psychology, Department of Brain and Cognition, Leuven Brain Institute, KU Leuven, Leuven, Belgium, (2)Leuven Autism Research (LAuRes), KU Leuven, Leuven, Belgium*

Background: Autism Spectrum Disorder (ASD) is characterized by heterogeneous social and non-social symptoms. Recent predictive coding theories have attempted to account for this heterogeneity in an integrated theory by suggesting that atypical perceptual learning could play a central role in ASD. Specifically, priors, which capture the underlying statistical regularities of the environment, may be atypically learnt in ASD.

Objectives: We aimed to investigate whether adults with ASD can learn and adjust their prior in a very uncertain environment.

Methods: Participants were 29 neurotypical (NT) adults (13 males,  $M = 23.5$  years old) and 25 adults with ASD (13 males,  $M = 27.2$  years old). In an associative learning task (384 trials), based on a study by Weinhhammer and colleagues (2018), participants heard a high or a low tone, then predicted the rotation direction of two dots (prediction response), perceived the actual rotation and reported their percept (perception response). The tone and rotation were congruent in 62.5% of the trials and incongruent in 25% of the trials to allow participants to learn the main contingency (total of 87.5% of unambiguous trials). In another 12.5% of the trials, the dot pair did not rotate (ambiguous trial) but could be perceived as rotating if priors biased percepts. Associative learning could be explicitly assessed with the prediction response, and more implicitly assessed with the perception response in ambiguous trials. The tone-rotation association changed every 16, 24 or 32 trials. Hierarchical Gaussian Modelling was used to characterize learning in this task.

Results: On average, NT and ASD participants had  $61\% \pm 7$  and  $58\% \pm 6$  of correct prediction responses. In order to assess how the prior about the cue-outcome association was updated after a change in contingency, we performed an ANOVA with the factor group and part (beginning vs. end, i.e., 8 first trials after a change vs. 8 last trials before a change). There was an interaction between group and part ( $p < .0005$ ), as the percentage of correct predictions significantly increased in the NT group (beginning:  $55\% \pm 5$ , end:  $64\% \pm 8$ ,  $p < .0001$ ), whereas there was no improvement in the ASD group (beginning:  $58\% \pm 6$ , end:  $58\% \pm 7$ ,  $p = .98$ ) (Figure 1). The percentage of ambiguous trials perceived according to the current contingency was above chance level in NT ( $61\% \pm 9$ ,  $p < .0001$ ) and ASD ( $56\% \pm 6$ ,  $p < .0001$ ), but this prior bias was smaller ASD ( $p < .05$ ). Computational models showed that the influence of associative learning was stronger in the NT than ASD group, while the learning rates did not differ.

Conclusions: Adults with ASD can learn priors in uncertain contexts but are less flexible to update their prior after a change in contingency. This is consistent with predictive coding theories suggesting more inflexibility in ASD. Using the same paradigm, we recently conducted an fMRI experiment to identify the neural correlates of prediction learning in ASD.

**412.002** (Poster) Atypical Temporal Distraction in Processing Visual Temporal Order in Individuals with Autism Spectrum Disorders.

*T. Atsumi<sup>1,2</sup>, M. Ide<sup>2</sup> and Y. Terao<sup>1</sup>, (1)Department of Medical Physiology, Faculty of Medicine, Kyorin University, Mitaka, Tokyo, Japan, (2)Department of Rehabilitation for Brain Functions, Research Institute of National Rehabilitation Center for Persons with Disabilities, Tokorozawa, Saitama, Japan*

Background:

Atypical sensory processing has been getting attention in researches for autism spectrum disorders (ASD). Individuals with ASD often show enhanced perceptual function, such as in efficiently finding a visual target from distractors (Motttron et al., 2006), implying a relationship between sensory dysfunction in their daily life and the atypical attention towards incoming sensory stimuli.

## Objectives:

We examined the potential linkage between sensory hyperresponsiveness and temporal processing in ASD by focusing on stimulus simultaneity and temporal order. A previous literature reported that temporal resolution of two distinct asynchronous stimuli in temporal order judgment (TOJ) was worsened by temporally distributed distractors in typically developed (TD) participants (Vatakis et al., 2007). In that experiment, temporal resolution for those asynchronous stimuli at the second and third serial positions of four successive sets was impaired. We hypothesized that magnitude of the distractive effect on temporal resolution may relate to sensory hyperresponsiveness in ASD.

## Methods:

Thirty-one Japanese participants (15 ASDs and 16 TDs) observed four successive sets of the left and right white gaussian blobs (Fig 1. left top). One out of the four sets were formed by two asynchronous blobs (Target) while the others involved synchronous blobs (Distractors); participants were required to report whether the two blobs perceived as simultaneous in all the sets (simultaneity judgment: SJ), and which blob was presented latter (TOJ). The asynchronous blobs were temporally separated by various gaps (stimulus onset asynchrony: SOA), and the serial position presented the target set was randomly changed in every trial. We also evaluated individual sensory hyperresponsiveness by using the Adolescent/Adult Sensory Profile (Brown et al., 2001).

## Results:

As demonstrated in the previous report, TD participants showed poorer temporal resolution in the serial positions surrounded by the sets with task-irrelevant synchronous stimuli (thus, the second and third positions) in the TOJ (comparisons with the first set using Wilcoxon signed rank test,  $ps < 0.05$ ). The temporal resolution of TOJ in the position 2 and 4 were worsened in ASD ( $ps < 0.05$ ), suggesting quicker return to the neutral temporal resolution from the distraction by preceding task-irrelevant stimulus set, than the TD group. None of the position-dependent differences in SJ was observed in either group. In the ASD group, the effect of distraction in the serial positions following the first set estimated by the difference between the mean temporal resolution in worsened sets (i.e., 2 and 4) and the one in intact set (i.e., 3) correlated with individual sensory hyperreactivity score (sum of Sensory sensitivity and Sensation avoiding) ( $r = -0.59$ , permutation-based correlation analysis,  $p = 0.02$ ). This relationship was not observed in the TD group.

## Conclusions:

Previous studies reported that individuals with ASD have difficulty in detecting the visual target among sequentially presented distractors because of continuous temporal attention (Keehn et al., 2016, 2017). Our results suggest that temporal attention towards stimuli during higher-order temporal processing (i.e., TOJ; Jaśkowski, 1991) is linked to sensory hyperresponsiveness, and its underlying mechanism may depend on shortened inhibition of temporal processing for incoming stimuli.

### **412.003 (Poster)** Autism Spectrum Disorder, Learning What to Ignore: Deficits in Psychological Priors over Attribute Informativeness

*W. W. Pettine and J. D. Murray, Yale University, New Haven, CT*

---

## Background:

There is an acute need for well-justified behavioral assays that enable detection and stratification of psychiatric disease. Autism spectrum disorder (ASD) in particular benefits from early detection and therapeutic intervention. Those with ASD have long been described as having issues with generalization and filtering of irrelevant information (1). Probands often display high precision in sensory representation and amazing attention to detail, along with pathologically rigid behavior (2). To investigate these phenomena, recent studies have examined how those with ASD use attribute information when inferring underlying latent states in the environment (3,4). They found that performance differences between those with ASD and neurotypicals are primarily driven by an altered way in which those with ASD assign informativeness to latent state attributes.

## Objectives:

We lack the kind of theoretical foundation for these behaviors that can provide insight into the etiology of ASD. Such tools can facilitate the design of tasks that are easily administered in clinical and online settings, advancing our ability both to study ASD, as well as produce behavioral markers that improve detection.

## Methods:

The emerging field of Computational Psychiatry aim to bridge the gap between a mechanistic understanding of brain function and the signs observed in disease. Two of the more successful frameworks that have enriched understanding a wide variety of psychiatric phenomenon are reinforcement learning and Bayesian inference. Reinforcement learning posits that by utilizing reward prediction errors (involving dopamine), we can develop an accurate value to assign to stimuli or actions. Bayesian inference is a statistical framework through which incoming information is integrated with prior assumptions. In this study, we utilized a latent-state reinforcement learning model to characterize the use of psychological priors over attribute informativeness.

## Results:

We find that generalization is primarily impacted by priors over attributes informative for distinguishing between latent states (rather than priors over defining latent states). Furthermore, we find in a behavioral experiment that human subjects perform as predicted by the model.

## Conclusions:

We propose that the over-attention to detail and difficulty in generalization observed in subjects with ASD results from a disruption in the formation of priors over attributes informative for distinguishing between latent states. We also present a specific, validated task for testing these predictions.

### 412.004 (Poster) Brain Imaging Investigation of the Hippocampal and Amygdala Structural Changes in Autism throughout Development

**P. T. Patenaude<sup>1</sup>, E. B. Barbeau<sup>2</sup> and X. Chai<sup>3</sup>,** (1)Integrated Program in Neuroscience, McGill University, Montreal, QC, Canada, (2)Cognitive Neuroscience Unit, Montreal Neurological Institute, McGill University, Montreal, QC, Canada, (3)Neurology and Neurosurgery, McGill University, Montreal Neurological Institute, Montreal, QC, Canada

---

**Background:** Autism spectrum disorder (ASD) is typically characterized by deficits in social communication and by restrictive and repetitive patterns in behaviour. Individuals with ASD have also been found to have impaired episodic memory which involves recalling one’s own experiences. Two important brain regions, namely the hippocampus and amygdala, have been linked to these episodic memory deficits in ASD. However, the structural changes occurring in the hippocampus and amygdala in ASD throughout development are poorly understood. In addition, previous studies have focused on whole hippocampal and whole amygdala volume and have not investigated the subfields of the hippocampus or nuclei of the amygdala in ASD. Given the differences in histological characteristics and function between hippocampal subfields and amygdala nuclei, it’s important to study these individual subfields/nuclei in order to have a comprehensive understanding of the structural changes occurring in these brain regions in ASD.

**Objectives:** Our aim was therefore to investigate the volumetric changes of hippocampal subfields and amygdala nuclei in ASD at various ages (5-21), allowing us to better understand the development of episodic memory deficits in ASD.

**Methods:** Magnetic Resonance Imaging (MRI) data from autistic (n = 195, mean age = 10.91, 33 females) and neurotypical (n = 109, mean age = 9.79, 48 females) participants aged 5 to 21 from the Healthy Brain Network, a large-scale open-source dataset, was used for this study. Participant’s T1-weighted MRI scans were analyzed using FreeSurfer. The “Segmentation of Hippocampal Subfields and Nuclei of the Amygdala (cross-sectional and longitudinal)” module of FreeSurfer (Iglesias *et al.*, 2015; Saygin *et al.*, 2017) was used to segment the amygdala into 9 nuclei and the hippocampus into 12 individual subfields and

3 merged subfields (ie. hippocampal head, body and tail). Volumetric measurements for these subfields and nuclei were then extracted for each participant and compared between groups.

**Results:** After correcting for age and sex, we found no significant differences in amygdala nuclei volumes between the ASD and neurotypical groups. The volume of the left hemisphere hippocampal cornu ammonis 1 (CA1) body subfield showed a significant difference between the groups. The left CA1 body volume was enlarged in the ASD group (t-value = 3.34, p-value = 0.0009) and increased with age ( $r^2 = 0.03$  and p-value = 0.02). No differences in volume were observed for the other hippocampal subfields.

**Conclusions:** This exploratory study provides evidence that the left hippocampal CA1 body is structurally abnormal in ASD. It also suggests that hippocampal volumetric differences exist between children and adolescents with ASD. These findings may help us better understand the pathophysiology and the neuroanatomical underpinnings of ASD. Given the critical role of the human hippocampal CA1 in autobiographical memory retrieval and for re-experiencing detailed episodic memories (Bartsch *et al.*, 2011), future work will examine how episodic memory deficits in ASD is linked with hippocampal subfield abnormalities.

**412.005 (Poster)** Cortico-Striatal Functional Connectivity Predict Higher Rates of Camouflaging and Better Cognitive Control in Females but Not Males with Autism Spectrum Disorder

*M. Walsh<sup>1</sup>, B. B. Braden<sup>2</sup>, C. J. Smith<sup>3</sup> and L. C. Baxter<sup>4</sup>, (1)Arizona State University, Tempe, AZ, (2)College of Health Solutions, Arizona State University, Tempe, AZ, (3)Southwest Autism Research & Resource Center, Phoenix, AZ, (4)Radiology, Barrow Neurological Institute, Phoenix, AZ*

---

**Background:** Research shows that females with autism spectrum disorder (ASD) engage in more camouflaging behavior than males with ASD and neurotypical (NT) groups. Higher rates of camouflaging in ASD have been linked to better cognitive control. However, little is known about sex differences in the neurocircuitry underlying increased camouflaging observed in females with ASD. Characterizing brain circuits underlying compensatory behaviors in ASD may inform future research investigating prognosis and sex-specific treatment development.

**Objectives:** This study aimed to characterize functional connectivity (FC) patterns supporting higher rates of camouflaging in females with ASD relative to males with ASD and NT groups as well as associations with cognitive control.

**Methods:** The sample comprised 71 non-intellectually disabled adults, including 18 females with ASD (ASDF; mean age: 38.6 [13.7, 19-60]), 18 NT females (NT-F; mean age: 41.6 [15.9, 18-65]), 19 males with ASD (ASD-M; mean age: 43.3 [11.2, 26-64]), and 16 NT males (NT-M; mean age: 44.6 [10.5, 26-62]). Camouflaging was measured via the Camouflaging Autistic Traits Questionnaire (CAT-Q) Compensation, Masking, and Assimilation subscales. Participants completed a six-minute, eyes-closed, resting-state fMRI scan. Resting-state data was preprocessed using SPM12. The CONN Toolbox was used for denoising (aCompCor, scrubbing, 12 realignment parameters) and group analysis. Group-MVPA identified clusters expressing sex-by-diagnosis differences in camouflaging-FC associations for the three CAT-Q subscales ( $p < .01$ , FDR-corrected, cluster-level, age/IQ covariates). Post-hoc seed-to-voxel analysis identified which MVPA clusters that expressed the interaction contrast of interest (ASD-F > ASD-M, NT-F < NT-M for camouflaging-FC associations;  $p < .01$ , FDR-corrected, cluster-level). Post-hoc analysis tested associations between identified FC patterns and cognitive control (Wisconsin Card Sorting Task Perseverative Errors;  $p < .05$ , uncorrected, age covariate).

**Results:** Behavioral results showed a significant sex-by-diagnosis interaction for the CAT-Q Compensation subscale (but not Masking or Assimilation), such that adults with ASD showed more camouflaging than NT adults with a greater magnitude of difference in females. Group-MVPA revealed no sex-by-diagnosis interactions for FC associations with CAT-Q Masking/Assimilation subscales. However, five clusters showed sex-by-diagnosis interactions for CAT-Q Compensation-FC associations (brainstem, left occipital pole, right pre-central gyrus, and left putamen/white matter). Post-hoc seed-to-voxel analysis revealed that only FC patterns with the left putamen cluster reflected the interaction contrast of interest (ASD-F > ASD-M, NT-F < NT-M for camouflaging-FC associations). Specifically, left putamen FC with two clusters associated with the salience network (right inferior frontal gyrus [IFG] and right supramarginal gyrus [SMG]) showed stronger positive associations with compensatory camouflaging for ASD-F and NT-M but not for ASD-M or NT-F. Post-hoc associations with cognitive control revealed significant FC-by-sex-by-diagnosis interactions, such that higher left putamen-right IFG/SMG FC uniquely predicted better cognitive control in ASD-F but not in ASD-M or NT-F/NT-M.

**Conclusions:** Cortico-striatal connectivity has been implicated in cognitive control in NT groups. In particular, the right IFG may play a role in error detection and punishment sensitivity, which may apply more broadly to social processes. Given the small sample with a broad age range, validation in a larger sample is needed as well as a detailed characterization of circuits supporting camouflaging in males with ASD.

**412.006 (Poster)** Creating Psychophysical Touch-Screen Paradigms to Test Sensory Processing in Young Children with and without Autism

**J. Koziel<sup>1</sup>, A. Pilkington<sup>1</sup>, A. N. de Rothschild<sup>1</sup>, A. Goodwin<sup>1</sup>, J. L. He<sup>2</sup>, N. A. Puts<sup>3</sup> and E. Loth<sup>1</sup>,** (1)Department of Forensic and Neurodevelopmental Sciences, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (2)Russell H. Morgan Department of Radiology and Radiological Science, The Johns Hopkins University School of Medicine, The Johns Hopkins University School of Medicine, Baltimore, MD, (3)Russell H. Morgan Department of Radiology and Radiological Science, The Johns Hopkins University School of Medicine, Baltimore, MD

---

### **Background:**

In the latest revision of the DSM, sensory atypicalities have been added as a core feature of autism. An increasing body of work suggests that alterations in lower-level sensory processing during early development may contribute to difficulties in higher-level processes that are characteristic of autism, such as altered social and cognitive development, language delay or restrictive and repetitive behaviours. Despite the need to understand trajectories of *early* sensory functioning in autism, we still lack sensitive experimental measures that allow for reliable, objective, and fast assessment of sensory processing across different sensory domains in young autistic children. Psychophysical approaches allow for differentiation of physiological function (e.g. detection, discrimination). While these approaches have long been used to objectively and reliably assess sensory perception, few studies have successfully applied psychophysics in young children.

### **Objectives:**

Our objective was to develop and validate appropriate psychophysical tasks in young children (particularly in children with autism) that can be used to remotely assess individual differences in low-level sensory processes using touch-screen appliances.

### **Methods:**

We developed auditory and tactile discrimination tasks. Both tasks were based on existing two-alternative force choice (2AFC) psychophysical paradigms, which had previously been successfully applied in older cohorts (Puts et al., 2017). The tasks were developed in Unity, a mobile app development platform. A full description of the tasks can be seen in the figure caption of Fig. 1A and 1B. The tasks were delivered remotely on touch-screen devices and were either parent or tester mediated. Additional questions were also provided to parents and caregivers to gauge inattention and comprehension (see Figure 1D). So far, data has been collected from 4 children with ASD and 15 TD children age between the ages of 18 months and 5 years.

### **Results:**

Figure 1C displays a typical example of staircase tracking in a single 2.5-year-old individual, showing that we can capture psychophysical properties in this young population. 75% of pre-schoolers with autism, as well as 86% of TD pre-schoolers successfully completed the tasks. The average frequency discrimination thresholds were 92.1 Hz for the TD group and 48.3Hz for the ASD group. Two participants completed the task more than once. Although preliminary, we then calculated the test-retest reliability for these participants by using a two-way mixed effect model. The computed intra-class correlation coefficient (ICC) of the frequency discrimination threshold was 0.64, showing moderate test-retest reliability of our paradigm.

### **Conclusions:**

We show that we were able to measure sensory thresholds using psychophysical tasks in pre-school children with and without autism, and that these can be performed remotely. Our preliminary evidence shows that these tasks are moderately reliable and comparable to lab-based reliability. Our conservative estimate is to recruit >100 participants in the coming months, through our existing pre-school studies (Preschool Brain Imaging Project, One of a Kind Project). After establishing reliability of a conservative 70% and an acquisition rate in autism of 70%, we hope to validate the tasks against questionnaire measures and create normative ranges.

**412.007 (Poster)** Enhanced Pseudoword Reading in Autism Is Supported By Differences in Ventral Visual Stream Activation  
**S. R. Cahalan<sup>1</sup>**, W. Graves<sup>1</sup>, H. Levinson<sup>1</sup>, L. Coulanges<sup>2</sup>, M. Pincus<sup>1</sup>, V. H. Bal<sup>3</sup>, C. Sancimino<sup>4</sup>, D. Cruz<sup>5</sup>, D. Karim<sup>1</sup> and M. Rosenberg-Lee<sup>1</sup>, (1)Department of Psychology, Rutgers University, Newark, NJ, (2)Psychology, University of Pittsburgh, Pittsburgh, PA, (3)Graduate School of Applied and Professional Psychology, Rutgers University-New Brunswick, Piscataway, NJ, (4)UCSD School of Medicine, Autism Center of Excellence, La Jolla, CA, (5)Hackensack Meridian Health – Mountainside Medical Center, Hackensack, NJ

---

#### Background:

Reading words is accomplished through a combination of applying learned letter to sound consistencies (i.e. orthography to phonology mappings) and applying knowledge of word meaning (i.e. semantics). For example, orthography-phonology mappings are sufficient to read consistent words like, “hash” and “cash”; however, semantics is useful for reading inconsistent words like “wash”. In contrast, for pseudowords (pronounceable but meaningless nonwords, like “fash”), readers only have the resource of orthography-phonology mappings to pronounce the novel letter strings. Thus, readers are at a disadvantage reading pseudowords compared to words. Prior studies suggest individuals with autism spectrum disorders (ASD) can be particularly proficient in applying orthography-phonology mappings, which may contribute to the incidence of hyperlexia in this population. This strength may also allow this population to overcome the disadvantage of novelty when reading pseudowords. Neurally, reading involves a generally left-lateralized network of brain regions, including those along the ventral visual stream, such as the visual word form area (VWFA), which plays a role in mapping orthography to phonology. Therefore, we predict that proficiency in applying orthography to phonology mappings in the ASD group will manifest as superior performance pronouncing pseudowords compared to neurotypical (NT) readers. Neurally, this advantage may be underpinned by the participants with autism recruiting additional neural resources, in the ventral visual stream, to support applying orthography-phonology mappings.

#### Objectives:

We examined the cognitive and neural processes of reading in autism by comparing behavioral performance and neural activation between neurotypical controls and participants with autism in a reading-aloud task with words and pseudowords.

#### Methods:

Age, PIQ, VIQ, and gender-matched ( $ps > .14$ ) English speaking undergraduates with ( $N = 19$ ) and without ( $N = 21$ ) autism read 110 monosyllabic words and 110 pseudowords aloud during an fMRI scan. Verbal responses were recorded and analyzed to determine trial-level pronunciation accuracies and response times. We tested for effects of group (ASD, NT) and item type (words, pseudowords) on pronunciation accuracy and response time. Finally, we contrasted brain activation between groups for responses to words and pseudowords.

#### Results:

Words were read more accurately than pseudowords,  $F(1, 39) = 62.024, p < .001$ . The ASD group trended towards greater overall accuracy than the NT group,  $F(1, 39) = 2.005, p = 0.165$ , driven by a trend towards greater accuracy reading pseudowords,  $t(39) = 1.59, p = 0.12$  (Figure 1A). Neurally, the NT group showed the expected pattern of left-lateralized activity for reading, while the ASD group showed comparatively greater activation in the right-hemisphere homologue of the VWFA for reading words and pseudowords ( $p < .005$ , uncorrected, Figure 1B).

#### Conclusions:

The ASD group’s superior task performance overall may be underpinned by recruiting both left and right ventral visual regions. Notably, right inferotemporal cortex is typically more responsive to social stimuli, such as faces, suggesting that altered organization of this region may contribute to both strengths and weaknesses in this population. Crucially, the ASD group’s enhanced reading performance was driven by the pseudowords, suggesting that extending VWFA activation by recruiting its right-hemisphere homologue may enhance use of orthography-phonology mappings.

**412.008** (Poster) Hidden Literacy in Minimally Verbal ASD Revealed By Eye Gaze: Reduced Pupil Dilation Hint at a Deficit in Recruiting Arousal That Impact Voluntary Behavior

*Y. S. Bonne<sup>1</sup>, K. Ellert<sup>2</sup> and N. Shefer - Kaufmann<sup>3</sup>, (1)School of Optometry and Vision Science, Bar-Ilan University, Ramat Gan, Israel, (2)School of Optometry and Vision Science, Bar-Ilan University, Ramat-Gan, Israel, (3)Clalit institute for child development, Tel-Aviv, Israel*

---

**Background:** Minimally verbal individuals with ASD (MV-ASD), estimated as 30% of the spectrum, who have little or no spoken language, typically fail the conventional tests for cognitive abilities. However, it is yet unclear whether these failures reflect a true cognitive impairment or, alternatively, a severe deficit in behavioral expressions of cognitive skills. Here we suggest that the main barrier for communication in this group is a severe deficit in the initiation and control of reliable voluntary actions, which calls for using involuntary or effortless measures such as small eye gaze lateralization. Preliminary results from our study of hidden literacy in MV-ASD were reported in INSAR 2019. Here we report a novel finding related to a possible cause for the deficit, which we explored by analyzing the transient pupil dilation during the task.

**Objectives:** Assess basic reading and lexical-semantic knowledge in young adults with MV-ASD using eye-movement measures in comparison to pointing performance and investigate transient pupillary responses as measures for Locus Coeruleus norepinephrine (LC-NE) activation.

**Methods:** Young adults with MV-ASD (N=25, ages 15-24, <30 communicative words) and 25 age-matched controls were tested on a novel "cued looking" paradigm watching a sequence of stimuli while their eyes were tracked. In each trial, a text word was presented at fixation (1s), followed by a pair of side-by-side pictures of familiar objects (1s), with next trial following after 800ms. There were 4 short (~1min) runs repeated 3-6 times with breaks. In additional experiments, the written words were replaced by recorded words, and both paradigms were repeated with pointing on cards. We analyzed the lateralization of the eye-gaze according to target side, the time course of correct gaze lateralization, and the transient pupil dilation associated with the gaze.

**Results:** 21 of the 25 MV participants showed a significant effect of reading as reflected by correct lateralization estimates of 72-100% (average 87%), with similar results obtained for vocal words. They made smaller lateral eye movements than controls but were as fast in terms of movement onset. In a striking contrast, most of the MVs who showed significant reading with the eyes were at or near chance level in pointing (40-65%) making their reading skills "hidden" to standard testing. To investigate the cause for this anomaly, we analyzed the transient pupil dilation associated with the eye gaze. We found a reduced pupil dilation in the MV-ASD group compared to controls, and a significant correlation (MV-ASD group) between the dilation and the eye gaze performance in reading ( $R=0.64, p=0.001$ ), and listening ( $R=0.57, p=0.01$ ).

**Conclusions:** These results provide the first systematic evidence for reading ability in individuals typically assumed to be severely language and cognition impaired. The results also demonstrate a striking anomalous gap between pointing performance and gaze, which opens the way for uncovering unknown cognitive abilities in MV-ASD. Our results of reduced pupil dilation provide a first hint at the possible cause of the anomaly in terms of reduced transient activation of the LC-NE system that reflects the recruitment of arousal subserving many cortical circuits that drive behavior.

**412.009** (Poster) Increased Context Adjustment with Higher Sensory Sensitivities Indexed By Auditory Mismatch Negativity

*R. Randeniya<sup>1</sup>, J. B. Mattingley<sup>1</sup> and M. I. Garrido<sup>2</sup>, (1)Queensland Brain Institute, The University of Queensland, Brisbane, QLD, Australia, (2)Melbourne School of Psychological Sciences, University of Melbourne, Melbourne, VIC, Australia*

---

**Background:**

Bayesian models of autism suggest that disruptions in context-sensitive sensory weighting may underpin sensory perceptual alterations, such as hypersensitivities. Mismatch negativity (MMN), an electroencephalographic (EEG) response to pattern violations in sensory stimuli, is an excellent measure to understand sensory learning in autism.

**Objectives:**

We aimed to identify if context adjustment as indexed by delta-MMN amplitudes (i.e., difference in MMN between contexts) differed between autistic and neurotypical groups. Furthermore, we investigated whether delta-MMN amplitude was associated with autistic traits and sensory sensitivities when all participants are aligned on a continuum.

## Methods:

We recruited autistic adults (AS group; N=29, *M* age = 25.57, 16 females and 13 males) and age and gender matched neurotypical adults (NT group; N=30). Participants underwent EEG recordings while listening to a stochastic auditory oddball paradigm. Participants listened to a stream of tones with frequencies drawn from two contexts of either high (200Hz to 4000Hz) or low (200Hz to 2000Hz) uncertainty, where the outlier sounds were of 2000Hz. MMN amplitude was measured at the Fz electrode between 125ms and 175ms. Participants completed the Autism Quotient (AQ; Baron-Cohen et al. 2001), which measures autistic traits, and the Sensory Processing Quotient (SPQ; Tavassoli et al 2014), which measures sensory sensitivities.

## Results:

We found no significant difference in delta-MMN between groups suggesting sensory context updating is intact in autism. However, group differences arose in the typical P300 time window, where the AS group showed a more negative difference in amplitude compared to the NT group. We also undertook a dimensional approach which revealed a positive correlation between delta-MMN and sensory sensitivities, but not with autistic traits.

## Conclusions:

Group findings suggests that while AS has greater reorienting for outlier sounds, context updating is intact. However this may be due to the AS group and NT group showing no significant differences in auditory SPQ scores. A dimensional analysis revealed finer context adjustment in people with higher sensory sensitivities. We suggest that autism MMN studies may benefit from accounting for sensory sensitivities in group comparisons.

### **412.010** (Poster) Intersecting Intention Encoding and Readout in Autism

---

**Background:** The ability to infer the intentions of others from subtle changes in the way they move is crucial to interpret and anticipate their behavior (Becchio et al., 2018). Children with autism spectrum conditions (ASC) show delays in the development of this ability, with knock-on consequences on social interaction across lifespan (Forbes and Hamilton, 2018). However, the exact nature of ASC difficulties in intention reading remains unknown. Here we report on a study combining motion tracking, psychophysics and computational modelling to compare how intention information encoded in single-trial kinematics is read out by typically developing (TD) children and children with ASC.

**Objectives:** To analyze how intention encoding – the mapping of intention to movement kinematics during action execution – and intention readout – the mapping of visual kinematics to intention during action observation – intersect at a single-trial level in TD children and children with ASC.

**Methods:** Eight- to thirteen-year-old TD children (n=37) and children with ASC without accompanying intellectual impairment (n=35) watched a hand reaching for and grasping a bottle, either to pour or to place, and judged on the intention of the observed grasp. In a within-subjects counterbalanced order, participants observed videos of grasping acts performed by TD children or children with ASC (see Fig. 1a). We devised a simple time-dependent model based on logistic regression to examine how intention encoding and readout intersect in TD and ASC observers. Adapting methods developed in Patri et al. (2020), we first determined the set of kinematic features that encode intention information in TD and ASC single movement kinematics. We then developed a readout model to examine how (and how well) TD and ASC observers read out such information. We finally computed how encoding and readout intersect at the single-trial level to inform intention choice in each group.

**Results:** In both ASC and TD observers, intention readout was sensitive to variations in the kinematics of the observed actions. However, the proportion of readers – individuals whose readout was sensitive to variations in single-trial kinematics – was lower in the ASC group than in the TD group ( $p < .01$ ; Fig. 1b). In the TD group, a significant proportion of readers was able to link informative kinematic features to the correct intention, particularly when observing TD actions (ASC actions:  $p < .01$ ; TD actions:  $p < .001$ ). In the ASC group, readers failed to map kinematics to intention. This failure was observed regardless of whether ASC readers observed TD or ASC actions.

Conclusions: Observers with ASC are less proficient intention readers not because they are blind to subtle variations in visual kinematics, but rather because they are unable to link these variations to the correct intention. These findings have implications for clinical assessment and intervention in ASC.

**412.011** (Poster) Investigating Timing Processes in Autistic Adults

**E. Gowen, L. Jones, E. Poliakoff and D. Poole, Division of Neuroscience and Experimental Psychology, University of Manchester, Manchester, United Kingdom**

---

Background:

It has been theorised that there are problems with timing in autism (Allman, 2011), impacting multiple domains encompassing the precision of duration perception, relative timing of sensory information and temporal cognition. To date, empirical findings regarding problems with timing are mixed, with differences likely to be dependent on the cognitive mechanisms and stimuli involved in specific timing tasks (Casassus et al, 2019).

Objectives:

We aimed to better characterise timing processes in autistic adults by measuring performance across multiple timing domains using scalar expectancy theory (SET; Gibbon, Church & Meck, 1984) as a theoretical framework. SET suggests an internal clock that accumulates pulses emitted by a centralised neural pacemaker controls timing of duration. We used tasks believed to target individual components of the timing system as understood within this framework.

Methods:

In this pre-registered study (<https://osf.io/pcahj/>), 58 autistic and 91 neurotypical adults completed a battery of visual and auditory temporal psychophysics tasks. The relative timing of brief stimuli was assessed using temporal order judgements. The perception of sub-second durations was assessed using tasks measuring basic discrimination (temporal difference thresholds), direct estimates of perceived duration (verbal estimation tasks) and involving memory and decision processes (temporal generalisation tasks). Participants also completed retrospective estimates involving judgements about durations of several minutes. Questionnaires were used to measure behaviours relating to time in daily life.

Results:

Differences between the groups were observed on questionnaire measures but, overall, measures of timing precision from experimental tasks were similar between the groups.

Conclusions:

The present study suggests that duration and relative timing precision is comparable between autistic and neurotypical adults. Differences on questionnaire measures indicate that behaviours relating to time in daily life may be impacted. In future work it would be valuable to consider the interaction between higher-order cognitive processes involved in everyday behaviour relating to time in autism.

---

**Background:** The first person diagnosed with autism spectrum disorder (ASD) is now entering advanced aging. Projections indicate that the number of older adults with ASD will increase dramatically over the next decades. Emerging cross-sectional cognitive aging research in ASD has shown mixed findings, with some evidence suggesting poorer cognitive and brain aging trajectories. Brain functional connectivity may reveal early biomarkers of cognitive aging.

**Objectives:** In our prior cross-sectional work, we showed age-group differences suggesting exacerbated reductions in functional connectivity (FC) affecting the fronto-parietal network (FPN) in adults with ASD (Walsh et al., 2019). This current, preliminary study extends these findings by longitudinally examining changes in FC of cognitive brain networks over a two-year follow-up period in a sample of mid-to-older adults with and without ASD and associations with cognitive control.

**Methods:** Participants included men ages 40-64 years at the start of the study (mean: 50.7[7.1]) of average intellectual ability (IQ>80) with and without ASD (ASD:  $n=13$ ; NT:  $n=18$ ). There were no significant differences between ASD/NT groups in terms of age at the start of the study. Follow-up intervals were two years on average. Participants completed a six-minute, eyes-closed, resting-state fMRI scan. Resting-state data was preprocessed using SPM12 (slice time correction, realignment, co-registration to anatomical image, and normalization via DARTEL with 8mm FWHM smoothing). Confound regression was conducted using aCompCor, scrubbing, and 12 realignment parameters. FC was calculated via independent component analysis using the CONN Toolbox and the FPN, dorsal attention (DAN), default mode (DMN), and salience networks (SN) were selected. Main effects of time and group-by-time interactions were modeled at the whole-brain level with FDR-correction ( $p<.05$ , cluster-level) with age as a covariate. Baseline and follow-up performance on the Wisconsin Card Sorting Task (WCST; Total Errors) was used to examine associations with cognitive control for participants with ASD.

**Results:** For the right lateralized FPN, a significant time-by-diagnosis interaction was observed, such that adults with ASD showed declines in FC between the left inferior frontal gyrus (IFG; pars triangularis portion) and the rest of the FPN that were not observed in NT participants ( $p=.018$ , FDR-corrected, cluster level). No other main effects of time or group-by-time interactions were observed for the right lateralized FPN or other networks investigated (left FPN, DMN, DAN, or SN). No significant effects of time or group-by-time interactions were found for the Wisconsin Card Sorting Task. However, poorer baseline ( $r_9=0.579$ ,  $p=0.062$ ) and follow-up ( $r_9=0.621$ ,  $p=0.042$ ) WCST performance was marginally and significantly associated, respectively, with larger decreases in FPN-IFG connectivity over time for participants with ASD.

**Conclusions:** FPN-prefrontal connectivity decreases with age in mid-to-older adults with ASD, but not NT adults, and this decreasing connectivity predicts poorer follow-up performance on a cognitive control task. Despite the small sample included in this preliminary analysis, these findings suggest a trend toward worse brain aging in ASD, which may predict poorer cognitive outcomes. Validation of these findings in a larger sample with a longer follow-up duration and utilizing structural and task-based neuroimaging methodology is warranted.

### **412.013 (Poster)** Measuring the Prediction of Observed Actions Using an Occlusion Paradigm: Comparing Autistic and Non-Autistic Adults

*E. Gowen<sup>1</sup>, E. Poliakoff<sup>2</sup>, H. Shepherd<sup>2</sup> and W. Stadler<sup>3</sup>, (1)Division of Neuroscience and Experimental Psychology, University of Manchester, Manchester, United Kingdom, (2)Division of Neuroscience and Experimental Psychology, The University of Manchester, Manchester, United Kingdom, (3)Department of Sport and Health Sciences, Technical University of Munich, Munich, Germany*

---

**Background:**

Action prediction involves observing and predicting the actions of others and plays an important role in social cognition, interacting with others as well as in many types of sports. It is thought to involve simulation, where the observer uses their own motor system, such as premotor cortex, to predict the observed actions. As many autistic individuals have motor coordination difficulties, it is possible that simulation ability is altered, leading to action prediction deficits and contributing to difficulties understanding the actions of others.

## Objectives:

To compare action prediction between autistic and non-autistic adults and investigate any relationship between prediction and motor coordination.

## Methods:

Twenty autistic and 21 non-autistic adults matched on age, gender and IQ watched 8 different videos of a female actor carrying out everyday actions (e.g. watering a plant). During each video, the action was transiently occluded 2-6 times by a grey rectangle for 1000ms. During occlusions, the video was allowed to continue as normal or was fast forwarded (i.e. appearing to continue too far ahead) or slowed down (i.e. appearing to continue too far behind). Participants were asked to indicate whether the action continued with correct timing or too far ahead/behind by pressing keyboard buttons. Motor ability was assessed using the adult Developmental Coordination Disorder (DCD) checklist.

## Results:

The autistic group reported significantly worse motor coordination skills as assessed with the DCD checklist. For prediction accuracy, autistic individuals were less accurate than non-autistic individuals, particularly when the video was slowed down during the occlusion time (i.e. actions appeared too far behind). Both groups selected a higher number of “correct timing” responses for the normal compared to fast forwarded videos. However, only the autistic group showed no difference in correct timing responses between the normal and slowed down videos, suggesting that they confused these two video continuations. There were no correlations between overall prediction accuracy and DCD checklist scores in either group.

## Conclusions:

Autistic adults were less accurate at predicting whether videos of everyday actions occurred at the correct speed, confusing actions that had been played too slow during the occlusion with those that occurred at the normal speed. While this finding needs to be replicated, these results potentially indicate that autistic individuals were slower to switch from action perception to internal simulation or had slower simulation processes (Prinz and Rapinett, 2008; Sparenberg, Springer and Prinz, 2012). While the autistic group had poorer motor coordination, this ability did not correlate with prediction accuracy.

---

**Background:** Over the past decade, studies of infants at risk for developing autism by virtue of having an older sibling with autism have made extensive use of event related potentials (ERPs), an EEG-based measure. Specifically, the negative central (Nc) ERP component has been associated with attention in response to visual stimuli such as faces or objects. Further, our lab has observed differences in the Nc responses to mother versus stranger faces between low- and high-familial-risk infants. However, whether the Nc response is related to clinical symptoms of ASD remains to be determined. Here, we present the results from an ERP study focused on infant siblings, the goal of which was to compare infants with high familial risk who develop ASD (HR-ASD), high risk infants who do not develop autism (HR-NoASD), and low risk controls (LRC).

**Objectives:** This study aims to characterize the neural correlates of face recognition in 12-months-old infants; specifically, we seek to determine (1) whether there are differences in the Nc response to faces between HR-ASD, HR-NoASD, and LRC infants and (2) how the Nc correlates with communication and social development.

**Methods:** Infants at 12 months participated in the Mother/Stranger visual paradigm (LRC  $n = 42$ ; HR-NoASD  $n = 40$ ; HR-ASD  $n = 20$ ), where EEG data was collected as infants looked at pictures of their mother and a similarly looking stranger. Communication measures at 12 months included: MacArthur Bates Communicative Development Inventory (CDI), deictic gestures counted during parent-child interactions, and Mullen Scales of Early Learning (MSEL) scores. Social measures at 18 months included: Autism Diagnostic Observation Schedule (ADOS) Social Affect Score, and Communication and Symbolic Behavior Scales (CSBS) Social Composite Score. Multiple linear regressions were conducted with maternal education and outcome groups as covariates.

**Results:** The difference in Nc amplitude in response to mother versus stranger (Mother/Stranger-Nc) was statistically similar across the three groups studied ( $F(2,41) = 0.16$ ,  $p = 0.85$ ). A larger Mother/Stranger-Nc was associated with higher raw scores on CDI Early Gestures only for the HR-ASD group ( $R^2\text{-adj} = 0.222$ ,  $B = 0.7277$ ,  $p = 0.050$ ), and higher MSEL Expressive Language standard scores, across all groups ( $R^2\text{-adj} = 0.111$ ,  $B = 0.9037$ ,  $p = 0.002$ ). Additionally, increased Nc difference in the HR-ASD group was associated with better social skills at 18 months as measured on the CSBS (Social Composite; Pearson  $r = 0.69$ ,  $p = 0.04$ ) with a similar trend on the ADOS (Social Score; Pearson  $r = -0.39$ ;  $p = 0.17$ ).

**Conclusions:** These data show the potential use of ERPs providing estimates in communication and social development. These data confirm that, while accounting for maternal education and regardless of diagnosis groups, there is a positive relationship between preferential attentional resources given towards mother and expressive language development. Additionally, specific to HR-ASD infants, more attentional resources towards mother at 12 months was associated with better social development at 18 months.

**412.015 (Poster)** Reduced Early Habituation to Repeated Sounds in Autism: An EEG Study

**J. Goris<sup>1,2</sup>, S. Braem<sup>1,2</sup>, M. Brass<sup>1,2,3</sup> and J. R. Wiersema<sup>2,4</sup>,** (1)Department of Experimental Psychology, Ghent University, Ghent, Belgium, (2)Research group EXPLORA, Ghent University, Ghent, Belgium, (3)Berlin School of Mind and Brain, Department of Psychology, Humboldt-Universität zu Berlin, Berlin, Germany, (4)Department of Experimental Clinical and Health Psychology, Ghent University, Ghent, Belgium

---

**Background:** Predictive coding accounts of autism spectrum disorder (henceforth ‘autism’) state that both social and non-social symptoms of autism can be accounted for by increased bottom-up sensory processing, which should result in decreased habituation to repeated stimulation. While there is indeed some support for reduced habituation to faces in ASD (Kleinhans et al., 2009), according to predictive coding accounts, this should also be the case for non-social stimuli such as repeated meaningless sounds. Previous studies that used a paired-click paradigm reported mixed results with both reduced and normal habituation in children and adolescents with autism (Chien et al., 2019; Kemner et al., 2002; Madsen et al., 2015; Oranje et al., 2013; Orekhova et al., 2008). In this paradigm, habituation is measured (and limited) by comparing the neural responses to two subsequent short tones. In the current study we applied an arguably more sensitive paradigm to investigate habituation, namely an auditory oddball paradigm, which allows to investigate responses to multiple repeated standard sounds. Indeed, there is evidence for reduced habituation using multiple repeated sounds in infants at high-risk for autism and adults with Fragile X syndrome (Ethridge et al., 2016, 2019; Guiraud et al., 2011). Surprisingly however, research using this paradigm to compare habituation between adults with and without a diagnosis of autism is still lacking.

**Objectives:** In the current study, we aimed to investigate whether autism is characterized by reduced habituation of neural responses to multiple standard tones in an auditory oddball task.

**Methods:** We investigated habituation of ERP responses in a sample of adults with autism ( $n = 38$ ) and control participants ( $n = 32$ ) matched on age, gender, handedness and IQ.

**Results:** Results show habituation in the P2 component in this task, and a reduced P2 habituation in the autism group only at the beginning of the experiment. Over time, habituation seems to normalize in the autism group.

**Conclusions:** Results are in line with predictive coding accounts that predict attenuated habituation and hence increased bottom-up sensory processing in autism. However, this deviation in autism may be more nuanced than was initially proposed, as habituation normalized over time.

---

**Background:**

It has been proposed that a predictive processing deficit might underpin core social, language, and sensorimotor behaviors in autism, although the neural bases of these challenges remain unclear. The cerebellum is one candidate: cerebellar circuits are engaged during autism-relevant tasks, and cerebellar structural and functional differences in right VII are well-documented in autism. The cerebellum supports prediction and learning through building and honing internal models of behavior. We hypothesized that cerebellar dysfunction in autism may disrupt predictive processing, and that cerebellar neuromodulation would alter performance on predictive tasks.

**Objectives:**

We used cerebellar transcranial direct current stimulation (tDCS) to investigate the impact of cerebellar neuromodulation on motor learning, language prediction, and social learning.

**Methods:**

Neurotypical adults (NT; n=12, 22.5 ± 2.5 yrs) and adults with autism (AG; n=10, 24.5 ± 9.0 yrs) performed three tasks: serial reaction time task (SRT, motor learning), sentence completion (language prediction), and Cyberball (social learning). Excitatory (anodal), inhibitory (cathodal), or sham tDCS (20 min, 1.5 mA) targeting cerebellar right lobule VII was administered to participants prior to the tasks. Each participant received all three tDCS conditions separated by one week. Prediction scores were calculated as the difference in accuracy and response times (RTs) between predictive and nonpredictive trials. Behavioral measures were assessed within subjects, between groups, and as a function of autism quotient (AQ) score using linear mixed effects models.

**Results:**

**Motor Learning:** At baseline, there were no significant group differences in accuracy, although accuracy and AQ scores were negatively correlated (p=0.05). AG baseline RTs were faster than NT (p=0.05), and RTs were negatively correlated with AQ score (p=0.01). Active tDCS reversed these trends selectively in the AG: anodal tDCS impaired accuracy (p=0.001), while anodal (p=0.02) and cathodal (p=0.0001) tDCS resulted in positively correlated RT and AQ score (p=8.8e-6, p=1.7e-5).

**Language Prediction:** At baseline, there were no significant group differences in task performance and no significant correlations between task performance and AQ scores. tDCS did not alter response times in either group. Anodal tDCS selectively improved accuracy in AG (p=0.029). Cathodal tDCS trended toward impairing AG accuracy (p=0.2), and accuracy was negatively correlated with AQ score (p=0.048) after cathodal tDCS.

**Social Learning:** At baseline, there were no significant group differences, although learning scores were negatively correlated with AQ scores in both groups (NT R = -0.33, AG R = -0.37). Anodal tDCS disrupted social learning in both groups (p=0.037), while cathodal tDCS improved social learning selectively in AG (p=0.006).

**Conclusions:**

Cerebellar tDCS altered prediction and learning across three separate task domains. On tasks with a specific learning component (social, motor), AQ scores negatively correlated with performance, indicating poorer learning in individuals with higher AQ scores. Following cerebellar tDCS, social learning and language prediction improved selectively in the AG. These results provide evidence for the cerebellum's involvement in prediction and autism, and demonstrate that cerebellar tDCS targeting right lobule VII selectively improves performance on cognitive predictive tasks in the AG.

**412.017 (Poster)** The Similarity and Differences in Aberrant Task-Induced Functional Connectivity Patterns Observed in ASD and ADHD: A Meta-Analysis Approach  
*A. Moses<sup>1</sup> and L. Chen<sup>2</sup>, (1)Santa Clara University, Santa Clara, CA, (2)500 El Camino Real, Santa Clara University, Santa Clara, CA*

---

**Background:** Autism spectrum disorders (ASD) and Attention deficit/hyperactivity disorder (ADHD) are traditionally considered as categorically different disorders related to aberrant brain connectivity during various cognitive tasks. However, recent research studies have shown that there is a high degree of comorbidity between the two disorders (15%~70%), but little is known about the similarity and differences in their functional connectivity patterns. Therefore, a comprehensive comparison of aberrant task-induced connectivities in ASD and ADHD could provide critical insights into the neurobiological basis for comorbid symptoms.

**Objectives:** Using a meta-analysis approach, we aim to examine existing studies of task-induced functional connectivity abnormalities in ASD and ADHD, in order to develop a model about the neurobiological basis of comorbid conditions. Specifically, we first examined the overlaps of reported seed regions of interest (ROIs) in ASD and ADHD studies, and then examined the similarities and differences in the observed abnormal connectivity patterns in both groups.

**Methods:** We conducted a literature search on PubMed and EBSCO databases using combinations of search terms including “ASD”, “ADHD”, “Autism”, “functional connectivity”, and “task”. After initial screening based on titles and abstracts, 64 papers were selected according to the following inclusion criteria: (a) published between 2010-2020; (b) reported data from either an ASD or ADHD group; (c) reported functional connectivity analysis; and (d) included a cognitive task. These 64 papers were further reviewed in-detail based on the following inclusion criteria: (a) presented task-based functional connectivity in fMRI; (b) used a seed-based approach to examine the functional connectivity; (c) included at least the qualitative data (region labels) for both seed and target ROIs; and (d) included a comparison between the patient group and a healthy control group. As a result, a total of 32 studies (13 ASD and 19 ADHD) were included in this preliminary meta-analysis.

**Results:** Although existing studies used different cognitive tasks in ASD and ADHD, we still found a set of common seed ROIs that were examined in both disorders, such as anterior cingulate cortex (ACC), dorsolateral PFC (dlPFC), inferior frontal gyrus (IFG), inferior parietal cortex (IPC), amygdala, and striatum. This suggests a common frontoparietal network with subcortical structures may underlie the cortical dysfunctions in both disorders during cognitive tasks. From these commonly-examined seed ROIs, the abnormal functional connectivities between frontal regions (ACC, dlPFC, IFG, etc.) and from right subcortical (amygdala and striatum) to left frontal regions were found overlapping in both ASD and ADHD (see Figure 1). Additionally, the left amygdala and striatum showed abnormal connectivity with various regions across different lobes in ASD, but the left frontal regions showed distributed connectivity abnormalities in ADHD.

**Conclusions:** Our meta-analysis revealed that the connectivity abnormalities in frontal executive control networks may underlie the common cognitive deficits in ASD and ADHD, suggesting a neurobiological basis for the comorbid conditions. By contrast, left amygdala and striatum for affective and motivational processing serve as specific hubs with abnormal connectivity in ASD, whereas the left frontal regions (e.g., dlPFC and IFG) for executive control serve as specific hubs with abnormal connectivity in ADHD.

**412.018 (Poster)** Variability in Movement and Visual Attention during a Behaviorally Adaptive Eye-Tracking and EEG Paradigm with Children with ASD  
*E. Cummings<sup>1</sup>, A. Naples<sup>1</sup>, J. M. Wolf<sup>1</sup>, C. C. Cukar-Capizzi<sup>1</sup>, G. T. Han<sup>2</sup> and J. McPartland<sup>1</sup>, (1)Child Study Center, Yale University School of Medicine, New Haven, CT, (2)Vanderbilt University, Nashville, TN, TN*

---

**Background:** Much neuroscience research requires participants to remain extremely still, maintain fixed visual attention, and comply with complex instructions. This approach limits the scope of research by excluding participants who have difficulty following verbal directives, such as minimally verbal children with ASD. This problem could be addressed by interactive paradigms that shape behavior and encourage compliance without the need for verbal instructions. The present study applies a novel eye-tracking (ET) and electroencephalography (EEG) data acquisition approach designed to monitor and respond to participant movement to shape behavior in real-time.

**Objectives:** To quantify change in the behavior of children with cognitive impairment and ASD during an ET and EEG paradigm designed to adapt to participant behavior in real time to improve data acquisition success.

Methods: Five children with ASD (7-11 years,  $M=9.2$ ,  $SD=2.0$ ) completed a co-registered ET-EEG paradigm with simultaneous eye and head movement tracking; data collection is ongoing. Progression of the paradigm was compliance-dependent, such that off-screen eye gaze or excessive movement (i.e., head movement exceeding baseline threshold determined during participant's initial viewing of a preferred video) paused experimental administration. For this participant-specific behavioral analysis, derived variables included timing of breaks and pauses, pause triggers (i.e., excessive movement or off-screen eye gaze), and two-dimensional head movement (i.e., front-to-back, side-to-side) derived from head position recorded at 2000Hz. ASD symptom severity was measured by the *Autism Diagnostic Observation Schedule-2* (ADOS-2) comparison score (CS), which ranged from 6 to 10 ( $M=8.8$ ,  $SD=1.6$ ). Cognitive ability was measured by the *Differential Ability Scales-II* (DAS-II) or *Mullen Scales of Early Learning*. FSIQs ranged from 22 to 73 ( $M=43.4$ ,  $SD=21.4$ ), verbal IQs ranged from 19 to 57 ( $M=35.6$ ,  $SD=15.5$ ), and nonverbal IQs ranged from 23 to 81 ( $M=47.6$ ,  $SD=24.2$ ).

Results: Overall, EEG session length ranged from 13.5 to 54.7 minutes ( $M=25.3$ ,  $SD=17.2$ ). Behavior-dependent pauses ranged from .01 to 208.83 seconds long ( $M=4.56$ ,  $SD=14.74$ ), with eye-gaze pauses ( $M=7.23$ ,  $SD=20.06$ ) being significantly longer than movement pauses ( $M=2.55$ ,  $SD=7.57$ ;  $t(519.18)=4.34$ ,  $p<.001$ ). Variation between participants emerged in the number of pauses during the session, ranging from 45 to 446 ( $M=187.60$ ,  $SD=159.21$ ). In particular, the number of eye-gaze pauses ranged from 34 to 176 ( $M=84.40$ ,  $SD=62.25$ ) and movement pauses ranged from 11 to 324 ( $M=103.20$ ,  $SD=127.12$ ). Frequency of eye-gaze and movement pauses remained stable over the course of the session. There was more movement during breaks than trials for four participants (all  $ps<.001$ ) and for the other participant, movement was greater during the trials than breaks ( $p<.001$ ). As the session progressed, movement increased for two participants ( $r_s=-.04$ ,  $r_s=-.14$ ;  $ps<.001$ ) and decreased for three participants ( $r_s=.15$ ,  $r_s=.02$ ,  $r_s=.06$ ;  $ps<.001$ ). Outcome measures for each participant are represented visually (e.g., Figure 1) and in summary statistics (e.g., Table 1).

Conclusions: Variability in individual behavioral responses highlights the potential benefit of adaptive experimental paradigms. Decreased movement across the EEG session demonstrated by most participants suggests that automated behavior modification can effectively be integrated with data acquisition to increase compliance without verbal instruction. These results hold promise for increasing representation of minimally verbal populations in neuroscience research.

## Communication and Language

### PANEL SESSION — COMMUNICATION AND LANGUAGE

#### Panel 224 - Vocal Development in Infants and Children with ASD and at Risk for ASD

**Panel Chair:** D. Kimbrough Oller, *School of Communication Sciences and Disorders, University of Memphis, Memphis, TN*

**Discussant:** Daniel S. Messinger, *University of Miami, Coral Gables, FL*

We focus on both the vocalizations of infants and children at risk for ASD and on parental responses to those vocalizations. The goals are 1) to help designate anomalies in very early vocal development associated with risk or diagnosis of ASD, 2) to characterize features of vocal development held in common early in life between infants at risk and not at risk for ASD, and 3) to address parental vocal responsivity patterns that may be special to the infant or child with or at risk for ASD and that may inform future approaches to intervention. The work involves both laboratory and home recordings, many of them all-day recordings, automated multitaper harmonic analysis to determine fundamental frequencies, functional data analysis with dynamic time warping to evaluate developmental trajectories, evo-devo inspired human coding of vocalizations in a multidimensional audio-video software environment, and comparisons across infants and children both at risk and not at risk for ASD along with additional infants and children with an ASD diagnosis. Infants were also racially and ethnically diverse. The speakers represent four nationalities as well as Asian, middle Eastern, and European ancestries. There are four universities represented, and speakers range from tenured to just completing the Ph.D.

**224.001 (Panel)** Developmental Cascades Linking Infant-Directed Speech, Infant Vocal Behavior and Social Contingency in Typical Development and ASD

**G. Ramsay<sup>1</sup>, M. Edwards<sup>2</sup>, J. Bailey<sup>3</sup> and S. Ghai<sup>4</sup>,** (1)Department of Pediatrics, Emory University, Atlanta, GA, (2)Emory University, Atlanta, GA, (3)University of Miami, Miami, FL, (4)Marcus Autism Center, Children's Healthcare of Atlanta, and Emory University School of Medicine, Atlanta, GA

*Background:* Adults habitually adopt a special vocal register when talking to children, exaggerating prosodic properties that are attractive to, and elicit responses from, typically developing infants. Children with ASD show early differences in social responding, and have specific impairments producing and perceiving prosodic contrasts, which may explain differences in infant-directed speech as well as infant vocal behavior observed in autism. The acoustic properties characterizing infant-directed speech change over the course of development, in response to changes in infant vocal behavior, but it is not yet known what drives those changes, either in autism or typical development.

*Objectives:* The goal of this study is to examine developmental progressions in infant-directed speech over the first two years of life, in typical development and autism, and to determine the origin of these changes in infant vocal signaling and response.

*Methods:* As part of an NIH Autism Center of Excellence (NIH P50 MH100029), we tracked vocal development among 45 high-risk infants with a family history of ASD and 35 low-risk controls. Each child wore a LENA recorder one day every month from 0-24 months to provide audio recordings of their vocal behavior and environment. Using speech recognition technology, we identified the number of vocalizations per hour for infant and caregiver, and calculated the rate of contingent interactions based on timing statistics. We also took random samples of infant vocalizations and infant-directed vocalizations throughout each day, and used multitaper harmonic analysis to calculate the mean, standard deviation and range of fundamental frequency contours. Using Functional Data Analysis, we determined developmental trajectories of these measures for each child and mean trajectories for each risk group. Using the transfer entropy, an information-theoretic metric of statistical causality between the past history of one stochastic process and the future of another, we calculated the graph of information flow between all profiles.

*Results:* Using permutation tests to identify significant differences ( $p < 0.05$ ) between trajectories, we found deviations between high-risk and low-risk groups in all measures. Declines in high-risk infant-caregiver interaction starting at 12 months, caregiver volubility at 15 months, and infant volubility at 18 months provide evidence that deficits in social contingency impact vocal responsivity in caregiver then infant. By the end of the first year, high-risk infants departed from the natural downtrend in fundamental frequency over time expected in low-risk controls, continuing to exhibit elevated and more variable pitch through the second year. Over the same period, high-risk caregivers either persisted later in infant-directed speech, or switched earlier into adult-directed register relative to the natural transition seen in low-risk controls. Examining the transfer entropy matrix, developmental changes in infant-directed fundamental frequency appear to be driven mainly by vocal contingency, which is impaired in high-risk infants.

*Conclusions:* These results provide further evidence for a developmental cascade whereby processes of early socialization shape adaptive mechanisms of infant-caregiver vocal signaling in typical development, but are serially disrupted in autism.

**224.002 (Panel)** Social and Endogenous Motivations of Canonical Babbling Development in Infants at Low and High Risk for Autism

**H. L. Long<sup>1</sup>**, G. Ramsay<sup>2,3</sup>, D. Bowman<sup>4,5</sup>, M. Burkhardt-Reed<sup>1</sup> and D. K. Oller<sup>1,5,6</sup>, (1)School of Communication Sciences and Disorders, University of Memphis, Memphis, TN, (2)Department of Pediatrics, Emory University, Atlanta, GA, (3)Marcus Autism Center, Atlanta, GA, (4)Department of Mathematics, University of Memphis, Memphis, TN, (5)Institute for Intelligent Systems, Memphis, TN, (6)Konrad Lorenz Institute for Evolution and Cognition Research, Klosterneuburg, Austria

---

*Background:* There is a growing body of research emphasizing the role of intrinsic motivation and endogenous activity to support the development of cognitive systems alongside the well-established role of social interaction. The present study longitudinally evaluated canonical babbling during social and non-social contexts across the second-half year of life, when canonical babbling becomes well-established. Canonical babbling (examples, baba, dada...) is recognized as forming a critical foundation for language because words are overwhelmingly composed of canonical syllables.

*Objectives:* We compared recorded segments that had been rated as having high vs low levels of turn taking (as a measure of social vocal activity) and high vs low levels independent vocal play (as a measure of nonsocial vocal activity) for infants at low and high risk for autism spectrum disorder. We predicted low-risk infants would produce higher canonical babbling ratios (CBRs, the number of canonical syllables divided by the total number of syllables in the sample) during segments rated as having vocal high turn taking compared to high-risk infants due to a greater intrinsic social motivation in low-risk infants. We also predicted high-risk infants would produce higher CBRs during segments rated as having high vocal play compared to low-risk infants as a potential early indicator of vocal self-stimulatory activity as a restricted and repetitive behavior.

*Methods:* Eight, five-minute segments were extracted from an average of five all-day home audio recordings of 98 infants to observe canonical babbling development between 6.5 and 13 months of age. CBRs were determined based on blinded human coding in real-time of each five-minute segment for canonical and noncanonical syllables followed by Likert-scale ratings on the level of turn taking and vocal play in each segment.

*Results:* More than 80% of the five-minute segments included at least some vocal play, while less than 20% included vocal turn-taking in these all-day recordings. The CBRs of infants at high and low risk for ASD were similar, contradicting our expectation. CBRs increased significantly across age in both groups. There were significant differences showing higher CBRs for both risk groups during segments with high vocal play, suggesting that endogenous vocal activity is associated with relatively advanced vocalization. High vs low levels of turn taking yielded a weaker effect on CBR, also suggesting more advanced vocalization during turn taking. There were also interactions of CBR with age, risk, and amount of vocal play or turn taking.

*Conclusions:* We conclude that social and endogenous/exploratory motivations may drive both high- and low-risk infant tendencies to produce their most speech-like vocalizations.

**224.003 (Panel)** Phonatory Control in Typically Developing Infants and Infants at Risk for Autism

**H. Yoo<sup>1</sup>**, G. Ramsay<sup>2</sup> and D. K. Oller<sup>3</sup>, (1)Communicative Disorders, The University of Alabama, Tuscaloosa, AL, (2)Marcus Autism Center, Children's Healthcare of Atlanta, and Emory University School of Medicine, Atlanta, GA, (3)School of Communication Sciences and Disorders, University of Memphis, Memphis, TN

---

*Background:* Human infants spontaneously explore different categories of speech-like vocalizations (i.e., protophones) from the beginning of life. These categories include squeals, growls and vowel-like sounds (vocants), reflecting different phonatory characteristics (different prosody and vibratory regimes). Phonatory control occurs before infants master supra-glottal movements (i.e., articulation). However, despite the importance of phonatory development, most research has been directed to articulatory development in both typically developing infants and infants at risk for autism. To our knowledge, this is the first empirical study investigating clustering patterns of phonatory categories in infants at risk and infants not at risk for autism. These clustering patterns, showing repetition of particular vocal types, may suggest practice and exploration on the part of infants; we propose there might be differences between the extent of such repetitive activity in infants at risk or not at risk for autism.

*Objectives:* If infants attempt to learn/explore a certain category (e.g., squeal or growl), they may tend to produce the same sound in clusters rather than at random. This exploratory pattern may be observed differently from session to session. The purposes of the study are (1) to investigate whether there are differences in clustering between infants at risk and not at risk for autism and (2) to investigate age effects whereby infants may change with regard to these clustering patterns across the first year.

**Methods:** 11 infants at risk for autism because they had an older sibling with an autism diagnosis and 11 infants not at risk for autism participated in ~ 8 all-day recordings in their homes as part of a longitudinal study across the first year of life. 21 five-minute segments were extracted at random from each recording (205 recordings, 4305 segments). Each vocalization was coded as squeal, vocant (vowel-like sound), growl, cry, whimper, laugh, or other. In the analysis, we compared segments for the proportions of squeals and growls, seeking to determine if they were randomly distributed across segments as opposed to clustered preferentially in some of them. Squeals and growls were selected because they occur fairly frequently and when they do occur they have been proposed to be an aspect of vocal play with prosodic categories having high (squeal) or low (growl) pitch.

**Results:** Consistent with our hypothesis of a practice-like serial-repetition pattern, infants produced significantly different proportions of squeals and growls across randomly-selected 5-min samples from the all-day recordings, and the extent to which this was true was different at different ages. According to chi-square tests 51% of recordings showed significant clustering patterns in infants not at risk while 74% of recordings were significant in infants at risk for autism.

**Conclusions:** Infants indeed seemed to practice different phonatory categories by showing clustering patterns of the vocalization types, squeal and growl. While both groups showed practice-like behaviors, the results suggest there may be differences between these groups regarding the extent of significant clustering or patterns of clustering.

**224.004 (Panel) Maternal Input Differences within Infant-Directed Speech and Volubility in Preschool Children with ASD**  
**L. K. Farran<sup>1</sup> and D. K. Oller<sup>2</sup>, (1)Communication Sciences and Disorders, University of West Georgia, Carrollton, GA, (2)School of Communication Sciences and Disorders, University of Memphis, Memphis, TN**

---

**Background:** Infant-directed speech (IDS), also known as "motherese", "baby talk", and baby register (IDS-BR), is a special way of communicating with infants and young children, characterized by salient features such as variable pitch, smooth intonation contours, and simple, short utterances, and thought to facilitate positive language and socioemotional outcomes in typically developing children. IDS in adult register (IDS-AR) is used much more frequently with older infants and presumably with more language competent children. While recent research suggests positive associations among IDS, various registers within IDS, and language development in typically developing children, little is known about this relationship in children with autism spectrum disorders (ASD), a developmental disorder diagnosed reliably by age 3 and marked by social deficits and high risk for speech and language disorders. Compared to typically developing children, children with ASD tend to demonstrate a (1) diminished preference for maternal speech, particularly IDS-BR; and a (2) limited ability to tune in to their mothers' language input. However, the extent to which mothers tailor their input to suit the language and communicative abilities of their children with ASD remains an open research question, particularly around the age of ASD diagnosis.

**Objectives:** The purpose of this study is to examine the association between maternal differential use of IDS registers (IDS-BR versus IDS-AR), volubility (frequency of vocalizations), and language ability in children with autism. We hypothesize that mothers tend to use less IDS-BR compared to IDS-AR when addressing their preschool children with ASD.

**Methods:** Participants are nine mothers and their three- to six-year-old children with ASD who participated in a longitudinal study that examines vocal development in preschool children. Ten minutes of free-play interactions were recorded in the participants' homes with two cameras simultaneously. In order to capture naturalistic interaction, mothers were instructed to communicate with their children as they usually do during these 10-minute recorded segments. *Measures:* The Mullen Scales of Early Learning. *Audio- and video-recordings* were coded in real-time using AACT, a speech analysis software. Maternal IDS and child utterances were classified as mutually exclusive, acoustically-based categories as defined in prior research from our laboratories. Total counts and proportions of maternal IDS (IDS-BR and IDS-AR) and child utterances were computed.

**Results:** The results showed a strong tendency ( $r = -.89$ ) for higher child volubility (the sum of all speech and speech-like vocalizations such as laughter and cry) to predict lower use of IDS-BR, and conversely higher use of the more adult-like speech register, IDS-AR. This result is surprising given that other aspects of the child vocalizations such as the number of real speech utterances ( $r = -.09$ ) or the number of speech-like utterances ( $r = .15$ ), showed much lower associations with maternal speech register.

**Conclusions:** The results suggest that mothers of preschool children with autism may adjust their speech register to include more adult-like characteristics of prosody (IDS-AR) as a function of the amount of infant vocalizations, irrespective of the nature of those vocalizations (i.e., speech or speech-like).

## POSTER SESSION — COMMUNICATION AND LANGUAGE

### Poster 413 - Communication and Language Posters

**413.001** (Poster) A Cross-Cultural Analysis of Narrative and Visual Attention in Autism Spectrum Disorder  
**J. Xing<sup>1</sup>, K. Nayar<sup>2</sup>, E. Landau<sup>2</sup>, X. Kang<sup>3</sup>, J. C. Lau<sup>4</sup>, G. E. Martin<sup>5</sup>, P. Wong<sup>3</sup> and M. Losh<sup>6</sup>,** (1)Communication Sciences and Disorder, Northwestern University, Evanston, IL, (2)Feinberg School of Medicine, Department of Psychiatry and Behavioral Sciences, Northwestern University, Evanston, IL, (3)The Chinese University of Hong Kong, Ma Liu Shui, Hong Kong, (4)Department of Communication Sciences and Disorder, Northwestern University, Evanston, IL, (5)Communication Sciences and Disorders, St. John's University, Staten Island, NY, (6)Communication Sciences and Disorders, Northwestern University, Evanston, IL

Background: Narrative (i.e., storytelling) is a primary form of communication that plays an essential role in social-communicative interactions. Narrative is impaired in individuals with autism spectrum disorder (ASD) (e.g., Loveland et al., 1993; Tager-Flusberg et al., 1995; Capps et al., 2000) compared to individuals with typical development (TD). Some evidence suggests that narrative atypicalities may be rooted in underlying visual attentional differences—e.g., attention towards protagonists versus background scenery may impact the content and quality of the narrative (Lee et al., 2019). Importantly, cultural and language differences are known to shape both narrative (e.g., Domino et al., 1987; Stein, 2004) and attentional biases (e.g., Blais et al., 2008; Chua et al., 2005), which may in turn influence narrative profiles in ASD. To examine this question, this study assessed narrative competence and visual attention profiles across English- and Cantonese-speaking individuals with ASD versus respective control groups.

Objectives: To explore the influence of culture and language on narrative and associated visual attention patterns in ASD.

Methods: Participants included age- and IQ- similar groups from the US (n=59 ASD; n=49 TD) and Hong Kong (HK) (n=25 ASD; n=52 TD). Participants narrated the wordless picture book *Frog, Where Are You?* (Mayer, 1969), which was presented on a Tobii eye-tracker. Narratives were coded for descriptions of characters' cognition and affect, causal explanations of story events, and narrative structure (e.g., inclusion of key story elements, establishing the theme). Gaze variables included percentage of looking time towards social and nonsocial information to examine social and non-social attention, respectively. Age and IQ were covaried for analysis.

Results: Individuals with ASD in both cultures produced narratives with fewer causal inferences ( $p = .002$ ) and missed more key story components ( $p = .001$ ) compared to TD controls. Interaction effects revealed that the US-ASD group included fewer descriptions of cognition and affect than the US-TD group ( $p < .001$ ), whereas the HK-ASD and HK-TD groups performed comparably. Both HK groups generated fewer descriptions of cognition and affect than their US counterparts ( $p < .001$ ), but were more likely to allocate descriptions of cognition and affect within causal frameworks ( $p < .001$ ). For narrative evaluation specifically, increased social attention and decreased non-social attention were correlated with increased descriptions of cognition and affect across diagnostic and cultural groups.

Conclusions: Results demonstrated unique patterns of narrative performance across diagnostic and cultural groups. Diagnostic effects were found in causal inferences and inclusion of key story components across both cultures, which might point to specific narrative deficits that express robustly across different cultures in ASD. Interaction effects further suggested that descriptions of cognition and affect may be more malleable to environmental influence in ASD, and may therefore be a possible target for intervention. Associations between gaze and narrative abilities revealed comparable gaze-narrative coordination among both ASD and controls across cultures, highlighting their interdependence and may implicate attentional profiles as importantly related to narrative and other social communicative impairments in ASD.

**413.002** (Poster) A Novel Method of Introducing Emotional Content in Synthesized Speech Via Facial Expression and Vocal Prosody  
**L. J. Brady, iTherapy, LLC, Martinez, CA**

Background: Autism Spectrum Disorder (ASD) is one of the leading causes of communication disorders. Acquiring functional language abilities can be difficult depending on the severity of the disorder. Some individuals are verbal and have stronger functional language abilities whereas others are minimally verbal or nonverbal, experiencing difficulties with speech production. Those who are minimally to non-verbal face great challenges when participating in daily communication. Effective communication relies not only on words but on tone of voice and facial expressions. The ability to express emotion through one's tone of voice, or prosody, clarifies the communicative intent behind a spoken message. While there are augmentative and assistive communication (AAC) systems that allow a person to communicate using digitally synthesized speech, these voices are

monotone and can be readily identified as computer generated. To be more effective, AAC products must convey emotions through prosody and have the ability to video-model a user's facial expressions to convey happiness, sadness, or anger.

**Objectives:** This research sought to identify and implement a set of a unique para-linguistic features that most realistically conveyed the emotions of happy, sad and angry. which can be critical for ASD individuals. A working prototype that synthesized emotional communication through speech and facial animation software designed for Apple iOS.

**Methods:** We administered a prototype with a diverse population of 14 adult male and female subjects aged 18-75 and recorded their ability to correctly label the emotions presented in each of the three VO, FO, and C groups. Subjects were given a combined total of 64 presentations for each stimulus. We conducted a one-way analysis of variance (ANOVA) to compare the three groups' mean identification scores (the mean number of correctly labeled emotions in each medium) with a P-value set at 0.05. The ANOVA allowed us to examine variations within each medium (such as subjects' variations between trials) along with variations among the three mediums, or whether the number of correctly identified emotions is the same for all three approaches.

**Results:** Analysis of the data produced an F-statistic of 10.0735, with two degrees of freedom, arriving at a P-value of 0.0001, which was statistically significant to reject our null hypothesis. In conclusion, given three different mediums — voice only (VO), facial expression only (FO), and combined voice and facial expression (C) — subjects most accurately categorized emotions that were conveyed through the combination of animated facial expressions with synthesized emotional speech (C). Along with the ANOVA, the responses in each medium were broken down into three categories: Total Recognized, Percent Recognized, and Label Substitutions.

**Conclusions:** We arrived at a statistically significant conclusion: individuals tended to improve their ability to identify synthesized human emotions when shown a combination of facial expressions and speech. This conclusion has a potentially high value proposition for current and future customer segments.

**413.003 (Poster)** A Systematic Literature Review of Autism Research on Caregiver Talk

**K. Bottema-Beutel<sup>1</sup>** and **S. Y. Kim<sup>2</sup>**, (1)*Lynch School of Education, Boston College, Chestnut Hill, MA*, (2)*Duksung Women's University, Seoul, Korea, Republic of (South)*

---

**Background:** Caregiver talk influences children's language acquisition, and may be a particularly important resource for autistic children. Caregiver talk also structures interactions that impact developmental milestones, including social-communication (Bottema-Beutel et al., 2018; Siller & Sigman, 2002; Yoder et al., 2015). Given that autistic children can exhibit language delays, and some do not go on to develop flexible language in any modality (Tager-Flusberg & Kasari, 2013), the features of caregiver talk that influence autistic children's language and social-communication development are of interest to discern. Describing the features of caregiver talk, and how it may differ between caregivers of autistic children and other populations is also of interest, because autistic children's caregivers may modify their talk in particular ways as a response to their children's social and language profiles (Nadig & Bang, 2017). However, there have not yet been attempts to systematically review the myriad ways caregiver talk variables have been conceptualized and measured.

**Objectives:** In this systematic literature review, we examine 294 caregiver talk variables extracted from 65 studies, provide a narrative overview of research findings, and link measurement approaches to various theories of language development.

**Methods:** We conducted a systematic search and selection process to gather studies that examined talk from caregivers of autistic children. Inclusion criteria were that articles must be peer-reviewed, group-design studies published in English between 1980 - present, and measure some aspect of talk in caregivers of autistic children. Caregiver talk variables were coded to identify how they were operationalized; see Table 1 for codes and definitions.

**Results:** See Table 2 for the number of reports and variables coded for each caregiver talk feature. Notably, the majority of variables included only talk directed to children and specified the speech act being performed. More than one-third of variables measured talk that was responsive to children's attention, activities, or communication (i.e., 'follow-in' talk), and slightly less than a third measured variables that elicited children's communication or engagement. We found strong support that talk related to children's attention is implicated in autistic children's language development, but this construct has varied in terms of semantic, structural, and functional features. There is also evidence that caregivers of autistic children modify their talk to accommodate their autistic children's needs, and for bi-directional relationships between caregiver's talk and autistic children's development on a variety of semantic and structural variables. Experimental evidence regarding the influence of caregiver talk interventions on autistic children's development is weak. Theoretical paradigms used by researchers included information processing, transactional, and speech act approaches.

**Conclusions:** We found inconsistencies in how researchers measured caregiver’s talk, but also uncovered promising leads with strong empirical support. We encourage researchers to reach consensus on how to operationalize variables such as follow-in talk, and to be clear about how conceptualizations of caregiver talk relate to theories of language and language acquisition. Further, researchers should consider supplementing caregiver talk research with interactional approaches that consider language-as-action, and do not restrict coding to the utterance level. These adjustments could provide foundational research for improving caregiver-talk related interventions.

**413.004 (Poster)** Acoustic-Perceptual Analysis of Oral Narratives in Individuals with Autism

*M. V. Andrianopoulos<sup>1</sup> and C. E. Gargan<sup>2</sup>, (1)Department of Communication Disorders, University of Massachusetts, Amherst, MA, (2)Communication Sciences and Disorders, Syracuse University, Syracuse, NY*

---

**Background:** Acoustic differences in the speech, voice and prosody of individuals with autism include increased pitch variability, atypical/shallow vocal quality, fast or slow rate, exaggerated/decreased pitch, and inappropriate phrasing, stress and resonance. Research supports that human listeners can perceive speech differences under controlled conditions that distinguish children with ASD from typically developing (TD) peers. For example, human listeners distinguished children with autism from TD controls as sounding significantly “different” on the basis of story sequencing, articulation, fluency, and emotional language (Andrianopoulos et al., 2015); using more words per utterance during elicited story telling tasks (Dahlgren, 2018); and speech intelligibility (Redford et al., 2018). There is limited consensus regarding which acoustic features contribute to the perception of prosodic differences in autism. The clinical usefulness of perceptual ratings of prosody remains limited. Continued empirical research investigating the ability of trained listeners to identify individuals with autism on the basis of speech, voice and prosody could contribute to the development of an objective definitions of “atypical prosody” to be used across clinical, diagnostic, and research settings.

**Objectives:** The following research questions were addressed: Do individuals with autism have acoustic differences in their speech, voice, and prosody during oral narrative productions compared to controls?; Are speakers with autism described by trained human listeners as sounding “different” with respect to perceptual correlates of prosody; Are speakers with autism identified by trained human listeners based on their speech, voice, and prosody?

**Methods:** A between-group study was conducted to investigate acoustic-perceptual features of the voice during an oral narrative re-telling task in individuals with autism (n=15; 12 males, 3 females) compared to TD controls (n=15;) matched for age, gender and language. Participants were monolingual speakers of English, between 7;10 to 15;1 years of age. Testing took place in a 1:1 setting in a sound-treated, double-walled chamber with an ambient noise level of 25 dBA. Participants’ produced an oral narrative using controlled picture stimuli, which was audio recorded for analysis. The duration of each story (seconds), average fundamental frequency (f0), f0 range, standard deviation of f0, rate, and intensity was measured per participant using the Multi-Dimensional Voice Program and compared between groups. Trained listeners used a novel perceptual rating tool consisting of Likert scales to describe the oral narratives with respect to pitch, intonation, rate, fluency, timbre, loudness, and group membership (ASD vs. TD).

**Results:** The acoustic-perceptual analysis of 18 participants’ oral narratives has been completed. The group means for duration and fundamental frequency during an elicited storytelling task are presented in Table 1. Data collection and analysis will be complete by December 2019. Planned statistical analysis includes one-way analysis of variance, t-tests, Fisher’s Exact, Cohen’s d, and Cohen’s kappa for intra- and inter-rater reliability of perceptual judgments.

**Conclusions:** Published empirical research findings are contradictory. The results of this study support differences in duration during elicited spontaneous storytelling tasks (Dahlgren et al., 2018; Redford et al., 2018). Clinical implications and directions for future research require reliable operational metrics to assess prosody in autism.

**413.005 (Poster)** Are Children with Autism More Likely to Retain Object Names When Learning from Colour Photographs or Black-and-White Cartoons?

*C. K. Carter and C. Hartley, Lancaster University, Lancaster, United Kingdom*

---

Background:

Many children with autism spectrum disorder (ASD) have difficulty learning words. Despite widespread use of picture-based communication interventions to facilitate their word learning, previous research indicates that some children with ASD have difficulty understanding pictorial symbols. Moreover, there are currently no data-grounded guidelines regarding which kinds of

pictures should be employed by interventions. Here, we examine how ASD impacts children's ability to learn words from pictures that vary on the dimension of iconicity – the extent to which a symbol resembles its intended referent.

#### Objectives:

This study investigated whether children with ASD and delayed language development map and retain novel object names more accurately when learning from colour photographs or black-and-white cartoons. We expected to observe superior retention when children learned from highly-iconic colour photographs, as high levels of visual detail may facilitate children's mapping of picture-object relationships and scaffold the formation of more robust representations of meaning.

#### Methods:

Children with ASD ( $n = 20$ ;  $M$  age = 80.35 months) and TD controls ( $n = 20$ ;  $M$  age = 41.55 months) matched on receptive language (ASD  $M$  age equivalent = 43.60 months; TD  $M$  age equivalent = 44.75 months) mapped novel word-picture relationships in a mutual exclusivity referent selection task. They completed two versions of this task on different days; in one condition the pictures were colour photographs and in the other the pictures were black-and-white cartoons (words and objects differed across versions - see Figure 1 for an illustration of each trial type). During eight referent selection trials, participants actively learned four novel words for pictures of unfamiliar objects. After a 5-min delay, we tested children's retention of the newly-learned words by asking them to identify their corresponding 3-D referents.

#### Results:

Both groups used mutual exclusivity to accurately map novel word-picture relationships, achieving ceiling level accuracy in both iconicity conditions (93-100%), but demonstrated substantially reduced retention accuracy. When learning from black-and-white cartoons, retention trial accuracy of TD children (37.5%) and children with ASD (32%) did not significantly differ ( $p = .39$ ). However, when learning from colour photographs, children with ASD achieved significantly greater accuracy on retention trials (47%) than TD children (33.3%;  $t = 2.55$ ,  $p = .013$ ). Children with ASD achieved significantly greater retention accuracy when learning words from photographs (47%) than cartoons (32%;  $t = 2.20$ ,  $p = .04$ ).

#### Conclusions:

Discrepancies between referent selection accuracy and subsequent retention accuracy suggest that these word learning processes are subserved by distinct mechanisms. The superior retention accuracy achieved by children with ASD in the photograph condition could be attributed to enhanced perceptual functioning which may afford an advantage over TD children when learning object names from highly-iconic colour photographs. TD children may not have benefitted from increased iconicity because of their propensity to focus on shape, at the expense of other details (e.g. colour), when learning new object names. From an applied perspective, our results provide a data-grounded rationale for using colour photographs in clinical and educational contexts.

**413.006 (Poster)** Assessing Vocabulary Differences in Infants with an Elevated Likelihood of ASD Using the n-CDI  
**Z. Belteki<sup>1</sup>, C. van den Boomen<sup>2</sup>, E. Ward<sup>3</sup>, S. Hunnius<sup>3</sup>, J. K. Buitelaar<sup>4</sup> and C. Junge<sup>5</sup>,** (1)Utrecht University, Utrecht, Netherlands, (2)Donders Institute for Brain, Cognition and Behaviour, Nijmegen, Netherlands, (3)Baby and Child Research Center, Radboud University, Nijmegen, Netherlands, (4)Department of Cognitive Neuroscience, Donders Institute for Brain, Cognition and Behaviour, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands, (5)Department of Developmental and Experimental Psychology, Utrecht University, Utrecht, Netherlands

**Background:** Infants with an elevated likelihood (EL) of autism diagnosis are shown to have smaller receptive and expressive vocabularies at various timepoints, when compared to their lower likelihood (LL) peers. Group differences in vocabulary size derive from a wide range of internal (e.g., infant behaviour, genetics) and external factors (e.g., environment). Such factors may also lead to differences in the *content* of the vocabularies of EL versus LL infants. In typically developing infants, for example, it has been shown that the language(s) to which an infant is exposed impact the timepoint at which the infant begins to learn different syntactical categories (e.g., nouns, verbs). Similarly, we may expect that the atypical internal and external factors of EL infants may also impact the words that make up their vocabulary (i.e., content) in such a way that it is distinguishable from their LL peers.

**Objectives:** We assess whether there are group differences in the vocabularies between EL versus LL infants at 14 and 24 months, examining both vocabulary size and content. This is an explorative study and the first step to subsequently complement

our findings via a pre-registered report with a larger data set from an international consortium covering more languages. To our knowledge, this is the first study assessing EL infants' vocabulary in this age group.

**Methods:** Fifty-nine infants (36 EL) were assessed using the Dutch version of MacArthur-Bates Communicative Developmental Inventory (N-CDI). Vocabulary size was assessed through infants' raw scores on the questionnaire. Vocabulary content was examined in two ways. First, a syntactic analysis focused on the word classes (i.e., nouns, predicates, function words, other). Second, a semantic analysis focused on the kind of words (i.e., more versus less social words).

**Results:** Although at 14 months there was no significant group differences for neither vocabulary size nor vocabulary content, results revealed clear differences in both at 24 months. EL infants had smaller receptive,  $U = 245.00$ ,  $p = .009$  and expressive,  $U = 187.00$ ,  $p < .001$  vocabularies than their LL peers. They also had lower proportions of 'predicates' (i.e., verbs and adjectives),  $U = 288.00$ ,  $p = .030$  and higher proportions of 'other' words (such as 'animal sounds'),  $U = 294.00$ ,  $p = .037$  in their total vocabularies compared to their LL peers (see Figure 1). The groups did not differ significantly in the proportions of 'more social' and 'less social' categories in their vocabularies.

**Conclusions:** While groups initially did not differ, differences in size and content became visible by 24 months: compared to their peers, EL produced fewer words, and the type of words they produced were relatively simpler: fewer 'predicates' but more 'other' words (e.g. 'animal sounds'). Arguably, predicates are more complex words because they describe the relationship between multiple entities, making them more abstract (e.g., verbs revolve around varying persons). At the same time 'animal sounds' are relatively concrete. Further research is required to see whether this pattern holds for more languages and to observe whether these differences in contents arise from the reported smaller vocabularies.

**413.007 (Poster)** Atypical Neural Representation of Phonological Working Memory in Children with Autism

**A. M. O'Brien<sup>1,2</sup>, Z. Qi<sup>2,3</sup>, H. Tager-Flusberg<sup>4</sup> and J. D. E. Gabrieli<sup>5</sup>,** (1)260 Longwood Avenue, Harvard University, Boston, MA, (2)McGovern Institute, Massachusetts Institute of Technology, Cambridge, MA, (3)Department of Linguistics & Cognitive Science, University of Delaware, Newark, MD, (4)Department of Psychological and Brain Sciences, Boston University, Boston, MA, (5)Brain and Cognitive Sciences, Massachusetts Institute of Technology, Cambridge, MA

**Background:** Despite the removal of language impairments from the diagnostic criteria of autism spectrum disorder (ASD) in 2013, a majority of children with ASD show borderline or impaired language (Kjelgaard & Tager-Flusberg, 2001). It is unknown whether the language impairments (LI) in ASD share the underlying neural bases of LI in neurotypical (NT) individuals. Nonword repetition (NWR) is a standard clinical measure for phonological working memory (PWM) with high sensitivity and specificity for developmental language disorders (Weismer et al., 2000). NWR involves three language processes: speech perception, PWM, and speech production. Research has suggested behavioral and neural differences in children with ASD for each of these processes (Tryfon et al., 2018; Habib et al., 2019; Williams et al., 2013; Pang et al., 2015). Comparing the precision of neural representations of PWM in children with ASD to those in NT controls would provide novel insight into the neural bases of LI in ASD.

**Objectives:** Our objective is to assess whether children with ASD and NT engage similar neural substrates of PWM as measured by decoding accuracy from a multivariate pattern analysis (MVPA) during NWR, and whether decoding varies by phonological skill (stronger vs. weaker).

**Methods:** Nineteen participants with ASD were matched with 19 NT peers by age, gender, NWR behavior, and IQ (Table 1). Each group was divided by in-scanner NWR performance (stronger (SP) and weaker performers (WP)) using an age-based median split. fMRI data were collected via sparse sampling. Participants repeated nonwords distributed across four NWR loads (2 to 5-syllables).

We used MVPA to decode the neural activation during challenging NWR tasks (5-syllable) from easier NWR tasks (2-syllable) within the NWR networks of interest: speech perception, verbal working memory, and speech production (Figure 1). Meta-analysis maps from Neurosynth.org were used as the network masks. We also performed decoding analyses on the combination and conjunction ROIs to determine if particular regions were driving accuracy across maps.

**Results:** A two-way ANCOVA revealed a main effect of diagnosis in the speech production network (greater decoding accuracy in NT than ASD), after correcting for IQ ( $F(1, 33) = 4.35$ ,  $p = 0.043$ ). There were no other main effects or interactions for the other networks. Because we found a main effect of diagnosis, but not phonological skill, we collapsed the data within each diagnosis and compared decoding to chance for each network. The NT group demonstrated above-chance decoding for the speech perception ( $p = 0.007$ ), speech production ( $p = 0.001$ ), and combination networks ( $p = 0.04$ ), while the ASD group did not

show above-chance decoding for any of the networks (Figure 1). Neither group performed above chance for the verbal working memory or conjunction ROIs.

Conclusions: Children with ASD showed reduced precision of neural representation in speech perception and speech production networks. The specificity of group differences in speech production was highlighted by the lack of significant decoding in the conjunction map. These results may implicate compensatory networks that support PWM in the ASD groups. Future analyses will use searchlight MVPA to verify this possibility.

#### **413.008 (Poster)** Audiovisual Integration of Speech and Gesture in Autism

*R. Hafner and A. Lambrechts, Psychology, City, University of London, London, United Kingdom*

---

##### Background:

Autistic people often find it difficult to integrate verbal and non-verbal cues effectively in communication, and show atypical prosody and use of gestures in conversations. Differences in multisensory integration, motor coordination, and temporal processing suggest that atypical speech/gesture delays could characterize the coordination and integration of audiovisual communication cues in autism. Perceptually, gestures have been found to facilitate comprehension to a lesser extent for autistic individuals than it does for their typically developing (TD) peers (Silverman et al., 2010). Prior research also found longer delays between gesture and speech production in autistic speakers (de Marchena and Eigsti, 2010); it remains unknown whether autistic listeners show similar differences in integrating perceived audiovisual communication.

##### Objectives:

This study investigated the preferred delay for audiovisual integration of speech and gesture in autistic and TD adults. To determine whether any differences observed pertained to all audiovisual stimuli or only to specific stimulus types (complex or linguistic stimuli), we measured participants' preferred delay using speech and gesture, dance and music, and the movement of abstract shapes to distorted speech (noise).

##### Methods:

26 adults ( $N_{ASD} = 14$ ,  $N_{TD} = 12$ ) viewed pairs of videos presented side-by-side and were tasked with deciding which video fitted an accompanying audio track more naturally. Each trial featured the original clip and a temporally-shifted version of the same clip, modified in relation to the original audio by one of eight delays ranging from  $\pm 240$  ms to  $\pm 2000$  ms. Trials were divided into three blocks based on stimulus type.

##### Results:

Results indicated that all participants showed an asymmetrical preference for video-lead compared to video-lag trials ( $F[1, 24] = 42.87$ ,  $p < .001$ ,  $\eta_p^2 = .641$ ), suggesting that participants tolerated (and sometimes preferred) delays between audio and video when video was leading, but less so when video was lagging. Our data also indicates a main effect of condition ( $F[2, 48] = 12.56$ ,  $p < .001$ ,  $\eta_p^2 = .344$ ); participants showed a stronger preference for the original clip in the speech condition compared to the dance ( $t = 4.80$ ,  $p < .001$ ) and abstract ( $t = -4.02$ ,  $p < .001$ ) conditions, however, participants did not differ in preference between the dance and abstract conditions ( $t = -0.27$ ,  $p = .79$ ). The data also indicated a significant interaction between group and delay; compared to the ASD group, TD participants showed a stronger shift in preference between video-lag and video-lead trials ( $F[1, 24] = 8.47$ ,  $p = .008$ ,  $\eta_p^2 = .261$ ).

##### Conclusions:

In line with prior research, findings indicated an asymmetrical preference for occurrences where gesture preceded the corresponding audio in naturalistic speech in both autistic and non-autistic participants. This preference extended to dance and abstract stimuli, suggesting it is not specific to complex or linguistic stimuli. Similar to the TD group, the preferred delay for the autistic group was around 240-480 ms. However, autistic participants exhibited a subtler shift in preference between delays, suggesting that the audiovisual integration process differs for simple and complex stimuli in autism.

#### **413.009 (Poster)** Characterizing Language Atypicality in ASD and ADHD

**J. K. Dolata**<sup>1,2</sup>, **S. Suarez**<sup>2</sup> and **E. Fombonne**<sup>3</sup>, (1)Department of Pediatrics, Oregon Health & Science University, Portland, OR, (2)Communication Sciences and Disorders, Pacific University, Forest Grove, OR, (3)Department of Psychiatry, Oregon Health & Science University, Portland, OR

---

**Background:** Pragmatic differences are prevalent in neurodevelopmental disorders, including Autism Spectrum Disorder (ASD) and Attention Deficit Hyperactivity Disorder (ADHD). Indeed, communication differences are a common impetus for assessment, and differential diagnosis between ASD and ADHD is sometimes difficult. Traditional assessment captures salient details regarding language form and content; however, challenges remain in formally assessing language *use* (i.e., pragmatics). There is a need to better understand differences in language profiles among clinical groups and review parent-reporting as a critical component of the diagnostic processes.

**Objectives:** With careful measurement, it is possible to examine discrete pragmatic differences and linguistic atypicality that can differentiate typical development (TD), ASD, and ADHD. While ADHD in isolation is not considered a communication disorder, symptoms of the disorder can interfere with communication and mimic the symptoms of ASD. Our primary aim is to describe how evaluation using a questionnaire with pragmatic subscales can be a robust indicator of group membership and differentiation between children with ASD, ADHD, and TD.

**Methods:** 174 children were involved in a study on functional magnetic resonance imaging: 101 with ASD (mean age: 11.3 years; 85 males), 28 with TD (mean age: 11.6 years; 12 males), and 45 with ADHD (mean age 11.5 years; 31 males). There were no significant group differences for age or race. Subjects participated in psychometric testing using the Autism Diagnostic Observation Schedule, Social Responsiveness Scale, the Wechsler Intelligence Scale for Children and the Children's Communication Checklist, 2nd Edition (CCC-2). Cognitive scores were significantly lower for the ASD group compared to TD and ADHD groups (98.8 vs 113.4 and 111.6,  $p < .001$ ). Language profiles were explored with the CCC-2, with subscales for linguistic and social communication features. Parents completed the CCC-2 to yield total, structural, and pragmatic scores for each child participant. Analysis of variance (ANOVA) and analysis of covariance (ANCOVA) were used to compare clinical groups.

**Results:** Nine ANOVA models revealed significant ( $p < .001$ ) between-groups differences. Games-Howell post-hoc tests revealed that children with ASD scored significantly lower on all CCC-2 scales than children with ADHD and TD. Effects sizes were larger for pragmatic ( $\eta^2$ : .56 - .65) than structural ( $\eta^2$ : .20 - .47) scaled scores. With the exception of two structural scales (Speech and Syntax), the ADHD group scored significantly lower than TD and their scores fell between the ASD and TD groups. Covarying Full Scale Intelligence Quotient scores (FSIQ) reduced the size of CCC-2 differences across groups only minimally. When structural scaled scores were covaried alongside FSIQ, pragmatic scaled scores remained different across diagnostic groups, with a very large effect size for the composite score ( $\eta^2$ : .49).

**Conclusions:** We compared specific linguistic and pragmatic aspects of language in children with ASD, TD, and ADHD. Using a validated parent-report questionnaire, we analyzed responses to explore language profiles among these groups. Results suggest that differences in pragmatic language are robust predictors of ADHD and ASD diagnoses even after accounting for cognitive and structural linguistic differences.

**413.010 (Poster)** Construct Validity of the Autism Classification System of Functioning: Social Communication (ACSF:SC) across Development

**D. Parvinchi**<sup>1</sup>, **P. Rosenbaum**<sup>2</sup>, **E. Duku**<sup>3</sup>, **M. J. Cooley Hidecker**<sup>4</sup>, **L. Zwaigenbaum**<sup>5</sup>, **C. Roncadin**<sup>6</sup>, **S. Georgiades**<sup>7</sup>, **S. J. Gentles**<sup>2</sup>, **H. Fang**<sup>1</sup> and **B. Di Rezze**<sup>1</sup>, (1)School of Rehabilitation Science, McMaster University, Hamilton, ON, Canada, (2)CanChild Centre, McMaster University, Hamilton, ON, Canada, (3)Offord Centre for Child Studies, McMaster University, Hamilton, ON, Canada, (4)Department of Communication Sciences & Disorders, University of Kentucky, Lexington, KY, (5)University of Alberta, Edmonton, AB, Canada, (6)Autism Spectrum Disorder Service, McMaster Children's Hospital - Hamilton Health Sciences, Hamilton, ON, Canada, (7)McMaster Autism Research Team, McMaster University, Hamilton, ON, Canada

---

**Background:** During typical development, children learn to communicate through social processes. Many children with autism struggle with social skills, which are associated with social communication difficulties. Categorization based on children's social communication abilities may be informative for clinical decisions such as what therapy modifications or support recommendations may help maximize therapeutic change. The Autism Classification System of Functioning: Social Communication – Integrated (ACSF:SC–I), describes a range of social communication abilities from Level I (most functional) to Level V (least functional) of children with autism 2-19 years of age. ACSF:SC–I ratings are reliable (intra- and inter-rater) for both parents and professionals to categorize children and youth on their 'Capacity' (what children do at their best) and 'Performance' (everyday function).

**Objectives:** To examine the construct validity of the ACSF:SC–I.

**Methods:** Participants included 95 children with autism (2-19 years). We present two effect size estimates (correlation coefficient & eta-squared) to quantify construct validity. The construct validity of ACSF:SC-I was examined by providing indices of its degree of convergent and discriminant validity. We used Social Responsiveness Scale 2<sup>nd</sup> edition (SRS-2) subscales and Behavior Assessment System for Children, third Edition – Parent Rating Scales (BASC-3 PRS) as comparison measures to examine construct validity. We used  $\alpha=.05$  for Spearman's Rho ( $r$ ) correlation analysis and defined Eta-squared ( $\eta^2$ ) < .06 as small,  $\eta^2 = .06$  to .14 as moderate, and  $\eta^2 > .14$  as larger effect sizes. To establish convergent construct validity of ACSF:SC-I, a priori hypotheses anticipated that parent ratings of Capacity and Performance scores would be significantly correlated with the Social Communication and Interaction (SCI; SRS-2), Functional Communication (BASC-3), and Social Skills (BASC-3) subscales. To determine discriminant construct validity of ACSF:SC-I, Capacity and Performance scores were expected to weakly correlate with the Attention Problems and Externalizing Problems (BASC-3) as these are distinct constructs independent from social communication.

**Results:** We found significant correlations between ACSF:SC-I and the SCI (Performance:  $r=.39$ ,  $p<.001$ ; Capacity:  $r=.39$ ,  $p<.001$ ), Functional Communication (Performance:  $r=-.37$ ,  $p<.001$ ; Capacity:  $r=-.44$ ,  $p<.001$ ), and Social Skills (Performance:  $r=-.25$ ,  $p=.02$ ; Capacity:  $r=-.39$ ,  $p<.001$ ) T-scores. The effect size of these convergent associations ranged from moderate to large for ACSF:SC-I Performance ( $\eta^2=.11$  to .19) and large for Capacity ( $\eta^2=.18$  to .21). Discriminant analyses showed weaker correlations between ACSF:SC-I ratings and comparison measures of Externalizing Problems (Performance:  $r=-.04$ ,  $p=.70$ ; Capacity:  $r=.01$ ,  $p=.93$ ) and Attention Problems (Performance:  $r=-.01$ ,  $p=.96$ ; Capacity:  $r=.06$ ,  $p=.57$ ) T-scores. The effect size of these discriminant associations was small for Performance ( $\eta^2=.04$  to .05) and small for Capacity ( $\eta^2=.004$  to .01).

**Conclusions:** The results provided support for construct validity of ACSF:SC-I with significant correlations in the predicted directions for convergent validity and weak correlations in the expected direction for discriminant validity. Findings also indicated stronger associations for Capacity than everyday Performance, suggesting that these may be distinct constructs within the social communication domain. This finding has implications for clinical practice and research such as whether interventions and research are targeting Capacity or everyday Performance and the predictive power of each for treatment outcomes (e.g., social isolation).

**413.011 (Poster)** Development of Conversation Abilities in Chinese-Speaking Preschoolers with Autism: The Contributing Role of Parents

*W. So<sup>1</sup> and X. Song<sup>2</sup>, (1)Educational Psychology, The Chinese University of Hong Kong, Hong Kong, Hong Kong, (2)Chinese University of Hong KONG, Hong Kong, Hong Kong*

---

**Background:** Children with autism are found to have deficits in conversation. Yet, the development of conversation abilities is understudied. A few studies reported that there are significant improvements in the ability to maintain a topic of discourse and in the length and frequency of communication interchanges. Additionally, findings of the role of parental inputs in shaping conversational abilities in these children are inconclusive. Abundant research has examined the relation between parental inputs and vocabularies, and shown that parental inputs have been shown to predict later vocabularies of children with autism. Yet, very little research studied the relation between parental inputs and conversational abilities. Besides, these studies focused on English-speaking children with autism. None of them has examined conversation abilities in Chinese-speaking children with autism, whose autism prevalence has been increasing.

**Objectives:** This study aimed to document the growth of conversational abilities in Chinese-speaking preschool children with autism and to investigate how parental inputs influenced these abilities.

**Methods:** Participants in the current study were taken from the larger intervention project for Chinese-speaking individuals with autism. A subset of these participants ( $N=37$ ; 32 males; Mean age: 5;6,  $SD=10.46$  months) contributed their language samples at four time points over a nine-month intervention. Children were administered Autism Diagnostic Observation Schedule (Second Edition), Kaufman Brief Intelligence Test (Second Edition), and Mullen Scales of Early Learning. They interacted with their caregivers at four time points, with each time lasting for 20 minutes playing a standard set of toys in a treatment room. Each session was video-recorded. We first identified the conversation topic for each utterance and who initiated the conversation. We also counted the numbers of conversation turns. Finally, for each utterance produced by the respondent during the conversation, we considered whether the respondent responded, and if so, whether the response was appropriate.

**Results:** Overall, there were 8817 conversation topics ( $M=60.39$ ;  $SD=19.31$ ) and 914.54 conversation turns ( $M=6.18$ ;  $SD=2.04$ ) across four time points. Separate Hierarchical Linear Modeling analyses were conducted to model the growth curve trajectories for different conversation abilities. Number of conversation turns and the proportion of children-initiated conversation (but not the proportion of children's appropriate responses) grew over the course of nine months ( $\beta=.15$ ,  $SE=.05$ ;  $\beta=.04$ ,  $SE=.01$ ). In separate random intercept models, after controlling for time, ADOS and Express Language age equivalent scores, we found that parents' appropriate responses positively predicted children's appropriate responses ( $\beta=.25$ ,  $SE=.07$ ). Parents' inappropriate

responses negatively predicted children's appropriate responses ( $\beta = -.51$ ,  $SE = .11$ ) and the number of conversation turns ( $\beta = -3.58$ ,  $SE = .95$ ). Interestingly, parent-initiated conversation negatively predicted the proportion of children's appropriate responses ( $\beta = -.28$ ,  $SE = .05$ ) and the number of conversation turns ( $\beta = -2.83$ ,  $SE = .45$ ). Absence of parent responses positively predicted children-initiated conversation ( $\beta = .71$ ,  $SE = .10$ ).

Conclusions: Some aspects of conversation abilities may grow over time in Chinese-speaking children with autism. Contingent and appropriate parent responses help children with autism to learn to formulate appropriate responses to maintain a conversation. Nevertheless, parent-initiated conversation might impose challenges for children to respond appropriately and even discourage these children from initiating conversations themselves.

**413.012 (Poster)** Differences in Conversational Prosodic Entrainment between Youth with and without ASD As a Function of Conversational Duration

**H. Lehnert-LeHouillier<sup>1</sup>** and **S. Sandoval<sup>2</sup>**; (1)Communication Disorders, New Mexico State University, Las Cruces, NM, (2)Klipsch School of Engineering, New Mexico State University, Las Cruces, NM

---

Background: Differences in speech prosody between those with and without ASD have been well-attested. However, the exact nature of these differences is as of yet not completely understood. A relatively new area of prosodic investigation in the speech of those with ASD is prosodic entrainment - the alignment of conversation partners in acoustic-prosodic features over the course of a conversation (Wynn et al., 2018; Lehnert-LeHouillier et al., 2020). Generally speaking, more entrainment in prosodic features is associated with positive interactions whereas a lack of entrainment as well as dis-entrainment – the divergence of conversation partners – is typically associated with negative relational attributes (i.e. Pickering & Garrod, 2004; Soliz & Giles, 2014). The current study furthers our understanding of differences in conversational prosody between individuals with and without ASD.

Objectives: This study set out to investigate the relationship between acoustic-prosodic entrainment in mean f0 and the length of the conversation in which speakers were engaged. It was hypothesized that longer conversations will exhibit more prosodic entrainment, which, in turn, may be reflective of better rapport between conversation partners.

Methods: Twenty-seven children and adolescents between the ages of 9 and 15 years participated in the current study; 14 (11 boys, 3 girls) participants had previously been diagnosed with ASD and 13 (10 boys, 3 girls) participants were neurotypical peers matched in age, gender, and nonverbal IQ. All participants completed IQ (K-Bit 2) and language (CELF-5) testing, and the participants in the ASD group were also administered the ADOS-2 to confirm the ASD diagnosis. Participants engaged in a goal-oriented conversation using the Diapix task (Baker & Hazan, 2011). All conversations were recorded and acoustically analyzed to derive measures of global prosodic entrainment in mean f0 as well as the duration of each conversation. The results were analyzed using linear regression modelling.

Results: The regression model included mean f0 entrainment as outcome variable and duration of the conversation, conversational effectiveness (measured as the number of differences found per minute), and overall language ability (measured by the CELF Core Language score) as predictor variables. The results suggest that no relationship between f0 entrainment and conversational effectiveness exists in our data set. We found a significant effect of overall language ability on mean f0 entrainment ( $b = -0.31$ ,  $SE = 0.11$ ,  $p < 0.01$ ) such that those participants with better language ability tended to show less mean f0 entrainment compared to those with lower CELF scores. This was true of participants with and without ASD alike. However, a significant interaction between participant group and duration of the conversation was found ( $b = 0.1$ ,  $SE = 0.04$ ,  $p = 0.01$ ). The participants in the neurotypical group that were engaged in longer conversations also exhibited more f0 entrainment, while participants in the ASD group who conversed for a longer time not only showed less mean f0 entrainment but actually dis-entrained from their conversation partners over the course of the conversation.

Conclusions: Conversation length is correlated with prosodic entrainment in neurotypical peers but not in youth with ASD.

**413.013 (Poster)** Difficulties with Personal Pronouns for School-Aged Children with ASD and ADHD in a Virtual Reality Task  
**C. Boo<sup>1</sup>**, **N. S. McIntyre<sup>2</sup>**, **P. Mundy<sup>3</sup>** and **L. R. Naigles<sup>1</sup>**, (1)Psychological Sciences, University of Connecticut, Storrs, CT, (2)University of California at Davis, Davis, CA, (3)University of California at Davis, Sacramento, CA

---

**Background:** Early in development, children with Autism Spectrum Disorder (ASD) show difficulties with producing personal pronouns, particularly non-first-person pronouns (Kelty-Stephen et al., 2020; Song et al., 2020). Furthermore, most of the research on pronoun production among school-aged children with ASD, and some on children with Attention Deficit/Hyperactivity Disorder (ADHD), primarily focuses on ambiguity/unclear uses (e.g. Kuijper et al., 2015; Novogrodsky & Edelson, 2016), without distinguishing these by personhood and sheer base rates of production. This current study examines personal pronoun production in a conversational context, where both first- and third-person pronoun usage is afforded.

**Objectives:** 1) To determine if and how pronoun challenges might persist in older, school-aged children with ASD. 2) To test whether a conversational context, which affords more discussion of others (i.e. family, friends, pets, etc.), expands children with ASD's pronoun type production.

**Methods:** Participants included 21 highly verbal children with ASD (HFA;  $M_{age} = 11.6$ ,  $SD = 2.2$ ), 24 children with ADHD ( $M_{age} = 11.9$ ,  $SD = 2.5$ ), 31 children with comorbid symptoms of both ASD and ADHD ( $M_{age} = 12.0$ ,  $SD = 2.3$ ), and 22 typically-developing (TD) children. Children were all within the normal range of Non-Verbal IQ. Language samples were collected during a virtual reality paradigm where children viewed a virtual classroom through a head-mounted display while they answered questions posed by a research assistant in a conversational format. Sample questions include: "Describe your family and who lives with you", "Talk about any pets you have now or had when you were younger", and "Talk about a favorite vacation you have had". Their responses were recorded and transcribed using CLAN (MacWhinney, 2000). CLAN algorithms were used to extract average mean length of utterances (MLU) and personal pronoun types and tokens.

**Results:** All groups produced significantly fewer third-person personal pronouns than first-person personal pronouns ( $ps < 0.001$ ), with no significant group differences in first-person pronoun production ( $p = 0.310$ ). However, significant group differences emerged in third-person pronoun frequency,  $F(3, 94) = 2.517$ ,  $p = 0.043$ ,  $\eta^2 = 0.174$ . A post hoc comparison using the Tukey HSD test revealed that the HFA ( $p = 0.018$ ) and Comorbid ( $p = 0.002$ ) groups produced significantly fewer third-person pronouns than the TD group (Figure 1).

**Conclusions:** Overall, third-person pronoun challenges still exist in school-aged children with ASD, including those with comorbid symptoms of ADHD. Although the children with ASD did not show difficulties with producing first-person pronouns, corroborating existing findings, children with ASD produced significantly fewer third-person pronouns in their responses, despite the fact that the conversational context probes for the use of third-person pronouns. For example, responding to the pet question, one TD child said: "So I used to have a pet named Goldie. She was really amazing actually." Responding to the same question, one child with ASD, matched on age and average MLU, said: "My dog Sky is brown. Sparky is like white and gray with curly fur." Despite the question affording the use of third-person pronouns, the child with ASD only used full noun phrases.

#### 413.014 (Poster) Distinctive Features of Pragmatic Expression in Adults with ASD

C. Yang<sup>1</sup>, D. Liu<sup>1</sup>, A. R. Canfield<sup>2</sup>, C. Hoffkins<sup>3</sup>, J. Aldrich<sup>3</sup>, S. Farash<sup>3</sup>, L. Silverman<sup>3</sup> and E. Prud'hommeaux<sup>1</sup>, (1)Boston College, Chestnut Hill, MA, (2)SUNY Upstate Medical University, Syracuse, NY, (3)University of Rochester Medical Center, Rochester, NY

Background: Autism spectrum disorder (ASD) is characterized by impaired pragmatic expression, which can lead to challenges establishing relationships, maintaining employment, and achieving independence. Although pragmatic language in children with ASD is well studied, there has been little research on pragmatics in the discourse of adults with ASD and their interlocutors.

Objectives: We investigate the degree of politeness, uncertainty, and informativeness of utterances in conversation between adults with ASD or with typical development (TD) and a neurotypical conversational partner while completing a collaborative task. The joint goals of this work are to identify distinctive pragmatic features of ASD and to determine how interlocutors adapt their own pragmatic expression in response to varied discourse input.

Methods: Twenty-two adult experimental participants (EP, ASD  $n=14$ ; TD  $n=8$ ) engaged in a collaborative navigation task with a neurotypical conversational partner (CP,  $n=11$ ). In addition to the general eligibility criteria (PIQ $\geq 80$ ; VIQ $\geq 80$ ; age $>18$ y; no history of speech, language, or auditory disorder, or hearing difficulty), participants with ASD met criteria for diagnosis on the ADOS. Each experimental participant (EP) completed a map navigation task with a conversational partner (CP), in which each person was provided with a map of the same area containing slight differences in landmarks, labels, and obstacles. The EP provided verbal directions to the CP to lead the CP from their indicated location to the EP's indicated location on the map. Three trials were carried out with three different maps. Using coding guidelines from previous work (Danesco-Niculescu-Mizil, 2013; Vincze, 2015; Pavlick and Tetrault, 2016), two annotators independently rated each utterance on 3-point ordinal scale for politeness (Krippendorff's  $\alpha=0.57$ ), uncertainty ( $\alpha=0.75$ ), and information content ( $\alpha=0.90$ ), and the ratings were averaged.

Results: Utterances produced by EPs with ASD were significantly more polite (ASD=2.01, TD=1.95,  $t=4.358$ ,  $p=0.00001$ , Cohen's  $d=0.17$ ) and less informative (ASD=1.61, TD=1.72,  $t=-3.846$ ,  $p=0.00012$ ,  $d=0.15$ ) than those produced by EPs with TD. Utterances produced by CPs of EPs with ASD were significantly more uncertain (CP:ASD=1.41, CP:TD=1.21,  $t=4.812$ ,  $p=0.0000016$ ,  $d=0.20$ ) and more informative (CP:ASD=1.65, CP:TD=1.56,  $t=2.510$ ,  $p=0.012$ ,  $d=0.11$ ) than those produced by conversational partners of EPs with TD. Group difference at the participant level followed similar trends but did not reach significance due to limited sample size. Correlations between the pragmatic features and time required for task completion were

calculated, revealing a negative correlation between experimental participant informativeness and time to complete the task (Pearson's  $r = -0.318$ ).

Conclusions: Adults with ASD exhibited pragmatic language patterns distinct from those of their TD peers when engaging in a collaborative task with a neurotypical conversational partner, which influenced both the pragmatic expression of their conversational partners and extrinsic measures of task success. In particular, we note that conversational partners' language increased in uncertainty in response to the less informative utterances of their ASD interlocutors. These results provide insight into the ways in which language differences observed in children with ASD might manifest in adulthood, which in turn may prove useful for clinicians developing interventions to improve personal and professional outcomes for adults with ASD.

**413.016 (Poster)** Do Preferred Interests Support Vocabulary Learning in Preschoolers with ASD? a Pilot Study

**T. Pelletier<sup>1</sup>** and **S. Arunachalam<sup>2</sup>**, (1)*New York University, New York, NY*, (2)*Communicative Sciences and Disorders, New York University, New York, NY*

---

Background:

While the intense, focused, preferred interests associated with ASD are sometimes viewed as restrictive (e.g., Dichter et al., 2010; Stocco, Thompson, & Rodriguez, 2011), many researchers argue that they should be considered strengths. Some studies find that incorporating preferred interests into intervention can support children's development of social skills (e.g., Gunn & Delafield-Butt, 2016; Vismara & Lyons, 2007). However, the role of preferred interests has not yet been studied in language learning. Approximately 90% of children with ASD have language delays and require language intervention (e.g., Pickles, Anderson, & Lord, 2014). Incorporating preferred interests may make this intervention more effective.

Objectives:

In this pilot study, we ask whether children demonstrate better learning of a new word when the learning situation involves their preferred interest as compared to a more neutral situation.

Methods:

Children with ASD ( $N = 5$ ) and typically developing children ( $N = 5$ ) have participated thus far in two trials (order counterbalanced). On each trial, children saw a video of a character or object performing an action (e.g., spinning) and heard a novel word (e.g., "Look, he is semming!").

On one of the trials, the character/object was the child's preferred interest, as reported by their parent (e.g., Mickey Mouse). On the other trial, it was not the preferred interest, and the parent rated it as neutral (neither hated nor particularly well liked). The child was then tested on whether they had learned the word: They saw the trained action (e.g., spinning) and a new action (e.g., bouncing) side-by-side, being performed by the same character/object as well as a new character/object to test generalization. See Table 1. Children's eye gaze was tracked. Their attention to the correct scene when prompted to, e.g., "find semming" was taken as an indicator of whether they learned the word.

Results:

A mixed-effects linear model with proportion of looking to the correct scene as the dependent variable, participant as random factor, and condition (preferred interest vs. neutral) as a fixed factor revealed a significant main effect of condition ( $\beta = 1.48$ ,  $t = 5.17$ ,  $p < .01$ ). This result indicated that children looked to the correct scene more in the preferred interest condition than the neutral condition. See Figure 1. Although we lack statistical power to look for differences between children with and without ASD, the majority of individual children in both groups showed this pattern.

Conclusions:

This pilot study suggests that children with and without ASD may more successfully learn vocabulary when the learning situation incorporates their preferred interest. This is true even though the word's meaning was not inherently about that interest—that is, although we might imagine that incorporating a preferred interest in dinosaurs would facilitate learning dinosaur-related vocabulary, our results further indicate that preferred interests can be helpful for vocabulary learning more generally. With additional data, we will look for differences between children with and without ASD, relations to ASD symptom severity, and

differences between the two test phases (preferred interest vs. generalization) to see how well learning generalizes.

**413.017** (Poster) Does a Naturalistic Coding Measure of Social Communication Predict Pragmatic Ability As Measured By the CCC-2?

**C. G. La Valle<sup>1</sup>, E. Johnston<sup>2</sup>, E. Clark-Whitney<sup>3</sup>, S. H. Kim<sup>3</sup> and H. Tager-Flusberg<sup>1</sup>,** (1)Department of Psychological and Brain Sciences, Boston University, Boston, MA, (2)Boston University, Boston, MA, (3)Psychiatry, Center for Autism and the Developing Brain, White Plains, NY

---

Background:

Previous work has used real-time coded natural language samples to derive general measures of spoken communication (utterances and conversational turns) for children and adolescents with ASD. Findings revealed high construct validity with the coding measures and caregiver report measures assessed at the same timepoint (Barokova et al., 2020). However, these studies did not examine the predictive role of language sample-derived measures to later language ability and did not include a naturalistic real-time coding measure of social communication. Social communication difficulties are a key characteristic of individuals with ASD (Young et al., 2005). In this study, we used our naturalistic real-time coding measure of social communication to assess whether it will predict pragmatic behaviors, as measured by caregiver report, 8-months later.

Objectives:

In a sample of verbally fluent kindergarteners with ASD, we aimed to examine how our naturalistic measure of social communication predicts pragmatic communication behaviors as measured by caregiver report over an 8-month period.

Methods:

Twenty-six kindergarteners with ASD (4 female;  $n=26$  ADOS mod. 3), ages 56-79 months, completed assessments at the start and end of kindergarten (8 months apart; Table 1). Assessments included the Differential Ability Scales (DAS-II; Elliott, 2007) to measure cognitive abilities, the Brief Observation of Social Communication Change (BOSCC; Lord et al., 2018), a 12-minute examiner-child interaction comprised of play and conversation, and the Children's Communication Checklist (CCC-2; Bishop, 2003), a caregiver report measure to assess children's communication skills, including pragmatics. Speech utterances from the BOSCC were segmented into communication units (Loban, 1976) in ELAN (Lausberg & Sloetjes, 2008). Each child utterance was then coded according to whether it was socially communicative or not. Socially communicative utterances (SCU) included intent to request, share, and/or redirect. Total SCU was converted to SCU per minute (FreqSCU).

Results:

All analyses involved linear regression and controlled for DAS full-scale IQ (FSIQ) scores measured at time 1. FreqSCU at time 1 predicted CCC-2 frequency of pragmatic communication behaviors at time 2 ( $\beta=.45$ ,  $t=2.15$ ,  $p=.042$ ; Figure A). CCC-2 pragmatic communication behaviors at time 2 and FSIQ explained 17.20% of the variability in FreqSCU at time 1. FreqSCU at time 1 also predicted CCC-2 frequency of nonverbal pragmatic communication behaviors at time 2 ( $\beta=.43$ ,  $t=2.55$ ,  $p=.018$ ; Figure B). CCC-2 frequency of nonverbal pragmatic communication behaviors at time 2 and FSIQ explained 22.51% of the variability in FreqSCU at time 1.

Conclusions: Our measure of social communication derived from the BOSCC protocol predicted pragmatic behaviors, including nonverbal communication (e.g., gestures) 8 months later as measured by caregiver report. Findings support the utility of our naturalistic real-time coding measure to capture broader and more nuanced pragmatic communication skills in young children with ASD. Future work should examine how our coding measure captures changes over time in the context of ASD interventions targeting social communication skills.

**413.018** (Poster) Early Expressive Language in Young Children with Autism Spectrum Disorder: The Importance of the Context  
**P. Pérez<sup>1</sup>, A. Nordahl-Hansen<sup>2</sup> and A. Kaale<sup>1,3</sup>,** (1)Department of Special Needs Education, University of Oslo, Oslo, Norway, (2)Faculty of Education, Østfold University College, Halden, Norway, (3)Norwegian Centre of Expertise for Neurodevelopmental Disorders and Hypersomnias, Oslo University Hospital, Oslo, Norway

---

Background: From research on children with typical development, we know that a) caregivers' child-directed speech have strong impact on early language development and b) objects, animals and persons in the child's environment define much of the semantic content of the child-directed speech of the caregivers. As most children with autism spectrum disorder attend preschool, they will encounter similar but also different objects, persons and places compared to home. The differences will affect words used by parents and preschool teachers and might subsequently affect words used by the child.

Objectives: This exploratory study aims to investigate how the expressive language of young children with ASD might be different across the home and preschool contexts. We compare the amount of words said by children with ASD at home and in preschool across 10 categories listing various types of objects, places, animals and persons that we assume to be typical for one or the other context. We also investigate the degree of overlap between the words reported to be used by the children at home and in preschool.

Methods: Fifty-eight 2-4 years-old children [ $M=48.8$  months ( $SD = 8,0$ ), 81% boys] with a confirmed ICD-10 diagnosis of childhood autism and their parents and preschool teachers participated in this study. Parent and preschool teacher separate ratings of the words said by the children on the 10 noun categories of MacArthur-Bates Communication Development Inventory (CDI) were used to study expressive language across the home and preschool context.

Results: There was no significant difference in the total number of words the children said at home or in preschool ( $M_{\text{home}} = 78.1$ ,  $SD = 78.4$ ;  $M_{\text{preschool}} = 70.5$ ,  $SD = 75.9$ ,  $p = .07$ ), but the children said significantly more words in the noun categories "Furniture and rooms" ( $M_{\text{home}} = 7.4$ ,  $SD = 8.8$ ;  $M_{\text{preschool}} = 5.4$ ,  $SD = 7.4$ ,  $p = .00$ ) and "People" ( $M_{\text{home}} = 6.0$ ,  $SD = 5.5$ ;  $M_{\text{preschool}} = 5.0$ ,  $SD = 5.8$ ,  $p = .04$ ) at home. Only one third (38%) of the words the children said were said both at home and in the preschool, while the other two thirds were said only at home or only in the preschool. The highest percentage of words said across both contexts was within the categories "Vehicles (real or toy)" (47%) and "Food and drinks" (44%), while the lowest percentage was in the categories "Furniture and rooms" (26%) and "Small things in the household" (27%).

Conclusions: The results suggest that although young children with ASD use similar amount of words at home and in preschool, their vocabulary is highly context-dependent, similarly to that of younger children with TD. The results also suggest that their early expressive vocabulary might be larger when these two contexts are taken into account. This novel study highlights the importance of investigating the early language in children with ASD in multiple contexts in order to better evaluate their vocabulary and to design appropriate language interventions.

#### **413.019** (Poster) Evaluating Atypical Language in Autism Using Automated Discourse Measures

A. C. Salem<sup>1</sup>, H. MacFarlane<sup>1</sup>, J. R. Adams<sup>2</sup>, G. O. Lawley<sup>3</sup>, J. K. Dolata<sup>4</sup>, S. Bedrick<sup>5</sup> and E. Fombonne<sup>6</sup>, (1)Oregon Health & Science University, Portland, OR, (2)Computer Science, Oregon Health & Science University, Portland, OR, (3)Computer Science and Electrical Engineering, Oregon Health & Science University, Portland, OR, (4)Department of Pediatrics, Oregon Health & Science University, Portland, OR, (5)Department of Medical Informatics and Clinical Epidemiology, Oregon Health & Science University, Portland, OR, (6)Department of Psychiatry, Oregon Health & Science University, Portland, OR

Background: Structural and pragmatic language deficits are core symptoms of Autism Spectrum Disorder (ASD) and predict long-term outcomes. Although language proficiency is a treatment target in early intensive behavioral interventions, measurement is cumbersome and costly. Better language outcome measures are needed. By analyzing language transcripts, our study generated Automated Discourse Measures (ADMs) that we tested for their convergent and discriminant validity across clinical groups.

Objectives: 1. examine language differences between three clinical groups (ASD, ADHD, and TD); 2. analyze the convergent validity of these measures by calculating correlations between the ADMs and standardized language measures; 3. investigate the accuracy of each individual ADM in predicting ASD status; and 4. examine if gains in accuracy would be obtained by combining all ADMs together in predicting ASD status.

Methods: 169 participants (96 ASD, 28 Typically Developing (TD), 45 Attention Deficit Hyperactivity Disorder (ADHD)) ages 7 to 17 were evaluated with the Autism Diagnostic Observation Schedule (ADOS-2), module 3. ADOS tasks were transcribed following SALT guidelines. Transcripts of one task were automatically analyzed with novel software to generate seven ADMs for each participant: Mean Length of Utterance in Morphemes (MLUM), Number of Different Word Roots (NDWR), um proportion, content proportion, unintelligible proportion, c-units per minute (CPM), and repetition proportion.

Results: With the exception of repetition proportion ( $p = .07$ ), nonparametric ANOVAs (Kruskal-Wallis) showed significant group differences ( $p < .01$ ). The TD and ADHD groups did not differ from each other in post-hoc analyses for the seven ADMs. The ASD group showed significantly lower language skills. The highest effects sizes were found for content proportion and CPM. The ADMs were correlated with standardized clinical evaluations of ASD, which provided support for their convergent

validity. In logistic regression analyses adjusted on age and IQ, four ADMs were found to significantly predict ASD versus non-ASD status with accurate classification ranging from 67.9% to 75.5%. When combined together in one model, an overall correct classification rate of 82.4% was achieved. We estimated ROC curves using the class prediction probabilities drawn from the logistic regression models. The combined model using all seven ADMs had the highest AUC of 0.9223, followed by the individual model for content proportion with an AUC of 0.8149.

Conclusions: All seven ADMs show an improved accuracy of ASD prediction over a baseline model using only age and IQ; a combined model achieves a highly improved prediction model for ASD diagnosis using easily classifiable language measurements. These ADMs offer a promising approach for generating novel outcome measures.

**413.020 (Poster)** Examining the Impact of Electronic Toys on Social Interactions between Young Children with Autism Spectrum Disorder and Their Parents

*M. Sturman<sup>1</sup> and C. E. Venker<sup>2</sup>, (1)CSD, Michigan State University, East Lansing, MI, (2)University of Wisconsin-Madison, Madison, WI*

---

Background: In recent years, ‘traditional’ toys have, in large part, been replaced by electronic toys with colorful flashing lights, talking voices, and musical tunes. Though electronic toys are often marketed as being beneficial for children’s development, numerous studies suggest that the opposite may be true. For example, electronic toy play has been shown to elicit fewer adult words, fewer parent-child conversational turns, and lower rates of maternal responsiveness than traditional toy play. Though most studies on electronic toys have focused on children with typical development, the effects of electronic toy play may be even more important to consider in the case of children with autism spectrum disorder (ASD), who are at heightened risk for language delays.

Objectives: The goal of this study was to determine how electronic toy play impacted the quality of parent language input, compared to traditional toy play.

Methods: Participants were 10 children with ASD (2-4 years old) and one of their parents. Most children showed severe delays in language and cognitive skills. Data collection is ongoing; additional data will be included in the presentation. Each parent-child dyad took part in two 10-minute play samples—one on each day of their two-day research visit. Parents were instructed to play with their child like they normally would at home. Dyads received the traditional toy set on one day and the electronic toy set on the other day (counterbalanced across participants). Each toy set included a barn with animals, a shape sorter, spiky sensory balls, three vehicles, a puzzle, and a pull toy dog (see Figure). Videos of the samples were transcribed by trained research assistants using Systematic Analysis of Language Transcripts (SALT) software.

Results: Given the limited sample size, Wilcoxon signed-rank tests were used to compare the quality of parent language input between toy types. Parent lexical diversity (number of different words per minute) was significantly higher during traditional toy play than during electronic toy play ( $p = .027$ ). Parent mean length of utterance did not significantly differ between toy types ( $p = .700$ ). The number of parent utterances per minute also did not significantly differ between toy types ( $p = .110$ ), though traditional toy play elicited more parent utterances than electronic toy play in an absolute sense. Parents paused between utterances significantly more often during electronic toy play than during traditional toy play ( $p = .010$ ).

Conclusions: Though preliminary, the findings of the current study suggest that electronic toy play may elicit lower quality language input from parents of children with ASD than traditional toy play. These findings mirror the results of experimental studies focused on children with typical development. Given the importance of providing high-quality language input to children with ASD, the potential impact of toy type should be considered in both clinical and research settings. Findings from this and future studies will help clinical professionals make informed recommendations to parents—particularly those taking part in parent-mediated interventions designed to facilitate children’s language and communication skills.

**413.021 (Poster)** Facing Your Fears: Collaborating with Autistic Young Adults to Adapt an Evidence-Based Anxiety Intervention

*K. L. Baldwin<sup>1</sup>, B. Freedman<sup>2</sup> and J. Monahan<sup>3</sup>, (1)Spectrum Scholars, University of Delaware, Newark, DE, (2)Center for Disabilities Studies, University of Delaware, Newark, DE, (3)University of Delaware, Newark, DE*

---

Background: While research on evidence-based interventions for children and adolescents with co-occurring autism and anxiety is available, a dearth of research exists on how autistic young adults experience anxiety and how interventions can support these challenges. Previous research on intervention design and implementation has largely neglected to account for the preferences and

self-reported needs of autistic students. Allowing students with autism to have a voice in how interventions for them are created or adapted can improve the validity and efficacy of a newly proposed intervention. Thus, in planning to adapt a current evidence-based anxiety intervention to meet the needs of autistic college students, critical feedback from autistic college students was gathered through focus group and online survey formats.

Objectives: This study sought to answer the following questions:

- How do autistic college students experience anxiety in the college setting?
- Given an evidence-based anxiety intervention for autistic adolescents, what recommendations do autistic college students have for adapting the curriculum to the college setting?

Methods: Students registered at the disability office at the University of Delaware who identified as autistic were recruited for participation in the focus group via email invitations. Five students attended the focus group. The focus group was held virtually over a 1.5-hour Zoom session. Following the focus group, twelve other students who expressed interest in study participation were sent a Qualtrics survey with the focus group questions. This data is currently being collected (and not included in the results below). The focus group data was coded using the Rigorous and Accelerated Data Reduction (RaDaR) technique (Watkins, 2017).

Results: According to initial analyses of the focus group, participants commonly experienced anxiety due to sensory overstimulation, presence in social spaces and situations, and academic- or career-related stressors. Descriptions of students' anxiety experiences varied from displaying anxiety-related behaviors to struggling to eat or feeling physical pain. Similarly, students found that their anxiety impacted them in many different circumstances, and they reported using a variety of coping strategies to manage their anxiety. Participants voiced that receiving social support from a peer or mentor, learning how to identify their anxiety symptoms, and promoting autistic students' independence by offering a treatment that limits parental involvement would be both helpful and appropriate goals for the adapted intervention.

Conclusions: Autistic college students experience anxiety in many ways that are similar to neurotypical students' experiences of anxiety. In terms of recommendations for adapting the *Facing Your Fears* intervention, participants' clear preference for excluding parents from involvement presents a challenge and opportunity, given the current use of parents as coaches in other versions of the intervention. Participants' viewpoints on parental involvement, as well as their expressed desires to learn about their anxiety and related coping strategies, can inform the further adaptation of interventions for young adults on the spectrum.

**413.022 (Poster)** Figurative Language Comprehension in Hong Kong Children with Autism Spectrum Disorders: The Role of Theory of Mind and Conventionality

C. C. H. Cheung<sup>1</sup>, Y. Rong<sup>1</sup>, Y. Xiong<sup>2</sup>, M. T. Leung<sup>2</sup> and T. P. Y. Tang<sup>2</sup>, (1)Research Centre for Language, Cognition, and Neuroscience, Department of Chinese and Bilingual Studies, The Hong Kong Polytechnic University, Hong Kong, Hong Kong, (2)Department of Chinese and Bilingual Studies, The Hong Kong Polytechnic University, Hong Kong, Hong Kong

---

Background:

While deficit in comprehending figurative language is regarded as a defining characteristic of individuals with autism spectrum disorders (ASD), the role of theory of mind (ToM) is controversial. Happé (1993) found that first- and second-order ToM understanding were needed for metaphor and irony comprehension, respectively, in English speakers with ASD. In contrast, Huang et al. (2015) showed that first-order ToM understanding was needed for Taiwanese autistic children's comprehension of metaphor and irony. However, Japanese autistic children lacking first-order ToM understanding were found to comprehend metaphors as well as their typically developing (TD) peers (Adachi et al., 2006). In sum, previous findings suggest that the relation between figurative language comprehension and ToM understanding is subject to cross-cultural variation (Huang et al., 2015), and the conventionality of the figurative language might play a role (Oi et al., 2013).

Objectives:

This study examined the comprehension of four types of figurative language (metaphor, irony, indirect request, and indirect reproach) in Hong Kong autistic children and their TD peers to investigate (i) the relation between children's figurative language comprehension and ToM understanding; and (ii) the role of conventionality in figurative language comprehension.

Methods:

37 Hong Kong Cantonese-speaking children with ASD (mean age = 8.64,  $SD = 1.33$ ) and 37 TD children (mean age = 7.94,  $SD = 0.78$ ) participated. To measure figurative language comprehension, 32 scenarios were described, each ending with a figurative utterance. Participants indicated the intended meaning of the figurative utterance by selecting among five choices. First- and second-order ToM understanding were assessed using the Sally-Anne test and the Ice-Cream Van test, respectively. Standardized tests measured language ability and nonverbal intelligence (Raven, 1989; T'sou et al., 2006). 52 Hong Kong adults rated the conventionality of each figurative utterance.

#### Results:

Regression analyses showed that for the ASD group, after controlling for the effects of age, language ability, and nonverbal intelligence, first-order ToM understanding predicted comprehension of metaphor and irony, while neither first- nor second-order ToM understanding predicted comprehension of indirect request and indirect reproach. For the TD group, after controlling for the same effects, neither first- nor second-order ToM understanding predicted comprehension of any type of figurative language. The results of pairwise comparison after Bonferroni adjustment showed that metaphor and irony were both rated as less conventional than indirect request and indirect reproach, while no significant difference was found between metaphor and irony, or between indirect request and indirect reproach.

#### Conclusions:

Our finding regarding autistic children's comprehension of metaphor is consistent with Happé's (1993) and Huang et al.'s (2015) findings, but differs from Adachi et al.'s (2006), thus providing additional evidence that the relation between figurative language comprehension and ToM understanding is subject to cross-cultural influence. Our finding also showed that metaphor and irony were considered less conventional compared to indirect request and indirect reproach, suggesting that autistic children's comprehension of less conventional figurative languages might rely more heavily on ToM understanding.

**413.023** (Poster) Frequency, Form, and Function: Question-Asking in Young Children with Autism Spectrum Disorder  
C. Mitchell<sup>1</sup>, R. J. Luyster<sup>1</sup> and L. R. Naigles<sup>2</sup>, (1)Communication Sciences and Disorders, Emerson College, Boston, MA, (2)Psychological Sciences, University of Connecticut, Storrs, CT

---

Background: Questioning is a social and linguistic tool allowing children to learn from the people in their worlds. Early questions vary in form; typically-developing (TD) children develop *Yes/No* questions by 24 months and use linguistically-complex *Wh*-questions by 30 months. Questions also vary in function, serving information-seeking (e.g., *What's that?*), conversational initiation and maintenance (e.g., *What?*), and directive (e.g., *Can you help me?*) purposes. While TD preschoolers use questions that vary in form and function, less is known about question-asking in preschoolers with autism spectrum disorder (ASD). Children with ASD produce fewer questions overall, but little research has documented question form or function in this population, nor whether the various question forms and functions are reduced to the same extent.

Objectives: We investigated the (1) frequency, (2) form, and (3) pragmatic functions of questions in preschoolers with ASD and TD preschoolers.

Methods: A detailed coding scheme captured question form (i.e., *Yes/No* [e.g., *Is that a dino?*], *Wh*- [e.g., *Where the kitty?*], *Intonation* [e.g., *Blocks?*]) and function (i.e., *Information-seeking* [e.g., *You hungry?*], *Initiation & Maintenance* [e.g., *Huh?*], *Directive* [e.g., *Can I have a turn?*]). Two independent raters coded four 30-minute play interactions, at four-month intervals, for each of 12 mother-child dyads (6 ASD; 6 TD), a subset of an existing longitudinal dataset. All child questions were coded; discrepancies were brought to consensus.

The groups were matched at the initial visit by child gender (five males and one female in each group) and language level. At the initial visit, the average mean length of utterance (MLU) for each group (i.e., >2.0) corresponded with a developmental period in which question-asking would be present (Table 1). Given the small sample size, these exploratory analyses are qualitative in nature.

#### Results:

*Frequency:* At each time point, children in the ASD group asked roughly half as many questions as their TD counterparts, confirming previous evidence of reduced question-asking among children with ASD (Figure 1).

*Form:* The ASD group relied disproportionately more than the TD group on *Yes/No* questions (see Figure 1).

*Function:* The groups were similar to one another in their proportional reliance on *Information-seeking* questions, with a substantial minority of *Directive* and *Initiation & Maintenance* questions. However, the TD group tended to ask disproportionately more *Initiation & Maintenance* questions than the ASD group, while the ASD group relied disproportionately more on *Directive* questions than their TD counterparts. See Figure 1.

*Conclusions:* Of note was the disproportionate reliance on *Yes/No* questions observed in the ASD group, a finding consistent with their delayed acquisition of *Wh-* questions. Despite these differences, children with ASD showed diverse question-asking capabilities, comprised of a flexible range of forms and functions. Questioning offers children the opportunity to practice their pragmatic skills and enhance their world knowledge. A reduction in question-asking frequency suggests that children with ASD may be missing out on important opportunities to learn from their social partners. Results support interventions targeting frequency of question-production in young children with ASD.

**413.024** (Poster) *Gesture Variability during Narrative Production in 5-7-Year-Olds: A Comparison of Children with ASD or TD*  
**K. Nguyen<sup>1</sup>, L. R. Naigles<sup>2</sup> and M. Jyotishi<sup>3</sup>, (1)Department of Psychology, University of Connecticut, Storrs, CT, (2)Psychological Sciences, University of Connecticut, Storrs, CT, (3)Applied Survey Research, San Jose, CA**

---

*Background:* Gesture use is frequently described as atypical in ASD. For example, early in development, both HR-ASD infants and preschoolers with ASD are reported to show slower rates of gesture development (Iverson et al., 2017), produce fewer gestures overall (LeBarton & Iverson, 2016), and specifically use fewer deictic gestures, than their TD and HR-noASD peers (LeBarton & Iverson 2016, Ozcaliskan et al. 2015). However, by adolescence, high verbal individuals with ASD have been found to use the same number and same types of gestures as language- and age-matched TD peers, with differences observed at more subtle levels, such as speech-gesture synchrony (deMarchena & Eigsti 2010). Investigations of the use of gesture in children between infancy and adolescence are rare, so it is unknown when in development children with ASD may ‘catch-up’ in their gesture usage.

*Objectives:* The current study investigates gesture usage during narrative production in children 5- to 7-years of age, who are either TD or diagnosed with ASD.

*Methods:* Participants included 14 children either TD (N=7, M=5.52 years) or diagnosed with ASD (N=7, M=6.38 years), who were participating in a longitudinal study on language development. At the longitudinal study’s onset, the children were language-matched; however, at this visit, the TD children’s TACL scores were significantly higher than those of the ASD group ( $M_{ASD}=83.71, M_{TD}=116.9, p=.009$ ). As part of their participation in the ADOS, each child narrated one story from a book (*Tuesday* or *Frog, Where Are You?*) and two from cartoons (monkey, fisherman) in which they were asked to retell the story from memory. All tasks were transcribed and coded for the type of gesture (deictic and iconic), the number of body parts used per gesture (1 hand, 2 hands, or full body), and whether the gesture included movement.

*Results:* Between-group comparisons of the children’s number of utterances ( $M_{ASD}=37.0, SD=9.29; M_{TD}=44.57, SD=8.36$ ) and total gestures ( $M_{ASD}=10.57, SD=8.65; M_{TD}=11.14, SD=8.36$ ) were not significant ( $p > .10$ ). Mann-Whitney U-tests also revealed no significant group differences for any gesture subtype (see Figure 1; Mann-Whitney  $U_s > 15, p_s > 0.25$ ). Enormous within-group variability in gesture use was observed, with every pattern of gesturing observed in the TD group also manifested by at least one child with ASD. For example, two children with ASD and one TD child each produced a high (>20) number of 1-handed deictic gestures; one TD child and one child with ASD both produced predominantly iconic two-handed or full-body gestures, and one child with ASD and two TD children each produced fewer than 5 gestures total.

*Conclusions:* All coded types of gesture were attested at similar frequencies in both groups. Overall, 6-year-old children with ASD appear to have caught up to the gesture usage of their TD peers. At this age, the children differed widely within groups, with some gesturing rarely, others primarily with points, and still others primarily with 2-handed or body movements. Future analyses will include at least 5 more children in each group and will investigate the developmental precursors to this variability in gesture use.

**413.025** (Poster) *Hierarchical Acoustic Structure during Parent-Child Interactions of Toddlers with Typical Development and Autism Spectrum Disorder*  
**O. Boorom<sup>1</sup>, V. A. Munoz<sup>1</sup>, C. Alviar Guzman<sup>2</sup>, C. Kello<sup>2</sup> and M. D. Lense<sup>1</sup>, (1)Vanderbilt University Medical Center, Nashville, TN, (2)University of California Merced, Merced, CA**

---

**Background:** Timing is essential for successful social interactions, as exemplified by interactional variables like interpersonal synchrony and parental responsiveness, which support the development of communication and language skills in children with and without ASD (Siller & Sigman, 2002; Hudry et al., 2013). The importance of timing is also evident in caregivers' vocalizations to young children: compared to adult-directed speech, the prosodic variation of infant-directed speech exhibits greater hierarchical temporal structure, or clustering of acoustic events across multiple linguistic timescales (e.g., syllables nested within phrases nested within utterances), which likely supports children's attention to the speech signal and their developing communication skills (Falk & Kello, 2017). However, hierarchical temporal structure has not yet been examined across a dyadic interaction, with both parent and child contributing to the acoustic signal, and has not been applied to a clinical population.

**Objectives:** In consideration of the transactional nature of parent-child interactions, we examined acoustic temporal clustering of parent-child interactions in dyads of toddlers with and without ASD.

**Methods:** 50 parent-child dyads (15 ASD; 36 TD (22 nonverbal MA-matched, 13 verbal MA-matched)) were audio-recorded during a 10-minute parent-child free play activity. Peak amplitude events in audio recordings were used to compute Allan Factor variances, which reflects event clustering at multiple time scales (from a 0.0146 second scale to a 30 second scale) Quadratic slopes were fit across each dyad's Allan Factor functions to quantify acoustic clustering patterns across timescales. Slopes of nonverbal MA-matched, verbal MA-matched TD dyads, and ASD dyads were compared using Welch two-sample t-tests.

**Results:** Overall, the slopes derived from Allan Factor analysis of dyadic interactions were significantly lower in the TD nonverbal MA-matched cohort ( $M = 0.68$ ,  $SD = 0.086$ ) than the ASD cohort ( $M = 0.75$ ,  $SD = 0.082$ ),  $t(28.7) = -2.76$ ,  $p = 0.01$ . However, the slopes were comparable in the ASD and verbal MA-matched cohort ( $M = 0.75$ ,  $SD = 0.074$ ),  $t(25.9) = 0.093$ ,  $p = 0.93$ . The magnitude of slopes indicates greater hierarchical clustering (steeper Allan Factor functions) of the acoustic signal in the dyads with children with ASD versus nonverbal MA-matched children with TD, particularly in longer timescales corresponding to phrase-level speech, but similar levels of hierarchical clustering when compared to the verbal MA-matched dyads.

**Conclusions:** This is the first study to examine multi-scale acoustic temporal structure across both partners in a dyadic interaction, as well as in a clinical population of toddlers with ASD. Results add to evidence that temporal clustering is impacted by social communicative factors with greater hierarchical temporal structure in parent-child dyads of toddlers with ASD versus TD nonverbal MA-matched toddlers. Accordingly, the similar degree of acoustic clustering between the ASD and verbal MA-matched sample indicate that higher slopes in the ASD cohort may be related to adaptations in interpersonal vocal dynamics based on the vocal skill of the communication partner. Future analyses will investigate characteristics, such as turn-taking and vocal durations, that may impact acoustic temporal clustering.

#### **413.026 (Poster)** How Do Bulgarian- and English-Speaking Parents Refer to Their Children with ASD?

*M. Barokova and H. Tager-Flusberg, Department of Psychological and Brain Sciences, Boston University, Boston, MA*

---

**Background:**

Almost every description of language ability in ASD contains a mention of pronoun difficulty (e.g., Lord & Luyster, 2009; Kanner, 1946; Rutter, 1979; Tager-Flusberg et al., 2005). In addition, parents of high-risk infants use their child's name more than parents of low-risk infants (He et al., 2018), and how parents use person-reference correlates with the way their children do (Barokova & Tager-Flusberg, 2019). However, all of these studies were done with English-speaking participants. The present study compares English and Bulgarian as a substantially different language (Gordon et al., 2005). Specifically, it is a pro-drop language (personal pronouns are optional), and it has a very rich diminutive system that allows common and proper nouns to be changed (e.g., slynce -> slunchice; Sasho -> Sashko -> Sashence). Furthermore, it is a common practice for parents to use kinship terms (mommy, daddy) to refer to their child.

**Objectives:**

To compare how Bulgarian- and English-speaking parents refer to their children with ASD (**Table 1**).

**Methods:**

37 (7F) Bulgarian-speaking children between 2;7 and 9;10 years ( $M = 70.62$ ) with a community diagnosis of ASD or PDD based on ICD-10, and confirmed on the ADOS-2 participated in this study. Parents completed a demographic questionnaire and played with their child with developmentally appropriate toys. These parent-child interactions were transcribed in SALT following

standard procedures (Miller et al., 2011), and coded for how the parent referred to and addressed their child and themselves (Table 1).

Transcripts of 37 (7F) English-speaking children with ASD between 1;8 and 4;9 years ( $M = 37.97$ ) (from Carter et al., 2007) were matched to the Bulgarian-speaking children on the Number of Different Words (NDW) they produced per minute during the parent-child interaction. The English transcripts were also coded for person-reference. Coding reliability ( $ICC > 90\%$ ) on 20% of the transcripts was achieved in both languages.

#### Results:

Parental input across languages was compared with independent-samples t-test and Mann-Whitney U tests, where appropriate, and the Bonferroni multiple-comparison correction was applied. Bulgarian parents used fewer personal pronouns (you, your;  $M = 34.86$ ,  $SD = 21.61$ ) than English-speaking parents ( $M = 71.66$ ,  $SD = 13.84$ ;  $t(72) = -8.956$ ,  $p < .001$ ), but used their child's name (John, Johnny) and kinship terms (ma, mommy, mom) significantly more (Table 2). In addition, Bulgarian parents had a significantly higher child reference type/token ratio (Mann-Whitney  $U = 107$ ,  $p < .001$ ).

#### Conclusions:

Bulgarian parents used significantly fewer personal pronouns, which could be attributed to the pro-drop nature of the language. Furthermore, they used more different ways to address their child (type/token ratio), which could be explained by the widely used diminutive forms of nouns. Interestingly, 20% of Bulgarian parents' person-reference was made up of kinship terms, which has not been reported in the ASD literature. Imagine a child being called Jonathan, John, Johnny, honey, sweetie, ma, mom, mommy in a single interaction, and how that could be associated with the child's ability to track the referent and language skills overall. Future studies should examine whether and how parent and child person-reference are associated.

**413.027 (Poster)** Investigating IQ, Sex, Attention, and Anxiety As Determinants of Social Communication Difficulties: Data from the Pond Network

**J. Nguyen<sup>1</sup>**, E. Anagnostou<sup>2</sup>, J. A. Brian<sup>1</sup>, E. Kelley<sup>3</sup>, M. Ayub<sup>3</sup>, J. Crosbie<sup>4</sup>, R. Schachar<sup>5</sup>, S. Georgiades<sup>6</sup>, R. Nicolson<sup>7</sup> and A. Kushki<sup>8</sup>, (1)Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (2)Autism Research Center, Bloorview Research Institute, Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (3)Queen's University, Kingston, ON, Canada, (4)Psychology, The Hospital for Sick Children, Toronto, ON, Canada, (5)Psychiatry, The Hospital for Sick Children, Toronto, ON, Canada, (6)McMaster Autism Research Team, McMaster University, Hamilton, ON, Canada, (7)University of Western Ontario, London, ON, Canada, (8)Bloorview Research Institute, Toronto, ON, Canada

---

#### Background:

Social communication difficulties are a core diagnostic domain of autism spectrum disorder (ASD), a multi-faceted neurodevelopmental disorder. They can affect academic, friendship and peer acceptance outcomes as social communication skills are required for everyday interactions.

Despite social communication difficulties being universally pervasive in ASD, the etiology is not well understood. In addition to proposed neurobiological mechanisms, other factors such as IQ, sex, attention, and anxiety have been found to affect social communication in ASD.

#### Objectives:

To determine the differential contribution of IQ, attention, and anxiety to social communication abilities across diagnoses (ASD, attention deficit hyperactivity disorder (ADHD), obsessive-compulsive disorder (OCD)) and typical development (TD).

#### Methods:

In the study, we included 565 participants from the Province of Ontario Neurodevelopmental Disorders (POND) network, a multi-centre research network that studies neurodevelopmental disorders. Participants included 310 with ASD (age =  $12.6 \pm 2.9$ ; 241 males), 121 ADHD (age =  $10.8 \pm 2.4$ ; 91 males), 80 OCD (age =  $12.9 \pm 2.5$ ; 43 males) and 54 TD (age =  $12.1 \pm 2.7$ ; 30 males).

27 items from the Social Communication Questionnaire - Lifetime (SCQ; Rutter et al., 2003), assessing social communication, reciprocal interaction, and reciprocal conversation, were used as the measure of social communication difficulties. The Wechsler Abbreviated Scale of Intelligence—Second Edition (Wechsler, 2011), Child Behavior Checklist (Achenbach & Edelbrock, 1983), and Revised Children's Anxiety and Depression Scales (Chorpita et al., 2014) were used to measure IQ, attention, and anxiety, respectively.

Multiple linear regression analysis was used to quantify the marginal effects of each determinant, controlling for the effects of diagnosis and age. For each of the 27 items, we conducted multiple logistic regression, controlling for diagnosis and age as well as applying Bonferroni correction for multiple comparisons.

### Results:

The results of the regression indicated that the linear model explained 54.2% of the variance and that the model was a significant predictor of social communication difficulties,  $F(8, 565) = 84.6$ , corrected  $p < 0.0001$ . While IQ ( $\beta = -0.081$ , corrected  $p < 0.0001$ ) and sex ( $\beta = 1.98$ , corrected  $p < 0.0001$ ) each contributed significantly to the model, with attention having a marginal effect ( $\beta = 0.068$ , corrected  $p = 0.071$ ). The effect of anxiety was not significant ( $\beta = 0.015$ , corrected  $p = 1.0$ ).

There were also significant item-level findings (Table 1). Anxiety was a significant predictor of neologisms. Attention was a significant predictor of stereotyped utterances, inappropriate questions, and neologisms. Male sex was a significant predictor of four items: imitative social play, imaginative play, interest in children, group play. IQ was significantly predictive of 18 out of 27 items, the top three items being pronoun reversal, conversation, and showing and directing attention.

### Conclusions:

Consistent with previous literature, we found a significant effect of IQ and sex on social communication difficulties, with male sex having the most pronounced association. We were unable to replicate a significant association between anxiety and anxiety with social communication. Our findings are a preliminary step toward determining potentially personalized supports.

#### 413.028 (Poster) Investigation on Examiner "Um" and "Uh" Usage in ADOS-2 Sessions

**G. O. Lawley<sup>1</sup>**, S. Bedrick<sup>2</sup>, J. K. Dolata<sup>3</sup> and E. Fombonne<sup>4</sup>, (1)Computer Science and Electrical Engineering, Oregon Health & Science University, Portland, OR, (2)Department of Medical Informatics and Clinical Epidemiology, Oregon Health & Science University, Portland, OR, (3)Department of Pediatrics, Oregon Health & Science University, Portland, OR, (4)Department of Psychiatry, Oregon Health & Science University, Portland, OR

Background: Studies have found that children with Autism Spectrum Disorder (ASD) use the filler "um" at a significantly lower rate than children with Typical Development (TD), with no difference in "uh" usage. Examiners' filler usage in similar conversational language samples has not been studied. We investigated whether differences in "um" and "uh" usage between ASD and TD children also characterize the speech of their conversational partners: the examiners.

Objectives: (1) Compare examiner usage rates of "um" and "uh" when conversing with ASD vs. TD participants; (2) Investigate whether within-group differences in examiner filler usage vary by participant age, intellectual ability, expressive language ability, or autism symptom severity.

Methods: Participants were recruited for an fMRI study. They were 7 to 17 years old, spoke native English, had full-scale IQ  $\geq 70$ , and consisted of 83 children with ASD (68 male) and 28 with TD (12 male). Language samples consisted of transcribed Autism Diagnostic Observation Schedule (ADOS-2) Module 3 sessions. Transcription was completed by trained transcribers who were blind to the participants' diagnostic status and intellectual abilities in accordance with the Systematic Analysis of Language Transcripts (SALT) guidelines. Four ADOS-2 tasks were chosen for analysis: *Emotions; Social Difficulties and Annoyance; Friends, Relationships, and Marriage; Loneliness*.

We computed three measures of filler usage:  $um\text{-rate} = total\ um / total\ words$ ;  $uh\text{-rate} = total\ uh / total\ words$ ;  $um\text{-ratio} = total\ um / (total\ um + total\ uh)$ . Examiner filler usage rates between diagnostic groups were compared using Wilcoxon-Mann-Whitney tests, with effect sizes calculated using Glass rank biserial correlation coefficients. Associations between examiner *um-rate* and participant-level measures were measured with Kendall rank correlation coefficients, with  $p$ -values adjusted using the Benjamini-Hochberg procedure to reduce false discovery rate.

Results: There was a significant difference in examiner *um-rate* between ASD and TD ( $U = 763.0, p = .007; ASD < TD$ ), with a medium effect size ( $r_{pb} = -.343$ ; Table 1). There was no significant difference in examiner *uh-rate* between ASD and TD ( $U = 1,038.0, p = .399$ ) or in examiner *um-ratio* ( $U = 1,017.5, p = .369$ ).

Examiner *um-rate* was significantly positively correlated with both participants' age ( $\tau_b = .280, p_{adj.} = .002$ ) and mean length of utterance in morphemes (MLUM) ( $\tau_b = .220, p_{adj.} = .018$ ; Table 2). There was no significant correlation between examiner *um-rate* and any of the following participant-level measures: full-scale IQ; number of distinct word roots; Children's Communication Checklist (CCC-2) General Communication Composite, structural language score, pragmatic language score; ADOS-2 Social Affect total, Comparison Score.

Conclusions: Examiners use the filler "um" significantly less with children with ASD than children with TD, which mirrors previous results on "um" usage in ASD and TD. We also found that examiner "um" usage is positively associated with participant age and MLUM but not with more strenuous participant-level measures of expressive language ability and autism symptom severity. Because analyses did not control individual differences between examiners, these results should be interpreted with caution. Further analyses that account for examiner-level measures are needed.

**413.029 (Poster)** Language Profiles of Russian Primary-School-Aged Children with Autism Spectrum Disorder  
*V. Arutunian<sup>1</sup>, A. Lopukhina<sup>1</sup>, A. Minnigulova<sup>1</sup>, A. Shlyakhova<sup>1</sup>, E. Davydova<sup>2</sup>, D. Pereverzeva<sup>2</sup>, A. Sorokin<sup>2,3</sup>, S. Tyushkevich<sup>2</sup>, U. Mamokhina<sup>2</sup>, K. Danilina<sup>2</sup> and O. Dragoy<sup>1,4</sup>*, (1)Center for Language and Brain, HSE University, Moscow, Russian Federation, (2)Federal Resource Center for ASD, Moscow State University of Psychology and Education, Moscow, Russian Federation, (3)Haskins Laboratories, New Haven, CT, (4)Federal Center for Stroke and Neurotechnologies, Moscow, Russian Federation

Background: Language impairments are usually co-occurred in children with Autism Spectrum Disorder (ASD) and affects all linguistic levels, from phonology to discourse (e.g., Jarrold et al., 1997; Kjelgaard & Tager-Flusberg, 2001). However, there is a high variability of language skills in ASD due to the high heterogeneity of autistic groups as well as criteria for including children into studies, e.g., age or non-verbal IQ.

Objectives: The goal of the present study is to investigate the language abilities of primary-school-aged Russian children with ASD at all linguistic levels (phonology, vocabulary, morphosyntax, and discourse) and to clarify which non-language factors, such as age, non-verbal IQ, and the severity of autistic traits, predict better the language functioning.

Methods: 107 children participated in the study: 82 children with ASD (17 girls,  $M_{age} = 9.11, SD = 11.5$ ), varying in non-verbal IQ (range 40 – 125), and a control group of 25 typically developing children, TD (11 girls,  $M_{age} = 9.1, SD = 1.0$ ). All children with ASD had a clinical diagnosis within the autism spectrum (F84.0, F84.1 or F84.5) according to ICD-10 and 67 out of 82 children with ASD were assessed by licensed psychiatrist with Autism Diagnosis Observation Schedule-2 (Lord et al., 2012).

Language abilities were measured with the Russian Child Language Assessment Battery (Lopukhina et al., 2019), consisted of 13 tests assessing all linguistic levels in production and comprehension (see detailed information on each test, <https://osf.io/h9jzbz/>). Non-verbal IQ of ASD children was screened with the Kaufman Assessment Battery for Children, K-ABC II (Kaufman and Kaufman, 2004), and Wechsler Intelligence Scale for Children – Third Edition, WISC-III (1991), only the non-verbal scale, where possible; non-verbal IQ of TD children with screened with the Raven's Colored Progressive Matrices (Raven 2000, 2004). The severity of autistic traits were measured with the Russian version of the Autism Spectrum Quotient: Children's Version, AQ (Auyeung et al. 2008) for both groups of children.

Results: We showed that children with ASD had lower scores in all language tests we used compared with TD children, excluding simplest *Word repetition* test (see tables with the model outcomes, <https://osf.io/275vq/>). Importantly, age and the severity of autistic traits did not predict language functioning in all tests in comparison to non-verbal IQ (Figure 1). Additionally, the results demonstrated that linguistic levels accounted for the general language abilities of children: according to more complex morphosyntax and discourse tests, fewer children with ASD were within the normal range unlike the results in simpler phonological and lexical tests.

Conclusions: Similarly to the previous studies, we showed a high variability of language skills in children with ASD and also that impairments appeared at all linguistic levels (Kjelgaard & Tager-Flusberg, 2001). Crucially, our results demonstrated that the severity of autistic traits and age did not predict language functioning whereas non-verbal IQ accounted for language abilities.

**413.030 (Poster)** Language Regression As a Predictor of Outcomes in Children with ASD through the Preschool Years

Background:

While Autism spectrum disorder (ASD) is characterized by difficulties in social/pragmatic communication, there is considerable variability in structural language outcomes. One early developmental factor that has been considered in explaining some of this variability is the early loss of previously attained skills, which is known as regression. Currently, evidence for differences in language outcomes between children with ASD with and without a history of regression is conflicting, due in part to inconsistencies in the operationalization of regression. By employing multiple definitions of regression, measuring outcomes with standardized language assessments at multiple time points, and distinguishing receptive and expressive language skills, the present study aimed to address several gaps in the current body of literature and provide needed clarification on language outcomes among children with ASD and regression.

Objectives:

This study sought to answer two primary research questions: 1) Do children with ASD and a history of language/communication regression demonstrate different language outcomes across the preschool years from children with ASD without a history of language/communication regression? 2) Among children with ASD with a history of language/communication regression, does number of words used before loss predict language outcomes across the preschool years?

Methods:

One hundred twenty-nine children with confirmed ASD diagnoses were followed through the preschool years (30-66 months) for a total of four visits. All participants met DSM-IV-TR criteria for ASD (the standard at the time of data collection) based on the Autism Diagnostic Observation Schedule (ADOS) Toddler Module, the Autism Diagnostic Interview – Revised (ADI-R), and clinician best estimate. At each visit, participants were administered a battery of assessments. ADI-R data from visit 1 (30 months) were used to define regression by three incrementally less strict criteria (see Table 1) and characterize pre-loss language skills. Language outcomes were measured by Preschool Language Scales 4<sup>th</sup> Edition (PLS-4) Expressive Communication (EC) and Auditory Comprehension (AC) raw scores from visit 2 (44 months) and visit 4 (66 months). Nonverbal cognition was measured by Mullen Scales of Early Learning (MSEL) nonverbal ratio IQ scores. Our analytic approach involved use of nonverbal cognition and age as covariates in analyses of covariance (ANCOVA) to examine group differences in language outcomes in question 1 and multiple regression models for predicting outcomes from words used before loss in question 2.

Results:

Children with a history of regression demonstrated lower receptive language skills and a greater discrepancy between expressive and receptive language skills (see Fig. 1) at 44 months, but not at 66 months. Among children with history of loss of any communication skill, number of words used before regression onset was predictive of receptive and expressive language skills at 44 months but not 66 months.

Conclusions:

Results indicated that regression in ASD may impair language development in the year following loss, but any negative impacts on language outcomes are transient and small in magnitude, disappearing by the time of school entry (66 months). These findings do not suggest that regression leads to a distinct language phenotype in ASD or requires a different approach to speech-language intervention.

**413.031 (Poster)** Lexical and Morphosyntactic Complexity of Echolalic Utterances in Low and Minimally Verbal Individuals with ASD

*L. Butler<sup>1</sup>, S. Shen<sup>2</sup>, C. G. La Valle<sup>3</sup>, S. Schwartz<sup>4</sup>, K. V. Chenausky<sup>5</sup> and H. Tager-Flusberg<sup>1</sup>, (1)Sargent College of Health and Rehabilitation Sciences, Boston University, Boston, MA, (2)Department of Speech, Language, and Hearing Sciences, Boston University, Boston, MA, (3)Department of Psychological and Brain Sciences, Boston University, Boston, MA, (4)Graduate Program for Neuroscience, Boston University, Boston, MA, (5)Neurology, Beth Israel Deaconess Medical Center, Boston, MA*

---

Background:

Echolalia is frequent in the speech of low verbal and minimally verbal (LV/MV) individuals with ASD, but it is often excluded from language sample analyses despite the communicative functions it serves (Prizant & Duchan, 1981; Roberts, 2014; Sterponi & Shankey, 2014). While evidence suggests that echolalic imitation does not affect the acquisition of grammar in children with ASD (Tager-Flusberg & Calkins, 1990), we do not know how it affects lexical development or its role in language use in LV/MV individuals with ASD (Tager-Flusberg & Kasari, 2013). In this study, we analyzed the lexical and morphosyntactic complexity of echolalic (versus nonecholalic) utterances in LV/MV individuals using recommended natural language sampling (Barokova & Tager-Flusberg, 2020).

Objectives:

1. How does the lexical complexity of echolalic utterances relate to the lexical complexity of nonecholalic utterances as measured by the number of different words (NDW)?
2. How does the morphosyntactic complexity of echolalic utterances relate to the morphosyntactic complexity of nonecholalic utterances as measured by mean length of utterance in morphemes (MLUm)?
3. How does the frequency of use of echolalic speech by MV/LV individuals relate to lexical and morphosyntactic complexity of nonecholalic utterances?

Methods:

We analyzed ADOS language samples from 49 individuals who had at least one intelligible nonechoed spoken word (MV: 34 (Module 1); LV: 16 (Module 2); age: 6-21,  $M=12.52$ ,  $SD=4.12$ ). Participant standardized assessment means are: ADOS overall CSS 7.46 (1.37), ADOS SA CSS 7.04 (1.42), ADOS RRB CSS 8.34 (1.55), nonverbal IQ 67.98 (20.72), PPVT raw score 55.96 (34.73). We used the Systematic Analysis of Language Transcripts software (SALT; Miller & Iglesias, 2015) to analyze lexical complexity (number of different words (NDW)) and morphosyntactic complexity (mean length of utterance in morphemes (MLUm)). Utterances were considered echolalic if they were repeated within the previous five examiner or examinee utterances. We included scripted recitation in echolalic utterances. Nonspeech and unintelligible utterances were excluded.

Results:

Analyses involved linear regression controlling for age, sex, nonverbal IQ and receptive vocabulary. For lexical complexity, echolalic NDW significantly predicted receptive vocabulary ( $\beta=.87$ ,  $t=2.74$ ,  $p<.01$ ) but not nonecholalic NDW (Figure 1). For morphosyntactic complexity, echolalic MLUm significantly predicted nonecholalic MLUm ( $\beta=.57$ ,  $t=3.26$ ,  $p<.01$ ). This result suggests LV/MV individuals with higher echolalic MLUm also have higher nonecholalic MLUm (Figure 2). For frequency of echolalia, the proportion of echolalic utterances predicted an interaction between nonecholalic NDW and receptive vocabulary ( $\beta=.00$ ,  $t=2.41$ ,  $p<.01$ ) (Figure 3). As the proportion of echolalic utterances decreased, nonecholalic NDW and receptive vocabulary increased.

Conclusions:

Morphosyntactic complexity in echolalic utterances predicted morphosyntactic complexity in nonecholalic utterances. This suggests that echolalia does not interfere with morphosyntactic development and aligns with previous findings that echolalia, in the form of imitation, does not affect the acquisition of grammar (Tager-Flusberg & Calkins, 1990). In terms of lexical development, however, we found echolalia in MV individuals with low nonecholalic NDW is more lexically complex and associated with lower receptive vocabulary. While echolalia does not affect morphosyntactic development, it interacts with lexical development. Future studies can further elucidate this relationship between echolalia and expressive/receptive vocabulary.

**413.032** (Poster) Making Autistic Children's Behavior Accountable: A Conversation Analytic Study of Classroom Interactions  
**S. Crowley<sup>1</sup>** and **K. Bottema-Beutel<sup>2</sup>**, (1)Boston College, Chestnut Hill, MA, (2)Lynch School of Education, Boston College, Chestnut Hill, MA

---

Background: Autistic children experience differences in social-communication, which impacts peer interactions. Within general education classrooms, paraprofessionals often guide autistic students through social interactions, under the assumption that paraprofessional support will foster social relationships (Giangreco, 2010). Few studies document how paraprofessional involvement influences autistic children's social interactions. In this qualitative, observational study, we micro-analyzed classroom interactions that included a paraprofessional, an autistic student, and at least one non-autistic student.

We focused on interactions in which participants provided an *account*. Accounts address unanticipated behavior (Scott & Lyman, 1968). Rejections, departures from routines, or violations of expectations, are often preceded or followed by accounts, which can be negotiated by participants until mutual understanding is reached (Firth, 1995; Raevaara, 2011).

**Objectives:** The purpose of this study is to use Conversation Analysis (CA) to explore: 1) how accounts are made relevant to interactions, and 2) who provides accounts, and whose conduct is construed as accountable.

**Methods:** Teachers and students from three elementary school classrooms in a school district participated. Each classroom had at least one autistic student who received special education services, and was assigned a paraprofessional. Classrooms were video-recorded three times, for thirty minutes each session. Following data collection, participants' talk was transcribed using detailed (CA) conventions (Jefferson, 2004). We then selected transcripts derived from video-recordings of small group activities that included the autistic student and paraprofessional. CA involves a period of 'unmotivated looking', whereby the research team examines transcripts to inductively identify phenomena related to the sequence organization of interaction (Schegloff, 2007). We selected *accounts* as a phenomena of interest.

**Results:** We found that autistic student's conduct was often construed as *accountable*, made evident when classmates, paraprofessionals, and sometimes autistic students themselves provided accounts for their words and actions. We identified 19 instances of accounts in our dataset. Interestingly, paraprofessionals provided accounts for mundane interactional moves made by autistic students. For example, Figure one provides a transcript of a paraprofessional providing an account for an autistic student who answers the question "when did you first lose a tooth" with the date she lost it ("January 23rd"). Thirty-seven percent of accounts addressed autistic students' talk and behavior and were provided by others, and only 21% were provided by the autistic student. In CA literature, accounts are almost always 'self-accounts'; they are provided by individuals accounting for their own behavior. 'Other-accounts', provided by someone other than who produced the behavior, are notable because they are often provided to a third party. This changes the participation framework so that the person whose behavior is deemed accountable becomes the subject of the talk, rather than a participant in talk (Goffman, 1981).

**Conclusions:** Because autistic children's behavior is often construed as departing from normative standards, accounts are an informative interactional phenomena for understanding how interactions with autistic children proceed. 'Other-accounts' provided by paraprofessionals addressed autistic children's mundane behavior that did not appear to be a threat to intersubjectivity. Additionally, these accounts have the unintended consequence of positioning autistic children as the 'talked about' rather than the 'talked to'.

**413.033 (Poster) Measurement of Pragmatic Language in ASD: Clinical Adaptations to the Pragmatic Rating Scale, School-Age (PRS-SA)**

**L. Bush<sup>1</sup>, E. F. Dillon<sup>2</sup>, N. Calderon<sup>1</sup>, A. Hirshman<sup>1</sup>, E. V. Ocampo<sup>3</sup> and L. Soorya<sup>3</sup>, (1)Psychiatry and Behavioral Sciences, Rush University Medical Center, Chicago, IL, (2)Psychiatry, RUSH University Medical School, Chicago, IL, (3)Department of Psychiatry, Rush University Medical Center, Chicago, IL**

---

**Background:** Pragmatic (i.e., social) language impairments are a core deficit among individuals with autism spectrum disorders (ASD). Available measures of pragmatic language, such as the Pragmatic Rating Scale for School-Age Children (PRS-SA; Landa, 2011) provide nuanced analyses of skills required in social interactions. The PRS-SA has been used extensively in research to evaluate pragmatic language during semi-naturalistic language samples in children with ASD (e.g., Klusek et al., 2014; Greenslade et al., 2018). However, it relies on long language samples (i.e., 45 minutes or more), and highly specialized and intensive training procedures, making it difficult for clinicians and researchers to easily implement in clinical contexts (Young et al., 2005). Thus, there remains a need for rapid assessment of pragmatics during naturalistic interactions.

**Objectives:** To evaluate preliminary reliability and validity of the PRS-SA on an abbreviated language sample to support assessment of pragmatic communication in clinical trials.

**Methods:** Preliminary data consisted of 13 children randomly selected from a larger participant sample of 40 children enrolled in an NIH-sponsored clinical trial targeting social behavior and social cognition (NCT02918864). The final sample will include all eligible and enrolled children. Children enrolled met criteria for ASD, were between the ages of 8 and 11, and had IQ scores greater than 80. The PRS-SA includes 34-operationally-defined items assessing discrete pragmatic language features. Items are scored using a three-point scale (0-2) indicating presence and degree of impairment for each item. The PRS-SA was coded by trained, reliable coders from video-recorded ADOS-2 samples in two ways: using the entire ADOS-2 assessment and using an abbreviated sample, i.e., first 15-minutes. Item-level reliability was examined to compare within participant scores between the two samples.

Results: The average percent of agreement between the two language samples was 53%. When items were collapsed (scores of 2 converted to 1) to indicate presence/absence of an item (regardless of severity), the average reliability was 66%. Items that occurred less frequently (e.g., overly formal language) and/or were dependent on quantifying the specific number of occurrences were less reliable than those items that were more global in nature and coding criteria (e.g., overall quality of reciprocal conversation).

Conclusions: Results from preliminary analyses highlight limitations of using an abbreviated language sample to capture pragmatic impairments. Given that many scores on the PRS-SA are based on counts of observed behaviors, the abbreviated sample may not provide enough opportunity to detect less frequent pragmatic features in children with less severe symptoms. However, more global rating items (e.g., reciprocal conversation; elaboration; eye contact) that do not depend on specific counts of observation but rather capture quality and appropriateness were significantly more reliable, particularly when using a two-point scale. Overall, preliminary findings suggest the need for continued investigation into adaptations of objective rating scales such as the PRS-SA to support clinicians and researchers in measuring this critical impairment. Future directions may include identification of the best types of abbreviated language samples for different language levels (e.g. conversation tasks) and reducing or adapting pragmatic language domains used in an abbreviated measure.

**413.034** (*Poster*) Moderators of Social Communication Growth during a Parent-Mediated Intervention.  
*K. M. Frost and B. R. Ingersoll, Psychology, Michigan State University, East Lansing, MI*

---

Background:

Recent research has demonstrated differences in developmental growth trajectories among children whose caregivers receive parent-mediated interventions. One study found that a parent responsiveness intervention showed effects for children with fewer baseline language skills (Siller, Hutman & Sigman, 2013). Another study of a parent-mediated naturalistic developmental behavioral intervention (NDBI) with infant siblings of a child with autism found that only children with the fewest cumulative risk factors demonstrated significant treatment effects (Yoder, Stone & Edmunds, 2020).

Objectives:

The goal of this study was to examine moderators of social communication growth in a heterogeneous sample of children on the autism spectrum.

Methods:

Participants were 68 children and their caregivers who participated in two research studies evaluating the efficacy of a low-dose parent-mediated NDBI delivered via telehealth. All caregivers in this sample received some study intervention, either self-directed or with the support of a coach, and most were enrolled in additional services in the community. Caregiver-child interactions of a play routine and a snack routine were filmed in family homes at three time-points (pre- and post-intervention, and a 3-month follow-up) and rated for child social communication using the Brief Observation of Social Communication Change (BOSCC). We evaluated moderators of social communication growth using multilevel linear growth models with child as the upper-level unit and trial as the lower-level unit. Specifically, we were interested in the effects of baseline age, autism symptom severity, and verbal developmental quotient on social communication growth over time. Our model included fixed main effects and interaction terms (with time) for each of our predictors of interest. We expected that children who were younger, with a higher verbal developmental quotient, and with lower autism symptom severity would demonstrate greater social communication growth.

Results:

We found significant main effects of time ( $p = .004$ ), baseline age ( $p = .006$ ), and verbal developmental quotient ( $p < .001$ ), but not autism symptom severity ( $p = .085$ ). The only significant interaction term was the time\*age interaction ( $p = .049$ ), such that children whose age was 1 standard deviation below the mean demonstrated significant improvement in BOSCC score over time ( $b = -1.00$ ,  $p = .009$ ), while children whose age was 1 standard deviation above the mean did not ( $b = .094$ ,  $p = .795$ ). The interaction between time and autism symptom severity ( $p = .172$ ) and between time and verbal developmental quotient ( $p = .898$ ) were not significant.

Conclusions:

Our study found that age significantly predicted subsequent social communication growth, while autism symptom severity and baseline verbal developmental quotient did not. Specifically, we found that younger children's social communication scores improved more over the course of the intervention period, consistent with the field's understanding of neuroplasticity and clinical recommendations for beginning social communication intervention early. Understanding for whom parent-mediated intervention are most efficacious has implications for treatment matching and the ideal timing of early social communication intervention.

**413.035 (Poster)** Multi-Talker Speech Perception Thresholds in Young Adults with Autism Spectrum Disorder

**K. A. Emmons<sup>1</sup>, A. M. Estes<sup>1</sup>, S. R. Dager<sup>2</sup>, A. K. Lee<sup>1</sup> and B. K. Lau<sup>3</sup>,** (1)Speech and Hearing Sciences, University of Washington, Seattle, WA, (2)Radiology, University of Washington, Seattle, WA, (3)Otolaryngology-Head and Neck Surgery, University of Washington, Seattle, WA

---

**Background:** When multiple people are talking at the same time, referred to as multi-talker situations, listeners must segregate competing voices into distinct auditory streams. Acoustic cues such as pitch and loudness as well as binaural cues stemming from differences between the two ears can aid segregation. Prior research suggests neurotypical listeners can use acoustic and binaural cues to selectively attend to the desired talker even when competing voices are louder. Auditory processing differences, including difficulty listening under noisy conditions, have been reported in individuals with autism spectrum disorder (ASD). Despite these reported challenges, few studies have investigated multi-talker speech perception in individuals with ASD.

**Objectives:** This study investigates differences in multi-talker speech perception thresholds in young adults with ASD and age- and sex-matched controls. We hypothesize that the ASD group will show greater difficulty attending to a single talker in the presence of competing talkers compared to the control group.

**Methods:** Twenty-four participants aged 21-23 years (n=12 ASD; n=12 Control) participated in this study. ASD participants were recruited from a larger longitudinal study conducted at the University of Washington Autism Center. All participants passed an audiometric screen ( $\leq 20$ dB hearing level at octave frequencies between 250 and 8000 Hz) to ensure clinically normal hearing thresholds. Auditory stimuli were sentences from the Coordinate Response Measure (CRM) corpus. Listeners were presented with three simultaneous CRM sentences: the target talker to be attended ( $0^\circ$  azimuth) and two spatially separated ( $\pm 45^\circ$  azimuth) competing talkers. Speech perception thresholds in terms of signal-to-noise ratios (SNRs), were estimated as the level difference (dB) between the target and the two competing talkers, where a positive SNR indicated that the target talker had to be louder than the competing talkers, and a negative SNR indicated that the target talker could be quieter than the competing talkers.

**Results:** Overall, all participants were able to perform this multi-talker speech perception task. This suggests that both ASD and control participants were able to utilize the available acoustic and binaural cues to segregate simultaneous speech streams (i.e., selectively attend to one talker when three people were talking at once). Preliminary analyses show a trend towards worse speech perception thresholds in the ASD group compared to the control group (two-tailed t-test;  $t=1.81$ ,  $p=.08$ ). As a group, most individuals with ASD required the target speaker to be louder than the two competing talkers ( $M=2.69$ ,  $SD=4.15$ ). In comparison, individuals in the control group were able to selectively attend to the target talker even when competing talkers were louder ( $M=-0.67$ ,  $SD=4.90$ ).

**Conclusions:** These results suggest young adults with ASD have the ability to use acoustic and binaural cues to listen successfully when multiple people are talking at the same time. However, as a group, adults with ASD in this sample required the person they were attending to be louder than competing voices. Understanding auditory processing differences in ASD may reveal new information about contributors to social and communication challenges.

**413.036 (Poster)** Narrative Abilities in Teens with Autism Spectrum Disorder across Two Contexts

**J. Carmona, C. Boo and L. R. Naigles,** Psychological Sciences, University of Connecticut, Storrs, CT

---

**Background:** Narrative macrostructure impairments are common among individuals with Autism Spectrum Disorder (ASD; Baixauli et al., 2016); however, differences between ASD and typically developing (TD) individuals on structural language measures (e.g., mean length of utterances (MLU), word types and tokens) while narrating from a storybook are rarely reported (Tager-Flusberg, 1995). Narratives can also be drawn from personal experiences, though. Losh and Capps (2003) found that school-aged TD children and children with ASD differed in complex syntax while telling personal narratives, but not storybook narratives. The current study compares TD adolescents and adolescents with ASD in both of these contexts to see how they may highlight different strengths and weaknesses in structural language abilities.

**Objectives:** To extend this storybook-personal narrative comparison by (a) assessing adolescents with a wider range of language abilities and (b) including pronouns, which have been shown to vary by group in different contexts (Song et al., 2020; Suh et al., 2014; Kelty-Stephen et al., 2020).

Methods: Participants included five teens with ASD ( $M_{\text{age}} = 16.60$ ,  $SD = 3.50$ ) and five TD children ( $M_{\text{age}} = 14.40$ ,  $SD = 3.14$ ). With this small sample, raw CELF vocabulary scores differed, with the TD group ( $M=37.0$ ,  $SD=2.19$ ) having significantly higher scores than the ASD group ( $M=28.6$ ,  $SD=4.80$ ),  $p < .05$ . Storybook narratives were elicited using the *Tuesday* wordless picture book. Personal narratives were elicited with the investigator prompting the teen to narrate specific events (e.g. “Can you tell me about a time you got jabbed by something?”). Participant videos were transcribed and CLAN algorithms were used to extract MLU, utterance count, and noun, verb, and pronoun types and tokens (MacWhinney, 2000).

Results: Qualitative patterns are reported, due to small sample sizes. As expected, TD teens ( $M_{\text{storybook}} = 11.72$ ,  $SD=5.01$ ;  $M_{\text{personal}} = 9.85$ ,  $SD=3.38$ ) produced longer MLUs than teens with ASD ( $M_{\text{storybook}} = 6.77$ ,  $SD=3.96$ ;  $M_{\text{personal}} = 6.69$ ,  $SD=5.78$ ), in both contexts. Interestingly, teens with ASD ( $M = 41.8$ ,  $SD=20.41$ ) produced more utterances than TD teens ( $M = 30.8$ ,  $SD=14.69$ ) in the storybook context, but not in the personal context ( $M_{\text{ASD}} = 10.0$ ,  $SD=5.1$ ;  $M_{\text{TD}} = 16.2$ ,  $SD 10.92$ ). We re-calculated noun, verb, and pronoun tokens as a function of number of utterances (see Figures 1 & 2). Both groups produced more nouns/utterance in the storybook context and more pronouns/utterance in the personal context. Teens with ASD also produced more verbs/utterance in the personal context, while the TD teens were equivocal. Finally, while both groups used varied pronouns in the storybook context, only the TD group used varied pronouns in the personal context; the ASD group only used “I” in this context.

Conclusions: Whereas storybook narratives illustrated some expected differences between groups, the personal narratives revealed both strengths and weaknesses in the teens with ASD’s pronoun use. In particular, teens with ASD consistently used pronouns self-referentially but not in reference to others. These preliminary findings support the idea that language varies by narrative context. Data collection, suspended due to COVID-19, has recently recommenced. Future analyses will examine pronoun usage in closer detail.

#### **413.037 (Poster) Narrative Production and Comprehension in Greek-Speaking Children with Autism Spectrum Disorders: Associations with Theory of Mind**

*E. Baldimtsi<sup>1</sup>, A. Nicolopoulou<sup>2</sup> and I. M. Tsimpli<sup>3</sup>, (1)School of Medicine, 1st Department of Neurology, Aristotle University of Thessaloniki, Thessaloniki, Greece, (2)Psychology Department, Lehigh University, Bethlehem, PA, (3)Department of Theoretical and Applied Linguistics, University of Cambridge, Cambridge, United Kingdom*

---

Background: Narrative abilities are consistently reported as problematic for children with autism spectrum disorder (ASD) [1,2]. While difficulties in narrative production are well-documented (mostly in English-speaking children with ASD), relatively less is known about narrative comprehension in these children [3,4,5]. Furthermore, the difficulties in narrative performance of individuals with ASD are often associated with impairments in theory of mind (ToM)[6,7].

Objectives: The present study aims to add to our knowledge by examining narrative production and comprehension of Greek-speaking children with ASD as compared to a control group of typically developing (TD) peers. In addition, we examine the links between different aspects of narrative production (microstructure, macrostructure, Internal State Language (ISL)) and narrative comprehension with cognitive and affective aspects of ToM.

Methods: Participants. A total of 48 Greek-speaking children participated: 24 children with ASD (Mean age: 9;66) and 24 age-, gender-, and language-matched typically developing controls (Mean age: 9;75). Materials. A wordless picture book was used to test children’s re-tellings of the story told to them by the Experimenter followed by comprehension questions that were immediately asked after the child had completed their retelling. Children’s narrations were analyzed for both microstructural (i.e., narrative length, lexical diversity, syntactic complexity and syntactic diversity) and macrostructural (narrative coherence and ISL) properties. Narrative comprehension was assessed by coding five general memory, factual and inferential questions. Children’s ToM abilities were evaluated using a battery of 14 cognitive and affective ToM tasks at two levels of complexity (first- and second-order) that tapped mental state reasoning across the domains of beliefs, perceptions, desires and emotions.

Results: Children with ASD produced shorter ( $p = 0.007$ ), less coherent ( $p = 0.003$ ) stories, and experienced difficulties with narrative comprehension ( $p = 0.021$ ) as compared to their TD peers. However, in terms of lexical diversity, syntactic complexity, and diversity of ISL children with ASD did not differ from their TD controls (see Table 1). Regression analyses showed that a total ToM (cognitive and affective) score uniquely predicted narrative coherence, while affective ToM (emotion recognition and understanding) predicted the use of IST in children’s narratives. However, ToM was not predictive of children’s narrative comprehension performance.

Conclusions: Our findings showed that children with ASD demonstrate some challenges with narrative production and comprehension compared to TD children. With regard to narrative productivity, results support previous research [3,8,9,10] suggesting that these areas of narrative language are problematic for children with ASD. It is possible that children with ASD are

facing difficulties in their ability to build a mental model of the story in order to retell a coherent and informative story. Additionally, difficulty with narrative comprehension supports previous findings, which have shown that children with ASD are experiencing difficulties that require the understanding of implied or inferential meaning [3,11,5]. Finally, our results support the assertion that ToM understanding can affect children's ability to retell a comprehensive story including more ISL in their stories. The overall findings reveal both strengths and weaknesses in the ASD group's narrative performance.

**413.038** (Poster) Naturalistic Joint Attention and Theory of Mind in Children with ASD and TD Peers  
*V. Tecoulesco and L. R. Naigles, Psychological Sciences, University of Connecticut, Storrs, CT*

---

Background:

Individuals with autism spectrum disorder (ASD) often show differences in theory of mind (ToM; the ability to take the perspective of another person), an integral skill for interpersonal interactions. Joint attention (JA) or the ability to coordinate with a person during communication has also been found to be a meaningful precursor to ToM ability in both children with ASD (Mundy et al., 1986) and typically developing (TD) peers (Charman et al., 2000; Nelson et al., 2008) as understanding of attentional state may underlie an understanding of mental state (Baron-Cohen, 1989). Research on JA to date has primarily focused on testing specific skills in constrained situations designed specifically to elicit JA and testing ToM in younger children.

Objectives:

Here we examine how parent-toddler engagement in JA during free-play, which captures how child and caregiver purposefully switch attention between each other and an object in more natural situations, relates to ToM performance 3 years later.

Methods:

Forty-two parent-toddler dyads (ASD: $n=20$ ; TD: $n=22$ ) participated in three, thirty-minute, semi-structured play sessions separated by four months as part of a longitudinal study of early language. The groups were matched on receptive language ( $t(40)=.03, p=.97$ ) at visit 1 (*Age* ASD=32months; *Age* TD=20 months). Sessions were recorded and coded for joint attention type (IJA, in which the child initiates; RJA, in which the child responds to the parent's initiation; and passive attention (PA) in which parent and child are focused on the same object but the engagement lacks referential looks at each other). ToM was assessed approximately 3 years later (*Age* ASD=6.4 years; *Age* TD=5.5 years); children were given both an unexpected change of contents and unexpected change of location task, which were summed for one composite score.

Results:

The TD group's (89% correct) performance was significantly higher on ToM than the ASD group (48% correct) ( $t(40)=4.42, p<.001$ ). When controlling for cognitive ability at Visit 1, JA performance at the initial visit did not relate to later ToM. RJA at Visit 2 was positively related to ToM for the ASD group ( $r=.484, p=.036$ ) and just missed significance for the TD ( $r=.449, p=.054$ ). IJA engagement at visit 3 was related to subsequent ToM for both groups (ASD:  $r=.504, p=.028$ ; TD:  $r=.546, p=.016$ ). When the entire sample was included in a regression of ToM performance on early IQ, early receptive language, visit 2 RJA, Visit 3 IJA and group, early IQ did not predict a significant amount of variance (.2%), early language predicted 14 % of variance, RJA 18%, IJA an additional 15%, and group an additional 9% of variance.

Conclusions:

When more naturalistic parent child encounters are analyzed, early JA performance relates to later ToM in both children with ASD and TD peers, indicating that JA is equally important for both groups in ToM development. Measuring ToM at this age left less variability in the TD group, while the older ASD group included many children with floor performance. Joint attention skills add important understanding to ToM above and beyond individual language ability.

**413.039** (Poster) Often Encountered but Rarely Reported - Challenges in Selecting Language(s) for Intervention in Bi/Multilingual Children with Autism Spectrum Disorder

Background: India is home to 22 official languages. Most often individuals grow up exposed to more than one language. Apart from exposure to native and community languages, there is a growing preference for English as the language of formal education and employment. Studies indicate that bilingual children with Autism Spectrum Disorder (ASD) develop language similar to their monolingual non-verbal IQ matched peers (Lund et al 2017). Yet, we see professionals working with bi/multilingual children with ASD advise families to limit exposure to a monolingual environment, often to English or the native language. Hence, there is an evident mismatch between literature and clinical practice.

Objectives: To provide insight on factors that influence the selection of language(s) for intervention in children with ASD in bi/multilingual environments.

Methods: We present a case series of four children with ASD, exposed to monolingual (n=1), bilingual (n=1) and multilingual environments (n=2). All four children had a primary diagnosis of ASD (mild to moderate) with varying comorbidities. Developmental and behavioral assessments, and detailed speech-language evaluation were conducted. In-depth information on home and school language environments, advice received for language choice for home conversations and intervention, and parental preferences for choice of language(s) were collected. Children were assessed at one time point only. A team of speech-language pathologists (SLPs) discussed each case scenario and helped parents arrive at a decision regarding choice of language(s) for intervention.

Results: Mean (SD) age of the four children (N=3 males) in the study was 38.75 (7.8) months; range 29-48 months. Children belonged to semi-urban/urban backgrounds. Three children were enrolled for education/intervention in non-native and one in native language. Parents of three children preferred bilingual and one a multilingual approach. Parents of all children expressed a preference for use of non-native language (English). Details of home language environment, medium of instruction in school are presented in table 1. Professionals other than SLPs recommended a monolingual approach for all children. Based on (A) language environment of the child, (B) parent/caregiver perspectives, and (C) medium of education and availability of services, SLPs recommended monolingual approach for two children and bilingual approach for the other two. Final decision after discussing with parents resulted in supporting bilingual approach for three children. Decision around choice of language became more complex with an increase in number of languages the child was exposed to (Figure-1). Factors such as occupation of parents (transferable jobs) and family structure (joint versus nuclear) influenced decision making.

Conclusions: Choosing language(s) for intervention in bi/multilingual environments is complex. The key is to involve families in this decision-making process and address their concerns around bi/multilingualism. This study reflects the urgent need to sensitize fellow professionals to existing literature, create a larger evidence base and formulate guidelines to assist the decision-making process for selecting language(s) for intervention/exposure in children with ASD growing up in bi/multilingual environments. In addition to limited sample size, a major limitation of the case series is lack of follow-up data which prevents us from critically evaluating children's language development across languages.

#### **413.040** (Poster) Otitis Media and Language Delays in Autistic Youth

*T. McFayden and T. H. Ollendick, Virginia Polytechnic Institute and State University, Blacksburg, VA*

---

Background: Acute Otitis Media (AOM) and Otitis Media with Effusion (OME) are types of ear infections commonly diagnosed in the first five years of life, with prevalence rates of 10.85% (Monasta et al., 2012). Chronic AOM/OME, while less common (4.76%), can contribute to hearing impairments and delayed language acquisition. In typically-developing toddlers, expressive language deficits are seen as early as 12 months in infants with AOM/OME (Wallace et al., 1988). In autistic youth, OME infections are diagnosed significantly earlier (Adams et al., 2016), and rates of AOM/OME are significantly higher than in typically-developing children (23.5%; Rosenhall et al., 1999). Despite the increase in AOM/OME frequency, no work has investigated the impact of AOM/OME on language in autistic youth. Given the high comorbidity between language delay and ASD, investigating the impact of ear infections on language acquisition is of high importance.

Objectives: The current presentation seeks to evaluate the relationship(s) between AOM/OME and expressive language delays in autistic youth.

Methods: Medical reports and language data from 2758 youth in the Simon Simplex Collection (SSC) were analyzed. Participants were ages 4-18 years ( $M = 9.02$  years,  $SD = 3.56$ ; 83.5% male) and identified as predominantly white (76%). Parents reported whether their child had been diagnosed with an ear infection (yes/no), and the number of discrete infections. Dependent

variables included the Expressive and Receptive Language T-scores from the Vineland Adaptive Behavior Scales, age of first words and age of first phrases from the Autism Diagnostic Interview-Revised (ADI-R), and dichotomous variables of a word delay and phrase delay derived from the clinician score on the ADI-R.

Results: Seventy-five percent of the sample reported having at least one ear infection in their lives; 70% reported having more than 2 infections ( $M = 4.84$  infections,  $SD = 2.85$ ). Children with AOM/OME were not significantly more likely to have a word delay or phrase delay compared to children without AOM/OME ( $\text{Chi}^2 = 2.432, 4.646$  respectively,  $ps > .122$ ). After accounting for age and sex, linear regression analyses indicated AOM/OME frequency did not account for significant variance in expressive language,  $B = -.024, p = .281$ , receptive language,  $B = -.028, p = .208$ , age of first words,  $B = -.023, p = .307$ , or age of first phrases,  $B = .00, p = .987$ . The results held when considering only youth 5 years and younger ( $n = 351$ ).

Conclusions: Results suggest a majority of autistic youth had at least one ear infection, with frequency rates being higher than previous reports in typically-developing youth (75% vs. 10.85%) and autistic youth (75% vs. 24%), which could be due to the parent-report modality. Despite high prevalence rates, the frequency of infection did not negatively impact language acquisition or contribute to a language delay. Although the sample was AOM/OME saturated, the sample's language skills were evenly distributed; thus, relationships should have been evident if present. These findings suggest other factors apart from OME are contributing to language acquisition in autistic youth such as intellect, parenting practices, or ASD severity.

**413.041 (Poster)** Parent Nonverbal Initiations and Child Responses during Free-Play Interactions between Young Children with Autism Spectrum Disorder (ASD) and Their Parents

**G. Mudhar<sup>1</sup>** and **A. Kaale<sup>2,3</sup>**, (1)Special Needs Education, University of Oslo, Oslo, Norway, (2)Department of Special Needs Education, University of Oslo, Oslo, Norway, (3)Norwegian Centre of Expertise for Neurodevelopmental Disorders and Hypersomnias, Oslo University Hospital, Oslo, Norway

---

Background:

Early joint attention learning often takes place in unstructured circumstances where parents provide an interactive context wherein children are assisted through mediated learning. Young children with ASD tend to be more responsive towards parent nonverbal initiations because they are developmentally closer to the child's current level of capabilities. While research supports such parental initiations and their overall effects on joint attention development, there is more to be learned about parent's contributions, more specifically to break down parents' nonverbal initiation bids and determine any differences in the type and frequency of such initiations separately and their overall effects, that is, which behaviors are most effective at eliciting responses in young children with ASD.

Objectives:

The purpose of the present study was to better understand the impact of parents' behaviors on children's responses by investigating type and frequency of (a) parents' non-verbal initiating bids during play with their child with ASD and (b) children's verbal and nonverbal responses to parents' bids.

Methods:

A total of 50 children ( $M=65.9$  months,  $SD= 6.7$ , range=48-79, 82 % boys) diagnosed with ASD and one of their parents (45 mothers/5 fathers) participated in the study. Video recordings of 10-min of free-play with a standard set of toys between parents and children from a previous study were re-coded. During the first stream we coded non-verbal initiations (i.e. pointing, showing, and giving) by the parents. During the second stream we coded a) whether the child responded or not to the parent's non-verbal initiations, and b) type of response (i.e. verbal response or non-verbal response defined as following point, reaching or taking toy, alternating gaze).

Results:

During the 10 min play parents on average displayed 12,8 ( $SD= 7.0$ ) nonverbal initiations towards their child. The most frequent was pointing towards a toy or object ( $M= 4.7, SD= 3.9$ ), followed by showing ( $M= 4.4, SD= 4.6$ ), and giving ( $M= 3.7, SD= 3.4$ ). The children responded to 72% of the parents' nonverbal initiations. Child nonverbal responses (74%) were more frequent compared to verbal responses (26%). There was a significant strong association between total parent initiations and total child nonverbal responses ( $rs= 0.80, p < 0.001$ ), but not between total parent initiations and total child verbal responses ( $rs= 0.26, p > 0.069$ ). Regression analysis revealed that parents' showing was the strongest predictor of total children's response ( $B= 0.748, p < 0.001$ ).

## Conclusions:

Parents play an integral role in facilitating joint attention with their child with ASD by adjusting their behaviors and providing effective initiatives. The current study results suggest parents' nonverbal initiations, especially showing of toys seems to be effective in eliciting a response in preschoolers with ASD. Thus, it is imperative that we help parents to be proactive, and use nonverbal initiatives, such as showing to effectively support their children.

**413.042** (Poster) Parent-Education Via Telehealth during the COVID-19 Lockdown in Beijing, China

*E. Ijalba<sup>1</sup>, W. Chen<sup>2</sup> and J. Song<sup>2</sup>; (1)Linguistics and Communication Disorders, Queens College, CUNY, Queens, NY, (2)Wucailu, Beijing, China*

---

## Background:

The COVID-19 pandemic forced an extended lockdown in China that lasted 10 weeks. Children with autism spectrum disorders (ASD) stayed home and did not attend school for several months. Children with ASD often show a protracted period of language development that can be stressful on families. Mothers play a crucial role in supporting their children's language and social development by using child focused activities, reciprocity, early-literacy and extended conversations. This study measured the effectiveness of parent-education on language development and social interactions in ten children with ASD (30-52 months) and their mothers' stress levels during the COVID-19 lockdown in Beijing.

## Objectives:

1. To improve children's expressive language (words spoken) during shared-reading and play, use of gestures and imitation of actions.
2. To improve reciprocal interactions between the children and their mothers.
3. To reduce the mothers' stress levels.
4. To compare a longer parent intervention (LPI) (10-weeks) and a shorter parent intervention (SPI) (5-weeks).

## Methods:

We observed children's use of language, gestures and imitation during shared-reading/play and home-based activities with their mothers. We used an AB design, baseline (4 observations) and intervention (5 and 10 observations). We measured the Improvement Rate Difference (IRD) for the LPI (10 observations) and for the SPI (5 observations). The LPI cohort included 6 children and the SPI 4.

Mothers received one weekly interactive picture-book with visual support for paired actions with toys and pretend play activities (i.e., bouncing a ball, cooking, shopping). Each topic was extended through complementary home-based activities (i.e., washing rice, sorting clothes, wiping toys). Mothers learned language-stimulation strategies (modeling, recasting, expansions) and a child-focused approach via telephone video-conferencing with a specialized teacher.

To monitor the children's progress, mothers sent three weekly five-minute videos. These videos were scored by two clinicians to measure the children's use of words, gestures, and imitation of actions. In addition, mothers reported progress on reciprocal interactions with their children and on their own stress levels, by completing a pre- and post-intervention checklist (Parenting Interactions with Children: Checklist of Observations Linked to Outcomes (PICCOLO) and the Perceived Stress Scale (Cohen, Kamarck, & Mermelstein, 1983).

## Results:

Both cohorts made IRD gains in their use of words (LPI 73%, CI 82-94.6; and SPI 80%, CI 78.6-81.4). However, IRD gains were below chance levels for gestures (LPI 48% and SPI 15%) and slightly above chance for imitation of actions (LPI 60% and SPI 55%). See Figures 1-10 for LPI and SPI scores. Mothers across cohorts reported improved reciprocal interactions with their children, dependent t-test  $p < .001$ ,  $d = 3.8$ , and reduced stress levels,  $p < .02$ ,  $d = 1.05$ .

## Conclusions:

This intervention was effective in improving children's expressive language, but not for improving children's use of gestures and imitation. The use of gestures and imitation proved to be more challenging than acquiring words. Such differences may be related

to the caregivers' direct teaching approach and may require additional specialized parent instruction. In spite of these differences, all mothers reported improved reciprocal interactions with their children and reduced stress levels. Our sample size was small and results cannot be generalized.

**413.043 (Poster) Parental Concerns of Children with ASD By Age: A Qualitative Analysis**

*E. F. Dillon<sup>1</sup>, P. Danika<sup>2</sup>, C. B. Hologue<sup>2</sup>, L. Kalb<sup>3</sup>, R. Reetzke<sup>2</sup> and R. Landa<sup>2</sup>, (1)Psychiatry, RUSH University Medical School, Chicago, IL, (2)Center for Autism and Related Disorders, Kennedy Krieger Institute, Baltimore, MD, (3)Department of Mental Health, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD*

---

**Background:** Eliciting parents' concerns about their children is an important initial step in the ASD diagnostic process. This information is often collected through forced-choice questionnaires utilizing professional terminology and may limit the potential concerns that can be reported. Studies examining parents' concerns to date have largely used deductive qualitative methods with only one age group of children. To capture a more thorough understanding of parental concerns without clinical interpretation, an open-ended form of questioning using an inductive method of qualitative analysis is needed. The advantage of this type of analysis is gaining direct information from parents without imposing preconceived categories, or professional terminology, onto their responses. This allows for the creation of a more holistic, parent-centered, understanding of parental concerns by permitting all types of concerns to be captured. No inductive qualitative studies to our knowledge have been conducted to investigate parents' concerns across age groups using a single coding scheme. Such research is important to better understand the specific language parents use to describe their concerns about children of different ages.

**Objectives:** The purpose of this study was to understand parents' concerns about their children with ASD, at the child's first ASD diagnostic evaluation. Using an inductive approach, we sought to identify: a) all parents' concerns about their children across age groups (toddler, preschool, middle childhood), b) concerns that were shared across age groups, and c) concerns that differed across age groups.

**Methods:** An inductive qualitative analysis process was employed to analyze concerns reported by parents of children ages 1-11 years on intake forms ( $n = 455$ ) at an urban outpatient ASD specialty clinic. Analyses were based on three age groups (toddler, preschooler, middle childhood).

**Results:** Using conventional content analysis, 12 categories of concerns emerged from parents' responses: communication, social, behavioral/emotional, cognition, life skills, atypical behaviors, sensory, academic, health, seeking diagnostic clarity or resources, developmental, and motor skills. We found that parents reported the same concerns about their children across age groups in six of the 12 categories. The biggest difference in reported concerns across age groups was that parents of children in the preschooler and middle childhood groups reported a greater number of concerns related to mental health than parents of toddlers.

**Conclusions:** While structured or forced-choice parent questionnaires have utility for eliciting parental concerns, parents should also have a way to report their concerns in an open-ended format, allowing researchers and clinicians to capture parents' concerns in their own words. The current study confirms previous research reporting the complex phenotype of ASD within child age groups and adds to it by capturing detailed information about this complexity. Our analysis yields specific information about similarities and differences in parents' concerns depending on their child's age. By eliciting detailed parental concerns before the evaluation, burden on both parents and providers may be reduced by identifying the necessary professionals and assessments needed ahead of time to ensure both timely diagnosis and identification of appropriate, comprehensive treatments.

**413.044 (Poster) Parents' Declarative Deictic Gesture Use Predicts Vocabulary Development in Infants at High and Low Risk for Autism Spectrum Disorder**

*A. B. Choi<sup>1,2</sup>, L. Castelbaum<sup>1,3</sup>, R. McKechnie<sup>3,4</sup>, M. Rowe<sup>2</sup>, C. A. Nelson<sup>1,2</sup> and H. Tager-Flusberg<sup>5</sup>, (1)Developmental Medicine, Boston Children's Hospital, Boston, MA, (2)Harvard Graduate School of Education, Cambridge, MA, (3)Boston University, Boston, MA, (4)Boston Children's Hospital, Boston, MA, (5)Department of Psychological and Brain Sciences, Boston University, Boston, MA*

---

Background:

We can identify factors associated with atypical language development in children with autism spectrum disorder (ASD) by studying the linguistic environment of infants at high familial risk for the disorder. Given the important role parents play in shaping their children's language development, analyses of parent-child interactions are of particular interest. Although previous studies have investigated various features of parent-child interactions, they have not examined if parents of high- and low-risk

infants differ on the communicative intentions behind their gestures. Also, while recent evidence suggests that parent's varying pointing intentions may be differentially related to language development of typically developing children, the question of whether the association between parental gesture intentions and children's vocabulary development is also found in high-risk infants remains unanswered.

#### Objectives:

This work aims to (1) examine deictic gesture intentions in parents of high-risk infants later diagnosed with ASD (HRA+), high-risk infants who were not diagnosed with ASD (HRA-), and low-risk comparison (LRC) infants at 12 months and (2) assess whether expressing declarative vs. imperative intentions via deictic gestures differentially predicts child vocabulary scores at 36 months.

#### Methods:

Participants included 70 parent-child dyads where infants were classified as high or low familial risk for ASD (HRA+:  $n = 17$ ; HRA-:  $n = 25$ ; LRC:  $n = 28$ ). At the infants' 12-month in-lab study visit, parents were asked to play with their child as they normally would during a 10-minute free play interaction. We later transcribed the videotaped interaction and coded parental deictic gestures at the level of communicative intention as declarative or imperative. Declarative gestures were defined as those intended to share interests with their infants or convey information about objects, persons, or events in the environment. Imperative gestures were defined as those utilized to direct or elicit a specific action from the child. Infants' vocabulary scores were measured at 36 months using the MacArthur-Bates Communicative Development Inventory (MB-CDI-III; Fenson et al., 1994). To determine infants' ASD outcomes, the Autism Diagnostic Observation Schedule (ADOS; Lord et al., 2000) was administered at 18, 24, and 36 months and used in conjunction with a clinical judgment estimate.

#### Results:

(1) Using ANOVAs and/or nonparametric tests (based on the distributions of data), we found that parents in the three groups produced similar numbers of declarative and imperative deictic gestures when interacting with their 12-month-old infants ( $\chi^2 = 4.58, p = .10$ ;  $F(2, 67) = 1.64, p = .20$ ).

(2) Using regression analyses, we found that across groups, 12-month parental declarative, but not imperative, use of deictic gestures was significantly, positively associated with children's 36-month vocabulary scores (Figure 1), even when controlling for levels of parental education, parental speech, child sex, and previous child language skills ( $b = 1.11, SE = 0.43, t = 2.59, p = .02$ ).

#### Conclusions:

These results suggest that parents who have a child with ASD provide gestural input of similar quality to parents who have a typically developing child. Encouraging parental use of declarative gestures with infants could have important implications for language development.

#### 413.045 (Poster) Patterns of Interactional Prosody in Youth with and without Autism

*N. G. Ward<sup>1</sup>, J. M. Contreras<sup>1</sup> and H. Lehnert-LeHouillier<sup>2</sup>, (1)Computer Science, University of Texas at El Paso, El Paso, TX, (2)Communication Disorders, New Mexico State University, Las Cruces, NM*

---

**Background:** Difficulties in social interaction and communication are defining features of autism, with prosodic differences often implicated. However, investigations of prosody in those with ASD have focused mostly on aspects relating to emotional and linguistic functions (Marchi et al, 2018), and the ways in which autistic people differ in the interactional aspects of prosody remain poorly understood.

Recent work in prosody modeling has developed the notion of "prosodic construction": a temporal configuration of multiple acoustic-prosodic features --- pitch, intensity, lengthening, reduction, voicing properties, and others --- that serves a specific function or family of functions (Ogden 2010, Niebuhr et al 2013). In English, prosodic constructions serve many functions relating to turn taking, topic management, information structure, speech acts, and the expression of stance (Ward 2019). Computational methods have been developed, notably including the application of Principal Component Analysis (PCA) to multiple robustly computed features over a corpus, for the automatic identification of common dimensions of variation. These

generally correspond to meaningful prosodic constructions, and support analysis of differences in construction form and frequency of use across subpopulations (Ward & Gallardo, 2017).

**Objectives:** In this exploratory study, we aim to identify ways in which interactional prosody differs between youth with ASD and their neurotypical peers.

**Methods:** From the NMSU corpus of autistic and neurotypical dialogs (Lenhert-LeHouillier et al, 2020), we selected 10 dialogs from each, totaling 83 and 72 minutes, respectively, whose recording conditions supported automatic analysis. In these dialogs, confederates engaged children and adolescents between the ages of 9 and 15 years (ASD mean = 12.66, NT mean = 12.57) in dialogs seeking to find differences in a pair of pictures. Applying PCA to 212 features computed across 400,000+ overlapping samples from each group's data, we examined the top 8 dimensions derived for each group, accounting for 44% and 33% of the variance, respectively. We noted differences between the constructions found and differences in the detailed forms.

**Results:** Contrary to our expectation, the youth with ASD generally exhibited prosodic patterns marking many of the same functions as the NT youth, including those used to mark contrast and correction, factual versus affective or personal stance, and topic keeping versus topic transitions. However there were often salient differences in the realization of these patterns. For contrast and corrections, for example, these included atypically strong use of high pitch and lengthening, marking with atypical features such as high harmonicity, and marking on only the content word rather than using the usual wider pattern. We also noted tendencies to not always use the typical prosody appropriate for the context, meaning that at such times the speaker's intent was often unclear. Further, we noted many cases of apparently non-functional and possibly uncontrolled occurrences of prosodic features, including wide pitch range, lengthening, and loudness.

**Conclusions:** The youth with ASD exhibited use of many of the prosodic patterns involved in pragmatic and interactional functions, but in many cases they were realized differently.

#### 413.046 (Poster) Perceptions of Conversational Responses in Adolescents with and without ASD

R. Grossman<sup>1</sup>, E. Zane<sup>2,3</sup> and A. Newberg<sup>4</sup>, (1)CSD, Emerson College, Boston, MA, (2)FACE Lab, Emerson College, Boston, MA, (3)Communication Sciences and Disorders, James Madison University, Harrisonburg, VA, (4)Emerson College, Newton, MA

---

Background: Successful conversation requires that both partners: A) respond to one another; B) produce responses that are interpretable. Existing evidence shows that individuals with ASD produce non-verbal conversational behaviors that are more difficult to interpret and less indicative of their partner's preceding behavior. (Sheppard et. al., 2016; Alkhaldi et. al., 2019), which could lead to misinterpretations and communicative breakdowns.

Objectives: The aim of this study was to determine whether naïve observers can interpret the non-verbal behaviors of NT and ASD adolescents as signaling surprise in response to an off-topic questions by an unseen conversation partner.

Methods: Stimuli were extracted from videos of ASD and NT adolescents in conversation with two adult research assistants (RAs). During the conversation, the RAs produced one on-topic and one off-topic question. We selected 2-5 second-long video clips for each adolescent showing their initial response to each question type. Video clips only showed the adolescents' face and body; the two RAs were not visible, and the clips did not include sound to avoid verbal clues about the preceding question type.

We presented 44 pseudo-randomized video clips from 22 adolescents (11 ASD: 11 NT, ASD verified via ADOS-2) in an online survey via MTurk. 158 NT adults completed the survey and used ungraduated slider bars (anchors: "not at all" to "very much") to respond to questions about the adolescents' reactions: "How surprised do you think the person was by what their conversation partner said?" and "How responsive do you think the person was to their conversation partner?"

Results: We conducted a 2 (adolescent diagnosis: NT or ASD) by 2 (question-type: on-topic or off-topic) repeated-measures ANOVA for each question and found significant main effects for question-type, with both groups perceived as more surprised ( $F(1,158) = 35.62, p < 0.001$ ) and more responsive ( $F(1,158) = 96.02, p < 0.001$ ) following off-topic than on-topic questions. NT adolescents were perceived as more responsive than their ASD peers ( $F(1,158) = 135.64, p < 0.001$ ) but not more surprised ( $F(1,158) = 2.00, p = 0.159$ ). Significant group-by-question-type interactions showed that the NT group had a greater increase in perceived responsiveness ( $F(1,158) = 8.25, p < 0.01$ ) and surprise ( $F(1,158) = 57.53, p < 0.001$ ) to the off-topic vs on-topic questions than the ASD group. Follow-up Tukey HSD tests revealed significantly higher perceived responsiveness ( $p < 0.01$ ) and surprise ( $p < 0.001$ ) for the NT adolescents following off-topic than on-topic questions. Adolescents with ASD are also perceived as significantly more responsive to off-topic questions ( $p < 0.001$ ) but not more surprised ( $p = 1.00$ ).

Conclusions: Both NT and ASD adolescents are perceived as more responsive to off-topic questions; however, only the NT group is perceived as conveying more *surprise*, which is the expected reaction to an off-topic question. This suggests that adolescents with ASD differentially react to off-topic vs on-topic questions, but that their nonverbal reactions are less specifically readable as displaying surprise. This could lead to communicative breakdown when conversation partners are not aware that their message was not understood.

**413.047 (Poster)** Phonological Awareness and Visual Spatial Abilities in School-Age Children with Autism

**C. Rimmer<sup>1</sup>, G. Philibert-Lignieres<sup>1</sup>, T. Q. Boucher<sup>2</sup>, G. Iarocci<sup>2</sup> and E. M. Quintin<sup>3</sup>,** (1)McGill University, Montreal, QC, Canada, (2)Psychology, Simon Fraser University, Burnaby, BC, Canada, (3)Educational & Counselling Psychology, McGill University, Montreal, QC, Canada

---

**Background:** Phonological awareness is an essential precursor to reading acquisition and refers to the awareness of sound structures in language and the ability to manipulate (i.e., blend, segment, and delete) sounds at both the syllable and individual phoneme levels. Phonological awareness development may be vulnerable in children with autism spectrum disorder (ASD) given that many children with ASD demonstrate delays in language and communication. The current literature yields mixed findings showing that preschool children with ASD demonstrate difficulties with phonological awareness, while some studies indicate phonological awareness as a relative strength within this population. Children with ASD present with heterogenous language and cognitive profiles, yet, an important overlap between oral language skills and nonverbal cognitive abilities has been identified.

**Objectives:** The current study aimed to investigate the phonological awareness skills of school-age children with ASD compared to children with typical development (TD), while exploring the role of individual differences in IQ and ASD symptom severity on phonological awareness abilities.

**Methods:** Eighteen children with ASD (age= 6-12,  $M=9$ ,  $SD=1.71$ , male  $n=16$ ) and seventeen TD children (age= 6-11,  $M=9$ ,  $SD=1.53$ , male  $n=8$ ) participated in this study. Phonological awareness was measured using the *NEPSY-II Phonological Processing* subtest, ASD symptomology using the Social Responsiveness Scale-2 (SRS-2), and cognitive abilities, including verbal and visual spatial abilities, were measured using the Wechsler Abbreviated Scale of Intelligence - 2<sup>nd</sup> Edition (WASI-II).

**Results:** MANOVAs revealed that the ASD and TD groups did not differ in their score on the NEPSY-II Phonological processing subtest ( $p > .05$ ) and the WASI-II ( $p > .05$ ), demonstrating similar phonological awareness and cognitive abilities. Within the ASD group, a regression analysis revealed that visual spatial, but not verbal cognitive abilities, predicted phonological awareness scores ( $p < .05$ ) and that autism symptoms did not predict scores in phonological awareness skills ( $p > .05$ ). Regression coefficients indicated that within the ASD group, participants with a higher visual spatial score obtained a higher score in phonological awareness skills compared to those with a lower visual spatial score. Within the TD group, a regression analysis showed that visual spatial abilities, verbal abilities, and autism symptoms did not predict scores in phonological awareness skills ( $p > .05$ ).

**Conclusions:** Results contribute to the literature in examining phonological awareness skills in school-age children with ASD, demonstrating that it is a relative strength within this population and is not related to autism symptom severity. Additionally, our findings support previous research showing a relationship between phonological awareness skills and nonverbal cognitive abilities in children with ASD. Given the increase in attention to the academic achievements within this population, findings add to our understanding of phonological awareness skills of children with ASD compared to aged-matched peers and can help inform instructional interventions aiming to increase reading success.

**413.048 (Poster)** Pragmatic Language Difficulties during Scripted Narratives in Autistic Adults and Significance to Clinical Diagnosis of Autism Spectrum Disorder

**N. Jadav<sup>1</sup>, C. JohnKlein<sup>2</sup>, L. T. V. Vo<sup>3</sup>, E. Wilkinson<sup>2</sup> and V. H. Bal<sup>2</sup>,** (1)Department of Psychology, Rutgers University-New Brunswick, Piscataway, NJ, (2)Graduate School of Applied and Professional Psychology, Rutgers University-New Brunswick, Piscataway, NJ, (3)Western New England University, Springfield, MA

---

**Background:** Pragmatic language difficulties have been observed in children and adults with ASD through analysis of their fictional narratives (e.g., Barnes & Baron-Cohen, 2012; Suh, et al., 2014). While studies have also analyzed children's scripted narratives (e.g., Volden, 2002), no studies have taken this approach to evaluate pragmatic difficulties in adults with ASD. Despite growing numbers of adults being referred for diagnostic evaluation and evidence that existing diagnostic tools may have reduced sensitivity in adult diagnostic referrals (deBildt et al., 2016; Langmann et al., 2017), relatively little research has been devoted to understanding the autism phenotype in adulthood. More information regarding pragmatic difficulties may provide insights into diagnostic markers for adults and inform development of diagnostic tools to improve adult diagnostic practices.

**Objectives:** 1) Delineate the pragmatic language features observable in autistic adults during a scripted narrative task. 2) Determine if verbal pragmatic language difficulties are mitigated by use of nonverbal communicative behaviors. 3) Examine associations between pragmatic language features and clinician diagnostic certainty ratings to identify potential diagnostic markers.

**Methods:** Participants ( $n = 45$ ) were recruited for studies aimed at improving diagnostic instruments and characterizing ASD in adulthood. The majority (82.2%) were male, had an ASD diagnosis (91.1%), and age ranged from 15-61 years old ( $M = 22.13$ ,  $SD = 7.22$ ). Mean verbal IQ was 99.38 ( $SD = 25.18$ ). The ADOS Demonstration Task was used as a scripted narrative task. Verbal descriptions were transcribed and then coded for five pragmatic language features: 1) number and coherence of events (e.g., turns on tap), 2) type and quality of details (e.g., water temperature), 3) use of filler words, 4) inclusion of tangential or task-irrelevant information, and 5) inclusion of personal details. Each category included broad summary codes to capture different aspects of abnormality (e.g., excessive detail, level of inappropriateness) and frequencies of category features (e.g., specific events, types of detail). Next, videos were coded using the same summary codes, as well as codes for body language, facial expression, tone, and gestures. Finally, clinicians experienced in ASD diagnosis used videos to rate their diagnostic certainty and explain behaviors influencing their certainty.

**Results:** Participants used an average of nine events ( $M = 9.90$ ,  $SD = 4.20$ ; range = 0-18) and an average of five details ( $M = 5.45$ ,  $SD = 5.15$ ; range 0-18) in their toothbrushing narratives. Females ( $M = 13.80$ ,  $SD = 3.70$ ) used more events than males ( $M = 9.08$ ,  $3.88$ ) [ $t(27) = 2.49$ ,  $p = 0.019$ ], but did not differ in number of details [ $t(27) = 0.45$ ,  $p = 0.658$ ]. Many participants included tangential or task-irrelevant information (58.6%). Preliminary analyses suggest higher overlap in summary code scores between transcript and video coding for cohesion (71.4%) and irrelevant information (71.4%), but lower overlap in domains of excessive detail (57.1%) and tangential information (57.1%).

**Conclusions:** Low overlap in excessive detail and tangential information coded from video vs. transcriptions of spoken language suggest the importance of integrating both verbal and nonverbal behaviors when considering pragmatic language. Further analyses are underway to explore associations between pragmatic features and clinician certainty.

#### **413.049 (Poster) Pragmatic Language and Aggressive Behavior in ASD: The ACE Gendaar Network**

*M. McCabe<sup>1</sup>, M. Santhosh<sup>2</sup>, E. Neuhaus<sup>1</sup>, A. Kresse<sup>1</sup>, S. J. Webb<sup>3</sup> and G. A. Consortium<sup>1</sup>, (1)Seattle Children's Research Institute, Seattle, WA, (2)Center for Child Health, Behavior and Development, Seattle Children's Research Institute, Seattle, WA, (3)Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA*

---

**Background:** Impaired pragmatic language (i.e., language use for social interaction) is a hallmark feature of Autism Spectrum Disorder (ASD); a neurodevelopmental disorder characterized by social, behavioral, and communication impairments. Aggressive behavior is an unfortunate comorbidity of ASD with nearly 22% of autistic youth demonstrating clinically significant levels of aggression (Hartley, Sikora, & McCoy, 2008). Past research indicates that higher levels of externalizing behaviors are associated with weaker expressive language skills and pragmatic language, however, these associations have not been uniformly observed specifically with pragmatic language and aggression (Boonen et al., 2014; Neuhaus et al. in press). To address the hypothesized connection between pragmatic language ability and aggressive behavior in individuals with ASD and to expand this work to include female youth, we analyzed data from the GENDAAR study, which focused on understanding sex-based differences in youth with ASD.

**Objectives:** To explore the relationship between pragmatic language ability and aggressive behavior in male and female youth with ASD.

**Methods:** In a one-site subsample from GENDAAR, 37 youth (19 females, 18 males) with ASD ages 8 to 18 years had data available for this project. All ASD youth had a community clinical diagnosis, confirmed via the ADOS, ADI-R, and DSM-IV criteria. All participants completed the DAS-II and had an IQ >70. Aggressive behavior was identified using the parent report Child Behavior Checklist (CBCL) aggression scale. Pragmatic language was coded using 20-minute language samples recorded during the ADOS. Two raters, unaware of diagnostic group, independently watched and rated videos using the Pragmatic Rating Scale – Modified, which includes emotional, communicative, overtalk, and general language scales.

**Results:** Preliminary analysis of group differences in pragmatic language between sexes showed that male youth with ASD had significantly lower pragmatic language ability ( $M = 8.6$ ,  $SD = 3$ ) than female youth with ASD ( $M = 11.6$ ,  $SD = 3.3$ ),  $t(35) = -2.7$ ,  $p = .01$ . However, no sex differences were found for aggressive behavior. Correlations were run to explore the relationships between pragmatic language and aggressive behavior. No associations were found for males ( $r(13) = -.06$ ,  $p > .05$ ), females ( $r(15) = -.02$ ,  $p > .05$ ), or the total ASD sample ( $r(30) = -.1$ ,  $p > .05$ ).

**Conclusions:** In this preliminary analysis, our results do not support a relationship between pragmatic language and aggressive behavior in youth with ASD. Sex differences were only observed for pragmatic language ability, suggesting that female youth had better pragmatic language ability than male youth. Previous work by our group (in the full GENDAAR sample) suggests that more severe aggression, specifically in males, was associated with difficulties in communication skills. Thus, we may be currently underpowered to identify this relationship. Further research will examine the relation between pragmatic language, age and other language measures.

**413.050 (Poster)** Predicting Language in Children with ASD Using Spontaneous Language Samples and Standardized Language Measures

**R. P. Thomas<sup>1</sup>, K. Wittke<sup>2</sup>, J. E. Blume<sup>3</sup>, A. Mastergeorge<sup>4</sup> and L. R. Naigles<sup>1</sup>,** (1)Psychological Sciences, University of Connecticut, Storrs, CT, (2)University of Connecticut, Storrs, CT, (3)Department of Human Development and Family Studies, Texas Tech University, Lubbock, TX, (4)Texas Tech University, Lubbock, TX

---

**Background:** Previous research has indicated that standardized measures of language are often not sensitive to the heterogeneity of language abilities in children with Autism Spectrum Disorder (ASD) (Kasari et al., 2013). One suggestion has been the use of spontaneous language samples to capture a wider range of grammatical abilities in children with ASD that are not always apparent on standardized instruments (Wittke et al., 2017).

**Objectives:** The current project examines the degree to which standardized measures and natural language samples predict change in language skills in a longitudinal sample of children with ASD.

**Methods:** A subset of participants from the *Autism Phenome Project* (APP;  $N=54$ ; 41 males) were selected for the current study. The APP is a longitudinal study intending to define clinically meaningful ASD subtypes based on behavioral and biological data. Participants were selected based on availability of video recordings of the *Communication and Symbolic Behavior Scales* (CSBS; Wetherby & Prizant, 2002) at initial visit (T1) and the *Autism Diagnostic Observation Schedule* (ADOS; Lord, Rutter, Dilavore, & Risi, 1999) three years later (T3). Coding of spontaneous language samples from CSBS and ADOS testing was used to calculate mean length of utterance (MLU) and total word types (TWT) at both T1 and T3. Mean age of participants at T1 was 33.9 months ( $SD=5.5$ ) and 67.2 months ( $SD=10.2$ ) at T3. In addition to MLU and TWT, formal testing at T1 from the Mullen Scales of Early Learning Expressive Language Raw Scores (MSEL-EL) as well as ADOS Social Affect (SA) and Restricted and Repetitive Behaviors (RRB) Total Scores were included as variables of interest.

**Results:** Two stepwise regression models evaluated predictors of language skills at T3; one for MLU and the other for TWT. T1 MSEL-EL ( $R^2_{adjusted} = .438$ ,  $F(1,52) = 42.327$ ,  $p<.001$ ) and T1 MLU ( $\Delta R^2 = .050$ ,  $F(2,51) = 25.343$ ,  $p=.029$ ,) separately accounted for significant amounts of variance in T3 MLU. In contrast, T1 MSEL-EL ( $R^2_{adjusted} = .533$ ,  $F(1,52) = 61.567$ ,  $p<.001$ ), T1 ADOS-SA ( $\Delta R^2 = .034$ ,  $F(4,49) = 19.298$ ,  $p=.043$ ), and T1 ADOS-RRB ( $\Delta R^2 = .040$ ,  $F(5,48) = 17.926$ ,  $p=.024$ ), each separately accounted for significant proportions of variance in T3 TWT.

**Conclusions:** Both standardized language and autism testing, and spontaneous language samples were unique predictors of later language skills in this heterogeneous sample of children with ASD. MLU at T1 accounted for a unique proportion of the variance in later MLU at T3, whereas ADOS SA and RRB accounted for variance in later TWT at T3. Thus, early grammatical language use significantly predicts later grammatical language use (T1 and T3 MLU, respectively) over and above standardized MSEL-EL scores. Moreover, higher levels of autism symptomatology negatively impacted later vocabulary skills (indicated by lower TWT scores). One potential explanation is that social interaction skills facilitate the acquisition of new words, although not (apparently) grammatical skills. These results suggest that valuable predictive information can be obtained from both standardized measures and natural language samples in children with ASD; especially, spontaneous language scores should be considered when predicting longitudinal change in how children with ASD use language.

**413.051 (Poster)** Predictors of Augmentative and Alternative Communication System Use in an Inpatient Sample of Youth with ASD

**E. A. DeLucia, T. M. Andrzejewski and C. G. McDonnell,** Department of Psychology, Virginia Polytechnic Institute and State University, Blacksburg, VA

---

**Background:**

Approximately 30% of children with autism spectrum disorder (ASD) are nonverbal or minimally verbal. Augmentative and alternative communication (AAC) systems, such as picture exchange communication systems (PECS) and voice output devices (VODs), are often recommended for this population. However, little is known about the factors that are associated with AAC use.

Previous research has suggested that child level factors, such as language level and ASD symptom severity, predict response to AAC systems. However, little research has examined family- or system-level predictors of AAC use.

#### Objectives:

The current study aims to 1) Describe the frequency of AAC use in an inpatient sample of youth with ASD and 2) identify child and family characteristics that are associated with AAC use.

#### Methods:

The current study uses data from the Autism Inpatient Collection, a large sample of children with ASD in inpatient hospital settings. A subset ( $n=132$ ) of the sample received a survey about communication system use, which inquired about what types of communication systems children utilized. First, descriptive statistics were used to determine the frequency of AAC use in the sample. Then, bivariate correlations examined the association between AAC use and child and family factors. Finally, logistic regression analysis was used to investigate interaction effects between child and family factors that may predict AAC use.

#### Results:

41.7% of parents in the sample reported that their child uses some type of communication system (including PECS, VODs, sign language, written/text communication, and other systems). Bivariate correlations found that child nonverbal IQ, verbal expression, and receptive language were negatively associated with communication system use. Child ASD symptom severity and most demographic factors were not associated with AAC use at the bivariate level. (See Table 1 for all correlations). Logistic regression analyses examined predictors of AAC use, revealing an interaction effect between expressive vocabulary and maternal education ( $p=.006$ ), as well as between child IQ and maternal education ( $p=.022$ ). The association between IQ and verbal ability with the likelihood of AAC use was stronger for children of parents with lower levels of education. At higher levels of IQ and verbal ability, children of parents with higher education levels were more likely to use an AAC.

#### Conclusions:

These findings suggest that a substantial portion of children with ASD in inpatient settings may use AAC systems to communicate. While language and IQ were negatively associated with AAC use, ASD symptom severity and child behavior problems were not related, which highlights the need to consider how communication systems may be utilized for a range of children. Given the frequency of their use, it is critical to consider how AAC systems can be better integrated into inpatient treatment plans. Parent education moderated the association between IQ and verbal ability and AAC use, suggesting that indicators of family socio-economic status may impact which children are likely to use a communication system. Future research should continue to investigate factors associated with AAC use, as well as consider how training and education may impact the usefulness of these systems in an inpatient setting.

**413.052** (Poster) Predictors of Discourse and Pragmatic Language Use in Preschoolers with Autism Spectrum Disorder  
*M. G. Pecukonis<sup>1,2</sup>, C. G. La Valle<sup>1,2</sup>, J. Leano<sup>2</sup>, E. Johnston<sup>2</sup>, D. Stewart<sup>2</sup>, S. Shen<sup>2,3</sup> and H. Tager-Flusberg<sup>1,2,3</sup>*, (1)Department of Psychological and Brain Sciences, Boston University, Boston, MA, (2)Center for Autism Research Excellence, Boston, MA, (3)Department of Speech, Language, and Hearing Sciences, Boston University, Boston, MA

---

#### Background:

Several studies have found that social communication skills, including initiation of and response to joint attention (IJA and RJA), play, and imitation, predict concurrent language abilities (Kasari et al., 2008; Luyster et al., 2008; Toth et al., 2006; Van der Paelt et al., 2014) and growth in language overtime (Thurm et al., 2007; Yoder et al., 2015) in young children with Autism Spectrum Disorder (ASD). These studies measured language using standardized assessments (e.g., Mullen Scales of Early Learning), which may be less effective at capturing “clinically-meaningful” change in discourse and pragmatic language abilities (Barokova & Tager-Flusberg, 2018). Natural language sampling, in contrast, is more sensitive to variations in language as it is used during everyday social interactions (Casenhiser et al., 2013).

#### Objectives:

In a sample of preschool-aged children with ASD, we aimed to 1) investigate the concurrent relations among social communication skills (IJA, RJA, play, imitation), discourse, and pragmatic language use, and 2) determine which of these social communication skills predict growth in discourse and pragmatic language use overtime.

### Methods:

A sample of  $N=24$  (4 females) children with ASD, ages 21-55 months, completed assessments at two visits that were approximately 4 months apart (range: 2-6 months). Assessments included the Early Social Communication Scales (ESCS; Mundy et al., 2003), Structured Play Assessment (SPA; Kasari et al., 2006), Elicited Imitation Battery (EIB—manual and object oriented imitations only; Rogers et al., 2003), and a 10-minute parent-child interaction (PCI). Speech utterances during the PCI were segmented into communication units (c-units; Lovan, 1976) to obtain the rate of conversational turns (CTs) per minute. Child utterances were also coded according to communicative function (e.g., share, request, redirect) to obtain the rate of Social Communicative Utterances (SCUs) per minute; non-communicative utterances (e.g., scripting, rote speech) were excluded from analyses. Change scores were calculated by subtracting CT/min and SCU/min rates at the second visit (time 2) from CT/min and SCU/min rates at the first visit (time 1).

### Results:

Controlling for chronological age and Mullen NVDQ scores measured at time 1, imitation scores were significantly correlated with concurrent CT/min ( $r_s(18)=-.536, p=.015$ ) and SCU/min ( $r_s(18)=-.791, p<.001$ ), and IJA was significantly correlated with SCU/min ( $r_s(18)=-.547, p=.013$ ). All other concurrent correlations between social communication skills and language were non-significant (Table 1). Controlling for chronological age and Mullen NVDQ and VDQ scores measured at time 1, as well as the number of months between visits, imitation was significantly correlated with change in CT/min ( $r_s(16)=-.840, p<.001$ ) and change in SCU/min ( $r_s(16)=-.737, p<.001$ ). All other longitudinal correlations between social communication skills and change in language were non-significant (Table 2). Controlling for time between visits, change in imitation scores were significantly correlated with change in CT/min ( $r_s(20)=-.506, p=.016$ ) and SCU/min ( $r_s(20)=-.501, p=.017$ ).

### Conclusions:

Imitation is a significant concurrent and longitudinal predictor of discourse and pragmatic language use in preschoolers with ASD. Findings suggest that the predictors of language abilities may vary depending on the method used to assess language (e.g., natural language sampling). Future work should explore how targeting imitation in ASD intervention can lead to direct improvements in discourse and pragmatic language use.

#### 413.053 (Poster) Production of Complex *Ba* and *Bei* Sentences in Mandarin-Speaking Children with ASD: A Corpus-Based Study

J. Liu<sup>1</sup>, Q. Xie<sup>1</sup> and Y. E. Su<sup>2</sup>, (1)Foreign Language Department, Central South University, Changsha, China, (2)Childa Language Lab, School of Foreign Languages, Central South University, Changsha, Hunan, China

**Background:** Children with Autism Spectrum Disorder (ASD) demonstrated strengths in simple grammar, but limited research has investigated their development of complex grammar (Naigles & Chin, 2015). In Mandarin Chinese, *Ba* sentences (active sentences in subject-*Ba*-object-verb order) and *Bei* sentences (passive voice in object-*Bei*-subject-verb order) are complex structures involving noncanonical word orders. Zhou et al. (2017) was the first to report difficulties in comprehending *Bei* sentences among Mandarin-speaking 4-5-year-olds with High-Functioning Autism (HFA).

**Objectives:** Beyond comprehension, this study aims to investigate the production of *Ba* and *Bei* sentences in Mandarin-speaking preschoolers with HFA and their age and MLU-matched TD counterparts, to deepen our knowledge of their development of complex grammar.

**Methods:** We examined the spontaneous speech of TD children and children with HFA matched on age and MLU from Shanghai corpus (ASD) and Zhou2 corpus (TD) in the Child Language Data Exchange System (MacWhinney, 2000). The 60-month group includes seven children with HFA and twenty TD children (MLU:  $2.82\pm.70$  vs.  $3.20\pm.46$ ), while the 66-month group includes five children with HFA and twenty TD children (MLU:  $3.10\pm.59$  vs.  $3.05\pm.54$ ) ( $ps > .05$ ). Fourteen types of *Ba* and *Bei* sentences were coded (Table 1).

**Results:** Table 2 showed that the production of *Ba* sentences didn't differ between 60-month-olds and 66-month-olds for either the TD or ASD group ( $ps > .05$ ); moreover, the age-matched TD and ASD groups didn't differ in production ( $ps > .05$ ). The

mean percentage of *Bei* sentences was extremely low in ASD group (0.05% in 60-month-olds and 0.28% in 66-month-olds), while TD group didn't utter any *Bei* sentences. Again, the production of *Bei* sentences didn't differ in TD and ASD groups at two age groups ( $ps > .05$ ). In both groups, most frequently occurring types of *Ba* sentences are those followed by the directional and resultative complement. However, the *Ba* sentence with resultative complements increased significantly between 60-month-olds and 66-month-olds in TD children,  $t(30) = 2.18$ ,  $p < .05$ , but there was no significant development of any types in ASD group ( $ps > .05$ ).

**Conclusions:** Production of complex *Ba* and *Bei* sentences appears challenging for both ASD and TD groups, with the *Bei* sentences being more difficult to acquire, possibly due to children's greater reliance on word order than morphological cues. Specifically, the reanalysis of *Bei* sentences against the surface word order posits difficulties for children with ASD with deficits in executive function (Zhou et al., 2017). Children with ASD are similar to TD children in producing resultative and directional complements for the *Ba* sentences, because of the high percentage of these types in the input (Deng et al., 2018) and the fundamental "action-result" model of cognition (Zhang, 2008). However, TD group, but not ASD group, showed significant development of resultative complements of the *Ba* sentence (indicating the completion of an event, frequently co-occurring with the perfective aspect marker *le*), which may be influenced by children with ASD's difficulties in analyzing and representing the temporal components of event structure (Boucher, 2000).

**413.054** (Poster) Profiles and Predictors of Reading Abilities in Chinese Children with Autism Spectrum Disorder  
J. LIU<sup>1</sup> and Y. Wang<sup>2</sup>; (1)Tsinghua University, Beijing, China, (2)Department of Psychology, Tsinghua University, Beijing, China

---

**Background:** Reading is an important approach for us to obtain information and good reading ability is the foundation for success in study and life. However, for people with Autism Spectrum Disorder (ASD), acquiring good reading skill is not easy. Most children with ASD have some deficits in their reading development. Previous studies mainly explored the development of reading ability of autistic children in the context of alphabetic language, but rarely referred to the reading development of Chinese autistic children. The writing system of Chinese is a kind of morphemic language, which is essentially different from the alphabetic language. Therefore, it is particularly important to explore the development and influencing factors of Chinese reading ability of autistic children in the Chinese language environment.

**Objectives:** In order to understand the uniqueness of the reading development of Chinese autistic children and to explore the influencing factors of their reading abilities, this study measured the Chinese reading ability and reading-related language and cognitive skills of 20 autistic children aged 4-14 years.

**Methods:** Chinese reading ability were assessed by Chinese word decoding, oral vocabulary and sentence listening comprehension, and reading related skills include phonological awareness, morphological awareness, orthographic awareness, rapid naming ability, verbal working memory and general cognitive ability.

**Results:** Results showed that there were 4 different Chinese reading profiles in children with ASD: subtype 1 showed both good word decoding and comprehension skill, subtype 2 showed good word decoding ability but weaker comprehension skill, subtype 3 presented with average word decoding but weaker comprehension skill, subtype 4 showed both weak word decoding and comprehension skill. Overall, the Chinese reading ability of autistic children is significantly related to sentence-level language comprehension ability, phonological awareness, rapid naming, morphological awareness, orthographic awareness, vocabulary skill, general cognitive ability, and verbal working memory. The results tentatively indicate that there are around 20% of Chinese autistic children show high word decoding paired with low language comprehension ability. Phonological awareness, morphological awareness, and vocabulary are significant predictors of reading abilities in Chinese children with ASD.

**Conclusions:** The findings highlight the necessity to pinpoint the profile of ASD children's reading ability and the need for additional investigation of early predictors of reading development across different profiles.

**413.055** (Poster) Pronoun Reversals in Mandarin-Speaking Preschool Children with Autism Spectrum Disorder  
C. Zhang<sup>1</sup>, Q. Xie<sup>1</sup> and Y. E. Su<sup>2</sup>; (1)Central South University, Changsha, China, (2)Child Language Lab, School of Foreign Languages, Central South University, Changsha, Hunan, China

---

**Background:**

Pronoun reversals—using first person pronoun (English 'I' or Mandarin 'wo3') for second person pronoun (English 'you' or Mandarin 'ni3') and/or second person pronoun for first person pronoun — have been claimed to be prevalent in children with Autism Spectrum Disorder (ASD) (e.g., Kanner, 1943, Tager-Flusberg, 1994). However, more recent studies among English-

speaking children with ASD have addressed their relatively rare reversals of pronouns in language development (Barokova & Tager-Flusberg, 2020; Naigles et al., 2016). These conflicting results invite further research involved children with ASD speaking typologically different languages.

Objectives:

The present study aims to explore pronoun reversals in Mandarin-speaking preschool children with ASD, to further investigate the prevalence and origins of pronoun reversal in children with ASD learning languages typologically distinct from English.

Methods:

The spontaneous speech of 6 Mandarin-speaking high-functioning children with ASD aged 4-6 years across 12 visits was analyzed. The spontaneous speech data were drawn from the Mandarin ASD (Shanghai) corpus in the Child Language Data Exchange System (MacWhinney, 2000). We coded the utterances with first person and second person singular pronouns. Following Naigles et al. (2016), pronouns were coded as “correct” and “reversed”; for “reversed” pronouns, the discourse context was further coded as “imitative” and “non-imitative” (i.e., first person reversal-imitative; first person reversal non-imitative; second person reversal imitative; second person reversal non-imitative).

Results:

For Mandarin-speaking children with ASD, the percentages of producing first and second person pronouns out of the total utterances were 2.66% (1334/48890) and 0.6% (317/48890) respectively. And a total percentage of 3.05% (50/1651) was detected for reversed pronouns out of the total production of first and second person pronouns, amongst which the mean percent was significantly higher for second person pronoun reversals than first person pronoun reversals,  $13.8\% \pm 7.0\%$  vs.  $1.47\% \pm 0.9\%$ ,  $t(5) = 4.267$ ,  $p = 0.008$ ,  $d = 0.89$ . Moreover, the mean percent of reversals children with ASD produced was significantly more in imitative than in non-imitative context for second person pronouns,  $11.3\% \pm 5.68\%$  vs.  $2.50\% \pm 3.18\%$ ,  $t(5) = 3.605$ ,  $p = 0.015$ ,  $d = 0.85$ . Besides, a negative correlation emerged between the percent of second person pronoun reversals and MLU scores in children with ASD,  $r = -0.847$ ,  $p = 0.033$  (Fig. 1).

Conclusions:

This paper found that pronoun reversals in Mandarin-speaking preschoolers with ASD were very rare, with first and second person pronouns reversed for only 3.05% of the total utterances. The lack of pronoun reversals among Mandarin-speaking children with ASD is consistent with recent findings among English-speaking children with ASD (Naigles et al., 2016, Barokova & Tager-Flusberg, 2020), suggesting that pronoun reversals probably should not be referred to as “prevalent” for children with ASD across languages. Moreover, higher percentages of reversals in the second person pronouns than in the first person pronouns may be attributed to the combination of more parental child-directed speech referring to the child than to the parent and the cognitive egocentrism of young children with ASD (Evans & Demuth, 2012). However, pronoun reversals in children with ASD appear more in the imitative context of parental utterances and are negatively associated with their development of syntactic complexity (Naigles et al., 2016).

**413.056** (Poster) Relating Metalinguistic Abilities and Social Communication Skills in Autism

*N. M. Carlson, K. E. Hannah, K. McRae and R. A. Stevenson, Psychology, University of Western Ontario, London, ON, Canada*

**Background:** Recent research suggests that autistic individuals exhibit differences in metalinguistic ability, or the ability to understand language outside the concrete meaning of words, relative to their typically-developing peers. Metalinguistic ability has an important role in social communication, including making inferences and understanding figurative language, leading to the possibility that differences in metalinguistic abilities may contribute to the differences in social communication observed in autism. To date, however, this relationship between metalinguistic abilities and social communication skills in autism has not been thoroughly explored.

**Objectives:** Our first objective is to assess group differences in metalinguistic abilities and social communication skills between autistic and non-autistic children. Our second objective is to analyze the relationship between metalinguistic abilities and autistic traits, specifically social communication difficulties, on a spectrum, ignoring diagnostic groups.

**Methods:** Data were extracted from 118 participants from the Healthy Brain Network, including 30 autistic children and adolescents, and 88 individuals without an autistic diagnosis. Measures included the CELF-5 Metalinguistics assessment

(Metasemantic, Metapragmatic, and Total Metalinguistic Indexes), Autism Spectrum Screening Questionnaire, Social Aptitudes Scales, Social Communication Questionnaire, and Social Responsiveness Scale. Student's or Welch's (*t<sub>w</sub>*) t-tests were used to determine potential differences between autistic and non-autistic groups in social communication skills and metalinguistic abilities. Additionally, Pearson's correlations were used to assess the relationship between metalinguistic ability and autistic traits, specifically social communication skills, for all measures. However, participants' metalinguistics ability ranged between very low to average according to standardized scores.

**Results:** Significant differences between the autistic and non-autistic groups were seen within questionnaire and metalinguistic ability scores. Autistic youth had significantly higher autistic traits ( $t_{w(38)}=-5.91, p<.001$ ), lower social aptitude ( $t(94)=4.182, p<.001$ ), lower social communication ( $t(114)=-5.92, p<.001$ ) and lower social responsiveness ( $t(112)=-5.187, p<.001$ ). Furthermore, autistic individuals presented significantly lower metalinguistic abilities compared to non-autistic individuals (Metasemantic Index:  $t_{w(35)}=2.029, p=.05$ ; Metapragmatic Index:  $t(112)=2.262, p=.026$ ; and Total Metalinguistic Index:  $t_{w(33)}=2.218, p=.034$ ). Additionally, Pearson's correlations revealed no significant associations between metalinguistic abilities and autistic traits, specifically social communication skills, for all measures. However, participants' metalinguistics ability ranged between very low to average according to standardized scores.

**Conclusions:** Autistic youth are more likely to have metalinguistic difficulties compared to non-autistic youth, highlighting the importance of further understanding metalinguistic abilities in autism. These group differences included both metapragmatic and metasemantic abilities. Contrary to our hypothesis, no relationships were observed between metalinguistic and social communication abilities. This may be due to the non-autistic population in the Healthy Brain Network presenting with a high rate of non-autism diagnoses, reflected by their relatively constrained distribution of metalinguistic abilities. It is unclear whether a different pattern would result with the inclusion of participants with higher metalinguistic abilities. Further analyses would benefit from a broader range of metalinguistic abilities, and could consider possible moderating factors, such as age or cognitive ability.

#### 413.057 (Poster) Relations between Mental Terms and Theory-of-Mind Understanding in Cantonese-Speaking Autistic and Typically Developing Children

C. C. H. Cheung<sup>1</sup>, Y. Rong<sup>1</sup>, Y. Xiong<sup>2</sup>, M. T. Leung<sup>2</sup> and T. P. Y. Tang<sup>2</sup>, (1)Research Centre for Language, Cognition, and Neuroscience, Department of Chinese and Bilingual Studies, The Hong Kong Polytechnic University, Hong Kong, Hong Kong, (2)Department of Chinese and Bilingual Studies, The Hong Kong Polytechnic University, Hong Kong, Hong Kong

---

**Background:** Previous studies have shown that children's understanding of first- and second-order theory of mind (ToM) correlates with their knowledge of the factivity semantics of mental terms. Specifically, Hong Kong typically developing (TD) children's comprehension of strong nonfactive verbs was found to predict their first-order ToM understanding (Cheung et al., 2009), while mainland Chinese TD children's comprehension of factive mental terms was found to predict both first- and second-order ToM understanding (Li & Leung, 2020). Although numerous studies have found that children with autism spectrum disorders (ASD) show deficits in mental term comprehension (Yi et al., 2013) and ToM understanding (Baron-Cohen et al., 1985), the relation between autistic children's ToM abilities and their understanding of the factivity semantics of mental terms remains understudied.

**Objectives:** This study examined whether comprehension of factive mental terms (*zidou6* 'know', *ng4gei3dak1* 'forget', and *hou2hoi1sam1* 'happy') and nonfactive mental terms (*ng6wui6* 'mistakenly think', *ji5wai4* 'falsely think', and *waan6soeng2* 'imagine') predicts first- and second-order ToM understanding in Hong Kong Cantonese-speaking children with ASD and their TD peers.

**Methods:** 40 Hong Kong Cantonese-speaking children with ASD (mean age = 6.92, *SD* = 1.47) and 63 TD children (mean age = 6.20, *SD* = 0.92) participated in this study. The ASD group and the TD group were matched on language ability, and participants in the ASD group were significantly older than those in the TD group. Knowledge of the factivity semantics of mental terms was tested using a sentence comprehension test modeled after Cheung et al. (2009), in which children judged the truth or falsity of the complement clause following the factive or strong nonfactive mental terms. Participants' first- and second-order ToM understanding was assessed using the Content False Belief task (Wellman & Liu, 2004) and the Ice Cream Van test (Perner & Wimmer, 1985), respectively. Participants' language ability and nonverbal intelligence were assessed using the Test of Hong Kong Cantonese Grammar of The Hong Kong Cantonese Oral Language Assessment Scale (T'sou et al., 2006) and the Primary Test of Nonverbal Intelligence (Ehrler & McGhee, 2008), respectively.

**Results:** Children with ASD performed significantly worse than TD children on both ToM and mental terms tests. The results of multiple linear regressions showed that after controlling for the effects of chronological age, language ability, and nonverbal intelligence, autistic children's comprehension of the three strong nonfactive mental terms ('falsely think', 'mistakenly think',

and ‘imagine’) significantly predicted their first-order ToM understanding. As for TD children, none of the mental terms significantly predicted their first- or second-order ToM understanding.

Conclusions: This study found that only strong nonfactive mental terms significantly predicted first-order ToM understanding in Cantonese-speaking autistic children. This provides new evidence that knowledge of strong nonfactive mental terms is crucial for autistic children’s understanding of first-order ToM. Our finding that neither factive nor strong nonfactive mental terms predicted first- or second-order ToM understanding in TD children could be attributed to their mastery of the factivity semantics of factive and nonfactive mental terms as well as to their first- and second-order ToM understanding.

**413.058** (Poster) Say That Again: Quantifying Patterns of Grammatical Production for Children with ASD Using Recurrence Analysis

A. Mankovich<sup>1</sup>, K. Wittke<sup>2</sup>, J. E. Blume<sup>3</sup>, A. Mastergeorge<sup>4</sup>, A. Paxton<sup>1</sup> and L. R. Naigles<sup>1</sup>, (1)Psychological Sciences, University of Connecticut, Storrs, CT, (2)University of Connecticut, Storrs, CT, (3)Department of Human Development and Family Studies, Texas Tech University, Lubbock, TX, (4)Texas Tech University, Lubbock, TX

---

Background:

Immense heterogeneity of grammatical abilities exists among children with ASD (e.g., Kjelgaard & Tager-Flusberg, 2001; Roberts et al., 2004; Wittke et al., 2017). Previous research has demonstrated that these individuals vary on broader measures (e.g., standardized tests, MLU); however, more detailed analyses are needed to investigate why some children habitually produce short/telegraphic utterances. Categorical recurrence quantification analysis (RQA) offers a novel approach to understand the nature of these production difficulties by quantifying the structure within sequences of categories. Previous applications often quantified grammatical alignment between two speakers (e.g., Dale & Spivey, 2005, 2006), but we evaluate changes within individual children at the level of grammatical form classes.

Objectives:

We perform RQA on noun phrases from 5-year-olds’ language samples, as this grammatical form class develops earliest.

Methods:

The present study uses a subset of the Autism Phenome Project dataset ( $n = 31$ ,  $M_{age} = 72.71$  months, 10 females,  $M_{NVIQ} = 95.32$ ,  $SD = 19.39$ ;  $M_{TOTALADOS} = 12.19$ ,  $SD = 4.86$ ). Language sample transcriptions were parsed for MLU and percent ungrammatical utterances (%UU), annotated for form classes (see Table 1) and analyzed via RQA. RQA measures instances of pairs of repeated units over time by creating recurrence plots (RP) and subsequently quantifying them through recurrence rate (RR) and determinism (DET). RR calculates the percentage of the RP containing filled-in points; high RR indicates frequent reuse of form classes. DET measures the structure of repeated sequences, which is visible on the RP as larger box structures rather than single dots. High DET indicates that children repeat form class combinations. Analyses differentiated between noun phrase (NP) and all other form classes (see Table 1) and investigated the extent to which RR and DET related to MLU and %UU.

Results:

Figure 1 shows four example RPs, highlighting the variability within our sample. Child A repeats many unit combinations verbatim (poor production), whereas B repeats less (good production; e.g., ‘adjective noun’ and ‘determiner possessive noun’). C repeats words often, testing few new words across many new sequences (moderately poor production; e.g., ‘determiner noun’ and ‘determiner adjective noun’), whereas D keeps using new units in new combinations without revisiting prior ones (moderately good production; e.g., ‘noun’ versus ‘adjective demonstrative pronoun’). Preliminary analyses revealed a negative association between RR [ $M = 5.38$ , Range = 3.54 10.47] and MLU [ $M = 4.64$ , Range = 1.90 9.14;  $r(29) = -.54$ ,  $p < .01$ ]; children who repeated NP-related *elements* more often had shorter MLUs. Moreover, a positive association emerged between DET [ $M = 21.77$ , Range = 7.26 37.37] and MLU [ $r(29) = .51$ ,  $p < .01$ ], in that children who repeated longer NP-related *sequences* had longer MLUs. Interestingly, neither RR nor DET were associated with %UU ( $p$ ’s  $> .09$ ). These persisted even after controlling for NVIQ and total ADOS score.

Conclusions:

These data illustrate that higher syntax levels may indicate adding new form classes to previously used sequences. Findings underscore the value of using RQA metrics as more fine-grained measures of grammatical production for extricating variability

among children with ASD.

**413.059** (Poster) School-Entry Language Skills As Predictors of Academic and Social Outcomes in Kindergarteners with ASD  
**E. P. McKernan**<sup>1</sup>, **A. P. Viggiano**<sup>2</sup> and **S. H. Kim**<sup>3</sup>, (1)Psychiatry, Center for Autism and the Developing Brain, Weill Cornell Medicine, White Plains, NY, (2)Weill Cornell Medicine Center for Autism and the Developing Brain (CADB), White Plains, NY, (3)Psychiatry, Center for Autism and the Developing Brain, White Plains, NY

---

Background: Language ability varies widely for children with ASD (Tager-Flusberg, Paul, & Lord, 2005). Among verbal children with ASD, the social use of language (pragmatics) may be still impacted even when syntactic or semantic skills are intact (Gorman et al., 2016). Language problems could also affect children's academic achievement and the development of peer relationships (Gibson et al., 2013; Helland & Helland, 2017). Therefore, exploration of how school-entry language skills predict academic and social outcomes can help to inform early interventions.

Objectives: (1) Compare language profiles of children with ASD and typically developing (TD) children at kindergarten-entry using the Children's Communication Checklist-2 (CCC-2). (2) Determine whether CCC-2 scores at kindergarten entry are predictive of academic achievement and peer interactions across the kindergarten year.

Methods: Participants included 97 children including 62 cognitively-able children with ASD and 35 TD children. Language abilities were assessed via caregiver report using the CCC-2 (Bishop, 1998). A syntactic/semantic domain was created by averaging scaled scores from the domains related to mechanics of language (speech, syntax, semantics, and coherence), and a pragmatics domain by averaging scaled scores for the initiation, scripted language, context, and nonverbal communication subtests. Subtests of the Woodcock Johnson III Tests of Achievement (WJ; Woodcock et al., 2001) were used to measure children's reading and math skills. Children's peer play interactions were assessed via caregiver report on the Penn Interactive Peer Play Scale (PIPPS; Fantuzzo & McWayne, 2002). Language scores of children with and without ASD were compared using linear regressions while controlling for age, gender, and NVIQ. Within the ASD group, linear regressions were conducted to evaluate the effects of kindergarten-entry language abilities as predictors of academic achievement and social functioning at kindergarten-entry and -exit while controlling for gender, age, NVIQ, and autism symptom severity (ADOS-2 Calibrated Severity Scores).

Results: Children with ASD showed significantly more impairments on all domains of CCC-2 at kindergarten-entry compared to TD children even after accounting for the effects of age, gender, and NVIQ. For the prediction of academic skills, when syntactical and pragmatic domains were entered into the same model, kindergarten-entry pragmatic skills significantly predicted concurrent WJ Applied Problems (math;  $B = -.287, p = .035$ ) and Letter Word Identification ( $B = -.352, p = .017$ ). Both syntactic and pragmatic language skills at kindergarten-entry significantly predicted future performance on WJ Letter Word Identification ( $B = .362, p = .012$ ;  $B = -.425, p = .004$ , respectively) and Passage Comprehension ( $B = .272, p = .047$ ;  $B = -.370, p = .008$ , respectively) at kindergarten-exit; pragmatic skills significantly predicted future performance on WJ Math Fluency ( $B = -.321, p = .024$ ). For the prediction of social outcomes, kindergarten-entry pragmatic language skills significantly predicted Play Disruption and Play Disconnection as measured by the PIPPS at kindergarten-entry ( $B = -.355, p = .016$ ;  $B = -.596, p < .001$ , respectively) and kindergarten-exit ( $B = -.506, p = .001$ ;  $B = -.294, p = .041$ , respectively).

Conclusions: Kindergarten-entry language skills in children with ASD predicted concurrent and year-end academic achievement as well as peer play skills, indicating the importance of language ability for kindergarten success. Specifically targeting pragmatic language prior to school-entry may promote better academic and social outcomes for cognitively-able children with ASD.

**413.060** (Poster) Social Language Use and Behavioral and Social Engagement in Inclusive Classrooms for Preschoolers with and without ASD  
**R. M. Fasano**<sup>1</sup>, **L. K. Perry**<sup>1</sup>, **S. Custode**<sup>1</sup>, **A. Adams**<sup>1</sup>, **L. Vitale**<sup>1</sup>, **R. Bulotsky-Shearer**<sup>1</sup> and **D. S. Messinger**<sup>2</sup>, (1)Psychology, University of Miami, Coral Gables, FL, (2)University of Miami, Coral Gables, FL

---

Background: Defined by disturbances in social communication and interactions, autism spectrum disorder (ASD) frequently involves delayed language and self-regulation skills. A common feature of children with ASD is deficits in social language with peers, defined here as talking with a peer while in close proximity and mutually oriented. Here we investigate talking with peers as our primary measure of social language. One key measure of self-regulation is behavioral engagement, or children's ability to stay on task and be self-reliant in the classroom.

**Objectives:** Here, we use innovative, automated measures and expert observations to examine whether differences in language abilities, particularly social use of language, in children with and without ASD relate to classroom behavioral and social engagement.

**Methods:** Participants included 84 preschoolers (36 female) enrolled in eight inclusive classrooms (27 with ASD, 26 with developmental delays [DD], and 31 typically developing [TD]). During monthly observations, children wore lightweight vests equipped with Language ENvironment Analysis (LENA) to measure vocalizations and two Ubisense tags to measure location. Ubisense measures of proximity/orientation were used to determine social contact, and synchronized to LENA data to assess each child's social language use (output) with peers. Children's end-of-year language abilities were assessed with the Preschool Language Scales (PLS-5). Researchers also observed each child using the INdividualized CLassroom Assessment Scoring System (inCLASS), which consists of four domains relating to children's social engagement with teachers and peers (e.g. eye contact), their behavior (or task) engagement (e.g. staying focused on an assigned task), and negative engagement (e.g., yelling). During each inCLASS assessment, a trained researcher observed one child at a time, scoring the child on each of the four domains; each domain had a possible range of 2-21 per observation. Each child was observed for four 10-minute periods over the course of one day. These scores were averaged across all four periods to create a composite score for each child in each domain. Here, we examine behavioral engagement and positive social engagement with peers in the classroom.

**Results:** Preliminary analyses from three classrooms indicated differences in social language use and behavioral and social engagement. TD children had higher behavioral engagement ( $M=8.61$ ), social engagement ( $M=9.52$ ), ( $M=.93$ ), and total PLS-5 scores ( $M=119.29$ ) than their DD/ASD peers (behavioral engagement  $M=6.09$ ; social engagement  $M=4.87$ ; social language use  $M=.62$ ; PLS-5 scores  $M=80.33$ ;  $ps<.05$ ). Linear regression indicated that social language use was associated with behavior engagement ( $p=.040$ ; Figure 1) and social engagement with peers ( $p=.048$ ; Figure 2), such that increases in social language use were associated with higher appropriate classroom behavior and positive peer interactions, regardless of diagnosis.

**Conclusions:** Overall, we found that children with ASD and DD had lower levels of language ability, social language use, and classroom behavioral and social engagement than TD children, but social language use predicted behavioral and social engagement for all groups of children. Thus, although children with ASD and DD may have particular difficulty with the behavioral skills needed for classroom engagement, their developing language skills can support the development of self-regulation.

#### **413.061 (Poster) Social Skills in Multilingual Children with Autism**

*M. Franco<sup>1</sup>, G. Steffgen<sup>2</sup> and A. P. Costa<sup>3</sup>, (1)University of Luxembourg, Esch-sur-Alzette, Luxembourg, (2)Institute for Health and Behaviour, University of Luxembourg, Luxembourg, Luxembourg, (3)University of Luxembourg, Esch sur Alzette, LUXEMBOURG*

---

**Background:**

Parents of children with autism spectrum disorder (ASD) are often advised to use only one language to simplify language acquisition for their child. However, monolingualism is especially difficult to implement in the more and more multicultural world and especially challenging in minority-language families, as the recommendation orients towards the geographically predominant language. Scientific research suggests that multilingualism is not related to language skills and other child development factors, and that using exclusively foreign languages may even impede social interaction between family members.

**Objectives:**

The present study investigated whether the choice of language in the upbringing of children with ASD is related to the children's social skills and to parents' ability to feel comfortable, authentic, and free to express themselves when interacting with their child.

**Methods:**

This study was offered as a quantitative online survey and was shared in countries all over the world. Children's and parents' sociodemographic data, language use and proficiencies, and parents' feelings regarding their choice of language use were assessed using questionnaires formulated for the purposes of this study. Children's social skills were assessed using the Social Responsiveness Scale™, Second Edition (SRS-2; Constantino & Gruber, 2012) and children's diagnosis was controlled using the Autism Spectrum Quotient – Children's version test (AQ-Child; Auyeung et al., 2008).

**Results:**

Data of 68 families with children with ASD from 25 different nationalities showed that the choice of language was not significantly related to social skills in children. However, parents using only their mother tongue felt significantly more comfortable [ $H(3) = 18.18, p < .01, r = .39$ ] than parents using exclusively a foreign language when addressing their child (see Figure 1). Also, parents using only their mother tongue felt significantly more authentic than parents using exclusively a foreign language [ $H(3) = 21.21, p < .01, r = .42$ ] and parents using multiple foreign languages [ $H(3) = 23.97, p < .05, r = .38$ ] (see Figure 2). In addition, parents using their mother tongue, either only their mother tongue or in combination with other languages reported feeling significantly more comfortable ( $U = 384.00, z = -2.37, p < .05, r = -.29$ ) and more authentic ( $U = 273.50, z = -3.74, p < .001, r = -.45$ ) than parents using exclusively foreign languages, either one or many. There were no significant differences between monolingual and multilingual families regarding all parents' feelings about their choice of language use.

#### Conclusions:

Our findings suggest that advising parents to discard their mother tongue and use only the culturally predominant language cannot be supported scientifically in terms of consequences for children's social skills and may have negative consequences for the parents. Our findings may encourage specialists to consider multilingualism more often and consult with parents whether monolingualism is worth risking the negative outcomes we have found. Advising parents to raise their child multilingually may facilitate access to therapeutic treatment, childcare, and social interaction in the multicultural society and family and thus improve support and orientation for families with a child with ASD.

**413.062** (Poster) Statistical Learning and Its Relation to Language in Young Children with Autism: An Eye-Tracking Study  
*A. Oldham<sup>1</sup>, A. Browngoehl<sup>2</sup>, N. R. Lee<sup>1</sup> and G. Vivanti<sup>2</sup>, (1)Department of Psychology, Drexel University, Philadelphia, PA, (2)A.J. Drexel Autism Institute, Drexel University, Philadelphia, PA*

---

**Background:** Research has consistently documented language difficulties in autism spectrum disorder (ASD). One plausible yet untested factor contributing to these difficulties is a deficit in statistical learning abilities. Previous research has shown that statistical learning, the ability to extract statistical regularities, is critical to language development in typical children. Its role in young children with ASD has not been studied due to methodological limitations. To address this gap in research, we created a novel eye-tracking task testing statistical learning.

**Objectives:** To test the hypothesis that performance in the statistical learning task contributes to variance in verbal language abilities of young children with ASD.

**Methods:** A group of 32 children with an ASD diagnosis, ages 25-35 months, was administered an eye-tracking task designed to test statistical learning. Statistical learning was indexed by participants' anticipatory gaze in response to the observation of patterns of events in two conditions. In the deterministic condition, a video-animation showed a sequence of events whereby a ball is descending down a waterfall, is occluded behind a bridge, and then descends down to three stream options, going down the same stream for four trials. In the probabilistic condition, the same scenario was presented, but the ball descended down the same waterfall in three of the four trials, while in one trial it descends down the opposite stream. Anticipatory gaze was computed as the duration of attention to the waterfall stream where the ball descended all the time (deterministic condition) or most of the time (probabilistic condition) before the ball was seen falling down stream. We examined the association between statistical learning in the two conditions (as indexed by the increase in anticipatory gaze over trials) and verbal ability as indexed by the communication subscales of the Mullen Scales for Early Learning (MSEL) and Vineland Adaptive Behavior Scales (VABS).

**Results:** In the deterministic condition, after observing that the ball was consistently descending down the left waterfall in the first two trials, children with ASD were showing anticipatory gaze towards the left waterfall in the following trials ( $p < .001$ ), thus demonstrating the ability to extract patterns, such as the direction of the ball's path, and anticipate future events. In the probabilistic condition there was no evidence of anticipatory gaze in the direction where the ball was falling in most trials ( $p = .27$ ). Statistical learning in the deterministic condition, but not in the probabilistic condition, was associated with verbal ability across standardized scores in the MSEL ( $p = .01$ ) and VABS ( $p < .05$ ).

**Conclusions:** Young children with ASD in this task showed evidence of statistical learning in the deterministic condition, but not in the probabilistic condition. This suggests that children with ASD might be able to learn "what is going to happen next" after observing repetitions of the same event in a deterministic but not in a probabilistic scenario. Children with better performance in the statistical learning task had better language skills, consistent with the prediction that statistical learning contributes to language development in this population.

**413.063** (Poster) The Association between Language Impairments and Behaviours of Concern in Autism Spectrum Disorder: A Systematic Narrative Review

A. Brignell<sup>1,2,3</sup>, K. Williams<sup>4</sup> and C. Y. Z. Chan<sup>5</sup>, (1)Murdoch Children's Research Institute and University of Melbourne, Melbourne, Australia, (2)Paediatrics, Monash University, Clayton, VIC, Australia, (3)Speech Pathology, Australian Catholic University, Fitzroy, VIC, Australia, (4)Department of Paediatrics, Monash University, Melbourne, VIC, Australia, (5)University of Melbourne, Melbourne, VIC, Australia

---

**Background:** Behaviours associated with risks to the individual and others are commonly observed in autism spectrum disorder (ASD) and collectively referred to as behaviours of concern (BoC). Other than potential direct harm, BoC impair social interactions and relationships, limit education and work engagement and reduce care and living options. BoC could, in part, be associated with language impairments.

**Objectives:** To systematically review existing evidence to assess if there is an association between language impairments and BoC in ASD.

**Methods:** We searched EMBASE, MEDLINE, PsycINFO and CINAHL to retrieve original published research. We also checked reference lists of all included studies and relevant reviews. Studies in English were included if the sample size was greater than ten participants with ASD, if there was a measure of language impairment and behaviour amongst the participants, and analysis of an association between these two factors. We included self-injurious behaviour (SIB), aggression, externalising behaviour, tantrums and disruptive behavior as BoCs. Language measures included those that predominantly focused on the structure of language (i.e. content and/or form) as compared with the social use of language. No limitations were placed on age of participants or date of study publication. Risk of bias was assessed. Results were presented using narrative synthesis.

**Results:** The titles and abstracts of 2,669 records were reviewed, with 109 selected for full text assessment. Eighty-six of these were excluded, resulting in 22 included studies (of 23 records). These studies included 7,937 participants, with studies conducted predominantly in the United States (N=15). Of the included studies, 19 collected data cross sectionally, while the remaining 3 were prospective cohort studies. Age of participants ranged from 1.25 to 52 years, with a mean age of 9.1 years. Male to female ratio was 5.3 to 1.

No significant associations were found between expressive language and tantrums, composite measures of language and externalising behaviour, receptive language and SIB, and adaptive language and SIB. There may be a negative association between expressive language and SIB, and expressive language and challenging behaviour. Only 10 of 22 studies adjusted for covariates in their analysis.

There was substantial heterogeneity in the definitions and measurement of language impairment and behaviour. There was a mixture of language domains studied, including expressive language, receptive language, composite measures or a combination of adaptive expressive and receptive language. Most authors that studied expressive language presented a parent-report language scale (e.g. no words, less than 5 words, or functional speech). Behaviour was also defined and measured in different ways.

**Conclusions:** There is no clear, strong consensus on the association between the various constructs of language and BoC. Different domains of language appear to have differential associations with BoC. The most consistent association was between expressive language and challenging and self-injurious behaviour. There is large variation in characterisation of both language and challenging behaviour, including the use of non-validated tools. These findings emphasise the importance of a detailed communication assessment when considering factors associated with BoC and when planning intervention for managing BoC in individuals with ASD.

**413.064 (Poster)** The Emotional Valences of Passive Sentences in Japanese By Adolescents with ASD Tendencies  
K. Yorozuya<sup>1</sup>, J. Adachi<sup>2</sup>, M. Saito<sup>3</sup> and R. Yorozuya<sup>4</sup>, (1)Education, Hokkaido University, Sapporo, Japan, (2)Graduate School of Education, Hokkaido University, Sapporo, Japan, (3)Department of Special Education, Hokkaido University of Education, Sapporo, Sapporo, Japan, (4)Department of English Language Education, Hokkaido University of Education, Sapporo, Sapporo, Japan

---

Background: Lartseva, et al. (2015) point out that "...individuals with ASD are able to correctly identify words, sentences or stories as emotionally positive or negative". However, it is not yet clear whether individuals with ASD can accurately classify them into positive or negative in a Japanese cultural context. Direct passive sentences in Japanese almost always convey either a positive or negative meaning, with the exception of passive sentences with inanimate subjects which are usually interpreted as having no benefit or damage connotations. Such passive sentences with inanimate subjects have an objective meaning and are uncommon in Japanese everyday life.

**Objectives:** The purpose of this study is to clarify how individuals with ASD tendency perceive passive sentences with inanimate subjects, compared with more common passive sentences with animate subjects. We measured the emotional values that people with a tendency towards ASD feel about direct passive sentences with positive, negative, or neutral meanings, in order to explore possible difficulties they experience in daily communication.

**Methods:** We measured the emotional values two subject groups placed upon three types of direct passive sentences (16 sentences respectively for damage, benefit, and neutral meanings) in 12 adolescents who had a tendency towards ASD and a control group consisting of 106 university students. They were asked to mark the strength of their feelings concerning each sentence on a straight line ranging from negative to positive (The visual analog scale: VAS). Emotional values were measured by the distance in millimeters from the center point (neutral) of the straight line to the mark the participants had made.

**Results:** As a result of comparing the two groups' reactions for each of the three types of direct passive sentences, a significant difference was observed only in the sentence with an inanimate subject and a neutral meaning ( $t(11.463) = 2.653, p = 0.022, d = 1.51$ ). Furthermore, a chi-square test was performed by dividing the emotional values the subjects put upon the direct passive sentences with inanimate subjects into three groups: negative: ( $\leq -5$  mm), neutral: ( $4 \text{ mm} \leq 5$  mm), positive: ( $> 6$  mm). The result revealed that most participants in the control group showed neutral emotional values, but the ASD tendency group tended to evaluate the sentences more positively ( $\chi^2(2) = 76.338, p < .01$ ).

**Conclusions:** One possible explanation for the outcome is that the subjects on the autism spectrum perceived objects and people as equivalent, so they may have undifferentiated psychological distances toward objects and people. Another possibility is that the two groups viewed the premise that sentences with inanimate subjects which have an objective meaning and are uncommon in Japanese everyday life differently. The cognitive background behind the different perceptions held by people with a tendency towards ASD regarding the emotional values they placed on passive sentences with inanimate subjects in Japanese could be clarified by performing the same study in English-speaking countries, which could provide indicators to help develop a support method for people with ASD concerning daily communication.

**413.067 (Poster)** "I Could Not Quite Figure out What It Was about. They Never Say It Directly" – Contextually Relevant Inferencing and Narration By Young Adults with and without an Autism Spectrum Disorder Diagnosis

**K. Dindar<sup>1</sup>, S. Loukusa<sup>1</sup>, E. Leinonen<sup>2</sup>, L. Mäkinen<sup>1</sup>, L. Mämmelä<sup>1</sup>, M. L. Mattila<sup>3</sup>, H. E. Ebeling<sup>3</sup> and T. Hurtig<sup>4</sup>,** (1)Research Unit of Logopedics, University of Oulu, Oulu, Finland, (2)Office of the Vice Chancellor, Murdoch University, Perth, Australia, (3)Clinic of Child Psychiatry and PEDEGO Research Unit, Oulu University Hospital and University of Oulu, Oulu, Finland, (4)Research Unit of Clinical Neuroscience, Clinic of Child Psychiatry and PEDEGO Research Unit, University of Oulu and Oulu University Hospital, Oulu, Finland

---

**Background:**

Interpreting and using language in a *contextually relevant* manner is considered challenging for many individuals diagnosed with autism spectrum disorder (ASD). Studies have shown that adults diagnosed with ASD can have challenges in responding to inference questions about others' mental states when viewing pragmatically complex social scenes (e.g. Heavey et al., 2000; Lönnqvist et al., 2017). Studies have also shown that compared to neurotypical individuals, adults diagnosed with ASD spontaneously tell more detail-focused narratives about the complex scenes viewed, with less engagement in inferencing the broader meaning of events (Barnes & Baron-Cohen, 2012). However, in spontaneous situations, little is known about the extent to which inferencing and narration by individuals diagnosed with ASD can be considered contextually relevant for the scenes viewed.

**Objectives:**

To explore whether young adults with and without an ASD diagnosis differ in terms of the contextual relevancy of 1) the inferences and 2) the narratives they spontaneously produce about pragmatically complex social scenes.

**Methods:**

Participants included Finnish young adults with a diagnosis of ASD (25 males, 7 females) and control participants without an ASD diagnosis (24 males, 10 females). The groups did not differ by age ( $Mdn_{ASD} = 22.9$  years;  $Mdn_{CONTROL} = 22.5$  years;  $U = 624.5, p = 0.302$ ) or Wechsler Adult Intelligence Scale IV Verbal Comprehension Index score ( $M_{ASD} = 108.3$ ;  $M_{CONTROL} = 106.9$ ;  $t(64) = 0.344, p = 0.732$ ). The participants were shown seven short video clips. The video clips involved pragmatically complex social interactions, such as deception, requiring the contextual inference of meaning. After viewing each clip, the participants

were asked to spontaneously narrate what they thought had happened in the clip. The narratives were analysed for the pragmatic elements presented in Table 1. Depending on the data distributions, a *t*-test or Mann-Whitney *U*-tests were used for statistical analysis. The analyses were corrected for multiple testing by controlling the false discovery rate (Benjamini-Hochberg procedure) with  $\alpha$  0.05. All the *p*-values reported as statistically significant remained significant after the correction.

#### Results:

The control group scored higher than the ASD group in inferring the pragmatic key elements of the scenes ( $t(64) = 2.720, p = 0.008$ ; see Table 2). The narratives of the control group included less meaning-related misunderstandings ( $U = 756.0, p = 0.005$ ), less focus drift ( $U = 629.0, p = 0.017$ ) and less extraneous details ( $U = 681.0, p = 0.009$ ). The groups did not differ in the number of narratives involving setting-related misunderstandings ( $U = 505.5, p = 0.531$ ), gap fill-in ( $U = 496.0, p = 0.529$ ), personal commenting ( $U = 604.0, p = 0.378$ ) or stimulus-related commenting ( $U = 586.0, p = 0.542$ ).

#### Conclusions:

Whilst the groups' narratives shared multiple elements, they also differed in key aspects, specifically in regard to using context to infer meaning. Narratives about pragmatically complex social scenes give insight into the groups' differences in interpreting social situations as well as into the challenges that individuals diagnosed with ASD might face when navigating social interactions.

# Diagnostic, Behavioral, Sensory and Intellectual Screening and Assessment

## PANEL SESSION — DIAGNOSTIC, BEHAVIORAL, SENSORY AND INTELLECTUAL SCREENING AND ASSESSMENT

### Panel 203 - Autism in Children with Hearing or Visual Impairment: Early Risk Signs, Atypical Profiles and Modified Diagnostic Assessment Approaches

**Panel Chair: Naomi Dale**, *Neurodisability Service, Great Ormond Street Hospital NHS Foundation Trust, London, United Kingdom, Clinical Neurosciences, UCL Great Ormond Street Institute of Child Health, London, United Kingdom, Neurodisability Service, Great Ormond Street Hospital NHS Foundation Trust, London, United Kingdom, Clinical Neurosciences, UCL Great Ormond Street Institute of Child Health, London, United Kingdom*

**Discussant: Cory Shulman**, *The School of Social Work, The Hebrew University of Jerusalem, Jerusalem, Israel*

Children with severe hearing or visual impairment are at additional risk of social communicative difficulties and autism spectrum disorder; meta-analysis shows a thirty one times higher risk in children with visual impairment compared to the typically sighted population. For clinical preventative and interventionist reasons and for greater scientific understanding of the early risks and atypical profiles and potential aetiologies, robust validated measures are required for assessing and diagnosing autism spectrum disorder in the context of hearing or visual impairment. This has raised high clinical and scientific challenges as existing validated instruments are dependent on functional auditory or visual abilities. To address this important clinical and scientific need, three paediatric centres, who have been leading in clinical experience and research in this area, bring together new research methodologies, insights and modified diagnostic assessment approaches to underpin the clinical practice and scientific research of the future with these populations. The topics covered are comparison of social communicative skills of young children with vision impairments and those with typical sight and autism spectrum disorder, modified assessment methods for diagnosing autism in children with hearing impairment and vision impairment and early social communicative risks predicting diagnostic profiles of autism in children with vision impairment.

**203.001 (Panel)** A Comparison of Social Skills of Children with Vision Impairments and Those with Autism Spectrum Disorders

**Z. Nir**, *The School of Social Work, The Hebrew University of Jerusalem, Jerusalem, Israel*

Background:

Vision impairment (VI) is a sensory disability that affects many areas of child development (Vann et al., 2015; Hobson, 2005). Research reveals an overlap of the social-communication challenges that children with VI face with those challenges that children with autism spectrum disorder (ASD) experience, but this overlap is not well understood (Hobson & Lee, 2010; Absoud, Parr, Salt & Dale, 2011; Do et al, 2017).

**Objectives:** The purpose of this research was to characterize and compare social, language and behavior profiles of preschool children with VI and with ASD. This study is a part of a wider research program investigating social skills of preschool children with VI and those with ASD.

**Methods:** Forty preschool children with congenital VI and forty preschool children with ASD, matched on gender, and chronological and mental ages participated in this research. The children's vision level, in the VI group, was divided into moderate (n=25) and severe to blind (n=15) according to an ophthalmologist assessment using the Snellen scale for vision acuity and ICD-10 criteria (Salt et al., 2007; WHO, 2016). Parents in both VI and ASD groups were interviewed by the Autism Diagnostic Interview (ADI-R) and all children were observed by the Autism Diagnostic Observational Schedule (ADOS-2). Both tools were modified for the VI group by omitting visual depended items.

**Results:** An item by item analysis of the data from the ADI-R and ADOS2, which accounted for VI severity level, revealed similar deficits in overall level of language, immediate echolalia and hand and finger mannerisms. Differences emerged, with the children with ASD revealing more repetitive and restrictive behaviors and less social initiation than the children with VI. Responsivity, conversation and unusual sensory interest had variations between parental report and direct observation. For

instance, parents in both group reported similar levels of deficits in responsivity in social interaction whereas on direct observation the ASD displayed higher level of deficits in responsivity in comparison to the VI group.

Conclusions: The findings from this study suggest a similar level of deficits in children from both groups in language development and excessive sensory interest. However, children with VI displayed better social skills, including social initiation and responsivity than children with ASD. Our conclusion is that, although there are similar challenges in the development of VI and ASD children, there is apparently a different course of development of social skills. These findings help to distinguish between children with VI and ASD and can further our ability to understand the similarities and differences among them. Further research will help clarify these issues.

**203.002 (Panel)** Modified Assessment Methods for Diagnosing Autism Spectrum Disorder in Children with Severe Hearing Impairment

**B. Wright**, *Child Oriented Mental health Intervention Centre, University of York, York, United Kingdom*

---

Background:

Deaf children and young people face a range of challenges that lead to poorer educational and life outcomes than their peers. This includes an increased chance of language deprivation and social emotional developmental delay in early life. These issues and profiles make assessment for autism spectrum disorders (ASD) very challenging.

Objectives:

To present the results of a large sample 5 year Medical Research Council study to adapt ASD assessment tools for use in deaf children and young people. The study has been undertaken by the Child Oriented Mental health Intervention Centre (COMIC) in conjunction with specialist National Deaf Child and Adolescent Mental Health Services (NDCAMHS) in England including deaf mental health practitioners, psychiatrists, speech and language therapists and psychologists who are expert in the psychological and developmental needs of children who are deaf working closely with people with lived experience.

Methods:

A large national sample was recruited through the National Deaf CAMHS (England) services. Children were assessed with the Autism Diagnostic Observation Schedule (ADOS-2) adapted for use with deaf people (using Modules appropriate to their developmental stage) with assessors working in sign language when the child's main language was sign. Parents filled in the Social Responsiveness Scale Deaf adaptation (SRS-2- DA) and were interviewed using the Autism Diagnostic Interview Deaf adaptation (ADI-R- DA). Members of the team independently assessed the children for ASD with gold standard blinded assessment.

Results:

We report the validation of these tools including deaf adaptations of the SRS-2, ADOS-2 and ADI-R. Results show good sensitivity and specificity scores from the modified assessments to the clinician formulations showing concurrent validity and that they are fit for purpose.

Some differences in presentation between deaf and hearing children with ASD are discussed.

Conclusions:

The ADOS-2 Deaf Adaptation has been used successfully for children who are deaf and administered with signing assessors, leading to reliability and 'fit for purpose' for future clinical usage by trained expert teams. This will permit the possibility of accurate diagnoses and future research opportunities to understand more about the different aetiologies and trajectories of deaf and hearing children who develop ASD.

**203.003 (Panel)** Modified Assessment Methods for Diagnosing Autism Spectrum Disorder in Young Children with Severe Visual Impairment

*N. J. Dale, Neurodisability Service, Great Ormond Street Hospital NHS Foundation Trust, London, United Kingdom*

---

**Background:**

Children with severe visual impairment (VI) are at high risk of developing autism spectrum disorder (ASD), but reliable validated clinical tools for identification and diagnosis have been lacking. The DAiSY project focused on development and validation of a modified version of the Autism Diagnostic Observational Schedule (ADOS-2®) with 4-7 year olds with VI, which is possibly the earliest age for more reliable diagnosis of *persistent* social-communicative and repetitive and restricted behaviour problems.

**Objectives:**

To design and validate the modified ADOS-2 ® (Module 3) for children with VI and to compare against independent paediatrician formulation and for concurrent validity with the parent-report questionnaires of Social Responsiveness Scale (SRS-2) and Children's Communication Checklist (CCC2).

**Methods:**

A representative national cohort of one hundred four-to-seven-years-olds (M=5.4 years), with congenital disorders of the anterior visual system and profound-severe VI (M=.98 logMAR) participated. 85 children had fluent language and engaged in social interaction and play using modified standard 'presses' of ADOS-2 (Module 3), with some additions. The modified ADOS-2 had no items or scoring ratings dependent on functional vision abilities. Assessors were trained in behavioural assessment methods using auditory and touch cues to help the child participate. The ADOS ratings were compared against independent paediatrician formulation (with expertise in VI and ASD) of Non-Spectrum, Autism Spectrum Disorder (ASD – below full ASD threshold, but ASD symptoms) and Autism (AUT) using DSM-V classification.

**Results:**

The modified ADOS-2 showed high internal consistency and inter-rater reliability. A ROC analysis revealed excellent predictive discriminant validity with high sensitivity and specificity against paediatrician ratings and identified a new diagnostic algorithm (according to Gotham et al 2007) and diagnostic thresholds for ASD and AUT. Concurrent validity showed significant large effect size differences on the SRS-Total, Social Communication and Repetitive Behaviour Subscales according to above or below diagnostic threshold (Non-Spectrum versus AUT). Significant differences were found on the CCC-2 Social Interaction Deviance Composite but not on the CCC-2 General Communication Composite where both groups had lower pragmatic skills.

**Conclusions:** The ADOS-2 (Module 3) can be modified successfully for children with VI, leading to strong internal coherence, construct validity, inter-rater reliability and predictive discriminant validity with high sensitivity and specificity against clinician formulation. The new diagnostic algorithm highlights similarities and differences between the population with VI and those who are sighted (Gotham et al 2007) and these are discussed further. The assessment and scoring methods therefore appear reliable and 'fit for purpose' for future feasibility trial in the clinic context. The parent questionnaires also appear valuable as an additional supplement but pragmatic communication deficits were widespread across the whole sample.

**203.004 (Panel)** Early Social Communicative Risks Predicting Diagnostic Thresholds of Autism in Children with Congenital Visual Impairment

*E. Sakkalou, UCL Great Ormond Street Institute of Child Health, London, United Kingdom*

---

**Background:**

Children with congenital profound-severe visual impairment (VI) are at high risk of ASD (prevalence rates ~30%, Do et al., 2017). Early differentiation of social communication risk is important for interventionist reasons; however the task is challenged by the impact of VI on general developmental processes (delays and atypical processes) and the lack of reliable validated measures of social communication/ ASD. Existing measures are validated for children with vision and involve visual approaches.

**Objectives:**

To investigate longitudinally whether the new Social Communication Schedule (SCS-VI) at 2 years old (Time 1 – T1) predicts later outcomes, including new diagnostic thresholds, on the modified ADOS-2 for children with VI (Time 2 – T2).

#### **Methods:**

Fifty four children with congenital disorders of the anterior visual system and severe-profound vision impairment at Time 1 (mean age 25 months, SD 2 months) were video'd and rated whilst engaging in social and independent play tasks and rated for positive abilities on the Social Communication Schedule - SCS (OPTIMUM study). Forty seven were followed through in the DAiSY project, leading to 37 in the verbal fluent stage participating in video'd play based observational assessment using a modified ADOS-2 (T2). Parents also filled in the SRS-2 and CCC-2. Validation was undertaken against independent clinician formulations (DSM-V). The children's vision was measured by logMAR resolution acuities. The SCS and modified ADOS-2 had no items or scoring ratings dependent on functional vision abilities. Assessors were trained in behavioural assessment methods using auditory and touch cues to help the child participate.

#### **Results:**

Clinician formulation divided the group into those with Non-Spectrum, Autism Spectrum Disorder – ASD (Autism features but not full threshold) and Autism- AUT (Autism features of full threshold) – T2. Ratings on the modified ADOS-2 led to new diagnostic thresholds against clinician formulation (see Dale et al). A logistic regression analysis with Non-Spectrum vs ASD and AUT clinician classification as outcome (T2) and predictor of SCS scores at T1 (controlling for age and logMAR vision level at T2) revealed a significant negative relation ( $p < 0.05$ ). The same analysis with the classifications of Non-spectrum and ASD vs Autism using the diagnostic thresholds of the modified ADOS-2 (T2) was also negatively related ( $p < 0.05$ ).

#### **Conclusions:**

Children with severe-profound VI with lower measurable social communicative abilities at 2 years old were significantly more likely to reach a clinician formulation or diagnostic threshold for ASD and AUT on the modified ADOS-2 at 4-7 years. This suggests that it is feasible to differentiate social communicative risk in the early years and provides the case for screening of social communicative risk even though visual impairment impacts adversely on all developmental processes. The evidence also suggests that early risk has longer term continuity even in the context of emerging language abilities to fluent level language in many cases of the children at school entry age, raising a strong case for social communicative/ ASD as an independent neurodevelopmental risk. The results convey further construct validity to the new SCS measure and the modified ADOS-2 diagnostic thresholds.

### **PANEL SESSION — DIAGNOSTIC, BEHAVIORAL, SENSORY AND INTELLECTUAL SCREENING AND ASSESSMENT**

#### **Panel 210 - Innovations in the Use of Telehealth for Evaluating and Treating Autism Spectrum Disorder**

**Panel Chair:** Charles Albright, *Nationwide Children's Hospital, Westerville, OH*

**Discussant:** Jeffrey Hine, *Vanderbilt University Medical Center, Nashville, TN*

Create and validating comprehensive telehealth service models to assess and treat Autism Spectrum Disorder (ASD) would aid in overcoming disparities in access to services caused by factors such as poor access to transportation and long distances from major healthcare systems, as well as make healthcare systems more agile in times of crisis, such as the current pandemic. This panel presents work being done to establish multiple ways telehealth could be used for service delivery of initial ASD screening, toddler evaluation, child and adolescent evaluation, and intervention. These presentations establish the utility of telehealth models across these domains, as well as highlight lessons learned while creating and establishing these services. Strengths across these models include the opportunity to highlight and benefit from strong partnerships with parents, as well as the ability to provide flexible and responsive models of care for all families. Limitations highlighted include technology needs and environmental and intrapersonal factors of families and children to consider when assessing fit for telehealth practice. This panel will also discuss the opportunities that telehealth options provide for extending care to families who would otherwise have difficulty accessing specialized Autism services, creating greater healthcare equity.

**210.001** (Panel) Utilising a Mobile Application for the Early Detection of Autism in Infants and Toddlers: Asdetect  
**J. Barbaro, N. Sadka, E. Beattie and C. Dissanayake, Olga Tennison Autism Research Centre, La Trobe University, Melbourne, VIC, Australia**

---

Background: Early detection of autism is critical as it provides access to early intervention, improving children's developmental outcomes and quality of life, and decreasing family stress. Over the past 15 years, two large-scale community-based studies for the early detection of autism have been conducted with Maternal and Child Health (MCH) nurses in Australia, using Social Attention and Communication Surveillance; SACS (Barbaro & Dissanayake, 2010; 2013; Mozolic-Staunton et al., 2020). Monitoring over 30,000 children, the SACS is the most accurate and sensitive developmental surveillance tool for autism in community-based samples, with 81-83% positive predictive value (PPV), 99% Negative Predictive Value (NPV), sensitivity of 82-84%, and specificity of 99-99.8%.

To make this research accessible to the world's population, including those in rural/regional/remote communities, low-resourced setting, and low and middle-income countries, a free mobile application was developed for parents based on the SACS tool. ASDetect (asdetect.org) is designed for the very early detection of autism in children aged 11-30 months, with short narrated videos demonstrating key social-communication behaviours, followed by a question; automatic calculation of a child's 'likelihood' for autism (high/low) is then presented.

Objectives: To determine the psychometric properties of ASDetect in sensitively and accurately identifying children with autism.

Methods: Parents of children aged 11-30 months were invited to participate via their MCH nurse, or via social media/word of mouth, with 1809 registrations. Parents registered their child's details on a webpage, downloaded ASDetect, and completed an assessment. Parents were also invited to complete the Social Responsiveness Scale (SRS) when their child was 30 months of age. All children at 'high likelihood' for autism on ASDetect were invited for a free diagnostic assessment by the ASDetect team; furthermore, children at 'low likelihood' for autism on ASDetect, whose parents were nonetheless concerned about their child's behaviour, and/or who met the autism cut-off on the SRS at 30 months, were also invited for an assessment. Children were assessed by blinded clinicians at intake and every 6 months until 24-30 months, with the Autism Diagnostic Observation Schedule-2, Mullen Scales of Early Learning, Autism Diagnostic Interview-Revised, and Vineland-III administered.

Results: Thirty seven percent of the 1,809 parents were from rural/regional areas, with 1,549 (86%) completing an ASDetect assessment for their child at least once. 327 children (21%) were identified at 'high likelihood' for autism, with 48.6% of parents having concerns about their child's development *prior* to completing ASDetect. Based on the follow-up diagnostic assessments, ASDetect has a sensitivity of 81.49%, specificity of 97.3%, PPV of 90.2%, and NPV of 94.5%. To further investigate the correctness of classification, likelihood ratios (weighed by prevalence), and Odds Ratio (OR), were calculated. Positive (LHR+) and negative (LHR-) likelihood ratios were 9.2 and .06, respectively, and OR was 158.92, indicating very high screening accuracy (Fischer et al., 2003).

Conclusions: The findings indicate that ASDetect has excellent psychometric properties for the early identification of autism, thus providing an easily accessible platform for parents to explore their child's social-communication development at home, and initiate the diagnostic process with their healthcare practitioner if required.

**210.002** (Panel) Initial Implementation of the Veda Telehealth Assessment Model of Autism Spectrum Disorder across Childhood

**E. Kryszak<sup>1</sup>, C. Albright<sup>2</sup>, K. G. Stephenson<sup>3</sup>, S. Harris<sup>4</sup>, M. Norris<sup>5</sup>, C. Burns<sup>6</sup>, A. Kalomiris<sup>7</sup>, A. Newmeyer<sup>8</sup>, T. Hollingsworth<sup>9</sup>, J. A. Mulick<sup>10</sup> and E. Butter<sup>11</sup>,** (1)Nationwide Children's Hospital, Westerville, OH, (2)Nationwide Children's Hospital, Westerville, OH, (3)Brigham Young University, Provo, UT, (4)Department of Pediatrics Division of Psychology, Michigan Medicine, Ann Arbor, MI, (5)Child Development Center, Nationwide Children's Hospital, Westerville, OH, (6)UNC Chapel Hill, Chapel Hill, NC, (7)Cincinnati Children's Hospital Medical Center, Cincinnati, OH, (8)Nationwide Children's Hospital/Ohio State University, Columbus, OH, (9)Nationwide Children's Hospital, Columbus, OH, (10)Ohio State University, Columbus, OH, (11)Nationwide Children's Hospital, Columbus, OH

---

Background: Innovative assessment models for Autism Spectrum Disorder (ASD) that include multiple assessment pathways, including telehealth, have the potential to provide comprehensive, individualized services for a greater number of families (Zwaigenbaum & Warren, 2020). Telehealth services would aid in overcoming barriers related to transportation difficulties and distance and allow service providers to adapt more effectively during times of crisis such as the current pandemic. While models of telehealth assessment for toddlers have been developed (Wagner, et al., 2020), there is a need to develop a comprehensive model to assess children across the age span.

## Objectives:

- Present a novel, comprehensive, interdisciplinary telehealth assessment model for children across age groups.
- Present preliminary data showing the *Adapted Virtual Autism Behavior Observation (AVABO)* protocol created for this model increased clinician confidence in diagnosis and is acceptable to clinicians.

**Methods:** A pilot feasibility study was completed assessing initial implementation of a telehealth model of interdisciplinary ASD assessments at a large children's hospital to continue care during COVID-19 restrictions. The best practice model already in use was altered to include a gold standard interview measure (*Autism Diagnostic Interview-Revised; ADI-R*), and an observation protocol (AVABO) was created that allows clinicians to partner with parents to engage a child in activities highlighting social communication skills and to monitor unusual behaviors. The sample of completed telehealth assessments from March–August 2020, was compared to the sample of assessments completed in-clinic from March–August 2019. Age range in both samples was about 18 months to 18 years. Each evaluation consisted of up to three appointments. After each telehealth appointment, clinicians rated diagnostic confidence. Contributors to clinician confidence were assessed using linear mixed-effects models. Fixed-effect predictors included evaluation timepoint, data sources available (ADI-R, AVABO), diagnostic decision (ASD/no ASD), child age, and presence of technical difficulties. Patient and clinician were included as random factors. Acceptability, appropriateness, and feasibility of the AVABO was also assessed.

**Results:** No significant differences were found between telehealth and in-clinic samples based on biological sex and proportion ASD diagnoses given or ruled out (Table 1). The average age for the telehealth group was slightly younger than the in-clinic group. Older age was significantly associated with diagnosis deferral in the telehealth sample (OR=1.11,  $p=.01$ ). Biological sex was not a significant predictor. Clinician diagnostic confidence was generally high ( $M=77%$ ,  $SD=24.6%$ ). On average, the AVABO increased clinician diagnostic confidence by 12.29% ( $p<.001$ ). Clinicians were 15.55% ( $p<.001$ ) more confident when they believed a child had ASD vs. not and significantly less confident with older vs. younger children ( $p<.001$ ). Technical difficulties were relatively rare (11.78% of visits) and did not significantly affect clinician confidence. Clinicians viewed the AVABO as acceptable, appropriate, and feasible (Table 2).

**Conclusions:** The VEDA model allowed assessment services to continue near typical rates despite pandemic restrictions, with approximately 10% of children needing further assessment when restrictions were lifted. Initial analyses indicated the AVABO is a promising telehealth tool. Lessons learned during implementation and limitations of the model and observational measure will be discussed, along with plans for further validation.

### **210.003 (Panel) Feasibility of Community-Based Autism Telehealth Parent Coaching during COVID-19**

**C. Nadler<sup>1,2</sup>, D. Olsen<sup>1,2</sup>, M. Campbell<sup>1,2</sup>, T. Perez Crawford<sup>1,2</sup>, L. Hansen<sup>1</sup>, C. Pittard<sup>1</sup>, A. Gibson<sup>1</sup>, M. Gibson<sup>1</sup> and M. Dreyer Gillette<sup>1,2</sup>, (1)Children's Mercy Kansas City, Kansas City, MO, (2)University of Missouri Kansas City School of Medicine, Kansas City, MO**

**Background:** Traditional autism assessment and intervention models have faced significant disruption in the wake of COVID-19. In many service areas these disruptions have been additive, with delayed access to diagnosis further delaying eligibility for and access to treatment. RUBI (Research Units in Behavioral Intervention; Bearss et al., 2015) is an evidence-based parent coaching model for disruptive behavior in young children with autism that has been piloted previously via telehealth (Bearss et al., 2018) and in clinic-based groups (Edwards et al., 2019; Burrell et al., 2020), but no large-scale community-based data exist demonstrating the feasibility of delivering these adaptations. Moreover, combination of RUBI group and telehealth modalities has not been previously attempted.

**Objectives:** To evaluate the feasibility of a rapid community roll-out of telehealth RUBI in the context of COVID-19, utilizing both individual and group formats for parents of children ages 2-10 diagnosed with (or suspected of having) autism and/or other developmental disabilities.

**Methods:** Upon local onset of restrictions, all hospital-based autism clinic assessment and outpatient therapy services were suspended. While telehealth diagnostic approaches emerged over the following months, individual RUBI telehealth service (audio/visual, as well as phone only) was immediately initiated for existing patients and offered to all eligible patients in diagnostic limbo with apparent developmental delays and disruptive behavior. After six weeks, group telehealth RUBI was initiated for the first time to accommodate escalating demand.

**Results:** In the six months prior to COVID-19 disruptions, staff delivered an average of 36 RUBI sessions per month; in the seven months following the transition to telehealth-only service, the average increased to almost 90 RUBI sessions per month (see

Figure 1). This dramatic increase in access occurred without any increase in staffing. Telehealth delivery increased scheduling flexibility for both parents and providers, and bypassed capacity limits imposed by the number and size of clinic rooms available. Group telehealth sessions (serving 3-5 families in 90 minutes, vs. 1 family in 60 minutes) further increased access to treatment. Phone-only sessions (7.6% of all individual telehealth) supported the access of families lacking high-speed internet connections due to geography or socioeconomic barriers. Participation in the program was stable, with no significant difference in the average number of sessions attended for families who began RUBI before vs. after COVID-19 and the transition to telehealth (9.4 vs. 8.4 sessions;  $t(39) = 0.656, p > .05$ ).

Conclusions: Telehealth roll-out led to an immediate and unexpected increase in service capacity, even prior to initiation of group telehealth options. Phone-only options preserved access for families with limited internet access, and attendance remained robust despite the change to telehealth in the context of pandemic stressors. Delivery of behavior management prior to diagnostic confirmation prevented COVID-related disruptions in assessment from delaying access to early intervention and support. While rigorous evaluation of treatment outcomes is still needed, these data support the feasibility of leveraging individual and group telehealth RUBI approaches to significantly increase clinical capacity in community settings where restrictions to in-person care and workforce shortages might otherwise impede access to evidence-based intervention.

**210.004 (Panel) Caregiver-Mediated Evaluations Via Telemedicine: A Response to COVID-19 for Young Children at Risk for Autism**

**L. Wagner<sup>1</sup>, J. F. Hine<sup>1</sup>, L. Corona<sup>2</sup>, A. S. Weitlauf<sup>3</sup>, K. L. Marsh<sup>4</sup>, A. F. Berman<sup>5</sup>, A. Nicholson<sup>6</sup>, C. Stone<sup>1</sup>, N. A. Broderick<sup>1</sup>, S. Francis<sup>6</sup> and Z. Warren<sup>1</sup>,** (1)Vanderbilt University Medical Center, Nashville, TN, (2)Vanderbilt University Medical Center - Treatment and Research Institute for Autism Spectrum Disorder, Nashville, TN, (3)Vanderbilt Kennedy Center, Vanderbilt University Medical Center, Nashville, TN, (4)Unumb Center of Neurodevelopment, Columbia, SC, (5)Vanderbilt University, Pleasant View, TN, (6)Vanderbilt University Medical Center - Treatment and Research Institute for Autism Spectrum Disorder, Nashville, NY

Background: The COVID-19 pandemic has exacerbated the delays families face in accessing ASD-related services. Telemedicine-based assessment has emerged as one opportunity for service continuation. Following suspension of in-person appointments, our group deployed a novel tool (TELE-ASD-PEDS; TAP), designed for the remote observation of ASD in young children (14-36 months). Given the pressing nature of the pandemic, and the absence of a universally-accepted and validated tool for tele-assessment of ASD, we launched a series of web-based trainings on our model. Our team has continued to collect and analyze clinical data, as well as data from external sites, to better understand how the TAP functions as a clinical tool. We also gathered input from providers and caregivers on their perceptions of tele-assessment and the TAP.

Objectives: We will provide data on our model of tele-assessment including number of children seen, diagnoses given, and factors contributing to diagnostic certainty for both the primary site and seven external sites. Additionally, we will present data on provider perceptions of tele-assessment, as well as preliminary data on caregiver perceptions of in-home, caregiver-mediated tele-assessment.

Methods: Over 2,100 providers across 39 states and seven countries attended web-based trainings on the TAP. Researchers analyzed data from 204 telemedicine evaluations completed through the primary site and 133 evaluations completed through seven collaborating sites. Providers (n=201) completed a survey on their use and perceptions of tele-assessment and the TAP approximately three months after the initial training. Additionally, a sample of caregivers (n=44) who participated in tele-assessment through the primary site completed a survey assessing their perceptions of the model.

Results: At the primary site, TAP scores predicted ASD status (Table 1), with ASD diagnosis representing a majority of the sample. Further, provider confidence scores were highest when issuing an ASD diagnosis, indicating preliminary support for use of this tool to confirm the presence of ASD via tele-assessment. Although the pattern of TAP scores across the external sites was similar across diagnostic groups, external providers reported the highest levels of diagnostic certainty when an ASD diagnosis was ruled out (Table 2). This group of children comprised a majority of the sample (51%), which has important implications for the functioning of the tool in a more heterogeneous group of children. Providers across all sites reported high levels of comfort completing tele-assessments, making diagnoses following tele-assessment, and providing feedback and recommendations. Further, the majority of caregivers reported that they understood the assessment process, found instructions easy to follow, found interaction with their child comfortable, and would recommend the procedure to other families.

Conclusions: By quickly converting diagnostic evaluations to a telehealth platform, providers across the country were able to continue to meet families' needs for timely access to ASD-related services, while considering family preference and adhering to social distancing guidelines. This rapid crisis response provides initial support and guidance for a re-conceptualization of ASD assessment, utilizing a novel tele-assessment tool that is both flexible and family-centered, that will undoubtedly continue to be

needed beyond the pandemic.

**POSTER SESSION — DIAGNOSTIC, BEHAVIORAL, SENSORY AND INTELLECTUAL SCREENING AND ASSESSMENT**

**Poster 414 - Diagnostic, Behavioral, Sensory and Intellectual Screening and Assessment Posters**

**414.001** (Poster) A Preliminary Investigation of Function of Fear in Those with ASD

**K. S. Ellison<sup>1</sup>, E. S. Ranzino<sup>2</sup> and T. E. Davis<sup>1</sup>,** (1)Department of Psychology, Louisiana State University, Baton Rouge, LA, (2)Department of Psychology, Louisiana State University, Baton Rouge, LA

Background: Children with Autism Spectrum Disorder (ASD) have been found to commonly experience fear (van Steensel et al., 2012) and this fear is experienced in different capacities as they get older. Determining what is causing or maintaining that fear (the function) is imperative to understanding how to approach treatment. While this can be done with unstructured, open interviews, more systematic, efficient, and structured methods would be helpful. Additionally, more research is needed to explore fears and phobias in children with ASD.

Objectives: This study investigated the functions of fear in youth with ASD. Descriptives related to the functions of fear as well as the types of fear experienced were explored.

Methods: Twenty-two youths with ASD (16 males;  $M=10.14$  years-old,  $SD=2.62$ ) were included as part of a larger IRB-approved study. Consent/assent was obtained. Diagnoses were confirmed by the *Childhood Autism Rating Scale, Second Edition (CARS-2)* or the *Autism Diagnostic Observation Schedule, Second Edition (ADOS-2)*. Full-Scale IQ, as measured by the *WISC*, for the sample (exclusion of 2 participants) ranged from 76 to 123 ( $M=93$ ,  $SD=11.83$ ). The *Motivation for Fear Questionnaire (MOTIF)*; adapted from the *QABF* was completed by each youth's caregiver in order to determine the function of fears/anxieties they may be experiencing. A preliminary factor analysis led to four factors being measured (positive reinforcement via receiving comfort or attention, negative reinforcement, control, and overall fear). The *Fear Survey Schedule for Children – Revised (FSSC-R)* was completed by each youth in order to capture the individual's total amount of fear as well as specific fear domains (fear of failure and criticism, fear of the unknown, fear of injury and small animals, fear of danger and death, medical fears).

Results: Preliminary descriptives were examined. Caregivers of youth with ASD reported a higher average total score on the positive reinforcement/comfort and attention factor ( $M=15.27$ ,  $SD=2.88$ ) compared to the other three factors. Spearman's Rho was calculated to examine associations between Age, IQ, and the *MOTIF* subscales. The *MOTIF* Control subscale was negatively associated with IQ ( $r_s=-.53$ ,  $p=.01$ ). Pearson's correlation coefficients between the *MOTIF* subscales and *FSSC-R* total score and *FSSC-R* subscales were conducted. Total Fears of the *FFSC-R* was significantly correlated with the *MOTIF* Control subscale ( $r=.49$ ,  $p=.02$ ) and the *MOTIF* Fear subscale and demonstrated a significant correlation with the *FFSC-R* Fear of Failure subscale ( $r=-.88$ ,  $p<.001$ ).

Conclusions: IQ was found to be related to the function of control as well as control being positively correlated with higher amounts of fears. This is not surprising giving that rigidity is a common symptom of ASD. Determining the function of fear in children with ASD may help elucidate the extent providers can guide families in helping their children overcome these fears. Recruitment is ongoing to allow for additional comparisons and further exploration of group differences.

**414.002** (Poster) A Qualitative Study on the Diagnostic Experience of Autistic Females in Hong Kong

**K. C. C. Chow and G. Y. H. Lam,** Department of Educational Psychology, The Chinese University of Hong Kong, Hong Kong, Hong Kong

Background:

Research on gender differences has suggested that the behavioural differences and diagnostic bias may have exaggerated the existent gender discrepancy in the incidence of Autism Spectrum Disorder (ASD) and a lack of services for autistic females. To date, however, there has been little research focusing on the experiences and needs of autistic females in Eastern countries. For example, the male-to-female ratio of autistic individuals in Hong Kong is around 7 to 1, which is higher than the ratio commonly reported in Western countries. It implies autistic females in Hong Kong might be further underdiagnosed when comparing to Western countries.

## Objectives:

This study aims to investigate the diagnostic experience of autistic females in Hong Kong. This study employs qualitative interviews to explore their perceptions of the existing autism assessment tools, diagnostic criteria, and their experiences with diagnostic services.

## Methods:

Participant recruitment and data collection are currently in progress. Data collection occurs via semi-structured interviews with ten clinically diagnosed or self-diagnosed autistic females of age 18 or above. The interview starts by filling out the Autism Spectrum Quotient (AQ). Although the scores from AQ are not being interpreted, the items and the survey experience are used to start the discussions on their views on the existing diagnostic tools. An interview guide with open-ended questions is used (e.g., “how did you find out about your autism condition?”, “How do you think the diagnostic criteria reflect your autistic characteristics?”). Thematic analysis is used to identify themes discussed by participants. Member checking is employed via brief phone calls to ask participants to review the findings to ensure the essence of their experiences is accurately captured.

## Results:

The following themes are tentative findings based on our pilot work and preliminary analysis.

First, autistic females experience delay/lack of diagnosis as clinicians are not sensitive enough with the unique features of autistic females. Autistic females display fewer outward social impairments but they have difficulties in maintaining long-term friendships and to cope with social conflicts.

Second, autistic females describe having more co-occurring internalising concerns than their male counterparts that mask their underlying autistic characteristics. Hong Kong women are expected to be shy and gentle, although these positively viewed traits might prevent clinicians from identifying their autistic characteristics and related stressors.

Third, autistic females learn to camouflage their autistic features. For example, they mimic others’ facial expressions and learn social behaviours from television shows. However, they tend to describe this camouflaging experience as “normal”, as the majority of people in a Chinese society tend to hide their true self and feelings in favour of the social norm.

## Conclusions:

The experiences of autistic females in Hong Kong will help researchers and clinicians better understand the different support needs for autistic females in Hong Kong. Findings will be valuable to suggest ideas to improve the diagnostic tools that could be tailored to females in Chinese culture.

### **414.003** (Poster) Adaptive Behavior in Racial/Ethnically Diverse Children with Autism Spectrum Disorder

**S. Vanegas<sup>1</sup>, M. Davila<sup>2</sup>, C. Le<sup>2</sup> and A. M. Hernandez<sup>2</sup>, (1)School of Social Work, Texas State University, San Marcos, TX, (2)Texas State University, San Marcos, TX**

---

**Background:** There is a growing need to understand Autism Spectrum Disorders (ASD) across underrepresented racial/ethnic and linguistically diverse populations. This is important due to the significant health and educational disparities that affect these communities (Jo et al., 2015; Magaña et al., 2013). The assessment of cognitive or IQ profiles of children with ASD is highly variable, with scores often dependent on instrument demands or children’s language abilities (Charman et al., 2004; Joseph et al., 2002). Thus, assessing adaptive behavior may be more informative for evaluating long-term outcomes of children with ASD, particularly from racial/ethnic diverse communities.

**Objectives:** This study aimed to examine adaptive behavior in a racial/ethnically diverse sample of children with ASD and explore factors associated with greater adaptive behavior.

**Methods:** This study is part of a larger medical record review study of a developmental disabilities clinic in the United States. Records of children with ASD between 3 and 12 years of age who visited the clinic between 2004 and 2014 were reviewed. Data were extracted from intake forms, completed assessments, rating forms, and other records. Children with data from the Vineland Adaptive Behavior Scales (VABS) were included in this study ( $n = 150$ ). Additional data were collected on demographic characteristics (nativity, language, co-occurring conditions, maternal nativity and education, insurance status).

**Results:** The sample included Latino (50%,  $n = 75$ ), White, (20%,  $n = 30$ ), and African American (30%,  $n = 45$ ) children with ASD. Separate hierarchical linear regression analyses were conducted on the VABS Adaptive Behavior Composite (VABS-ABC) and the individual domains (Communication, Daily Living Skills, Socialization, Motor). A co-occurring intellectual disability was entered in Step 1, with additional factors entered in Step 2 (i.e., race/ethnicity, sex, age of ASD diagnosis, verbal status, speech-language impairment diagnosis, ADHD diagnosis, other diagnoses, maternal nativity, maternal education, insurance status, home language environment). These analyses found that a co-occurring intellectual disability was a significant predictor for all domains of adaptive behavior. Verbal status was a significant predictor for all except the Motor domain. Child sex was a significant predictor only for the Socialization domain ( $p < .05$ ). Child race/ethnicity was a significant predictor for the Communication, Daily Living Skills, and Socialization domains. These results suggest that having an intellectual disability, being primarily nonverbal, being male, and being of Latino or African American background were associated with lower adaptive behavior. Additional analyses will explore unique profiles of adaptive behavior across racial/ethnic groups.

**Conclusions:** This study focused on evaluating factors associated with adaptive behavior among children with ASD from racial/ethnic minority backgrounds. Significant factors that emerged were child sex, race/ethnicity, verbal status, and intellectual disability on predicting adaptive behavior, with distinct relations across domains. Adaptive behavior is critical to assess in children with ASD as it has been linked to outcomes in adulthood (Farley et al., 2009). Further studies may address how interventions can support racial/ethnic minority children with ASD on adaptive behavior. We recommend providing more services to children with ASD from racial/ethnic communities by utilizing evidence-based intervention to improve adaptive behavior.

**414.004 (Poster) Agreement and Discrepancies in Parent, Teacher and Observational Reports of Emotional and Behavioural Problems in Young Autistic Children**

**M. Palmer<sup>1</sup>, J. Tarver<sup>2</sup>, V. Carter Leno<sup>1</sup>, J. Paris Perez<sup>1</sup>, M. Frayne<sup>1</sup>, V. Slonims<sup>3</sup>, A. Pickles<sup>1</sup>, S. Scott<sup>1</sup>, E. Simonoff<sup>1</sup> and T. Charman<sup>1</sup>, (1)King's College London, Institute of Psychiatry, Psychology and Neuroscience, London, United Kingdom, (2)Aston University, Birmingham, United Kingdom, (3)Guy's & St Thomas' NHS Foundation Trust (Evelina Children's Hospital), London, United Kingdom, (4)Department of Psychology, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom**

**Background:** Emotional and behavioural problems (EBPs) frequently co-occur in young autistic children. The use of multiple informants, such as parents and teachers, and also naturalistic observations of EBPs is necessary for a comprehensive understanding of the individual across contexts. Similar to children who are typically developing or have other psychopathology, discrepancies in reports of EBPs are common in autistic children and can lead to uncertainty in formulation, diagnosis and care planning. There are a range of factors, not related to measurement error, that may influence observation and reporting of child EBPs and lead to differences between informants. Some factors, such as situational specificity (De Los Reyes et al., 2013), and certain informant characteristics may influence reports in ways similar to non-autistic children. Whereas other factors may have differing explanations and be autism-specific (e.g. verbal ability, autism severity). Parenting stress may be a particularly important factor as parents of autistic children report elevated levels of stress when compared to parents of children with other developmental disabilities. High levels of parenting stress could confound reports of EBPs.

**Objectives:** To examine the parent, teacher and researcher observed child EBPs and explore factors associated with reports of EBPs and discrepancies between informants.

**Methods:** The sample were 83 4–8-year-old autistic children (47% minimally verbal; 53% verbal) and their parents/carers and teachers who participated in the Autism Spectrum Treatment and Resilience (ASTAR) pilot randomised controlled trial. ASTAR was designed to be as inclusive as possible, so no exclusion for child EBPs was used; nor for verbal ability or IQ. Parents and teachers completed the irritability and hyperactivity subscales of the Aberrant Behaviour Checklist (ABC-Irritability; ABC-Hyperactivity) and internalising and externalising subscales of a new measure of mental ill health in autism (The Assessment of Concerning Behaviour; ACB-Internalising; ACB-Externalising). Self-reported measures of parenting stress and wellbeing were obtained, and a parent-child/researcher-child interaction observation was completed from which a researcher coded rate of child behaviours that challenge (BTC) was derived. *T*-tests and cross-informant intraclass correlation coefficients (*ICCs*) examined differences and agreement between informants. Multivariate and univariate regression models explored factors (e.g. child verbal ability, parenting stress) associated with EBPs and discrepancies between reports.

**Results:** Parents reported significantly more child EBPs than teachers (e.g. ABC-Irritability 16.4 vs. 9.2,  $p < .001$ ; ACB-Internalising 21.5 vs. 14.7,  $p < .001$ ). *ICCs* and correlations between parents and teachers on these measures were low (*ICCs*=0.04-0.30); internalising behaviour had the lowest agreement. After controlling for other child and informant characteristics, greater self-reported parenting stress was a consistent predictor of more parent-reported, but not teacher-reported nor researcher-rated EBPs. More verbal language was associated with higher parent-reported EBPs on some measures and being minimally verbal predicted more researcher-rated child BTC.

**Conclusions:** The discrepancies between informants highlight the need for assessments of child EBP to take a cross-setting, multi-informant approach. High levels of parenting stress could be associated with more EBPs in the home environment, or alternatively parenting stress may confound parental reports. Further research is needed to better understand the relationship between parental stress and increased EBPs in the home.

**414.005 (Poster)** An Evaluation of Tele-Assessments: Perspectives of Adult Clients, Carers, and Clinicians

*R. Y. Cai<sup>1</sup> and V. Gibbs<sup>2</sup>, (1)Aspect Research Centre for Autism Practice, Autism Spectrum Australia, Melbourne, VIC, Australia, (2)Aspect Research Centre for Autism Practice, Autism Spectrum Australia, Sydney, NSW, Australia*

---

**Background:** The COVID-19 pandemic has seen a rapid increase in the use of telehealth to deliver services to autistic individuals and their families. In response to restrictions on in-person services, Autism Spectrum Australia (Aspect) developed a new telehealth model to deliver diagnostic assessments for autism (tele-assessments). Research into the provision of tele-assessments is limited and no study to date has explored the clinician perspectives of delivering telehealth assessments.

**Objectives:** The aim of this study is to capture the perspectives on this tele-assessment service from participants and clinicians.

**Methods:** Sixteen adult clients ( $M_{\text{age}} = 39.00$ ,  $SD_{\text{age}} = 14.39$ ) and fifty-six carers and parents ( $M_{\text{age}} = 44.09$ ,  $SD_{\text{age}} = 9.87$ ) completed an online survey about their attitudes and experiences of tele-assessments. A subgroup of six clients and twelve carers and parents were also interviewed. Seven Aspect clinicians were interviewed.

**Results:** Overall, the responses of adult clients, parents and carers to tele-assessments were positive. Almost all participants would consider a tele-assessment option in the future and would recommend tele-assessments to others. Satisfaction levels of participants did not correlate with client age. Although the clinicians were slightly less satisfied with tele-assessment process compared to face-to-face and relied on external sources of information more than they would during a face-to-face assessment, their overall confidence in their diagnostic decision making remained high for tele-assessments.

**Conclusions:** Based on the findings from this research, a number of considerations should be made when conducting autism assessments via telehealth, including screening suitability of clients and adequately preparing clients for tele-assessments.

**414.006 (Poster)** Assessment Profiles of Toddlers Referred for ASD Concerns Based on Foster Care Status

*L. J. Dilly<sup>1</sup>, K. Railey<sup>2</sup> and A. Pavlov<sup>1</sup>, (1)Marcus Autism Center, Atlanta, GA, (2)Emory University School of Medicine and Children's Healthcare of Atlanta, Atlanta, GA*

---

**Background:** Research indicates that the overall risk of experiencing foster care in childhood is roughly 6% (Wildeman & Emmanuel, 2014), and approximately 104,000 children under the age of 3 are in foster care on any given day in the United States (U.S. Department of Health and Human Services, 2017). Young children in foster care placement are known to have an increased risk for autism spectrum disorder (ASD) and developmental disabilities (Cidav, Xie, & Mandell, 2018; Kistin et al., 2016). Although it is difficult to disentangle the specific consequences of early adversity (e.g., maltreatment, unstable caregiving conditions) on developmental and behavioral functioning, research suggests that children in foster care experience an increased risk for delayed language development, social delays, and behavioral problems (Leve et al., 2012; Stock & Fisher, 2006). Given that differentiating between the presence of ASD from general developmental delays that are often present in children in foster care can be difficult, research in this area is warranted.

**Objectives:** The purpose of the current study is to consider differences in assessment profiles of toddlers referred for ASD based on foster care status and final diagnosis.

**Methods:** Retrospective chart reviews were conducted for toddlers referred for ASD evaluations who received the Autism Diagnostic Observation Schedule, 2<sup>nd</sup> Edition (ADOS-2) Toddler Module from 2/2015 to 5/2019 at a large autism center. Child-level demographic, developmental assessment results, and diagnostic information was gathered. Children in the foster care group were either in a foster care placement with a relative, foster family, or group home at the time of evaluation or had previously been in a foster care placement.

**Results:** See Table 1 for demographic information. A chi-square test of independence, which examined the relation between ASD diagnosis and foster care placement, was significant,  $\chi^2(1, N = 302) = 16.48, p < 0.01$ . Results indicate that children in foster care ( $M = 12.11, SD = 7.87$ ) had significantly lower Total ADOS-2 scores than children who were not in foster care ( $M = 22.45, SD = 6.08$ ),  $t(299) = -6.69, p < 0.01$ . In addition, when considering *Little to No Concern* and *Moderate to Severe Concern*

ADOS-2 severity levels, the overall sensitivity of the ADOS-2 for children in foster care placement and those with no foster care involvement, respectively, was 100% and 83%. The respective specificities were 88% and 97%.

**Conclusions:** Toddlers in foster care referred for ASD evaluations are less likely to receive an ASD diagnosis than toddlers who are not in foster care. However, children in foster care who do not receive ASD diagnoses demonstrate similar developmental profiles as children who are not in foster care and receive ASD diagnoses (Stock & Fisher, 2006). Results indicate that the ADOS-2 reliably identifies toddlers in foster care with and without ASD. Findings also highlight the continued need for research on factors that may differentiate between common developmental deficits from ASD-specific deficits in children in foster care.

**414.007 (Poster)** Associations between Objectively Measured Social Movements during the ADOS-2 and Autism Symptoms in Preschool Age Children with Suspected ASD

**J. M. Moffitt<sup>1</sup>, Y. Tao<sup>2</sup>, Y. A. Ahn<sup>3</sup>, S. Custode<sup>4</sup>, A. L. Beaumont<sup>5</sup>, S. M. Cardona<sup>6</sup>, M. Parladé<sup>5</sup>, J. Durocher<sup>5</sup>, M. N. Hale<sup>5</sup>, M. Alessandri<sup>5</sup>, L. K. Perry<sup>4</sup>, M. L. Shyu<sup>5</sup> and D. S. Messinger<sup>5</sup>, (1)Center for Autism, California State University, Fullerton, Fullerton, CA, (2)University of Miami, Miami, FL, (3)Seattle Children's Research Institute, Seattle, WA, (4)Psychology, University of Miami, Coral Gables, FL, (5)University of Miami, Coral Gables, FL, (6)Electrical and Computer Engineering, University of Miami, Coral Gables, FL**

---

Background:

Autism spectrum disorder (ASD) is characterized by deficits in social communication along with restricted/repetitive patterns of behaviors. Current best practice for measuring ASD symptom severity involves expert clinician observation during the Autism Diagnostic Observation Schedule-2 (ADOS-2). Objective behavioral measurement has the potential to improve our understanding of ASD symptom presentations and the utility of assessment data (Dawson & Sapiro, 2018). Initial studies indicate that objective measurements of both language use (Oller, et al., 2010) and movement (Cohen et al., 2014) suggest meaningful behavioral differences between young children with ASD and their peers.

**Objectives:** To investigate associations between objectively measured movement, language use, and examiner-rated ADOS-2 calibrated severity scores (CSS) during the ADOS administration.

Methods:

Thirty-five children (24 boys,  $M_{age}=41.49$  mo,  $SD=10.76$ ) with suspected ASD (32 diagnosed with ASD) were administered the ADOS-2 during a clinical diagnostic evaluation. Twenty-two children identified as White, 12 as Black, 1 as mixed race, and 24 as Hispanic/Latino. A research-reliable, hypothesis-blind examiner provided total Calibrated Severity Scores (CSS) and CSS for Social Affect (SA CSS) and restricted/repetitive behavior (RRB CSS). The assessments were recorded using a ceiling-mounted camera to track movement. Audio was recorded via examiner-worn eyeglasses and processed with the Language ENvironment Analysis (LENA) software, LENA SP Hub Version 3.3.0 (Perry et al., 2018). Videos from the ceiling-mounted camera were processed by a Mask Regional Convolutional Neural Network (R-CNN) to detect the locations of child, parent, and examiner (He et al., 2017). Objective measures included total counts of adult-child conversational turn-count and adult word count, the mean distance between the child and each adult (parent and examiner), the number of seconds the child spent within 1 meter of each adult, and the mean child velocity in moving both toward and away from each adult. The child's age at the observation was positively associated with both adult word count,  $r = .47, p < .01$ , and adult-child turn-count,  $r = .39, p < .05$ —but was not associated with any other variables.

Results:

Adult-child turn-count was negatively associated with the average velocity of the child's movements toward the parent,  $r = -.40, p < .05$ , and the examiner,  $r = -.36, p < .05$ , as well as with the average distance between the child and examiner,  $r = -.37, p < .05$ . Adult word count positively related to the number of seconds the child spent within 1 meter of the examiner,  $r = .36, p < .05$ . Finally, ADOS-2 RRB CSS was positively associated with the child's average velocity when moving toward their parent,  $r = .34, p < .05$ .

Conclusions:

Automated analysis of children's movement and language use shed new light on a gold standard procedure. Less language was produced with (turn-counts) and around (adult word count) children who move more quickly during the ADOS, and children who

moved more quickly toward their parents had greater RRB symptoms. The current study suggests that automated measurement of child movement during the ADOS-2 is associated with how adults (likely the examiner) engage vocally with children.

**414.008** (Poster) Autism Assessment in Low- and Middle-Income Countries: Feasibility and Usability of Western Tools  
**K. Bauer<sup>a</sup>, K. L. Morin<sup>a</sup> and A. Blasko<sup>a</sup>, (1)Lehigh University, Bethlehem, PA, (2)University of North Carolina, Chapel Hill, Chapel Hill, NC**

---

Background: Autism is a global health concern, but distribution of research is inequitable and occurs primarily in high-income countries (Elsabbagh et al., 2012). Current estimates place global prevalence at 1-2% (CDC, 2017; WHO, 2017); however, this is likely an underestimate of true rates as little is known about prevalence in low- and middle-income countries (LMIC). The lack of prevalence data in LMIC is problematic as it results in an incomplete and potentially biased understanding of ASD which may miss important cultural, social, or biological variability within ASD (Hilton et al., 2010). Additionally, prevalence data are crucial for being able to identify and plan for educational, social, and medical service needs (Myers et al., 2019). One possible explanation for the scarcity of prevalence data in LMIC is lack of access to validated screening and diagnostic tools that are feasible to implement in resource poor settings (Durkin et al., 2015). Many “gold standard” diagnostic tools are costly, time-consuming, require extensive training in order to use, and require an extensive list of materials in order to complete the assessment.

Objectives: This study examined (1) logistics (i.e., cost, number of items, training required for use, restrictions on purchasing, and materials needed), (2) readability, and (3) presence of items focusing on expressive and receptive language abilities that may inhibit the feasibility and usability of five common ASD assessment tools for determining prevalence rates in LMIC.

Methods: Assessments were analyzed for (1) readability (i.e., calculated using the Flesch Reading Ease, Flesch-Kincaid Grade Level, and Coh-Metrix L2 Reading Index), (2) logistics of assessments (i.e., initial and continued cost, training required, restrictions on purchasing, materials required), and (3) presence of items assessing functional and nonfunctional expressive and receptive language.

Results: Results of the study indicated that the majority of validated ASD assessment tools present a multitude of barriers for use in LMIC. Although most could be implemented without the need for additional materials, the start-up and continued costs for use make them not feasible for use in LMIC. Additionally, although most items could be responded to without consideration of the child’s receptive and expressive language abilities, many of the assessments fall well above basic literacy levels and had high Coh-Metrix scores indicating they would be difficult for non-native English speakers to read and comprehend.

Conclusions: Majority of screeners reviewed are not feasible for LMIC use due to cost, readability levels, and comprehension difficulties for multilingual individuals. The lack of available validated screeners that are feasible for use in LMIC represents a significant concern within the field of autism research because it prevents the collection of prevalence data and empirical research in LMIC. As a result, our understanding of ASD remains incomplete and potentially biased, and there may be important cultural, social, or biological variability that is being missed. It is critical that future researchers target the development of feasible and culturally appropriate screening and diagnostic tools for use in LMIC.

**414.009** (Poster) Autism Related and Traditional Presentations of Anxiety in Autistic Children  
**J. Eastland<sup>a</sup>, M. Freeston<sup>a</sup>, D. Garland<sup>a</sup>, J. Goodwin<sup>a</sup>, V. Grahame<sup>a</sup>, A. Kernohan<sup>a</sup>, M. Labus<sup>a</sup>, M. R. Rodgers<sup>a</sup>, (1)Newcastle University, Newcastle Upon Tyne, United Kingdom, (2)Cumbria, Northumberland, Tyne and Wear NHS Foundation Trust, Newcastle upon Tyne, United Kingdom, (3)Population Health Sciences Institute, Newcastle University, Newcastle Upon Tyne, United Kingdom, (4)Research and Enterprise Services, Faculty of Medical Sciences, Newcastle University, Newcastle Upon Tyne, United Kingdom, (5)South Tyneside’s Kids And Young Adults Klub - Special needs support group (KAYAKS), South Shields, United Kingdom, (6)Population Health Sciences Institute, Newcastle University, Newcastle upon Tyne, United Kingdom, (7)Child and Adolescent Mental Health Service, Northumbria Healthcare NHS Foundation Trust, North Shields, United Kingdom**

---

Background:

Anxiety is more prevalent in autistic children; however, reported prevalence varies greatly. One explanation is that the measures used with autistic children are not developed and validated with autistic children. Research indicates that anxiety experienced by autistic children may be ‘traditional’ anxiety which fits the DSM criteria and ‘autism related’ anxiety which is related to autistic traits. The Anxiety Disorders Interview Schedule has been revised to include an autism addendum (Autism Spectrum

Developmental Disorders [ADIS-ASDD]), to capture autism related presentations of anxiety, to aid differential diagnosis of anxiety in autistic children.

Objectives:

Using the ADIS-ASDD we aimed to:

1. Identify traditional and autism related presentations of anxiety in a treatment seeking sample of autistic children
2. Explore and describe the nature of these anxiety sub-types.
3. Finally, we aimed to explore the relationships between the anxiety sub-types and other anxiety and autistic characteristics, assessed by additional measures.

Methods:

Baseline data from 49 families from a randomised controlled trial of parent group-based intervention aimed at increasing tolerance to uncertainty in autistic children were analysed. The children were aged 6 – 16 years, had a diagnosis of autism, and were experiencing anxiety related to difficulties tolerating uncertain situations in their daily lives. Parents completed the ADIS-ASDD interview about their child's anxiety. Data from the ADIS-ASDD was coded using a coding scheme developed for the purposes of this study. The coding scheme captures data from most items in the interview, allowing a rich picture of the child's presentation as opposed to a summary of diagnoses. Inter-rater reliability between the two coders was strong ( $k=0.972$ ).

Results:

Preliminary findings show the most common 'traditional' anxiety disorders identified in our sample were: Specific Phobia (overwhelming fear of objects or situations; e.g., dogs), Generalised Anxiety Disorder (anxiety/worry about a wide range of situations) and Social Phobia (fear of social situations). Autism specific diagnoses were also present: 51% met criteria for fear of change (anticipatory worry about change to routine or environment), 35% for idiosyncratic phobia (unusual or uncommon phobias e.g. apples), 16% had special interest fear (excessive worry about access to special interest) and 16% had other social fear (an unusual presentation of social anxiety which can include lack of social motivation and/or awareness).

Conclusions:

All children in the study met the clinical criteria for at least one DSM 5 anxiety diagnosis and 94% met criteria for more than two anxiety or autism specific diagnoses. Our data highlights the complexity of anxiety in autistic children and the relationship between anxiety and characteristics of autism. This demonstrates the benefit of using the ADIS-ASDD as a more accurate measure of anxiety in this population. Therefore, interventions to tackle anxiety in autistic children should consider the interplay between anxiety and autism-related characteristics.

**414.010** (Poster) Autism Spectrum Disorder Evaluation in Children with a History of Foster Care or Trauma Exposure  
*H. Adams, L. Swails and E. Zhang, University of Kansas Medical Center, Kansas City, KS*

---

Background: Children in foster care are at an increased risk for developmental delays (DD) and behavioral/mental health conditions (Simms, Dubowitz, & Szilagyi, 2000), and children entering care are almost twice as likely to have an existing diagnosis of ASD (Bilaver & Havlicek, 2013). Children with ASD/DD, are at increased risk for experiencing maltreatment (Dinkler et al., 2017), and therefore encounter the foster care system. However, trauma exposure and ASD have many overlapping symptoms, such as social impairment, emotional dysregulation, reduced eye contact, flat affect, behavioral rigidity, and sound sensitivity. Understanding the differences between trauma symptoms and ASD could potentially improve ASD diagnostic services as well as inform screening and referral processes.

Objectives: This study examined the prevalence of foster care or trauma exposure in a sample referred for evaluation for ASD/DD. Furthermore, this study sought to establish the rate of *diagnosis* in children with and without a history of foster care or trauma exposure.

Methods: A retrospective chart review was completed of 1,717 children and adolescents who were referred for interdisciplinary ASD evaluation at an academic medical center (mean age=6.38). Children in the study completed evaluation in a specialty ASD/DD clinic, including assessment tools such as the CARS-2 and ADOS-2. Foster care status was determined by reviewing intake forms, and children who were either in kinship care, foster care, or other "guardianship" settings were included in the

sample. Trauma exposure was determined by caregiver completion of the same intake form, where they could indicate exposure to physical or sexual abuse. The sample was primarily White (66.42%; 33.57% racial/ethnic minority) and male (74.27%, 25.15% female).

Results: Among all individuals referred for evaluation 2.5% were in foster care, compared to 0.6% of children nationally and 1.1% in the state of Kansas (Kids Count, 2018). Preliminary results indicated that those referred in foster care were also 11.9% less likely to receive a new ASD diagnosis  $\chi^2(1, N = 1230) = 6.055, p = .014$ . Those with a history of trauma exposure were 33.8% less likely to receive a diagnosis than those with no history of reported abuse,  $\chi^2(1, N = 1230) = 30.855, p = .000$ . Results of ADOS-2 comparison scores indicate that children with a history of trauma exposure or foster care also had lower observed symptoms of possible ASD,  $t(57) = 5.529, p = .000, t(892) = 3.501, p = .000$ , respectively.

Conclusions: Although children with ASD/DD are at higher risk of experiencing trauma, results from the current study indicate that children with a history of foster care/trauma may be *less* likely to have a diagnosis of ASD after being referred for evaluation. The reasons for this are unclear. Future studies may examine the overlap in symptoms of trauma exposure and ASD, which could lead to over-referral for ASD evaluation. Alternatively, it is possible that symptoms of ASD are overattributed to trauma, in a case of diagnostic overshadowing. Results of this study would be beneficial for those working in ASD diagnostic evaluation, foster care, or child welfare.

#### **414.011 (Poster) Behavioral Gender Differences in School-Age Children with ASD**

**M. S. Sanchez<sup>1</sup>, J. C. Bullen<sup>2</sup> and P. Mundy<sup>3</sup>, (1)School of Education, University of California Davis, Davis, CA, (2)University of California, Davis, Davis, CA, (3)University of California at Davis, Sacramento, CA**

---

Background: Boys are 4.3 times more likely to be diagnosed with Autism Spectrum Disorder (ASD) than girls. It is possible that behavioral differences between boys and girls contribute to differences in the ease or rate of identification of autism across genders. Girls tend to present internalizing behaviors such as poor self-regulation, difficulty concentrating, anxiety, and depression (Bauminger, Solomon & Rogers, 2010) Whereas boys tend to exhibit externalizing behaviors such as being more aggressive, stealing, vandalism, conduct issues and bullying others (Bauminger, Solomon & Rogers, 2010). These behavioral differences between boys and girls with ASD are not well understood, but may be important to understand with respect to differences in rate of diagnoses in boys and girls (Miller et. al, 2016).

Objectives: To examine the gender differences in parental reports of behavior problems in children with ASD. It was hypothesized that boys will exhibit more externalizing behaviors than girls, whereas girls will exhibit more internalizing behavior than boys. Since internalizing problems may be less obvious than externalizing symptoms this may contribute to fewer girls coming to the attention of diagnosticians.

Methods: Ninety-one children participating in a study of academic development in students with ASD provided data for this study: 17 girls ( $F = 11.0$  years,  $SD = 1.8$ ) and 74 boys ( $M = 11.4$  years,  $SD = 2.2$ ). Boys and girls were matched based on ADOS symptoms and IQ ( $FIQ > 64$ ). Externalizing behaviors such as anger control, bullying others, social disorders and internalizing behaviors such as emotional self-control and negative emotion were measured using the parent report on the Behavioral Assessment System for Children (BASC). The Manifest Anxiety Scale for Children (MASC) and the Conners-3 were used to assess externalizing symptoms associated with ADHD. Intellectual status for all children were estimated with Weschler Abbreviated Intelligence Scale (WASI). Lastly, the Social Response Survey (SRS) was used to evaluate social impairments.

Results: Unexpectedly, parent reports indicated that girls exhibited more externalizing behavior problems than boys, but not more internalizing behavior problems (Table 1). More detailed scale analyses indicated that girls displayed more evidence of negative emotional dysregulation on the BASC Anger Control,  $F(1,85) = 6.91, p < .01, \eta^2 = .07$ , Bullying  $F(1,85) = 9.73, p < .01, \eta^2 = .10$ , and Emotional Self-Control,  $F(1,85) p < .01, \eta^2 = 0$  scales. Reportedly, girls also exhibited more problems on the SRS Communication subscale compared to boys (Table 1) and the differences on this scale were correlated with BASC emotion dysregulation scores for both genders. Lastly, there were no significant correlations observed between the behavioral measures and intellectual status.

Conclusions: Contrary to the study hypothesis, parent report suggests that girls exhibited more externalizing than internalizing behaviors than boys. These problems were especially prominent with respect to negative emotion dysregulation. The small sample size of girls was a study limitation. Nevertheless, the data suggest that additional research on the role negative emotion dysregulation may play in gender differences in the diagnosis of autism is warranted.

#### **414.012 (Poster) Behavioral and Cognitive Impairments in Comorbid ASD+ADHD Group Compared to ASD and ADHD: A Preliminary Meta-Analysis**

**Background:** A dual diagnosis of autism spectrum disorder (ASD) and attention-deficit/hyperactivity disorder (ADHD) was only available after the implementation of DSM-5. Recent evidence has shown that 50–70% of youth with ASD meet the diagnostic criteria for ADHD, and about 15–25% of youth with ADHD meet the diagnostic criteria for ASD. However, research is yet to characterize how severe the behavioral and cognitive impairments of individuals with comorbid conditions are compared to those with a single diagnosis of either ASD or ADHD, because a direct comparison of all three groups is rarely reported. Therefore, little is known whether the ASD and ADHD symptoms will have an additive or superadditive impact on the comorbid group's behavioral and cognitive impairments.

**Objectives:** Our overarching goal is to employ a meta-analysis approach to compare individuals with comorbid ASD+ADHD to individuals with only ASD or ADHD on various behavioral and cognitive measures (social, attentional, executive, etc.) to characterize their relative severity of impairments. Specifically, if the comorbid condition occurs as only an additive outcome of ASD and ADHD, we predict that the ASD+ADHD group would show no difference from the ASD or ADHD groups. However, if the coexistence of ASD and ADHD symptoms has superadditive effects, we predict that the ASD+ADHD group would show more severe impairments to at least one of the single-condition groups.

**Methods:** We conducted a literature review search on PsycINFO and PubMed, using combinations of the following search terms: “ASD,” “ADHD,” “autism,” “attention deficits,” and “comorbidity.” After initial screening, 60 papers were selected based on the following inclusion criteria: (a) published after 2010; (b) presented data on behavioral or cognitive measures; (c) included a comorbid ASD+ADHD group and at least one of ASD or ADHD groups. After reading each paper in-detail, we only included papers that presented information on sample size, group means, and standard deviations to calculate the effect sizes. In the preliminary analysis presented here, we included 14 studies that met the inclusion criteria. We used the *Robumeta* (V2.0) package in R (V3.6.1) to conduct the meta-regression analysis with random effects and small-sample corrections.

**Results:** A total of 9 studies with 74 effect sizes were entered into the meta-regression model comparing the ASD+ADHD and ASD groups, and we found a significant effect,  $est. d=0.276, t=9.17, p=.025$ , suggesting a better performance of ASD over the ASD+ADHD on behavioral and cognitive measures. For the comparison between ASD+ADHD and ADHD groups with 10 studies of 80 effect sizes, we found a marginally significant effect,  $est. d=0.497, t=3.54, p=.073$ , suggesting a less reliable finding that ADHD has milder symptoms than the comorbid group.

**Conclusions:** Our preliminary results suggest that the comorbid condition suffers from a superadditive effect from the ASD and ADHD conditions. The coexisting ADHD symptoms make behavioral and cognitive impairments in ASD+ADHD more severe than the ASD but not much to the ADHD group.

#### 414.013 (Poster) Characteristics of Children with Conflicting ASD Diagnoses

---

**Background:** Diagnosis of Autism Spectrum Disorder (ASD) is currently based on behavioral assessment according to the Diagnosis and Statistical Manual of Mental Disorder - 5th edition (DSM-5). The “Autism Diagnostic Observation Schedule - 2nd edition” (ADOS-2) is a standardized protocol for observation of behavioral symptoms, which has been developed to assist clinicians in ASD diagnosis. However, ADOS-2 classification is sometimes at odds with the final clinical diagnoses. Identifying factors associated with disagreement between ADOS-2 ASD classification and the final clinical decisions could help improve the accuracy of ASD diagnosis.

**Objectives:** To assess psychometric characteristics (i.e. sensitivity, specificity, positive and negative predictive values [PPV and NPV]) of ADOS-2 compared to DSM-5-based clinician diagnosis, and to identify characteristics associated with disagreement between these two diagnosis approaches.

**Methods:** A cross-sectional study of children enrolled at the National Autism Research Center of Israel (NARCI) and completed both ADOS-2 assessment and DSM-5 diagnosis protocol at Soroka University Medical Center (SUMC) between the years 2015-2019. Children with ADOS-2 classification of “mild-to-moderate” or “moderate-to-severe” concerns in the toddler module and “Autism” or “Autism spectrum” in modules 1-4, were assigned an “ADOS-2 ASD diagnosis”. We used the DSM-5-based

clinician diagnosis as the gold-standard reference to define true-positive (TP), true-negative (TN), false-positive (FN) and false-negative (FN) ADOS-2 diagnoses accordingly. Sociodemographic and clinical characteristics of these children were obtained from the NARCI database and compared between study groups using appropriate statistical tests.

Results: Overall, 792 children (613 males, mean age=41.8 months) participated in this study. There was agreement between the ADOS-2 scores and the final clinical diagnosis in 627 of the children (TP=500, TN=127) with a sensitivity=92%, specificity=51%, PPV=80.5% and NPV=74%. Noticeable differences were apparent across the different ADOS-2 modules with the toddler's module being the most sensitive and least specific (sensitivity=98%, specificity= 37%) and modules 2&3 being the least sensitive and most specific (sensitivity=82%, specificity= 67%). Furthermore, ADOS-2 scores exhibited higher specificity and lower sensitivity in non-verbal children vs. verbal children (sensitivity: 95% vs. 88% and specificity: 44% vs. 56%;  $p<0.001$ ). Finally, IQ and ABAS scores of children with FP and FN diagnoses were significantly higher than the scores of children in the TP group and significantly lower than the scores of children in the TN (**Figure 1**).

Conclusions: Our findings suggest that the specificity and sensitivity of the ADOS-2 changes with the age, language abilities, cognitive abilities, and adaptive behaviors of the examined child. Accounting for these characteristics in the ADOS-2 classification algorithm may improve its agreement with the ASD diagnosis by clinicians.

**414.014 (Poster)** Characterizing Dysregulation in Autistic Youth Using the Child Behavior Checklist-Dysregulation Profile  
**K. Schauder, S. Rau, A. C. Armour and L. Kenworthy, Center for Autism Spectrum Disorders, Children's National Hospital, Washington, DC**

---

Background: Dysregulation is often seen in autistic youth. The Child Behavior Checklist-Dysregulation Profile (CBCL-DP), defined as the sum of T-scores across three CBCL subscales (anxious/depressed, aggressive behavior, attention problems), provides a symptom-based characterization of dysregulation. In autism, ratings on this index have been linked to poorer adaptive functioning, increased co-morbid psychiatric diagnoses, and higher autistic symptomatology, indicating that autistic youth with high levels of dysregulation represent a particularly vulnerable subgroup within autism.

Objectives: To characterize the CBCL-DP in a large sample of autistic youth and investigate relationships with age, IQ, gender, and executive functioning (EF).

Methods: CBCL data from a clinical/research database was available for 1,105 youth ages 6-18 (M=10.5) with a DSM-5 diagnosis of autism spectrum disorder. There were 219 females and 876 males; full scale IQ ranged from 32 to 149 (M=95.8). First, the CBCL-DP was calculated for each subject and youth were characterized into three established categories based on severity of dysregulation: normal (CBCL-DP < 180), moderate (210 > CBCL-DP  $\geq$  180), severe (CBCL-DP  $\geq$  210). Relationships between CBCL-DP and age were investigated using a Pearson correlation. In subsamples with available data, relationships between CBCL-DP and intellectual and executive functioning were probed using Pearson correlations with full scale IQ and the Global Executive Composite (GEC) from the BRIEF-2 caregiver questionnaire. A t-test was used to test for gender differences.

Results: Of the 1,105 autistic youth, 32.9% had CBCL-DP scores in the normal range, 45.6% in the moderate range, and 21.4% in the severe range. There were no relationships between CBCL-DP and either age ( $r=.03, p=.37$ ) or IQ ( $r=.00, p=.99$ ). There was a strong relationship between GEC and CBCL-DP,  $r(827)=.70, p<.001$ . Females had slightly but significantly higher reported CBCL-DP scores compared to males,  $t(1093)=2.75, p=.006$ , Cohen's  $d=0.21$ , driven by significantly higher ratings on the attention problems subscale  $t(1093)=5.2, p<.001$ , Cohen's  $d=0.40$ . Reported correlations did not differ in males and females (all  $p$ 's>.39).

Conclusions: In the largest sample to date to investigate the construct of dysregulation using the CBCL-DP, our findings support previous literature suggesting that 55-80% of autistic youth are characterized by moderate to severe levels of dysregulation. The lack of relationships of dysregulation with either age or IQ highlights the relevance of this construct across ages and functioning levels. Interestingly, slightly higher dysregulation, driven by increased attention problems, was observed in females compared to males, suggesting possible important gender differences in dysregulation that may contribute to higher vulnerability for poorer outcomes in females. The strong correlation between executive functioning and dysregulation is consistent with prior literature linking poor EF to symptoms associated with psychopathology and should be explored further. Future directions also include incorporating task-based measures of EF and other informant ratings of psychopathology (e.g., clinician, teachers) to better understand relationships with the CBCL-DP. Longitudinal analyses, including younger children, will provide important information about how the CBCL-DP may predict future outcomes, including adaptive functioning and co-morbid psychopathology.

**414.015** (Poster) Characterizing the Heterogeneity in ASD Symptomatology in Individuals with ASD Compared to TD Controls  
**J. Benes<sup>1</sup>** and **L. Chen<sup>2</sup>**, (1)Santa Clara University, Santa Clara, CA, (2)500 El Camino Real, Santa Clara University, Santa Clara, CA

---

**Background:** Heterogeneity is a core feature of Autism Spectrum Disorders (ASD), but existing data-driven clustering approaches diverged on the number of clusters or symptom presentations in subgroups so that the heterogeneous patterns of symptomatology in ASD are yet to be characterized. The mixed findings resulted from variations in sample size, diagnostic and symptom measures included for clustering, and clustering methods. In addition, it is well-known that the symptom representations differ drastically across age, gender, and cognitive-ability groups in ASD, but clustering studies rarely examined how subgroups may differ in age, gender, and cognitive abilities (e.g., IQ). Furthermore, existing studies have not included a typically-developing (TD) group for the clustering, so little is known how symptom presentations in ASD subgroups differ from TDs.

**Objectives:** The overarching goal of this study is to characterize the heterogeneity of symptom presentations in ASD with a large sample using a systematic clustering approach. First, we determined the optimal number of clusters in ASD and examined the sub-cluster differences in age, gender, and IQ scores. Second, we conducted the clustering analysis in TD for a comparison with ASD.

**Methods:** Combining Autism Brain Imaging Data Exchange (ABIDE) datasets I and II, we used valid subscale scores from ADI-R ( $N_{ASD}=616$ ; Female: 91;  $M_{age}=13.27$ ; 5-39 yrs old) and from SRS ( $N_{ASD}=379$ ; Female: 55;  $M_{age}=14.78$ ; 5-62 yrs old;  $N_{TD}=442$ ; Female: 120;  $M_{age}=14.61$ ; 5-64 yrs old) for our clustering analysis. We used the *NbClust* package (*V3.0*) in *R* (*V3.6.1*) to conduct the hierarchical clustering with Euclidean distance, and used the majority vote from 30 metrics to determine the optimal number of clusters between 2 and 10.

**Results:** Based on ADI-R in ASD, 2-cluster solution was recommended with a severe-symptom subgroup ( $N=255$ ) scoring higher on social ( $t(614)=25.62, p<.001$ ), verbal ( $t(614)=27.23, p<.001$ ), and repetitive-restrictive behavior ( $t(614)=10.00, p<.001$ ) than the mild-symptom subgroup ( $N=351$ ). Two subgroups differed in IQ ( $M_{severe}=103.88, M_{mild}=108.12, p=.002$ ), but not in age and gender. Based on SRS in ASD, a two-cluster solution was also recommended with a severe-symptom subgroup ( $N=308$ ) scoring higher on all SRS subscale scores ( $ps<.001$ ) than a mild-symptom subgroup ( $N=61$ ), but not in age, gender, or IQ. In comparison, based on the SRS in TD, three subgroups were found ( $N_{mild}=311, N_{severe}=128, N_{extreme}=3$ ). We only compared the mild-symptom and severe-symptom subgroups, and found significant differences in all SRS measures ( $ps<.001$ ) and age ( $M_{mild}=13.44; M_{severe}=17.32, p<.001$ ).

**Conclusions:** Heterogeneity in symptomatology in ASD varies on a quantitative continuum from mild symptoms to severe symptoms across all domains, showing no qualitative difference between subgroups. The similar finding in TD further suggests that ASD symptomatology is presented in a continuous format from TD to ASD. However, the heterogeneity is related with cognitive abilities in ASD but with age in TD.

**414.016** (Poster) Children with Minimal Verbal Skills and Autism Use of Communicative Functions and Communication Partner across Naturalistic Setting  
**S. Suswaram<sup>1</sup>** and **N. Brady<sup>2</sup>**, (1)Speech Language Hearing: Sciences and Disorders, University of Kansas, Lawrence, KS, (2)University of Kansas, Lawrence, KS

---

**Background:**

Two million people in India are suspected to have Autism Spectrum Disorder (ASD; Dababnah et al., 2018), and 30% of them fail to develop verbal communication skills (minimally verbal; Salley et al., 2019). Because of the delayed diagnosis, prevalence of children with ASD that are minimally verbal are higher in Indian context than other Western countries (Singh & Bunyak, 2019). For supporting children in developing verbal communication skills, we must assess the child's skills accurately. Most assessment materials available for evaluating communication skills require verbal responses from the children, developed for Western population (Muller et al., 2020), and without cultural adaptation for Indian context (Krupa et al., 2018). Information on assessment practices used by professionals in India for children with minimal verbal abilities remains negligible (Franz & Dawson, 2019). This study surveyed professions working on communication skills in children with ASD who are minimally verbal from Bangalore, India, on assessment practices.

**Objectives:**

## Survey professional Practice with Communication Assessment

### Methods:

A total of 22 participants completed the survey and worked with children with ASD who are minimally verbal from Bangalore, India. Majority of the participants identified as Speech-Language Pathologists (77%) and the rest as Special Educators (23%). We used survey design, which has 16-questions, separated over three subsections, ASD caseload, assessment practices, and demographics details of the participants. The electronic survey developed over the Qualtrics Survey Software were distributed to the professionals working with children with ASD in Bangalore, India.

### Results:

- Most participants reported using the Assessment of Language Development (ALD; Lakkanna, Venkatesh, & Bhat, 2008; 68%), followed by Receptive-Expressive Emergent Language test (Bzoch et al., 2003; 46%), Speech and language development chart (Gard et al., 1993; 18%), Communication DEALL developmental checklists (Comm.DEALL; Karanth, 2007; 14%), Bankson Language Screening Test (BLST; Bankson, 1977; 9%), and Northwestern Syntax Screening Test (Ratusnik et al., 1980; 4%).
- Content analysis revealed of all the assessment materials requires verbal response from the child. However, participants reported that these assessment materials directly measure the child's nonverbal communication (68%), communicative functions (55%), and allows to evaluate child's communication in naturalistic environments (55%).
- Further, the participants reported using these assessment materials for forming clinical decisions such as setting goals for interventions (91%), monitoring progress (77%), and using the test outcomes during discussions with the family members on a child's progress with intervention (72%).
- Surprisingly, most of the participants also relied on informal interviews to gain further clarity over the children's communication abilities (86%) in addition to using standardized assessment.

### Conclusions:

Professionals working on communication skills in children with minimal verbal abilities use informal assessment method guided by standardized assessment for making most of the clinical judgements. Majority of the assessment materials reported in the survey other than ALD and Comm. DEALL are not developed for Indian population. Future studies child examining the benefits and limitations of using Western assessment materials along with the informal assessments on communication development in children that fail to develop verbal communication skills in Indian context.

**414.017 (Poster)** Cognitive and Communication Profiles of Minimally Verbal Children with Autism Spectrum Disorder  
**M. Pizzano<sup>1</sup>** and **C. Kasari<sup>2</sup>**, (1)Education, University of California, Los Angeles, Los Angeles, CA, (2)University of California, Los Angeles, Los Angeles, CA

Background: Autism spectrum disorder (ASD) is characterized by variability in communication and cognition. Current descriptions of heterogeneity are generally comprised of single characteristics or predictors versus comprehensive patterns of behavior and cognition (e.g. Tager-Flusberg & Joseph, 2003; Georgiades, et al., 2013). Less is known about minimally verbal children with ASD. The minimally verbal definition varies from 30 spoken words to zero, and encompasses a range of cognitive skill (Yoder & Stone, 2006; Kasari, et al., 2013; Bal, et al., 2016). These children are frequently absent from disability and intervention literature though they stand to benefit the most from intervention.

Objectives: The present examination identifies profiles of heterogeneity across cognitive and language measures in minimally verbal children with ASD age three to eight years old.

Methods: This secondary data analysis combines baseline data from two multisite intervention studies to yield a total of 354 participants. All children had 30 different spoken words or less, were three-eight years old, and were recruited from local public schools. Latent profile analysis was used to identify subgroups with common patterns of characteristics. Profile variables were indicators of nonverbal cognition (play diversity, nonverbal age equivalent, receptive language age equivalent) and communication behavior (total spontaneous requests, social affect, total spontaneous communication to share, number of spontaneous utterances, and number of different words). Of these variables, nonverbal age equivalent (MSEL, Mullen, 1997), receptive language age equivalent (VABS-II, Sparrow, et al., 2005), and social affect (ADOS, Lord, et al., 2012) were standardized. Play diversity (SPA; Ungerer & Sigman, 1981), total requesting & sharing communication (ESCS, Mundy, et al., 2003), and spontaneous utterances & number of different words (fNLS or PCX, Kasari, et al., 2014) were from behavioral

observations and assessments. The appropriate latent profile model was determined via examination of fit indices- information criteria (ICs), Likelihood Ratio Tests (LRTs), Bayesian fit indices, and entropy (Masyn, 2013).

Results: Results indicate that the four-profile model emerged as best fit to the data (entropy= 0.88; BPLRT=  $p < 0.001$ ). These four profiles represent distinct nonverbal versus verbal cognitive patterns. Profile 1 (n= 39) consists of those who were exhibiting the strongest skills across all variables, both verbal and nonverbal. Profile 2 (n= 69), represents those who had nonverbal skill as strong as those in Profile 1, but verbal skill that was less strong and at the sample mean. Profile 3 (n=56) represents those who had mixed skills, with nonverbal scores as strong as Profile 1, but verbal scores that were equal to Profile 4. Profile 4, the largest group, (n= 193) represents those who had the weakest scores on all measures, both verbal and nonverbal.

Conclusions: Identified profiles are largely defined by verbal versus nonverbal cognition and behavior. This comprehensive classification of minimally verbal heterogeneity in early childhood prior to intervention into an intervention study represents an important step in determining the response of children with different profiles to different treatment approaches.

**414.018 (Poster)** Comparison of Autism Diagnostic Observation Schedule (ADOS-2) Standardized Procedures to Assessment with Safety-Related Modifications Due to COVID-19

**G. Binion<sup>1</sup>, J. Ferguson<sup>2</sup>, C. Klaiman<sup>3</sup>, S. P. White<sup>4</sup> and S. Sivathanan<sup>5</sup>,** (1)Clinical Assessment and Diagnostics, Marcus Autism Center, Atlanta, GA, (2)Clinical Assessment and Diagnostics, Marcus Autism Center, Atlanta, GA, (3)Marcus Autism Center, Children's Healthcare of Atlanta and Emory University School of Medicine, Atlanta, GA, (4)Department of Pediatrics, Emory University, Atlanta, GA, (5)Educational & Counselling Psychology, McGill University, Montreal, QC, Canada

---

**Background:** The recent SARS-CoV-2 pandemic has created challenges for conducting timely diagnostic evaluations in a standardized fashion. The Autism Diagnostic Observation Schedule, Second Edition (ADOS-2) is the gold-standard observational tool for assessing symptoms of ASD, however, the pandemic has necessitated safety-related modifications to standardized assessment procedures. Such modifications have not been standardized and their impact on diagnostic accuracy has yet to be established. This is particularly relevant for certain ADOS modules (Toddler Module, Module 1, Module 2) which may be more significantly impacted by the use of face masks/shields and the omission of activities which promote the spread of respiratory viruses (e.g., balloon, snack). These modules are also those most likely to be used when assessing young children who are in a “critical period” for benefiting from early diagnosis and intervention. Given this, it is essential to determine the impact to diagnostic accuracy of safety-related modifications to in-person ADOS.

**Objectives:** The purpose of this study is to assess the convergence of ADOS-2 algorithm and comparison scores obtained by assessment with safety-modified administration with scores obtained with standardized administration.

**Methods:** Children aged 1-5 years are being recruited to this ongoing study if they completed a standardized in-person ASD diagnostic evaluation at our clinic between January and March 2020. Families are being invited to participate in reassessment if they completed an assessment in English and completed an ADOS-2 Module 1, 2, or Toddler during their evaluation. Participants are being invited to participate in an in-person assessment modified in the following ways – use of face masks/shields by the examiner and parents and the omission of activities which increase transmission of respiratory viruses (inflatable balloon activity) or are not possible with masks (snack, social smile).

**Results:** A total prospective sample of 195 children from racially and ethnically diverse backgrounds is currently being recruited. In their original assessment, 42% (n = 82) of children completed an ADOS-2 Toddler Module, 38% (n = 75) completed a Module 1, and 20% (n = 38) completed a Module 2. Eighty-three percent of these children received a primary diagnosis of ASD, while 16% received a non-ASD diagnosis (e.g., Language Disorder), and 1% received no diagnosis. Correspondence between standardized and adapted procedures will be assessed via Pearson correlations for the ADOS-2 algorithm and comparison scores, with adequate convergence represented by a correlation of  $r = .7$ . A priori power analysis indicates the present sample has greater than 99% power to detect target effects. Because this study is embedded in a larger study on safety adaptations to standardized assessment, correspondence of adapted in-person assessment will also be compared to correspondence of measures administered via telehealth (Childhood Autism Ratings Scale, Brief Observation of Symptoms of Autism).

**Conclusions:** This study will inform the degree to which results of ASD assessment completed with safety modifications correspond with assessment using standardized procedures. Results will provide vital information regarding the validity of adapted assessment procedures and will thus inform the quality of care received by families for whom standardized and/or telehealth assessment is not feasible.

**414.019 (Poster)** Comparison of COVID-19 Adapted Telehealth Versus Standard-of-Care Protocols for the Diagnostic Assessment of Autism Spectrum Disorder

**S. Sivathasan<sup>1</sup>, G. Binion<sup>2</sup>, J. Ferguson<sup>3</sup>, S. P. White<sup>4</sup> and C. Klaiman<sup>5</sup>,** (1)Educational & Counselling Psychology, McGill University, Montreal, QC, Canada, (2)Clinical Assessment and Diagnostics, Marcus Autism Center, Atlanta, GA, (3)Clinical Assessment and Diagnostics, Marcus Autism Center, Atlanta, GA, (4)Department of Pediatrics, Emory University, Atlanta, GA, (5)Marcus Autism Center, Children's Healthcare of Atlanta and Emory University School of Medicine, Atlanta, GA

---

**Background:** The current COVID-19 global pandemic has created new challenges and significantly worsened existing systemic issues associated with timely and equitable access to comprehensive diagnostic evaluations for children suspected of having Autism Spectrum Disorder (ASD). This has necessitated significant changes to ASD assessment protocols, with pivoting to telehealth being a widely-implemented adaptation. However, there currently exists limited evidence for the efficacy of ASD assessment and validity of ASD diagnosis among children, using live-feed video-conferencing platforms that incorporate the use of gold-standard, reimbursable assessment measures (i.e., ADOS-2 Module 1; Reese et al., 2015). During the present pandemic, there exists an urgent need to evaluate whether a standardized, comprehensive ASD assessment battery—often required by insurance companies and in order to access time-sensitive interventions—is comparable to a standardized ASD assessment when administered via telehealth.

**Objectives:** The purpose of this study is to assess the degree to which telehealth-specific adaptations to assessment procedures influence the validity and diagnostic accuracy of gold-standard ASD assessment.

**Methods:** Children are being recruited to this ongoing study if they received a complete standard in-person ASD diagnostic evaluation (i.e., a Mullen or DAS-2, and an ADOS-2) by a licensed psychologist and/or supervised trainee at a large ASD specialty assessment clinic, between January and March 2020, prior to assessment modifications due to the pandemic. Participants are being invited to complete a re-assessment adapted to a telehealth context, involving a cognitive and ASD assessment battery. Specifically, participants are asked to complete the Developmental Profile-4, Ages and Stages Questionnaire-3, and/or Developmental Assessment of Young Children-2 cognitive measures via clinician-caregiver interview and child observation via Zoom. The Childhood Autism Ratings Scale, Second Edition (CARS-2) and Brief Observation of Symptoms of Autism (BOSA) are completed using standardized clinician observation and coaching of the caregiver-child interaction.

**Results:** The total prospective sample includes 246 children aged 1-14 years from racially and ethnically-diverse backgrounds. Eighty-percent of this sample received a primary diagnosis of ASD, while 16% received non-ASD primary diagnoses (e.g. ADHD, GDD), and 4% received no diagnosis. Thirty-three percent completed the Toddler Module, 36% completed a Module 1, 20% completed a Module 2, and 11% completed a Module 3. For this ongoing study, convergent validity will be assessed via correlations between initial evaluation and telehealth measures. To achieve good convergent validity ( $r = .7$ ),  $\alpha = .05$  and power of  $.8$ , we require 13 participants per measure comparison. Our goal is to conduct each possible comparison (e.g., Mullen–DAYC-2, DAS-2 School Age–DP-4, ADOS-2 Tod Mod–CARS-2-ST), which would result in  $n=130$  cognitive measure comparisons and  $n=156$  autism measure comparisons. Interrater reliability on study measures will also be ascertained via live or video review by senior clinicians.

**Conclusions:** If it is determined that adapted telehealth procedures are as efficacious as gold-standard assessment in the diagnosis of ASD, the implications for this research involve expanding access for families who otherwise may not have timely specialized diagnostic assessment available to them, due to several factors including the current pandemic.

**414.020 (Poster) Concordance between Parent and Child Report of Sleep Disturbance and Sleep-Related Impairment in Autistic and Non-Autistic Youth**

**L. D. Yankowitz<sup>1</sup>, K. Bevans<sup>2</sup>, J. R. Schuchard<sup>3</sup> and L. J. Meltzer<sup>4</sup>,** (1)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (2)Rehabilitation Sciences, Temple University, Philadelphia, PA, (3)Children's Hospital of Philadelphia, Philadelphia, PA, (4)Pediatric Behavioral Health, National Jewish Health, Denver, CO

---

**Background:** Sleep problems, which contribute to quality of life, are common in children with autism spectrum conditions. In gathering information about sleep problems, the choice of informant – child self-report or parent proxy – may impact the quality of information gathered, with evidence supporting the use of child self-report in typically developing adolescents. There is increased attention from the autistic community on quality of life outcomes, and prior work indicates that many autistic youth are able to report on their own quality of life across a number of domains. However, the ability of youth on the spectrum to report accurately on their own sleep quality has not been assessed. It is important to understand the accuracy of autistic youth's self-reported sleep issues to guide sleep measurement in clinical settings.

**Objectives:** To assess parent-child concordance in the Patient Reported Outcome Measurement Information system (PROMIS) Pediatric Sleep Disturbance (SD) and Sleep-Related Impairment (SRI) short forms in large samples of children with and without autism.

**Methods:** Participants were recruited from the GfK Knowledge Panel (an online sample representative of the U.S. population), and two online registries (autismMatch and the Interactive Autism network (IAN)). A total of 1355 parent-child dyads completed the PROMIS SD (Autism N = 306, No Autism N = 862) and/or SRI (Autism N = 296, No Autism N = 863) 8-item scales (see Table). Weighted kappa ( $\kappa$ ) was used to examine the agreement between parent-proxy ratings and child ratings among autistic and non-autistic children. A discrepancy score was calculated by subtracting child ratings from their own parent's ratings, and these were compared between groups using t-tests.

**Results:** On the Sleep Disturbance scale, agreement between autistic children's ratings and their parents' was substantial ( $\kappa = 0.69$ ), and was similar to the agreement between non-autistic children and their parents ( $\kappa = 0.69$ ). Similar results were observed for the Sleep-Related Impairment scale (autism  $\kappa = 0.59$ , non-autism  $\kappa = 0.65$ ). Expressed as Pearson's  $r$ , the relationship between child-parent report of SD was  $r = 0.73$  in autism, and  $r = 0.68$  in non-autism. The relationship between child-parent report in SRI was  $r = 0.61$  in autism,  $r = 0.64$  in non-autism. When parent-child discrepancy scores were compared between autism and non-autism, significant differences were observed for both SD (autism  $M = 3.63$ , non-autism  $M = 0.51$ ,  $t(523) = 6.35$ ,  $p < 0.001$ ) and SRI (autism  $M = 3.30$ , non-autism  $M = 0.25$ ,  $t(437) = 5.06$ ,  $p < 0.001$ ). This indicates that the magnitude of parent-child discrepancy is larger in autism dyads, with parents endorsing more symptoms than their children on average.

**Conclusions:** Overall, parent-child agreement was similar between autistic and non-autistic youth, with some evidence of greater under-reporting of symptoms by autistic youth than non-autistic youth compared to their own parents. This suggests that autistic youth with the cognitive and language ability to complete these scales are capable reporters of their own sleep in clinical and research contexts, with the caveat that they may slightly underreport compared to their parents.

**414.021 (Poster) Concurrent Validity of Parent Report and Behavioral Assessments of Communication and Social Skills in 18-Month-Old Infants at Low- and High-Familial-Risk for ASD**

*M. Hartney<sup>1</sup>, L. Castelbaum<sup>1,2</sup>, C. L. Wilkinson<sup>1</sup>, H. Tager-Flusberg<sup>2</sup> and C. A. Nelson<sup>1</sup>, (1)Developmental Medicine, Boston Children's Hospital, Boston, MA, (2)Department of Psychological and Brain Sciences, Boston University, Boston, MA*

---

**Background:** Parent report measures are commonly used to screen and assess development in young children. However, the concurrent validity of these measures has been questioned in at-risk populations. Children who have an older sibling with autism spectrum disorder (ASD) are at increased risk of developing ASD and/or language difficulties (Marrus et al., 2018; Ozonoff et al., 2011). Early detection of delays in the high-risk infant sibling population relies on accurate parent report and screening measures. Understanding the relationship between parent report measures and direct behavioral assessments that are typical in research studies is especially important during COVID-19 when in-person assessments cannot be carried out.

**Objectives:** This work aims to evaluate the concurrent validity between parent report measures and in-person developmental and behavioral assessments in 18-month-old infants at low- and high-familial-risk for ASD.

**Methods:** Participants included 151 18-month-old children with high-familial-risk for autism (HRA,  $n=53$ ), defined as having an older sibling with an ASD diagnosis, or with low-familial-risk for autism (LRA,  $n=98$ ), defined by having no first-degree relative with an ASD diagnosis. Parent report measures included the MacArthur-Bates Communicative Development Inventory: Words and Gestures (MB-CDI W&G; Fenson et al., 2007), the Language Use Inventory (LUI; O'Neill, 2009), and the Ages and Stages Questionnaire (ASQ; Bricker et al., 1999). In-person developmental and behavioral assessments included the Mullen Scales of Early Learning (MSEL; Mullen, 1995) and the Autism Diagnostic Observation Schedule (ADOS-2; Lord et al., 2000). Concurrent validity was determined using Pearson's correlation coefficients between parent report measures and developmental and behavioral assessments. P-values shown have been corrected for multiple comparisons. Raw scores were used for all measures.

**Results:** Across low- and high-familial-risk groups, MSEL Expressive Language Scores were significantly correlated with ASQ Communication ( $r(134) = .72$ ,  $p < .001$ ), MB-CDI Words Produced ( $r(129) = .73$ ,  $p < .001$ ), and LUI Communication with Words (Part 2) scores ( $r(129) = .72$ ,  $p < .001$ ). Correlations between MSEL Receptive Language scores were also significantly correlated with ASQ Communication ( $r(134) = .56$ ,  $p < .001$ ), MB-CDI Phrases Understood ( $r(129) = .46$ ,  $p < .001$ ), and MB-CDI Words Understood scores ( $r(129) = .42$ ,  $p < .001$ ), although to a lesser degree.

Within the HRA sample, ADOS Social Affect subscale scores were significantly correlated with ASQ Communication ( $r(45) = -.52$ ,  $p = .001$ ), MB-CDI Phrases Understood ( $r(41) = -.62$ ,  $p < .001$ ), and MB-CDI Total Gestures scores ( $r(41) = -.49$ ,  $p < .005$ ). Interestingly, while ASQ Personal Social scores were significantly correlated with ADOS Social Affect scores, Pearson's  $r$  ( $r(45) = -.46$ ,  $p < .005$ ) was lower than the ASQ communication correlation.

**Conclusions:** This work highlights the ability for parent report measures to capture these differences across familial risk groups (HRA & LRA). ASQ Communication was most strongly correlated with MSEL Expressive Language. Within the HRA group, it was also significantly correlated with ADOS Social Affect. Future directions include investigating earlier and later time-points to determine whether parent report measures can serve as a potential alternative to in-person assessments at varying time-points.

**414.022 (Poster)** Consistency of Reporting Presence and Severity of Restricted and Repetitive Behaviors on Parent and Clinician Based Measures

*B. Rozumny<sup>1</sup>, S. Mussarrat<sup>2</sup> and E. Hanson<sup>3</sup>, (1)Developmental Medicine, Boston Children's Hospital, Boston, MA, (2)Boston Children's Hospital, Boston, MA, (3)Boston Children's Hospital/Harvard Medical School, Boston, MA*

---

**Background:** Restricted and repetitive behaviors (RRBs) are seen in many developmental disorders and are a necessary symptom for the diagnosis of Autism Spectrum Disorder (ASD) (American Psychiatric Association, 2013). These behaviors can also cause significant familial stress (Harrop et al, 2016) and impede learning in children with ASD (Leekam et al., 2011). Studies have shown discrepancies in reporting of RRBs between two of the “gold standard” measures of Autism: the Autism Diagnostic Interview (ADI-R), a parent report measure of their child’s behaviors, and the Autism Diagnostic Observation Schedule (ADOS), a clinician scored assessment of the child (Lord et al., 1994; Lord et al., 2003). These discrepancies may exist for a number of reasons including if parents fail to understand the questions asked and misrepresent their child’s behaviors, and/or clinicians do not have sufficient opportunity to assess all details of RRBs in this type of brief observation (Kim & Lord, 2010; Moore & Goodson, 2003). Excluding the RRBs domain of the ADI-R leads to higher agreement between the measures (Wiggins & Robbins, 2008). However, to best understand a child’s current behavior, it is important that measures reliably capture the prevalence and severity of RRBs. The Behavior and Sensory Interests Questionnaire (BSIQ) is a parent interview that looks at the presence and severity of a large number of individual RRB’s. (Hanson et al., 2015). Comparing ratings for current RRBs across the ADOS, ADI-R and BSIQ may give insight into the most reliable combination of measures to assess these symptoms.

**Objectives:** To evaluate consistency of reporting the presence and severity of RRB’s across ADOS, ADI and BSIQ.

**Methods:** Preliminary data analysis included 30 participants (77% males, ages 61-239 months, mean = 121.7, SD = 50.21) recruited from The Phenotypic and Genetic Factors in ASD study, the Boston Autism Consortium and The Simons Variation in Individuals Project. RRB’s on the ADOS, ADI-R and BSIQ are coded on a severity scale with 0 = not present, 1 = mild and 2-3 = severe. These behaviors were sorted into three groups: 1. Unusual Sensory Interest (USI), 2. Hand/Finger and Other Complex Mannerisms (HF) and 3. Self-Injurious Behavior (SIB). Groups were broken down into behavior present (p) or not present (np) (i.e., USIp, USInp), as well as average severity (i.e., USImild, USIsevere), and compared across measures.

**Results:** T-tests showed significant differences for the following conditions: USIp/np between ADOS and BSIQ ( $p=0.04$ ); USIp/np between ADI and BSIQ ( $p=0.02$ ); HFp/np between ADOS and BSIQ ( $p=0.05$ ); and SIBp/np between ADOS and BSIQ ( $p=0.04$ ). No significance was found in other conditions. One-way ANOVA determined significance for USI severity between the ADOS and the BSIQ [ $F(2,87)=2.52, p=0.04$ ] but not between other conditions.

**Conclusions:** Preliminary results show discrepancies in prevalence and severity ratings of RRBs across the BSIQ, ADI-R and ADOS, supporting findings of previous studies. A larger sample size and more RRB groups will be analyzed in subsequent analyses.

**414.023 (Poster)** Creating Clinically Significant Cut Points within a Social Communication Measure: Application of Machine Learning to the Assessment of Minimally Verbal Children with ASD

*A. J. Schlink and C. Kasari, University of California, Los Angeles, Los Angeles, CA*

---

**Background:**

Intervention research involving minimally verbal (MV) children with autism is currently in a predicament. Many communication-based interventions aim to improve the core ASD deficits of social communication, yet methods to accurately and sensitively measure these improvements are insufficient (McConachie et al., 2015). To sensitively track and subsequently understand subtle behavioral improvements over time, researchers should first thoroughly understand children’s set of skills before intervention (Georgiades & Kasari, 2018). However, relating children’s variability in specific joint attention (JA) skills to their broader social communication ability may be difficult (Spence and Thurm 2010). This study aims to characterize MV children’s abilities at baseline by calibrating JA skills to global clinical social communication ratings within a randomized controlled trial.

**Objectives:**

To use machine learning methods to identify patterns in the variation of JA scores within the Early Social Communication Scales (ESCS; Mundy et al., 2003) and create cut points relating to varying degrees of social communication severity as measured by the Clinical Global Impressions-Severity Scale (CGI-S; Guy, 1976).

### Methods:

Baseline data (N=194) were used from a large multi-site clinical trial for MV children with ASD, AIM-ASD (NIH/NICHHD RO1HD073975).

This study primarily used a machine learning method known as classification and regression trees (CART; Breiman et al., 1984). The original dataset was split into training (70%) and testing (30%) datasets that preserved the ratio of CGI-S ratings. Building the classification tree was a recursive partitioning process that created splits among explanatory variables that produced the largest decrease in the impurity criterion, the Gini index. Splits continued until homogeneous subgroups were created. A 100-fold repeated cross-validation was used to assess the stability of the tree.

In order to corroborate variable importance, an ensemble method known as a random forest was used. A random forest fitted a more accurate model by averaging many trees together, thus reducing the variance and potential overfitting within a single tree.

All statistical analyses were conducted using R version 3.6.1 (R Core Team, 2013).

### Results:

In the model, the explanatory variables were the four main measurements from the ESCS: initiations of JA, initiations of behavior regulation, responses to JA bids, and responses to behavior regulation bids. The binary outcome variable was high or low social communication ratings from the CGI-S, which corresponded to more or less severe social communication impairment, respectively. In this sample, the three most important variables in both the CART and random forest models were 1) response to JA bids, 2) behavior regulation initiations, and 3) response to behavior regulation bids.

### Conclusions:

This study attempts to address the difficulty in JA measurement and subsequent clinical interpretation among MV children with autism (Kasari et al., 2013). Using CART, we classified specific cutoffs in JA scores into global clinical social communication severity, thus, giving more interpretability to JA frequency scores in this sample. Within this study of MV children, creating clinical cutoffs and a hierarchy of variable importance at baseline may help researchers gauge specific JA skills to target and then understand the robustness of progress made via intervention.

**414.024 (Poster)** Critical Examination of Five Major Level Two Screeners for Autism Spectrum Disorder  
*N. Bergamo<sup>1</sup>, M. Stoll<sup>1</sup>, M. A. Volker<sup>1</sup> and S. L. Brennan<sup>2</sup>, (1)Counseling, Educational Psychology, and Special Education, Michigan State University, East Lansing, MI, (2)Department of Counseling, Educational Psychology, and Special Education, Michigan State University, East Lansing, MI*

---

**Background:** As the prevalence of autism spectrum disorder (ASD) increases (Maenner et al., 2020), there is an increased need for reliable and valid assessment tools, prioritizing cost-effectiveness and efficiency (Zwaigenbaum & Penner, 2018). In ASD screening and diagnosis, rating scales are commonly used because they can include and allow for comparison of information from multiple raters, in addition to gathering data beyond a singular observation (Norris & Lecavalier, 2010; Scahill & Lord, 2004). Rating scales for ASD can be categorized into level one screeners (e.g., assessing for broad, atypical development) and level two screeners (e.g., assessing for more specific diagnostic criteria), and, in addition to screening, can also play a role in a more comprehensive diagnostic assessment (Kuriakose & Shalev, 2016; Norris & Lecavalier, 2010). This poster presentation will discuss and review five commonly used ASD level two screeners (Benson et al., 2019; Kuriakose & Shalev, 2016): the GARS-3 (Gilliam, 2013), SRS-2 (Constantino & Gruber, 2012) CARS2 (Schopler et al., 2010), ASRS (Goldstein & Naglieri, 2009), and SCQ (Rutter et al., 2003a). Specifically, this poster will critically review each rating scale in terms of intended use(s), characteristics and expectations of raters and examiners, psychometric evidence, and strengths and limitations. A summary table will be provided to guide clinicians in their choice of assessment tools, and important directions for future research are discussed.

**Objectives:** Presentation objectives are as follows: (a) examine the normative sample, reliability, and validity as reported in the manual of commonly used level two screeners for ASD, (b) highlight reviews and critiques of the screeners from independent

evaluators and researchers, and (c) provide a summary table for clinicians to guide their choice in assessment tool and/or to reference in the use of assessment.

**Methods:** For each of the five selected ASD level two screeners, researchers critically and systematically examined the published manual and test reviews from independent evaluators. Additionally, researchers examined independent research that supported, contextualized, or criticized information reported in the manual.

**Results:** Table 1 presents information across the five selected rating scales. Readers can compare versions, raters, ages, subscales, intended uses, and rater characteristics. Additionally, a summary of strengths and limitations are presented for each measure.

**Conclusions:** While these level two ASD screeners are all frequently used in applied settings (e.g., Aiello et al., 2017; Benson et al., 2019; Kuriakose & Shalev, 2016), these findings are important to consider when determining whether and/or which to use. For each rating scale, researchers examined characteristics of the rated individual and practical considerations included use with individuals of specific chronological or mental ages, features of the normative sample (e.g., lack of diversity in race and/or gender), screening specificity in relation to other diagnoses (e.g., differentiation from ADHD, ID, etc.), and potential adjustment of the cut score (e.g., SCQ). Each of these assessment tools has its own strengths and limitations for screening and/or as part of a more comprehensive diagnostic assessment, with this review clarifying the conditions for reasonable use and highlighting important questions for future research.

**414.025 (Poster)** Demonstration of Behavioral and Emotional Problems in Children with ASD Presented By the Dbc-P Scale  
**C. V. Tran<sup>1</sup>** and **P. N. Nguyen<sup>2</sup>**, (1)Department of Educational Sciences, VNU University of Education, Hanoi, Viet Nam, (2)VNU University of Education, Hanoi, Viet Nam

---

### **Background:**

Besides core symptoms in social interaction and restricted, repetitive behaviors and interests, children with ASD also face other problems with emotions and behaviors like all other children. This simultaneous appearance causes the impairments worse, making intervention complicated and difficult. Evaluating these problems provides the chance for children with ASD to receive the optimal intervention. The Developmental Behavior Checklist – Parent report form (DBC-P; Einfeld & Tonge, 1992, 2002) was specially designed to capture this population's behavioral and emotional problems.

### **Objectives:**

The study's goal was to examine the prevalence of behavioral and emotional problems among children with ASD on the DBC-P scales; correlations between these DBC-P scales and related variables to provide useful suggestions for professionals in the field.

### **Methods:**

Fifty-eight children identified as having ASD participated in the study. The consent form was received from parents/caregivers of those children. Besides collecting demographic information like the age of the children with ASD and their parents, gender, and birth order, two primary research methods were used: interviewing parents/caregivers on the DBC-P scale and measuring children's intelligence by the Color RAVEN (Raven's Progressive Matrices; Raven, 1948). The age of children who participated in the study ranged from 4 to 11 years old. 87.9% were male, and 12.1% were female; 60.3% are the first child in the family, 34.5% are the second one, 3.4% are the third one, and 1.7% are the fourth child. The mean age was 62.91 months.

### **Results:**

The data shows that 39.7% of the sample having Disruptive/Antisocial, 55.2% of them have Self-Absorbed, 62.1% have Communication Disturbance, 29.3% have Anxiety, and 65.5% have Social Relating are reported. There is no significant difference between males and females in all subscales. There was negative correlations between intelligent index (RAVEN) and Self Absorbed ( $r = -0.39$ ), Social Relating ( $r = -0.25$ ), but positive correlation with Anxiety ( $r = 0.22$ ). There was a positive correlation between Disruptive/Antisocial and age ( $r = 0.20$ ). Most of the subscales have a very low correlation with parents' age when the children were born.

### **Conclusions:**

Communication disturbance and social relating, and self-absorbed are the most seen in children with ASD according to the DBC-P. These abnormal behaviors have a relationship with the children's intelligence index. The higher an intelligence level is, the lower the severe level of maladaptive behavior, and the higher an intelligence level is, the higher the anxiety severity. In conclusion, this present study's results can help professionals better understand children with ASD and enhance their knowledge and skills in working with families and children with ASD.

**414.026** (Poster) Detecting Feeding Problems in Young Children with Autism Using a General Screener  
*E. M. Blijd-Hoogewys<sup>1</sup>, M. Buruma<sup>1</sup> and M. W. van Dijk<sup>2</sup>, (1)INTER-PSY, Groningen, Netherlands, (2)Developmental psychology, University of Groningen, Groningen, Netherlands*

---

#### Background:

Roughly 44-89% of children with ASD have feeding problems (Seiverling et al., 2018). The most prevalent is food selectivity. Parents also report disturbing feeding behaviors, such as walking away from the table, whining, and yelling, throwing or dumping foods, difficulty eating at restaurants, aggression and tantrums during eating. Also, food rituals and food anxiety are reported, which can be related to compulsive rituals, avoidance of certain types of food, and the insistence on specific methods of food preparation, food types and mealtime rules. Additionally, atypical ways of eating are reported, such as gagging, pica, overeating, rapid eating, vomiting, regurgitation, and rumination (Ledford & Gast, 2006).

Feedings problems increase the risk of malnutrition (e.g. undernutrition), suboptimal or stunted growth, and developmental and cognitive delays. Caregivers show higher levels of parental stress, including parent-child conflict and parent-spouse stress (Kuschner et al., 2017). Without adequate diagnosis and treatment, feeding problems tend to persist throughout childhood and adulthood, and may lead to eating disorders (Westwood & Tchanturia, 2017). Because feeding problems in early childhood have such aversive consequences for child development and family wellbeing, early detection is important, also in children who are yet not diagnosed with ASD.

#### Objectives:

Evaluate the use of a short general screener for feeding problems (MCH-FS) in young children with ASD.

#### Methods:

Participants were selected from a clinical ASD sample (ASD, retrospective chart review;  $n = 80$ ; 55 boys, 25 girls;  $M = 17.25$ ,  $SD = 4.8$  months; ADOS-2:  $M = 14.75$ ,  $SD = 5$ ; IQ:  $M = 90.32$ ,  $SD = 18.25$ ) and a general population sample (GPS,  $n = 1389$ ;  $M = 14.12$ ,  $SD = 7.41$  months). The Dutch version of the Montreal Children's Hospital Feeding Scale (MCH-FS; Ramsay et al., 2011; Van Dijk et al., 2011) was used to assess severity of feeding problems. This questionnaire, filled in by caregivers, measures seven main constructs: parental concern, family reactions, compensatory strategies, appetite, mealtime behaviors, oral sensory behavior, and oral motor behavior.

#### Results:

The internal consistency of the MCH-FS was good in both samples (ASD:  $\alpha = .828$ , Guttman's  $\lambda-2 = .839$ ; GPS:  $\alpha = .847$ , Guttman's  $\lambda-2 = .856$ ). In general, caregivers of children with ASD reported more feeding problems than from GPS (Mann-Whitney U test;  $U = 73.358$ ,  $z = 4.826$ ,  $p < .001$ ). Also, the score distribution in ASD seemed to be much less positively skewed than in GPS (see violin plot in Figure 1).

The response patterns on the individual MCH-FS items was highly similar. There was a slight increase in feeding problems with age for the GPS ( $\chi^2(5) = 138.282$ ;  $p < .001$ ), but not the ASD sample ( $\chi^2(5) = 4.015$ ,  $p < .547$ ).

#### Conclusions:

The MCH-FS can be used in populations that include children with ASD. Caregivers of children with ASD scored higher on this questionnaire, evidencing more feeding problems in their children. Our results are consistent Dovey and colleagues (2020) who revealed more similarities than differences in feeding problems between typically developing children and children with ASD, ARFID and picky eating.

**414.027 (Poster)** Development and Initial Validation of Simba: Sensory Sensitivity Instrument Measuring Behavioural Responses in Autism

**M. Balabanovska<sup>1</sup>**, K. Leadbitter<sup>1</sup>, C. Ellis<sup>1</sup>, K. James<sup>2</sup> and J. Green<sup>3</sup>, (1)University of Manchester, Manchester, United Kingdom, (2)Institute of Psychiatry, Psychology & Neuroscience, King's College London, London, United Kingdom, (3)University of Manchester, Manchester, United Kingdom of Great Britain and Northern Ireland

---

**Background:** Many children diagnosed with Autism Spectrum Disorders (ASD) display sensory sensitivities (SS)<sup>1,2</sup>. In clinical practice and research SS are frequently assessed through parent questionnaires which, while valuable, are prone to biases<sup>3</sup>. Behavioural assessments are less commonly used; require specialist training and specific play settings<sup>4</sup>. There is a lack of detailed observational measures of SS that could be applied during play-based assessments of autism<sup>4,5</sup>.

**Objectives:** Development and validation of an observational measure to allow detailed SS coding during play-based assessments of core autism symptoms.

**Measure development** The Sensory Sensitivity Instrument Measuring Behavioural Responses in Autism (SIMBA) covers four domains: (A) Sensory Preoccupations, (B) Sensory Avoidances, (C) Sensory Actions and (D) Social SS. Coded items, developed from the literature on SS<sup>6,7,8,9</sup>, aim to capture key clusters of observed behavioural responses to sensory stimuli elicited during play-based clinical/research assessments such as ADOS-2: Autism Diagnostic Observation Schedule-2<sup>10</sup> and BOSCC: Brief Observation of Social Communication Change<sup>11</sup>.

The coding within each domain item is made along three dimensions: frequency, duration and intensity. Observed frequency of behavioural response to a stimulus is the primary coding. If present this is then qualified with a coding for duration and/or intensity depending on item specifics. Domain specific and a total SS score are generated.

**Methods: Sample** Seventy-two children, all with core autism, recruited into the PACT-G trial<sup>12</sup>. Participants had mean age 5.38 years (SD=1.84), 77.7% were male. SIMBA was coded on videos of adult-child interaction during BOSCC administration. The same 10-minute video-samples were used as in the BOSCC coding. 103 SIMBA ratings across the 72 participants were used for validation, some subjects sampled at multiple timepoints. Inter-rater reliability was tested through independent double coding of an additional 20 videos. **Other measures** BOSCC, ADOS-2. **Analysis** Data were analysed using IBM SPSS Statistics, version-26. Two-Way Random Inter-class Correlation Coefficients (ICC) were used for calculating inter-rater reliability. Convergent and divergent validity was explored through correlations between the total SIMBA scores and appropriate scores from the concurrent BOSCC and ADOS assessments used in the PACT -G trial<sup>12</sup>.

**Results:** The total SIMBA score was normally distributed with a mean of 9.26 (SD=5.29; range 0-24). A Cronbach's Alpha =.68 across all items suggested acceptable internal consistency. Coding showed high inter-rater reliability (Table 1): SIMBA Total score: ICC = .96; Sensory Preoccupations: ICC=.95; Sensory Avoidances: ICC=.73; Sensory Actions: ICC=.75 and Social SS: ICC=.97 Construct and criterion validity was supported by the strong positive correlation between total SIMBA score and selected concurrent BOSCC scores and moderate positive correlation with independently sampled ADOS total and item scores reflecting SS (Table 2).

**Conclusions:** This initial development and validation study of SIMBA shows promising results. It shows high inter-rater reliability and promising construct and criterion validity against relevant items on BOSCC and ADOS. It produces a fine-grain profile of SS with greater detail than that available from those instruments alone. Further validation studies will be necessary, but these initial results demonstrate the potential utility of SIMBA as an instrument giving a detailed evaluation of SS from general adult-child interactions.

**414.028 (Poster)** Development of a Tablet-Based Measure of Concept Formation Ability for Children with ASD and Other Neurodevelopmental Disorders

**E. E. Condy<sup>1</sup>**, L. Becker<sup>2</sup>, A. J. Kaat<sup>3</sup>, N. Sullivan<sup>4</sup>, L. Soorya<sup>5</sup>, C. Michalak<sup>6</sup>, N. Berger<sup>7</sup> and A. Thurm<sup>1</sup>, (1)National Institute of Mental Health, Bethesda, MD, (2)NIH, Bethesda, MD, (3)Department of Medical Social Sciences, Northwestern University, Chicago, IL, (4)Boston Children's Hospital, Boston, MA, (5)Department of Psychiatry, Rush University Medical Center, Chicago, IL, (6)Rush University Medical Center, Chicago, IL, (7)Michigan State University, East Lansing, MI

---

**Background:** There is a lack of appropriate longitudinal cognitive assessment tools for clinical trials of neurodevelopmental disorders (NDDs). Appropriate and engaging measures across functioning, with sensitivity to incremental change in ability across repeated administrations, are limited. These limitations appear particularly problematic for children with ASD due to frequently observed cognitive delays and the common discrepancy between verbal and nonverbal skills. One potential solution is the

development of computer adaptive tests. Such tests minimize practice effects and maintain sensitivity to change while increasing compliance by capitalizing on motivation for technology-based formats and increasing efficiency by using performance on previous items to select future items, reducing the number that need to be administered.

Additionally, skills domains measured by such tests are crucial. For cognition, developmental scales, which test early foundational skills, or traditional IQ tests, which test higher-level cognition, may not be appropriate as they do not capture a wide range of functioning. Instead, “transitional skills” which bridge skills from developmental scales and traditional IQ tests, should be considered. Concept formation is a transitional cognitive skill that allows one to distinguish between exemplars that belong to particular perceptual or semantic categories through allocation of attentional processes toward attributes of interest.

**Objectives:** The present study aimed to develop a tablet-based assessment of concept formation skills in young children being assessed in NDD clinics and test its feasibility.

**Methods:** A team of subject matter experts developed a bank of items aimed at capturing varying levels of concept formation ability, from exact matching through semantic categorization. Additionally, design elements to aid in nonverbal administration were discussed and integrated into the test (Figure 1). A prepilot of items and task design on a tablet confirmed that children would engage with the task on a tablet with minimal verbal instruction. Items were then integrated into an experimental iPad application using the NIH Toolbox shell. Pilot participants with NDDs were recruited through the National Institutes of Mental Health ( $n=9$ ) and Rush University Medical Center ( $n=6$ ) and feasibility was assessed through systematic observation of engagement and response.

**Results:** Children between the ages of 2-16 years old ( $N=15$ ) completed a cognitive assessment including the pilot test (IQ  $M=55.91$ ,  $SD=20.32$ ,  $n=11$ ). Pilot data shows that the majority of children were able to pass the teaching items. Administration issues identified for further development in children who passed the teaching items included: issues with the response modality (i.e., difficulty dragging target to response stimulus) (3/12), noncompliance (2/12), and understanding task demands (5/12) even after completing the practice.

**Conclusions:** A high percentage of children passed the teaching items on a pilot version of a nonverbal, tablet-based assessment of concept formation, indicating initial feasibility in children with NDDs. Issues with administration appeared largely related to motor demands of the response modality or task understanding. Future iterations of the task will allow for flexibility around response options (e.g., examiner assistance), and increase the number of teaching items before proceeding to live items to increase feasibility of this iPad-based measure of concept formation in children with NDDs.

**414.029 (Poster)** Developmental Trajectories in Autism Based on Symptoms Measured By the Vineland Adaptive Behavior Scale Second Edition Using Observational Data from North America and Europe  
*C. Liu<sup>1</sup>, M. Silkey<sup>1</sup>, H. Furby<sup>2</sup>, Y. Zhu<sup>1</sup>, T. Charman<sup>3</sup> and M. Johnson<sup>2</sup>, (1)Personalised Health Care, F. Hoffmann-La Roche Ltd, Basel, Switzerland, (2)Personalised Health Care, F. Hoffmann-La Roche Ltd, Welwyn Garden City, United Kingdom, (3)Department of Psychology, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom*

---

**Background:**

Symptoms and developmental profile heterogeneity among individuals with autism spectrum disorder (ASD) makes interpreting endpoint variation in response to a clinical intervention challenging. Developmental trajectories models are valuable to understand condition progression and to support clinical interpretation.

**Objectives:**

To understand natural subgroups of developmental trajectories for individuals with ASD based on symptoms measured by the Vineland™-II two-domain composite score of communication and socialization (Vineland™-II 2DC) in North America and Europe.

**Methods:**

This non-interventional longitudinal study pooled data from three sources (Autism Treatment Network [ATN], EU-AIMS Longitudinal European Autism Project [LEAP], and InFoR [Inserm, la Fondation FondaMental et Roche]) across different ages and regions. Up to four repeated measurements of Vineland™-II 2DC were available from ATN, typically within 3 years' post-

baseline assessment; one was available from EU-AIMS LEAP, 12–24 months after baseline; up to three were available from InFoR, 3, 12, and 24 months after baseline. Among 876 individuals (ATN [North America] N=526; EU-AIMS LEAP [Netherlands and UK] N=253; InFoR [France] N=97) with repeated measurements of Vineland™-II 2DC, growth mixture models were fitted to identify classes of adaptive behavior. Relationships between class and baseline characteristics were explored using multinomial logistic regression applied to baseline predictors in a complete-case analysis.

#### Results:

Two developmental trajectories were identified as measured by Vineland™-II 2DC: most individuals (836 [95.4%]) had a stable profile, and 40 (4.6%) had a steeply declining trajectory (**Figure 1**). Vineland™-II 2DC is age-adjusted, therefore these classes correspond to individuals who maintain their ability to adapt (stable profile) and those who progress but fall behind their typically developing peers (declining trajectory). Complete data to explore predictors of trajectory class were available for 705 individuals. Individuals were aged 1–55 years (median 9.8, interquartile range 5.3–14.5 years, based on age at first Vineland™-II assessment), primarily male (79.7%), and most had IQ  $\geq 70$  (72.8%). Significant predictors of trajectory class varied according to region, with IQ identified as a predictor in North America (odds ratio [OR] 1.03, 95% confidence interval [CI] 1.002–1.05,  $p=0.033$ ), indicating that individuals with lower IQ were more likely to be in the declining trajectory. Age and baseline Vineland™-II 2DC were identified as predictors in Europe (age: OR 1.17, 95% CI 1.06–1.29,  $p=0.003$ ; baseline Vineland™-II 2DC: OR 0.90, 95% CI 0.85–0.95,  $p<0.001$ ), indicating that younger children with lower baseline Vineland™-II 2DC scores were more likely to be in the declining trajectory class (**Figure 2**).

#### Conclusions:

Our study identifies developmental trajectories of ASD using a latent variable approach based on observational data from North America and Europe, thus providing insight into the progression of communication and socialization skills over time for individuals with ASD. To date, no published study has used such a range of locations and ages. Future research could assess additional Vineland™-II measurements and alternative measures of ASD symptoms. Application of these methods on cohorts in national and international registries will provide insights into the nature of the identified trajectories and may provide better understanding of subgroups that could gain most benefit from additional care/therapy.

#### 414.032 (Poster) Do the SF-36 and the Whoqol-Bref Measure Similar Aspects of Quality of Life in Autistic Adults?

N. C. Russell<sup>1</sup>, D. B. Kay<sup>1</sup>, Z. Simmons<sup>2</sup>, D. Cimmino<sup>1</sup> and M. South<sup>3</sup>, (1)Psychology, Brigham Young University, Provo, UT, (2)Brigham Young University, Provo, UT, (3)Psychology & Neuroscience, Brigham Young University, Provo, UT

Background: Quality of life (QoL) is an important construct within the autistic population, particularly for understanding health-related impact. To measure QoL in autism, the Medical Outcomes Study 36-item short form survey (SF-36) and the World Health Organization Quality of Life BREF survey (WHOQOL-BREF) are frequently utilized, almost interchangeably; however, research has suggested that they measure QoL differently across populations and little is known about their similarity in autistic adults.

Objectives: We examined the relationship between the reports of autistic adults using the SF-36 and the WHOQOL-BREF to better understand how similarly they measure QoL. Pearson correlations were employed as a measure of effect size.

Methods: Data were collected from healthy controls ( $n = 21$ ), individuals with insomnia ( $n = 23$ ), and individuals with autism ( $n = 22$ ). Both measures were completed by the participants at the same sitting as part of a larger battery of measures. We compared the physical functioning, emotional well-being, and social functioning domains of the SF-36 with the physical health, psychological, and social relationships domains of the WHOQOL-BREF - being the domains that descriptively appear most closely related across measures.

Results: For the physical domains of the SF-36 and the WHOQOL-BREF, significant correlations were found for the autism ( $r = 0.60$ ), insomnia ( $r = 0.56$ ), and neurotypical ( $r = 0.48$ ) groups. For the emotional well-being/psychological domains, significant correlations were again found for the autism ( $r = 0.88$ ), insomnia ( $r = 0.86$ ), and neurotypical ( $r = 0.71$ ) groups. However, for the social domains, no significant correlations were found within any group. Rather, in the autism group, the social domain of the SF-36 was significantly correlated with the physical domain of both measures ( $r = 0.50$  for the SF-36 and  $r = 0.69$  for the WHOQOL-BREF), while the social domain of the WHOQOL-BREF was significantly correlated with the psychological domains of both measures ( $r = 0.80$  for both the SF-36 and the WHOQOL-BREF).

Conclusions: The SF-36 and WHOQOL-BREF demonstrated moderate to strong correlations for the physical and emotional/psychological domains (as well as other domains) in each population, with stronger correlations being found for the psychological domains. However, this was not found for the social domains, likely due to the differing content focus of each measure – with the SF-36 focusing on interference with social functioning and the WHOQOL-BREF focusing on satisfaction with relationships. While either measure may be appropriate for assessing physical and psychological factors of quality of life in an autistic adult population, further consideration is needed when considering social factors of quality of life.

**414.033** (Poster) Does Knowledge of Child Development Predict ASD Knowledge, Stigma, Recognition, and Treatment-Seeking?

*M. M. Abdul-Chani<sup>1</sup>, F. J. Biasini<sup>2</sup> and S. E. O'Kelley<sup>3</sup>, (1)Psychology, The University of Alabama at Birmingham, Birmingham, AL, (2)Psychology, University of Alabama at Birmingham, Birmingham, AL, (3)The University of Alabama at Birmingham, Birmingham, AL*

---

Background: General knowledge on child development could aid in recognition of atypical development. Research suggests that delays in autism identification could be due to low knowledge about child development and developmental milestones. Little research has focused on understanding the influence of general child development knowledge on autism-specific knowledge and stigma.

Objectives: To examine the influence of general child development knowledge on autism-specific knowledge and stigma, as well as the endorsement of needing and seeking treatment.

Methods: A total of 190 participants completed an online survey as part of a larger study, including a demographics questionnaire, random assignment to one of two vignette conditions depicting symptoms of ASD without mentioning the diagnosis, a mixed-method intervention-seeking measure regarding the vignettes, the Caregiver Knowledge on Child Development Inventory (CKCDI) measuring general child development knowledge, and the Autism Stigma and Knowledge Questionnaire (ASK-Q) measuring ASD-specific knowledge and stigma. Responses from the intervention-seeking measure were Yes/No to assess whether the vignette warranted professional treatment and whether one would take action to seek treatment.

Results: A series of linear and binomial logistic regressions examined the relation between CKCDI total score and ASK-Q knowledge and stigma scores, as well as dichotomized endorsement of the vignettes warranting and taking action to seek professional treatment. CKCDI score did not significantly predict ASD knowledge,  $F(1, 189) = 1.89, p > .05$ , or ASD stigma,  $F(1, 189) = 3.34, p < .10$ . ASD knowledge was independently examined as a potential moderator for the relation between CKCDI score and ASD stigma, but was not significant ( $p > .05$ ). However, CKCDI significantly predicted identification of need for evaluation,  $\chi^2(1) = 4.45, p < .05$ . The model explained 3.3% (Nagelkerke  $R^2$ ) of the variance in identification of the need for treatment and correctly classified 71.2% of cases. Those who responded “Yes” to the vignette warranting professional treatment had 1.049 times higher odds of having a higher CKCDI score than those who responded “No.” CKCDI score did not significantly predict taking action to seek treatment,  $\chi^2(1) = 1.72, p > .05$ .

Conclusions: General child development knowledge did not significantly predict ASD-specific knowledge, was trending towards significance with ASD stigma, and those who responded “Yes” to the vignette warranting professional treatment were more likely to have a higher CKCDI score than those who responded “No.” These results suggest that general child development knowledge does not significantly predict ASD knowledge, but may influence ASD stigma, increase one’s ability to recognize atypical behavior, and allow one to acknowledge when professional treatment could be warranted. However, the results also suggest that low knowledge of developmental milestones may not impact ASD-specific knowledge as it appears that ASD knowledge is a concept that stands apart from general child development knowledge. Moreover, while CKCDI score significantly predicted recognition of needing professional treatment, it did not predict one’s intent to seek treatment suggesting that a variety of factors may influence one’s decision to seek treatment. Future research should explore which facets of ASD knowledge predict treatment-seeking and which are deficit areas for parents.

**414.034** (Poster) Early Detection for Better Outcomes: Building Capacity to Identify and Support Children with Early Signs of Autism in Early Childhood Education and Care Settings

*B. Mozolic-Staunton, Health and Human Sciences, Southern Cross University, Gold Coast, QLD, Australia*

---

Background:

Access to early intervention is dependent on timely and accurate identification of children showing early signs of developmental challenges, yet 22 % of Australian children have developmental delays that are undetected prior to school. Many children miss out on access to the National Disability Insurance Scheme (NDIS) due to high rates of under-identification of autism.

## Objectives:

This research programme aimed to build capacity within the early childhood education sector to monitor the development of young children in their care using evidenced- based processes to improve rates of detection of developmental delay in young children and facilitate access to early intervention.

## Methods:

Outcomes of developmental surveillance using The Social Attention Communication Surveillance- Revised (SACS-R) and the Parents Evaluation of Developmental Status (PEDS) in community health and early education settings were investigated and 14,113 children were monitored across health and early childhood education settings to establish effectiveness in the early identification of children with developmental challenges. Perspectives of stakeholders about early detection and accessibility of intervention through the NDIS are reported.

## Results:

Agreement between PEDS and SACS-R in identification of early signs of autism across both settings is only 54.84%;  $k = 0.161$ , 95 % CI (0.81 to 0.241,  $p < .0005$ ). Sensitivity of SACS-R (82%) was substantially higher than the ASD pathway on PEDS (6.7%) while interrater reliability between maternal child health nurses and early childhood education professionals was very high ( $k = 0.909$ ).

## Conclusions:

Strategic collaboration and implementation of evidence-based tools across health and education sectors can improve outcomes for children and promote access to funded early intervention supports.

**414.035** (Poster) Early Detection of ASD By Community-Based Screening Focusing on Sensory Processing Patterns  
**M. Adachi**<sup>1,2</sup>, **M. Takahashi**<sup>1,2</sup>, **T. Hirota**<sup>3</sup>, **M. Mikami**<sup>4</sup>, **H. Shinkawa**<sup>5</sup>, **H. Mori**<sup>5</sup>, **T. Mikami**<sup>5</sup>, **M. Saito**<sup>6</sup>, **T. Hagiwara**<sup>7</sup> and **K. Nakamura**<sup>5,6</sup>, (1)Department of Clinical Psychological Science, Hirosaki University, Hirosaki, Japan, (2)Research Center for Child Mental Development, Graduate School of Medicine, Hirosaki University, Hirosaki, Japan, (3)University of California, San Francisco (UCSF), San Francisco, CA, (4)Graduate School of Health Sciences, Hirosaki University, Hirosaki, Japan, (5)Research Center for Child Mental Development, Graduate School of Medicine, Hirosaki University, Hirosaki, Japan, (6)Department of Neuropsychiatry, Graduate School of Medicine, Hirosaki University, Hirosaki, Japan, (7)Hokkaido University of Education, Asahikawa, Asahikawa, Hokkaido, JAPAN

---

**Background:** It has become widely known that Autism Spectrum Disorder (ASD) has sensory problems. However, there are few studies on "patterns" of sensory processing. Identification of sensory processing patterns specific to ASD may contribute to early detection.

**Objectives:** The objective of this study was to identify specific classes of sensory processing patterns for the early detection of ASD.

**Methods:** This study targeted the total population sample of 3-year-old children in Hirosaki city, Japan (N = 1375). Caregivers of 3-year-old children completed questionnaires, including Sensory Profile short-version (SSP) and Social Responsiveness Scale Second Edition (SRS-2). We performed latent class analysis (LCA) to identify patterns of responses to the 7 domains of the SP-short (Tactile Sensitivity, Taste/Smell Sensitivity, Movement Sensitivity, Under-responsive/Seeks Sensation, Auditory Filtering, Low Energy/Weak, Visual/Auditory Sensitivity). After identifying classes, t-test was performed to compare SRS scores between classes. Logistic regression analysis was conducted with the latent classes as the predictive variables and the SRS-2 cut-off scores as the objective variables.

**Results:** In LCA with the 7 section of SSP, a two-class solution was found to be the best solution. The class 1 was a group showing the average SSP score, accounting for 82.8% of the community. While, the class 2 was a group having atypical characteristics of sensory processing in which the scores of all SSP subscales were higher than those of class 1 ( $p < .001$ ,  $\eta^2 = .12-.51$ ). Comparing the SRS-2 scores between the groups, the score of class 2 was significantly higher ( $t = -24.7$   $df = 1374$   $p < .001$   $d = 1.58$ ). Logistic regression analysis with class 1 as the reference group revealed that the class 2 significantly predicted the cut-off classification of SRS-2 (Odds ratio = 18.5, 95%CI = 12.6 – 27.1  $p < .001$ ).

Conclusions: In the community-based screening, we conclude that certain patterns of sensory processing could support the diagnosis of ASD. We plan to track these children up to 5 years old, who will undergo in-person assessment for ASD. This will allow us to examine how adding sensory profile items to other questionnaire improve predictive validity of ASD diagnosis.

**414.036 (Poster)** Evaluating Feasibility and Acceptability of a Telehealth Model for Autism Spectrum Disorder Diagnostic Evaluations from Toddlerhood to Adulthood

*N. L. Matthews, E. Skepnek, A. Malligo, J. James, M. Mammen, S. Kiefer, A. Lyon, M. Mitchell and C. J. Smith, Southwest Autism Research & Resource Center, Phoenix, AZ*

---

Background: Considerable delays between parents' first concerns related to ASD and formal diagnosis are well-documented. Public health initiatives designed to slow the spread of COVID-19 have presented even more obstacles for families seeking a diagnosis and warrant the development and testing of alternative diagnostic models (Narzisi, 2020).

Objectives: 1) To describe a telehealth diagnostic model implemented at an autism center to safely provide ASD diagnostic evaluations during the pandemic. 2) To document patient and psychologist acceptability of the telehealth model.

Methods:

Study procedures were approved by the Western Institutional Review Board. Participants included diagnostic patients seen through the clinic's telehealth diagnostic model ( $n = 99$ ; 26 females;  $M$  age = 9.10 years,  $SD = 7.65$ ; range = 1.25-38.42) from March through September of 2020. Parents of minor patients were invited to complete an online client satisfaction questionnaire ( $n = 48$ ). Telehealth acceptability questionnaires were completed for each patient by one of five licensed clinical psychologists.

Evaluations involved parent/caregiver interviews (90-minute phone interview adapted from ADI-R; 60-minute videoconference developmental history, and 45-60 minute phone or videoconference interview about adaptive functioning) and direct observation of the diagnostic patient, facilitated by telehealth technology. Parents of patients 7 years and younger used the Naturalistic Observation Diagnostic Assessment (NODA; Smith et al., 2017), a store-and-forward telehealth platform, to collect in-home videos prior to the telehealth appointment ( $n = 52$ ; NODA was used with some older children initially and upon parent request). When video evidence from NODA was inconclusive, the psychologist conducted a 45-minute structured behavioral observation through videoconferencing (developed by our clinic's team in response to the pandemic) on the day of the telehealth appointment. The structured behavioral observation was also used with all patients 8 years and older.

A feedback session was conducted through videoconferencing on the day of the telehealth appointment. If telehealth procedures were insufficient to make a diagnostic determination, the patient was scheduled for an in-person assessment.

Results:

A diagnostic determination was made for 92% of participants using only telehealth procedures. Seven participants (2 females; ages 3 to 11 years) required an in-person evaluation. Results from client satisfaction and psychologist acceptability questionnaires are reported in Tables 1 and 2. Patient age was not associated with parent-rated acceptability; however, there was a marginal negative association between patient age and psychologist reported effectiveness of NODA ( $\rho = -.21, p = .09$ ) and a significant positive association between patient age and psychologist-reported patient attentiveness during the behavioral observation ( $\rho = .47, p = .007$ ). Parents of females reported higher acceptability of telehealth procedures than parents of males (Table 1). Psychologist ratings did not differ significantly by patient gender (Table 2).

Conclusions:

Findings indicate that telehealth diagnostic procedures were acceptable for most diagnostic patients and highlight the potential of telehealth to increase families' access to diagnostic professionals. Interpretations of differences in parent acceptability by patient gender and associations with age will be discussed.

**414.037 (Poster)** Evaluating Reporter Agreement and Implications for Clinical Diagnosis of Autism Spectrum Disorder and Intellectual Disability

*M. Stevens<sup>1</sup>, K. Selders<sup>2</sup>, O. Jeckel<sup>1</sup>, V. Brownfield<sup>1</sup> and K. Nowell<sup>1</sup>, (1)University of Missouri, Columbia, MO, (2)Thompson Center for Autism and Neurodevelopmental Disorders, Columbia, MO, (3)Thompson Center for Autism & Neurodevelopmental Disorders, Columbia, MO*

---

**Background:** To receive a clinical diagnosis of intellectual disability (ID) and autism spectrum disorder (ASD), deficits in cognitive functioning and adaptive behavior must be present (*American Psychological Association*, 2013). Comprehensive clinical evaluation includes the use of multiple informants (Mash & Hunsley, 2005), but discrepancies occur between adaptive skill measures of youth with ASD, and youth with ID and ASD (Dickson, 2018; McDonald et al., 2016). Various factors may influence how informants respond to clinical rating scales including informant education level (Hattier et al., 2013) and youth cognitive ability (Dickson, 2018). More research is needed to evaluate discrepancies on adaptive measures and identify variables that predict discrepancies.

**Objectives:** We aimed to investigate discrepancies between parent and teacher ratings on a measure of adaptive behavior (*Adaptive Behavior Assessment System, Third Edition* [ABAS-3]) in a well-characterized clinical sample of 107 youth (*M* age 9y.,9m; 3y., 3m. to 17y, 7m) with ID (*n*=5), ASD (*n*=83), or co-occurring ID and ASD (*n*=15). We will investigate potential factors predicting discrepancies.

**Methods:** Data from youth who participated in evaluations at a specialist center for autism and neurodevelopmental disorders were extracted from an on-site database. Individuals were included if they received a diagnosis of ASD, ID, or ID and ASD and had scores from both a parent and teacher ABAS-3. Variables of interest included socio-demographic measures (e.g., caregiver SES), final diagnosis, IQ, and ABAS-3 standard cores (i.e., General Adaptive Composite [GAC], Conceptual, Social, Practical). Discrepancies between parent and teacher rating scores were identified using paired-sample *t*-tests (with Bonferroni correction) for the whole sample, and for the ID, ID and ASD, and ASD only subsamples. A Dirichlet component regression (Gueorguieva et al., 2008) will be used to evaluate predictors of identified discrepancies on ABAS-3 ratings.

**Results:** For the whole sample, parent and teacher ratings were moderately correlated for the GAC ( $r=.59, p<.001$ ), Social ( $r=.43, p<.001$ ), Conceptual ( $r=.60, p<.001$ ), and Practical scores ( $r=.59, p<.001$ ). Parent and teacher GAC scores were significantly different. Teacher ratings were higher on all domains (i.e., GAC:  $t[105]=-8.79, p<.001$ ; Conceptual:  $t[105]=-5.89, p<.001$ ; Social:  $t[105]=-8.46, p<.001$ ; Practical:  $t[105]=-9.87, p<.001$ ). This pattern held true for the ASD only subsample but not for the ID only, or the ID and ASD subsamples. The only significant difference in the ID and ASD subsample was on the Social domain with higher scores on teacher completed measures ( $t[14]=-3.05, p<.01$ ). No significant differences between ratings were found in the ID only group.

**Conclusions:** Teacher ratings on the ABAS-3 in this sample tended to be higher than parent ratings, but this pattern differed depending on final diagnosis. These findings are consistent with previous research evaluating informant discrepancies on the ABAS-3 for youth with ASD (Jordan et al., 2019), but the current study also included youth with ID, participants represented a larger age range, and a clinical sample was used. Additional analyses will investigate predicting variables. Limitations will be noted. Implications for practice in clinical and school settings will be discussed.

**414.038 (Poster)** Evaluating the Measurement Invariance of the CBCL between Minimally Verbal and Verbal Children with Autism Spectrum Disorder.

*M. Fok<sup>1</sup>, E. A. DeLucia<sup>1</sup>, T. M. Andrzejewski<sup>1</sup>, A. Scarpa<sup>2</sup> and C. G. McDonnell<sup>1</sup>, (1)Department of Psychology, Virginia Polytechnic Institute and State University, Blacksburg, VA, (2)Virginia Polytechnic Institute and State University, Blacksburg, VA*

---

Background:

Autism spectrum disorder (ASD) comprises a diverse range of language and cognitive abilities. Individuals with ASD experience high rates of co-occurring emotional and behavioral symptoms (EBS), although little research has considered EBS among autistic children of varying language abilities. An estimated 30% of individuals with ASD have minimally verbal language abilities (Howlin et al., 2014, Pickles et al., 2014). The relationship between language and EBS may depend on the type of measure of EBS (Fok & Bal, 2019). The Child Behavior Checklist (CBCL) is widely used in the assessment of EBS in children with ASD but may not appropriately estimate EBS in less verbal children because some items rely on verbal expression (Achenbach & Rescorla, 1991). While Dovgan et al., (2019) have demonstrated poor invariance of the CBCL in ASD with and without intellectual disability, previous work that compares CBCL scores across language groups should be interpreted with caution since there have been no studies that have specifically tested the invariance across language levels.

Objectives:

To determine the measurement invariance of the CBCL broadband internalizing and externalizing scales across minimally verbal (MV) and verbal (V) groups.

Methods:

Participants included 2,089 6-18 year old children ( $M_{age}=10.3$  years; 87% male) from the Simons Simplex Collection (Fischbach & Lord, 2010). Children were classified as MV if they received ADOS module 1 ( $n=311$ ), and V if they received ADOS modules 2-4 ( $n=1778$ ). The CBCL factor structure consists of two broadband (internalizing, externalizing) and five syndrome factors (Figure 1). We conducted a multi-group confirmatory factor analysis to examine the factorial invariance of the broadband factor structure across language groups using T-scores. We examined the configural, metric (constrained loadings), and scalar (constrained intercepts) invariance levels of model fit sequentially using statistics of chi-square, comparative fit index, and root mean squared error of approximation. Invariance models that change more than 0.015 with each sequential test indicate non-invariance (Chen, 2007).

Results:

At the configural and metric invariance levels, the CBCL broadband level demonstrates good overall model fit and equivalent factor loadings between the language groups (Table 1A). However, when we constrained the intercepts at the scalar level of invariance, there was a significant decrement in model fit indicating non-invariance (Table 1A). Further examination of the modification indices demonstrated significant differences due to the intercepts of the anxious/depressed ( $MV<V$ ) and withdrawn/depressed ( $MV>V$ ) scales (Table 1B).

Conclusions:

The 2-factor structure of CBCL internalizing and externalizing symptoms achieved configural and metric invariance, providing support for the continued use of the CBCL *within* varying language levels of ASD. However, the CBCL internalizing and externalizing breakdown was non-invariant at the scalar level, as the MV group demonstrates a lower intercept for the Anxious/Depressed syndrome scale but higher on the Withdrawn/Depressed syndrome scale. Due to intercept non-invariance, examiners cannot validly compare CBCL internalizing and externalizing T-scores *across* language groups. Future development of measures that are invariant across language groups is a critical research priority that will advance understanding of transdiagnostic mechanisms of EBS across different ability levels.

**414.039** (Poster) Evidence Map of Spanish-Language Measures of Autism Symptoms: A Review of Translation Methods and Psychometric Properties

*M. DuBay<sup>a</sup>, H. Lee<sup>b</sup> and K. Boettcher<sup>c</sup>, (1)University of North Carolina, Chapel Hill, NC, (2)Chan Division of Occupational Science and Occupational Therapy, University of Southern California, Los Angeles, CA, (3)University of Virginia, Charlottesville, VA*

---

Background:

Spanish is the primary language of 20 countries, the second most common native language spoken in the world, and the fourth most common language spoken overall (Eberhard et al., 2020). In the last several decades, many clinical and research instruments measuring behavioral features of autism have been translated into Spanish. Traditionally, a forward-back translation approach has been used with parent-report and self-report instruments, with the assumption that psychometric properties of the tools (e.g. diagnostic validity, reliability, etc.) is naturally maintained from the original version (Soto et al., 2015). However, recent studies suggest that this approach may not be sufficient to maintain various dimensions of equivalence between language versions of an instrument, including psychometric properties (DuBay et al., 2019). Further, transparency in the translation and re-norming process is imperative to document relevant information that will help inform clinical and research teams who wish to use such instruments (Maneesriwongul et al., 2004; Swaine-Verdier et al., 2004).

Objectives:

The objective of this poster is to catalogue the parent- and self-report autism measures that are available for clinical or research use in the Spanish language (all dialects). We will describe translation methods and psychometric properties observed among Spanish speaking populations for each tool.

Methods:

A literature search was conducted via seven databases, using terms such as "autism," "translation," "assessment," "validation," and "Spanish." A list of instruments with Spanish translations was compiled via these searches, similar Google Scholar searches, and publishing company websites. Additional sources of data will include grey literature, instrument manuals, publishing companies, and original instrument developers in order to catalogue translation methodology and psychometric data for each identified instrument.

#### Results:

Instruments with Spanish translations include the Modified Checklist for Autism in Toddlers- Revised, Autism Spectrum Rating Scales, the Social Responsiveness Scale, Social Communication Questionnaire, Gilliam Autism Rating Scale, Parents' Evaluation of Developmental Status, and the Childhood Autism Rating Scale, among others. Descriptions of translations methods and observed psychometric properties will be presented for each tool and translation.

Preliminary results indicate that translations made prior to around 2010 typically follow the traditional forward-back methodology. Instrument developers often fail to re-assess psychometric properties in a Spanish-speaking sample for these translations. When psychometric properties are re-assessed, discrepancies are noted in many cases. Translations made after around 2010 frequently include more rigorous quality checking or cultural adaptation approaches, such as multiple translators, expert review panels, and qualitative pre-testing. Additionally, re-assessment of psychometric properties is more common among these translations, with translations meeting higher levels of standards. Also, most identified translations use the Spain dialect of Spanish, with several translations designed specifically for Latin American dialects, such as US Spanish, Mexican Spanish, Chilean Spanish, and Argentine Spanish. Translations and norming studies are extremely limited, if not absent, in other Latin American dialects.

#### Conclusions:

Findings from this review will provide much needed overview of the state of translated instruments in Spanish language up to date. This knowledge will enable researchers and clinicians searching for effective and reliable tools to utilize in their work with Spanish-speaking populations.

#### **414.040** (Poster) Examining Sex and Ethnic Parity in the Psychometric Properties of the Screening Tool for Autism in Toddlers (STAT)

**S. M. Attar<sup>1</sup>, L. V. Ibanez<sup>2</sup> and W. L. Stone<sup>3</sup>, (1)University of Washington, Seattle, WA, (2)UW READi Lab, Seattle, WA, (3)Psychology, University of Washington, Seattle, WA**

---

**Background:** Sex and ethnic disparities exist in the ages and rates at which children receive an Autism Spectrum Disorder (ASD) diagnosis (Wallis et al., 2020). A contributing factor may be that DSM diagnostic criteria are based primarily on characteristics present in white males (Halfon & Kuo, 2013). Early ASD screening is critical for improving long-term child and family outcomes by leading to early diagnosis and ASD-specific intervention (Zwaigenbaum et al., 2015), yet it is unknown whether screening tools may also be contributing to sex and ethnic disparities in detection, and specifically whether they are biased toward detecting white males. The purpose of this study was to examine whether the Screening Tool for Autism in Toddlers (STAT; Stone 2000, 2004), a 20-minute play-based stage-2 ASD screening measure, shows sex and ethnic parity in its screening properties. The STAT is used in a variety of contexts, including early intervention programs, primary care settings, and specialized ASD clinics, with a diverse population across urban and rural settings. It is therefore important to assess whether the STAT is equally effective across sex and ethnic groups.

**Objectives:** This study used an expanded version (STAT-E) that was developed for a formative research project for the National Children's Study (NCS). This version can be scored using the original scoring system as well as a system that incorporates examiner subjective ratings of children's social engagement (SE), atypical behavior (AB), and language level (LL). We examined: (1) whether the STAT-E, with its original scoring, showed sex and ethnic disparities when used in the diverse NCS sample, and (2) whether the examiner ratings of SE, AB, and LL increased the sex and/or ethnic parity of the STAT-E in this sample.

**Methods:** Logistic regression, ROC curves, and classification matrices were used on a sample of 236 two-year-old children to determine the psychometric properties of the STAT-E scored traditionally and with the new ratings for each of the four groups (male, female, Non-Hispanic, Hispanic). Screening results were compared to gold-standard clinical diagnoses using the ADOS-2. Chi-square tests were used to determine whether the true positive rates between groups were statistically different.

**Results:** The original STAT scoring system resulted in appreciably better psychometrics for males than females, i.e., correctly identifying 12% more males than females (Table 1). When including the new STAT-E ratings of SE, AB, and LL, the overall sensitivity of the STAT-E increased for all groups and the sex and ethnic parity increased for all psychometric statistics Table 2). However, there was no statistical evidence that the true positive rates for the STAT-E, scored traditionally, showed disparities for sex ( $X^2 = 1.3554$ ,  $df = 1$ ,  $p = 0.2443$ ,  $\phi = 0.09$ ) or ethnicity ( $X^2 = 0$ ,  $df = 1$ ,  $p\text{-value} = 1$ ,  $\phi = 0$ ).

**Conclusions:** Including subjective examiner ratings of SE, AB, and LL improved the sex and ethnic parity of the STAT-E, which is important for a stage-2 screener. Further studies are needed before these ratings can be included in formal scoring algorithms.

**414.041 (Poster)** Exploration of Anxiety Symptoms in Three-Year-Olds with and without ASD Reveals Distinctive Symptom Structure

*D. M. Goncalves Fortes, C. Banarjee, H. Feiner, M. Butler, E. Diamond, R. Foster, A. Boxberger, E. Brennan-Wydra, S. Macari and K. Chawarska, Child Study Center, Yale University School of Medicine, New Haven, CT*

---

**Background:** Anxiety disorders are the most prevalent form of psychopathology in youth (Vasey et al. 2014; Lepine 2002), including youth with ASD (van Steensel et al. 2011). Anxiety typically emerges at school age (Vasey et al. 2014) but symptoms may appear earlier (Vasa et al., 2020). It is not known whether anxiety presents similarly in children with and without ASD (Kreiser & White 2014). Instruments measuring anxiety in young children have been constructed using typically-developing samples; validity in children with ASD is not fully established (Grondhuis & Aman 2012). We describe exploratory analyses of two parent-report anxiety measures in a sample of three-year-olds with ASD and a clinically heterogeneous, age-matched comparison group.

**Objectives:** (1) Assess three-year-olds with and without ASD on subscales of the Early Childhood Inventory-5 (ECI-5; Gadow & Sprafkin 2017) and Preschool Anxiety Scale-Revised (PAS-R; Edwards et. al. 2010). (2) Explore the structure of anxiety symptoms in three-year-old toddlers and assess potential ASD-specific differences.

**Methods:** The parents of age-matched three-year-olds ( $N=138$ ,  $M_{Age}=39.04\text{mo}$ ,  $SD=3.01$ ) with ASD ( $N=60$ ,  $M_{Age}=39.30\text{mo}$ ,  $SD=3.30$ ) and without ASD ( $N=78$ ,  $M_{Age}=38.83\text{mo}$ ,  $SD=2.78$ ) completed the ECI-5 and the PAS-R, anxiety measures normed on 3-to-5-year-olds. The non-ASD group encompassed siblings of children with ASD, as well as typically-developing and developmentally-delayed toddlers. We assessed internal reliability with Cronbach's alpha ( $\alpha$ ) and evaluated group differences in scores using Wilcoxon tests. Exploratory factor analysis (EFA) was performed on all items from both instruments, using principal axis factoring with Varimax rotation. We assessed group differences in factor scores using Wilcoxon tests.

**Results:** Both ECI-5 ( $\alpha$ : Generalized Anxiety(GAD)= 0.74, Social Anxiety(SA)= 0.58, Separation Anxiety(SEP)=0.63) and PAS-R ( $\alpha$ : GAD=0.75, SA=0.76, SEP=0.68, Specific Phobia (SP)=0.76) subscales showed only low to moderate internal reliability. Group differences were found for ECI-5 GAD (ASD>Non-ASD,  $p<0.0001$ ), SA (ASD>Non-ASD,  $p= 0.0020$ ), and SP (ASD>Non-ASD,  $p=0.0052$ ) subscales but none of the PAS-R subscales. The combined item-set was suitable for factor analysis (KMO=0.72, Bartlett's test: $p <0.001$ ). Six factors (eigenvalues>1) were retained from EFA (39.5% variance, RMSEA=0.065, RMSR=0.06, BIC=-3290) and did not entirely align with either instrument's published structure. Group differences in factor scores were found for three factors ([F2: ASD>Non-ASD, $p<0.0001$ ], [F4: Non-ASD>ASD,  $p=0.0069$ ], [F6, Non-ASD>ASD,  $p=0.0052$ ]), with a fourth approaching significance (F1, ASD>Non-ASD,  $p=0.055$ ) (see Table 1 and Figure 1).

**Conclusions:** Three-year-olds with and without ASD differed in the GAD, SA, and SP subscales of the ECI-5 but low-to-moderate internal reliability warranted investigation. Besides showing that the structure of anxiety symptoms in clinically-heterogeneous three-year-olds may not conform to that of published measures, EFA suggested that multiple sub-constructs exist for GAD. Items loading onto F2 (ASD > Non-ASD) concern activity level, inattentiveness, and irritability; in contrast, F4 (Non-ASD > ASD) items describe worry and complaints about health. The finding of group differences in sub-constructs of GAD suggests that ASD-specific anxiety symptom patterns in very young children may be obscured by published subscales. Further examination of anxiety symptom structure in children with and without ASD within narrow developmental epochs will inform development of valid measures of anxiety for very young children with ASD.

**414.042 (Poster)** Exploring Caregiver Differences in Naturalistic Developmental Behavioral Intervention (NDBI) Strategies  
*N. Cristallo<sup>1</sup>, D. Swain<sup>2</sup>, K. Tang<sup>3</sup>, A. M. Estes<sup>4</sup>, S. J. Rogers<sup>5</sup>, C. Lord<sup>6</sup> and S. H. Kim<sup>1</sup>, (1)Psychiatry, Center for Autism and the Developing Brain, White Plains, NY, (2)Virginia Polytechnic Institute and State University, Blacksburg, VA, (3)University of Notre Dame, South Bend, IN, (4)Speech and Hearing Sciences, University of Washington, Seattle, WA, (5)Department of Psychiatry and Behavioral Sciences, The Medical Investigation of Neurodevelopmental Disorders (MIND) Institute, UC Davis School of Medicine, University of California Davis, Sacramento, CA, (6)University of California, Los Angeles, Los Angeles, CA*

---

Background: Caregivers strategy use plays a critical role in caregiver-mediated intervention for children with ASD. Most caregiver-mediated interventions target increasing engagement level between children with ASD and caregivers by supporting caregivers in the use of NDBI strategies (Beaudoin, Sébire, & Couture, 2019). Yet, little research has examined individual differences among caregivers in their use of NDBI strategies. Even fewer studies have examined the effect of caregiver gender on variability in NDBI strategy use or fathers' involvement in early intervention (Saunders et al., 2001).

Objectives:

1. Compare mothers' and fathers' use of NDBI strategies with their child during free play.
2. Explore individual differences across NDBI strategy use.
3. Examine relationship between caregiver NDBI strategies and dyadic engagement.

Methods: Participants included 35 triads of toddlers ( $M_{\text{age}} = 20.54$  months) and their mothers and fathers. Mothers and fathers differed significantly in age ( $p < 0.05$ ) but not education level. Families were enrolled in a randomized control trial of Early Start Denver Model (ESDM; Rogers et al., 2019) vs a standard of care control group. Caregiver-child interaction videos were included if mother-child and father-child timepoints were within one month of one another (82.8% within 1 week of each other). To minimize variability due to treatment effects, ESDM groups only included caregivers with timepoints within a month of each other *at baseline*; these criteria were not used for families assigned to the control condition. A Measure of NDBI Strategy Implementation-Caregiver Change (MONSCI-CC; Vibert et al., 2019) was used to assess 5 strategies (Table 1) and the level of dyadic engagement. Paired sample t-tests compared scores on the MONSCI-CC by caregiver gender. Follow-up analyses using ANCOVA were run to control for a confounding effect of caregiver age. Pearson correlations examined the relationship between dyadic engagement and caregiver strategies.

Results: Results from the paired sample t-tests revealed significant differences between mother and father use of active teaching and learning ( $t[34]=2.83, p=.01$ ) and naturally reinforcing and scaffolding strategies ( $t[34]=2.13, p=.04$ ). Controlling for caregiver age, caregiver gender differences remained significant for active teaching and learning strategies ( $p=.046$ ) but not naturally reinforcing and scaffolding strategies ( $p=.50$ ). As shown in Figure 1, significant variability was found across caregivers regardless of gender. Within mothers, dyadic engagement was significantly correlated to strategies targeting opportunities for engagement ( $r=.38, p=.02$ ). Within fathers, dyadic engagement was significantly correlated to strategies targeting opportunities for engagement ( $r=.42, p=.01$ ) as well as those targeting environmental set-up ( $r=.43, p=.01$ ) and active teaching and learning ( $r=.57, p<.01$ ).

Conclusions: Mothers and fathers demonstrated similar levels of many NDBI strategies, but significant differences emerged regarding active teaching and learning strategies. These caregiver gender differences in the levels of NDBI strategy use, combined with variability among individuals, call for a personalized approach when programming intervention focused on improving caregiver use of NDBI strategies. Although exploratory, strategies focused on opportunities for engagement (e.g., providing choices, turn-taking, expectant waiting) may be helpful for both mothers and fathers to build increased rates of dyadic engagement.

**414.043** (Poster) Feasibility of ASD Risk Assessment Training and Real-Time Support Via the Paisley Digital Platform: Preliminary Convergent Validity of the ASD-PEDS with Established Instruments

**J. W. Wade<sup>1</sup>**, A. Swanson<sup>2</sup>, A. S. Weitlauf<sup>3</sup>, N. Sarkar<sup>4</sup> and Z. Warren<sup>5</sup>, (1)Adaptive Technology Consulting, Murfreesboro, TN, (2)Vanderbilt Kennedy Center, Vanderbilt University Medical Center, NASHVILLE, TN, (3)Vanderbilt Kennedy Center, Vanderbilt University Medical Center, Nashville, TN, (4)Mechanical Engineering; Electrical Engineering and Computer Science, Vanderbilt University, Nashville, TN, (5)Vanderbilt University Medical Center, Nashville, TN

Background: Primary care providers (PCPs), who are on the frontlines of developmental assessment, often lack adequate training in the early identification of ASD. Existing tools require extensive time, training, and financial investment, making them impractical in most community settings. As a result, many PCPs screen children for risk and then refer them either to overburdened diagnostic centers or to early intervention systems where services are limited without a clear diagnosis. To support PCPs that want to provide diagnostic feedback within primary care, any tool developed should provide real-time guidance in recognizing ASD symptoms as well as clear indicators of probability of ASD presence.

Objectives: In prior work, we developed Paisley—a digital platform for guided and rapid early assessment of ASD risk in toddlers—and demonstrated its feasibility across a range of health care professionals. Having demonstrated the feasibility of Paisley usage, we now examine the preliminary construct validity of an ASD risk assessment tool (ASD-PEDS) as delivered via Paisley. Specifically, we assess the convergent validity of the ASD-PEDS as delivered by providers using Paisley with established instruments, including a parent-report screener (Modified Checklist for Autism in Toddlers, Revised [M-CHAT-R]),

a gold standard diagnostic tool (Autism Diagnostic Observation Schedule, Second Edition [ADOS-2] Module 1 and Toddler Module), and an adaptive behavior interview (Vineland Adaptive Behavior Scales-III [VABS-III]).

Methods: Participants included 31 children (ages 18-36 months; 23 male and 8 female) clinically referred for ASD evaluation. Nine pediatric providers representing a range of professional backgrounds (e.g., developmental therapists, clinical psychologists) conducted screening assessments using the ASD-PEDS as guided and scored by Paisley. A separate provider, blinded to the results of the Paisley/ASD-PEDS assessment, then completed a comprehensive assessment using the MCHAT-R, ADOS-2, and VABS-III, and provided a “best estimate” clinical diagnosis (Yes/No ASD) for each child.

Results: We computed Pearson correlation coefficients between the ASD-PEDS total score and the scores of the aforementioned instruments. The ASD-PEDS total score is computed as the sum of seven behavioral codes, each taking on a value between 1 and 3, thus yielding a score range of 7-21, with larger scores corresponding to greater likelihood of ASD presence. The ASD-PEDS total score showed (a) a statistically significant positive association with the M-CHAT-R total score ( $r = 0.51, p = .005, CI .18 \text{ to } .74$ ), (b) positive associations with the total scores of both the ADOS-2 Module 1 ( $r = 0.54, p = .069, CI -.05 \text{ to } .85$ ) and the Toddler Module ( $r = 0.86, p < .001, CI .62 \text{ to } .96$ ), and (c) a statistically significant negative association with the VABS composite score ( $r = -0.64, p < .001, CI -.82 \text{ to } -.37$ ). The directions of all of these associations are consistent with expectations, supporting the preliminary convergent validity of the ASD-PEDS severity score

Conclusions: Research remains ongoing and further work is needed to demonstrate the discriminant validity and reliability of the tool. Although preliminary, the observed correlations between the ASD-PEDS total score and other established metrics provide early evidence of the convergent validity of the novel instrument.

#### **414.044** (Poster) How Does Parent and Examiner Question Use Differ during Natural Language Sampling?

**H. Baker-Harvey<sup>1</sup>, M. Barokova<sup>2</sup>, C. G. La Valle<sup>2</sup>, H. Tager-Flusberg<sup>2</sup> and L. Raymond<sup>1</sup>, (1)Boston University, Boston, MA, (2)Department of Psychological and Brain Sciences, Boston University, Boston, MA**

---

Background: Natural language samples (NLS) are a rich source of information about the verbal abilities of minimally and low-verbal (MLV) individuals with ASD (Barokova & Tager-Flusberg, 2018). Past research has shown that children and adolescents with autism speak more and use a higher number of different words when with their parents than when with examiners but these measures were not related to the child's speech (Barokova et al., 2020; Kover et al., 2014). Here we focus on the administrator's use of questions in this same data set because grammatically complex and open-ended questions have been reported to promote child language (Capps et al., 1998; Goodwin et al., 2015; Nadig & Bang, 2017). Examining the grammatical and semantic complexity of adult questions may provide insight on why MLV children/adolescents use more lexically diverse speech when with their parents.

Objectives: To compare **I.** the grammatical complexity and **II.** the semantic complexity of adult questions during an NLS. **III.** To examine associations between adult and child/adolescent speech.

Methods:

Twenty-two (4 females) children/adolescents with ASD (ages 6;6 to 19;7 ( $M=12;6$ )) participated. Examiners in the lab and parents in their home collected a NLS following ELSA-A protocol (Barokova et al., 2020b) that were transcribed using SALT (Miller et al., 2011). Questions were coded using a novel scheme for grammar/form, and lexical/semantic complexity. Form codes included Yes/No, Wh-, or No Syntax/Intonation. Semantic complexity codes included Closed (most constrained), Open-Low, or Open-High (least constrained) depending on the constraints on potential responses. Additional measures of grammatical complexity (noun-verb ratio) and lexical diversity (number of different words; NDW) were extracted for all questions. A kappa above .8 was achieved for reliability for 20% of transcripts at all coding levels.

Results:

Analyses involved paired t-tests (or its nonparametric equivalent) and Spearman's rank correlations (multiple comparisons correction critical **p-value is .01**). Questions made up 31.7% of parent speech ( $SD=.10$ ) and 31.37% of examiner speech ( $SD=.09$ ;  $t(21)=.003, p<0.913$ ).

**I.** Parents used significantly fewer Yes/No questions than examiners ( $t(21)=3.849, p=.001$ ), but not for other forms (**Table 1**). Parents questions had a higher ratio of nouns to verbs ( $t(21)=-4.945, p<.001$ ).

II. Parents' questions had lower NDW than examiners' ( $t(21)=4.44, p<.001$ ), but there were no differences in the degree of semantic openness.

III. The noun-verb ratio of examiner questions was positively correlated with participants' frequency of utterances ( $r_s=.562, p=.006$ ). No other measures of examiner or parent question use were correlated with measures of child/adolescent expressive language (Table 2).

Conclusions:

Parent and examiner questions differed in form, grammatical complexity, and lexical diversity. However, only grammatical complexity of examiner speech correlated with participant speech. These results suggest that parents elicit more speech from their children not because of linguistic differences, but perhaps because of non-linguistic factors such as familiarity and comfort level.

**414.045 (Poster)** I Know How I Am Feeling! Understanding Similarities and Discrepancies between Adolescent-Parent Dyads' Reports of Autistic Youths' Emotional States across a Randomised Controlled Trial of Kontakt®

**B. Afsharnejad<sup>1</sup>, M. H. Black<sup>2</sup>, M. Falkmer<sup>3</sup>, A. Fridell<sup>4</sup>, C. Coco<sup>5</sup>, S. Bolte<sup>6</sup> and S. J. Girdler<sup>2</sup>,** (1)Autism Research Team, Telethon Kids Institute, Perth, Australia, (2)School of Occupational Therapy, Social Work and Speech Pathology, Curtin University, Perth, WA, Australia, (3)Curtin University, Bentley, Australia, (4)Karolinska institute, Stockholm, Sweden, (5)Karolinska Institutet, Stockholm, Sweden, (6)Center of Neurodevelopmental Disorders (KIND), Centre for Psychiatry Research; Department of Women's and Children's Health, Karolinska Institutet, & Stockholm Health Care Services, Region Stockholm, Stockholm, Sweden

Background: Autistic youth have historically been perceived as inherently unreliable in reporting their emotional states, with parent proxy-report currently the primary measure used to understand their emotional experiences. There is however growing recognition of the importance of capturing autistic adolescents' self-reports, acknowledging that they are the experts of their own experiences.

Objectives: This study employed experience sampling method (ESM) to understand the similarities and discrepancies between autistic adolescents self-reported and their parents' proxy reports of adolescents' emotional states while participating in a 7-month randomised controlled trial (RCT) evaluating the efficacy of KONTAKT® social skills group training intervention compared to an active control cooking group (Super Chef).

Methods: Adolescents and their parents rated the adolescent's daily emotional states (happy, calm, anxious, lonely and afraid) on a 10 point Likert scale for the 7 month period. Overall, 62 autistic adolescents aged 12 to 17 ( $m=13.8, SD=1.5$ ) with an  $IQ>70$  and their parents met inclusion criterion of both answering 33% of daily texts (210 texts).

Results: An overall response rate of 64.8% (33.6-97.7) indicated a good adherence to ESM. Multilevel analysis comparing adolescent self-reports and their parents' proxy reports showed a small, but significant difference between the dyads' reports regardless of their group allocation, with adolescents perceiving all their emotions, with the exception of happiness, more positively than their parents. No further difference was observed between adolescent-parent dyads' reports for associated factors including age, gender, internalising and externalising behaviours, and group allocation over the 7 months of the trial.

Conclusions: Given the length and intensity of data collection employed in this study, these findings present strong evidence that autistic adolescents are capable of self-reporting their emotional states via ESM, highlighting the utility of ESM as a tool in enabling insight into the emotional state of autistic youth.

**414.046 (Poster)** Identifying Which Patients Seeking Autism Spectrum Disorder Evaluation May Receive Diagnostic Clarity through an Initial Virtual Assessment

**R. A. Phelps, E. Sample, R. K. Greene, A. Shahabuddin and S. W. Duvall,** Oregon Health & Science University, Portland, OR

**Background:** Due to the COVID-19 pandemic, evaluation of autism spectrum disorder (ASD) has taken on different assessment modalities. Traditionally, ASD evaluations are completed in-person and include caregiver interview, behavioral observations, cognitive testing, and ASD specific measures (e.g., Childhood Autism Rating Scale, 2<sup>nd</sup> Edition; Autism Diagnostic Observation Schedule, 2<sup>nd</sup> Edition) with some measures requiring in-person administration. As a result of social distancing and safety precautions, virtual visits (VV's) evaluating for ASD have become common practice. VV's have the potential to increase access to evaluation and decrease health risks while expediting the patient's access to ASD specific treatments. However, it is unclear which patients are likely to receive diagnostic clarity during a VV and which patients are likely to be referred for further testing.

**Objectives:** The current study investigates which patients are likely to receive diagnostic clarity during an ASD VV and which patients are likely to be referred on for further in person testing based on information found within intake paperwork (e.g., demographic, psychiatric, adaptive, and educational factors) prior to being seen.

**Methods:** The sample included 38 children (24 males;  $M_{age} = 7.78$ ,  $SD_{age} = 4.65$ ; Caucasian = 75.7%) and their caregivers who engaged in ASD VV's. Demographic variables (e.g., sex, age), adaptive skills (i.e., Adaptive Behavior Assessment System, 3<sup>rd</sup> Edition; ABAS-3), psychiatric history, behavior and psychiatric concerns (i.e., Behavioral Assessment System for Children, 3<sup>rd</sup> Edition; BASC-3), individualized education plan (IEP) classification, and outcome of the VV (i.e., ASD diagnosis, further testing recommended) were collected. Thirteen participants (34.21%) received an ASD diagnosis during VV while 23 participants (60.53%) were referred for in-person testing. Two participants (5.26%) were given other psychiatric diagnoses and ASD was ruled out. These 2 participants were excluded from analyses (final  $n=36$ ). Ultimate diagnostic outcomes from in-person testing have not yet been collected for participants referred for further testing.

**Results:** Sex ( $r=0.19$ ,  $p=.307$ ) and age ( $r=-0.04$ ,  $p=.849$ ) did not significantly relate to VV diagnostic outcome and were not considered further. Regression analyses revealed higher parent-reported behavioral concerns ( $b=-0.03$ ,  $SE=0.01$ ,  $\beta=-0.84$ ,  $t=-3.36$ ,  $p=.015$ ) and not having an IEP classification of ASD ( $b=-0.90$ ,  $SE=0.24$ ,  $\beta=-0.57$ ,  $t=-3.68$ ,  $p=.014$ ) were predictive of recommendation of in-person testing. While not significant, the number of previous psychiatric diagnoses trended to recommendation of in-person testing ( $b=-0.13$ ,  $SE=0.05$ ,  $\beta=-0.37$ ,  $t=-2.35$ ,  $p=.066$ ). Adaptive skills were not related to VV diagnostic outcome ( $b=-0.01$ ,  $SE=0.01$ ,  $\beta=-0.21$ ,  $t=-1.47$ ,  $p=.201$ ).

**Conclusions:** VV's have limitations such that not every patient is able to receive diagnostic clarity, at which time a referral for in-person testing may be deemed appropriate. Findings suggest individuals presenting for a virtual ASD evaluation with comorbid behavioral concerns and prior psychiatric diagnoses, as indicated by intake paper, may require in-person evaluation for diagnostic clarity. Data indicate patients with fewer behavioral and mental health concerns, as indicated by intake paperwork, as well as a pre-existing educational classification of ASD are more likely to receive an ASD diagnosis during a VV. VV's may decrease burden on families who may not require in-person testing.

#### **414.047 (Poster) Innovative Approaches Implemented By UK Childhood Autism Diagnostic Services to Manage Increased Referrals and Reduce Waiting Times**

**S. Wigham<sup>1</sup>, W. Farr<sup>2</sup>, I. Male<sup>3</sup> and J. R. Parr<sup>1</sup>.** (1)Population Health Sciences Institute, Newcastle University, Newcastle upon Tyne, United Kingdom, (2)Sussex Community NHS Trust, Haywards Heath, United Kingdom, (3)Mid Sussex Child Development Team, Sussex Community NHS Trust, Haywards Heath, United Kingdom

*Background:* Accessing a childhood autism diagnostic assessment is a key step to gain subsequent appropriate support; however, UK NHS waiting lists are longer than those suggested by national guidance. The number of assessments teams are required to complete is a significant barrier to timely diagnosis. Identifying novel and effective methods to deliver high quality, timely assessment is a clinical and parent priority.

*Objectives:* Identify innovative approaches implemented by UK childhood autism diagnostic assessment services to improve provision.

*Methods:* A UK clinical practice survey was developed in consultation with clinicians and parents (semi-structured format with open/closed response options). UK childhood autism diagnostic assessment services (for children aged 1-18 years) were recruited through clinical and professional networks and mailing lists from June-November 2020. Data collection was via online survey. Analysis used descriptive statistics and content analysis.

*Results:* Responses were from 101 UK childhood autism diagnostic assessment services. Teams were from a range of locations: mixed urban/rural (64%) urban (31%) and rural (5%). 49% of respondents ( $n=49$ ) were from Paediatric services (Community/Neuro-disability/Child development teams); while 40% ( $n=41$ ) were from Child and Adolescent Mental Health Services (CAMHS) and Children and Young People's Services (CYPS). 11% of respondents ( $n=11$ ) were from integrated, independent and learning disability services. 25% of teams ( $n=25$ ) had access to data on referrals and assessments during the years 2015-19. Of those, 88% reported increasing referrals. The median number of referrals in 2015 was 150, rising to 378 in 2019; a 152% increase. 76% of teams ( $n=19$ ) reported increased assessments; the median number of assessments in 2015 was 130 rising to 218 in 2019; a 67% increase.

Teams described capacity challenges with completing the required number of assessments. 48% ( $n=48$ ) described one or more long-term staff vacancies; 70% ( $n=70$ ) described difficulties having the right MDT expertise to undertake the assessments required.

Teams described adaptations they had made to service provision in order to address challenges. 57% of teams (n=57) changed their multidisciplinary team (MDT) skill mix e.g. by employing teachers, nurse specialists, or by training more professionals to be diagnosticians. 19% of teams (n=19) had integrated local Paediatric services with CAMHS/CYPS. 71% of teams (n=71) adjusted how they obtain good quality information at point of referral e.g. from Early Help Services, nursery or school. 66% of teams (n=66) had introduced questionnaires for parents and education professionals to complete prior to referral/pre-first assessment appointment. Finally, 45% of teams (n=45) had introduced the use of digital technology/computerised systems/software. Further innovations described by teams included involving non-qualified staff in assessments (e.g. trainees, assistants and education staff), virtual assessments, group assessments, training CAMHS professionals to take a developmental history and screen for co-occurring conditions, and using private contractors to complete diagnostic assessments.

*Conclusions:* Innovative approaches that are being used in UK NHS autism diagnostic assessments are relevant internationally. The next stage in our research programme is identifying which approaches are most effective in reducing waiting times, whilst delivering high quality assessments that lead to valid diagnostic outcomes and high levels of parent and young person satisfaction.

**414.048 (Poster)** Intellectual Disability in a Group of African Children with Autism Spectrum Disorder: Associated Factors and Implications for Educational Placement

*M. Bello-Mojeed<sup>1</sup>, A. Adeyemi<sup>1</sup> and M. Bakare<sup>2</sup>, (1)Medical, Federal Neuropsychiatric Hospital, Yaba, Nigeria, (2)Federal Neuro-Psychiatric Hospital, Upper Chime, New Haven, Enugu, Enugu State, Nigeria, Enugu, Nigeria*

---

**Background:** Intellectual disability and autism spectrum disorder are chronic, commonly co-occurring and severely disabling neuro-developmental disorders yet diagnostic distinction is obscure and often overlooked especially among African children. Distinct diagnoses and associated factors are implicated in the appropriate intervention and optimal child outcome for children with developmental disabilities.

**Objectives:** This study examined prevalence of intellectual disability and its correlates in a group of children with Autism Spectrum Disorder in Nigeria, sub-Saharan Africa.

**Methods:** In a cross-sectional study, seventy-five children with ASD were recruited from the Child and Adolescent Mental Health Service Centre in Lagos, Nigeria. The instruments used for data collection were the socio-demographic and clinical questionnaires, the Indian scale for Assessment of Autism (ISAA), Ravens Progressive Matrices (RPM) and comprehensive clinical assessment. Data was analysed with the use of Statistical Package for Social Sciences.

**Results:** The mean age of the study participants was  $9.12 \pm 4.23$  with a male predominance (69.3%). The prevalence of intellectual disability among children with Autism Spectrum Disorder was 64%. Factors that were significantly associated with intellectual disability in ASD were female gender ( $p = 0.001$ ), low child educational level ( $p = 0.002$ ), school type ( $p = 0.012$ ), big family size ( $p = 0.013$ ), seizure ( $p = 0.001$ ), and ASD severity ( $p = 0.002$ ).

**Conclusions:** Intellectual disability is highly prevalent in African children with diagnosis of ASD. Socio-demographic and comorbidity factors are strongly associated with the developmental disability. Findings of this study have important implications for clinical assessment and educational planning for individuals with autism spectrum disorder in Africa.

**414.049 (Poster)** Interaction of Sex and Items on the M-CHAT Increases Specificity of Autism Identification

*K. D. Riley<sup>1</sup>, F. Shic<sup>2</sup>, S. Schjolberg<sup>3</sup> and R. A. Øien<sup>4</sup>, (1)Seattle Children's Research Institute, Seattle, WA, (2)Center for Child Health, Behavior and Development, Seattle Children's Research Institute, Seattle, WA, (3)Norwegian Institute of Public Health, Oslo, NORWAY, (4)The Arctic University of Norway, Tromsø, NORWAY*

---

**Background:**

Risk for ASD is strongly impacted by biological sex<sup>1</sup>. However, sex is seldomly explicitly incorporated into screening tests for ASD<sup>2</sup>. The Modified Checklist for Autism in Toddlers (M-CHAT) is a validated screening tool used to evaluate ASD risk in toddlers<sup>3</sup>. An open question is how M-CHAT sex-specific differences<sup>4</sup> combine to predict risk and subsequently impact overall screening performance.

**Objectives:**

To explore the interaction of sex and M-CHAT items and how incorporation of these interactions impact M-CHAT sensitivity.

## Methods:

This study uses data from the Autism Birth Cohort Study (ABC), a sub-study of the Norwegian Mother, Father, and Child Cohort Study (MoBa), a prospective general population pregnancy study<sup>5</sup>. 54,455 participants (26,646 females, 27,809 males) born 1999-2009 completed the M-CHAT as part of an 18-month developmental questionnaire. ASD diagnostic status was determined at approximately 42 months in the ABC clinic or by the discharge diagnosis in the National Patient Registry. Of the 54,455 participants, 332 received ASD diagnoses. Logistic regression modelled ASD outcome prediction based on contributions of (1) individual items and (2) individual items interacting with sex. These models were compared to M-CHAT-R<sup>6</sup> scoring algorithms applied to the M-CHAT data (here called the M-CHAT-20 model), which yielded baseline sensitivity=27.6%, specificity=94.9%. We compared sensitivity between models at the baseline 94.9% specificity using McNemar tests and explored significant contributors to prediction in both models.

## Results:

Not including sex in the model, nine items significantly contributed to ASD prediction (Table 1), yielding a sensitivity of 30.1% in males, 30.9% in females, and 30.3% overall. Including sex in the model, five items contributed to increased general risk for ASD, and one additional item was associated with increased ASD risk for males (Table 2), resulting in a sensitivity of 38.3% in males, 23.6% in females, and 36.0% overall. As expected, sex coefficients indicated lower risk for ASD in females versus males (log-odds  $M=-1.82$ ,  $SD=.21$ ,  $p<.001$ ). The sensitivity in the model including sex was significantly greater than in the M-CHAT no-sex model ( $p<.001$ ) and in the M-CHAT-20 model ( $p<.001$ ). The strength of the sex model compared to no-sex model was driven by the significant improvement in sensitivity in males ( $p<.001$ ). Sensitivity was not significantly different between models for females ( $p=.134$ ).

## Conclusions:

These results suggest that explicit inclusion of sex into screening development may yield additional strategies for optimizing screening performance. For the M-CHAT, not looking to where a caregiver points was associated with increased risk for ASD for boys but not girls, and several items did not contribute significantly to models once sex was included. Future investigations are required to unpack the contributing factors responsible for differences induced by explicitly modeling sex in risk prediction, potentially resulting in more streamlined screening for ASD by sex, as well as to examine potential differences in the M-CHAT-R (vs. M-CHAT) once data from longitudinal prospective population studies are available.

**414.050** (Poster) Interdisciplinary Assessment for Autism in Young Children: Comparative Analysis of Two Interdisciplinary Clinics at an Academic Medical Center

**R. Sumner<sup>1</sup>**, C. Gilchrest<sup>1</sup> and L. Gardner<sup>2</sup>, (1)Johns Hopkins All Children's Hospital, St Petersburg, FL, (2)Johns Hopkins All Children's Hospital, St. Petersburg, FL

---

Background: Although the behavioral symptoms of autism generally become apparent between 1 and 2 years of age for experienced clinicians (Kozlowski et al., 2011), many children do not receive a diagnosis until later childhood. The CDC established Autism and Developmental Disabilities Monitoring (ADDM) Network reports a much later median age (i.e., four years, five months) for earliest ASD diagnosis. Early diagnosis of ASD can be delayed by a myriad of factors including presentation of behaviors, comorbid disorders, race, gender, and limited access to qualified providers. It is widely accepted that early diagnosis of ASD is imperative given the considerable effect early intervention has on later outcomes. The “gold standard” for a diagnostic evaluation of ASD involves the clinical judgment of a qualified interdisciplinary team to determine diagnosis,

which includes utilizing empirically- sound diagnostic instruments, clinical assessment, caregiver report, and behavior observations. The core features of an evidence-based assessment for ASD includes caregiver reporting on interviews and questionnaires, autism-specific diagnostic tools and observation instruments, standardized assessment of intellectual functioning, speech/language assessment, and adaptive behavior assessment (Ozonoff, Goodlin-Jones, & Solomon, 2005). The Autism Program included in this study provides diagnostic evaluations to young children (i.e., ages 4 years, 11 months and younger) through two separate interdisciplinary clinics. These clinics prioritizes evaluations for high-need patients to assist in early diagnosis and access to early intervention.

**Objectives:** To assess differences in patient wait-time for access to care, patient age at evaluation, and diagnostic outcomes between two separate interdisciplinary evaluation clinics at an academic medical center.

**Methods:** Patients aged 4 years, 11 months and younger were evaluated through two separate interdisciplinary clinics. Both clinics prioritize evaluations for patients seeking developmental assessment and treatment recommendations. The four-discipline clinic evaluates patients 4 years, 11 months and younger. The two-discipline clinic evaluates patients between the ages of 24-36 months. We contrasted length of wait-time for evaluation, age at diagnosis, and diagnostic outcomes for 25 patients seen through these two interdisciplinary clinics.

**Results:** Average wait-time for the four-discipline clinic was 9.76 months ( $SD=3.82$ ) months from submission of patient history questionnaire (PHQ) to diagnostic evaluation. Average wait-time for the two-discipline clinic was 4.84 months ( $SD=3.16$ ) from the submission of PHQ to diagnostic evaluation. Average age of diagnosis was 41.92 months ( $SD=8.4$ ) for the four-discipline clinic and 31.33 months ( $SD=3.98$ ) for two-discipline clinic. ASD diagnosis rates were approximately the same (76.9%) for patients seen in the four-discipline (76%) versus those evaluated in the two-discipline clinic (75%).

**Conclusions:** Patients seen through the four-discipline clinic waited approximately three times longer for diagnostic evaluations than those evaluated through the two-discipline clinic and were approximately ten months older at age of initial diagnosis. Results provide preliminary support for the use of two-discipline interdisciplinary team evaluations for young children to decrease wait-time and increase early diagnosis and access to early intervention services while maintaining best-practice assessment methods and diagnostic accuracy.

**414.051 (Poster)** Investigating the Validity and Reliability of the Dutch Translation of the Camouflaging Autism Traits Questionnaire (CAT-Q-NL)

*W. J. van der Putten<sup>1,2</sup>, J. Agelink van Rentergem<sup>1</sup>, T. A. Radhoe<sup>1</sup>, C. Torenvliet<sup>1</sup>, A. P. Groenman<sup>1</sup>, A. Mol<sup>1</sup> and H. M. Geurts<sup>1,2</sup>, (1)University of Amsterdam, Amsterdam, Netherlands, (2)dr. Leo Kannerhuis, Amsterdam, Netherlands*

---

**Background:** Camouflaging behavior is defined as using strategies to hide characteristics of autism spectrum condition (ASC; Hull et al., 2017). The Camouflaging Autism Traits Questionnaire (CAT-Q; Hull et al., 2019) is the first self-report questionnaire measuring camouflaging behavior. However, psychometric properties of translated version(s) of the CAT-Q have not yet been investigated.

**Objectives:** In this study we aim to investigate the validity and reliability of the Dutch translation of the CAT-Q (CAT-Q-NL).

**Methods:** The CAT-Q-NL and the Autism Spectrum Quotient (AQ; Baron-Cohen et al., 2001) were administered to 669 adults (356 ASC; 52% males; 313 comparison; 54% males) aged 30 to 92 (AsPredicted #37800). In a subsample of autistic adults (N=94), the Autism Diagnostic Observation Schedule (ADOS2; Lord et al., 2012) was administered. Cronbach's alpha was calculated to determine internal consistency and we tested whether we could replicate the original CAT-Q factor structure using confirmatory factor analyses. Convergent validity was assessed by comparing the CAT-Q-NL to the discrepancy between the ADOS2 and AQ as proxy for camouflaging behavior (Lai et al., 2016).

**Results:** Preliminary analyses showed an acceptable fit for the original factor structure. However, as measurement invariance was insufficient, further analyses will be conducted to investigate whether a different factor structure is more suitable. Using the original factors, high internal consistency was found for the total score and factor scores ( $\alpha = .82$  to  $.93$ ). Small correlations were found between scores on the CAT-Q-NL and the proxy of camouflaging behavior ( $r = .11$  to  $.25$ ). Finally, autistic adults scored higher than non-autistic adults on overall camouflaging behavior and on separate factors.

**Conclusions:** Preliminary analyses using the factors of the CAT-Q, seem to indicate good reliability and, in general, group differences seem to be in line with earlier studies. However, the low correlation between the CAT-Q-NL and the discrepancy measure, raises questions about the validity of camouflaging measures and the interpretation of obtained group differences.

Before concluding this is indeed a problem, we need to determine whether a different factor structure is more appropriate and if altered scales are solving this issue. These analyses will be run for INSAR 2021.

**414.052** (Poster) Measurement Invariance across Gender of the ASRS in a Non-Clinical Diverse Sample

**M. E. Golson<sup>1</sup>**, S. E. Schwartz<sup>1</sup>, M. McClain Verdoes<sup>1</sup>, K. Bakner<sup>1</sup>, T. P. Gabrielsen<sup>2</sup> and B. Harris<sup>3</sup>, (1)Psychology, Utah State University, Logan, UT, (2)Counseling & Special Education, Brigham Young University, Provo, UT, (3)Department of Pediatrics, University of Colorado, Denver, CO

---

**Background:**

Accurate identification of autism spectrum disorder (ASD) relies on the use of appropriate, reliable, and valid measures. This is vital when conducting ASD evaluations for female clients. Research indicates male children are 4.3 times more likely to be identified with ASD than girls (Maenner et al., 2020). Notably, the masking effect (Bargiela et al., 2016), gender differences in symptom presentation, such as better imitation skills and more age-appropriate restricted interests (Duvekot et al., 2017; Lai et al., 2015), and a skew in the ASD research toward primarily male samples (Lai et al., 2015) may contribute to the misdiagnosis and delayed identification of females. When females are identified late or incorrectly, they miss opportunities for early intervention services.

The Autism Spectrum Rating Scales (ASRS; Goldstein & Naglieri, 2010) is one of the more common rating forms in clinical and educational practice. The ASRS is a valid and reliable measure that assesses symptoms and behaviors related to ASD through parent and teacher report. There are several forms to accommodate different informants and child age. The current study focuses on the ASRS Parent Form for children aged 6-18. Exploratory factor analysis results indicate the ASRS has a three-factor model measuring Social/Communication (SC), Unusual Behaviors (UB), and Self-Regulation (SR). No confirmatory factor analysis (CFA) was reported.

**Objectives:**

The purpose of this study was to investigate the measurement invariance of the ASRS across child gender in a diverse non-clinical sample. Evaluations of measurement invariance allow researchers to test whether relationships between items and latent constructs remain the same across groups (Pendergast et al., 2017), an essential prerequisite to the use of measures in minoritized populations, such as females with ASD. Further, an adequate understanding of how the ASRS functions in all populations, including non-clinical cases, is necessary for comparisons across groups.

**Methods:**

Parents of children between 6 and 18 years of age ( $N=806$ ) participated in the current study. Participants reported their child's gender as male ( $n=468$ ) or female ( $n=338$ ). Participants were recruited through Amazon's Mechanical Turk. Following informed consent, parents completed a demographic survey and the ASRS. Internal consistency, differential item functioning analyses using item-response theory (DIF IRT), and multiple group CFA (MG-CFA) were performed.

**Results:**

All three subscales demonstrated high internal consistency. All three subscales exhibited test-level invariance in DIF IRT analyses. Additionally, item-level invariance was found for all but one item across groups. MG-CFA results indicated the UB subscale demonstrated measurement invariance while SC and SR had only partial invariance after the sequential release of several test items.

**Conclusions:**

Results provide some support for use of the ASRS with female children. The measurement invariance analyses suggest the factor structure of subscales operate largely the same between males and females, with differences arising at the item level. The

invariant items may suggest parents perceive specific ASD symptoms and behaviors differently for male and female children. Clinicians should consider these differences when utilizing the ASRS in the evaluation of females for ASD.

**414.053 (Poster)** Modality Influences Parents' Responses to MCHAT-R Follow-up Items

**K. D. Kelly<sup>1</sup>, L. E. Bradstreet<sup>2</sup>, S. M. Attar<sup>3</sup>, R. K. Ramsey<sup>4</sup> and D. L. Robins<sup>1</sup>,** (1)*A.J. Drexel Autism Institute, Drexel University, Philadelphia, PA*, (2)*Pediatric Psychology and Neuropsychology Department, Nationwide Children's Hospital, Columbus, OH*, (3)*University of Washington, Seattle, WA*, (4)*Nisonger Center, The Ohio State University, Columbus, OH*

---

**Background:** Screening is critical for early detection of autism. The Modified Checklist for Autism in Toddlers, Revised with Follow Up (M-CHAT-R/F) is a widely used, 2-stage validated toddler screening tool. For stage 1, caregivers answer 20 Yes/No questions ( $\leq 5$  minutes). For stage 2, caregivers of screen-positive children scoring in the moderate range (3 to 7 at risk responses) are asked structured follow-up questions to obtain additional information (5-10 minutes with a professional). Various barriers impact the screening to evaluation process, such as lack of time and resources to complete stage 2 follow-up questions and limited communication between caregivers and primary care providers (PCPs). Using an electronic adaptation of the M-CHAT-R/F addresses these screening challenges. Preliminary results (Robins et al., 2016) indicated that follow-up items performed differently when parents reported during electronic administration vs. interview with a professional.

**Objectives:** The current study evaluated Follow-Up items that demonstrated differential low- and high-risk responses based on the modality in which parents completed the questions.

**Methods:** A total of 17,558 toddlers were included (8,758 males, 8,512 females, 288 unspecified). Of this sample, 11,458 families received the paper M-CHAT-R/F with a phone follow-up (paper-phone modality), and 6,100 received the electronic version with either an immediate electronic follow-up ( $n = 3,309$ ; all-electronic modality) or a phone follow-up ( $n = 2,791$ ; electronic-phone modality). Children who screened positive, including high risk children in stage 1 or failed follow-up in stage 2 ( $n = 442$ ), were invited for diagnostic evaluations that included the Autism Diagnostic Observation Schedule (ADOS) 1<sup>st</sup> or 2<sup>nd</sup> Editions. Of the 442 children invited for diagnostic evaluation, 266 children completed evaluations, and children were classified as either ASD ( $n = 90$ ) or Non-ASD ( $n = 103$ ) for diagnostic outcomes. Chi-square analyses were used to compare at-risk and not-at-risk response rates for each item;  $p < .0025$  was used as the threshold to control for multiple analyses.

**Results:** Paper-phone and electronic-phone modalities showed no significant differences and were combined for analyses. Eight of the 20 M-CHAT-R/F follow-up items were significantly different between phone and electronic modalities (see Table 1); parents continued to endorse risk more often in electronic reporting for items assessing unusual finger movements, pointing, response to name, sensitivity to noise, walking, following gaze, and understanding language. Examination of subitems revealed significant differences in three items: Holds hands close to face (Item 5b), how child draws attention (7e), and walking without holding on (13b).

**Conclusions:** There are observable differences in reporting between electronic and phone follow-up modality. However, these differences seem to be distributed across items rather than localized to certain items or subitems of the follow-up. Although the all-electronic modality of the M-CHAT-R/F may be a valid alternative to the more labor-intensive interview administration, future research should examine additional factors that may account for the discrepancies in parent responses based on modality. Although the all-electronic M-CHAT-R/F leaves PCPs better equipped to overcome important screening challenges, specificity may be reduced. Future studies should address the utility and acceptability of different methods of screening in community populations.

---

#### Background:

It is widely acknowledged that there is under-diagnosis of autism in females. Girls and women may often not be identified and diagnosed due to a combination of factors. Females who receive early diagnosis are likely to exhibit relatively severe autistic symptomatology, often with other clear signs of developmental disability, such as delays in language, communication and cognitive ability. Furthermore, females are often under-represented in research investigating gender differences.

#### Objectives:

To investigate differences in the profiles of girls and boys diagnosed with autism at 3 years and in mid-childhood in relation to measures of cognitive ability, socialisation and autistic symptomatology. We consider two competing hypotheses: 1) in order to receive a diagnosis of autism girls would need to demonstrate more significant levels of autistic symptomatology, social and/or cognitive impairments than boys; and 2) autistic girls would show less severe levels of autism, social and/or cognitive impairments than autistic boys, but were still identified as autistic by the research team.

#### Methods:

Participants were taking part in a prospective, longitudinal study of infants at elevated likelihood (EL) of autism due to having an older sibling with autism. Children were assessed at approximately 8, 14, 24 and 36 months and then a proportion of these children were seen again in mid-childhood (between 6 and 10 years of age). At the 3-year and mid-childhood visits various assessments were conducted, including standardised tests of cognitive ability, adaptive behaviour and autism diagnosis. Following each of these later visits, a best estimate research diagnosis of autism or not autism was made.

#### Results:

Two hundred and forty-eight EL children (122 girls; 126 boys) were seen at the 3-year visit. Of these 12 girls (9.8%) and 34 boys (27%) were diagnosed with autism. Seventy-nine children (41 girls; 38 boys) were seen at the mid-childhood visit. Of these 12 girls (29.3%) and 17 boys (44.7%) were diagnosed with autism. Main effects for diagnostic outcome were found for all measures at both time points except for cognitive ability in mid-childhood, and for gender only for cognitive ability at 3 years, and there were no interaction effects of diagnosis and gender. There were no significant differences on any measure at either age between females and males with autism.

#### Conclusions:

Neither of our two stated hypotheses stand: no significant differences between girls and boys with autism were found in either direction, both at 3 years of age and in mid-childhood. Clearly our sample is small, particularly at the mid-childhood time-point, and the children with autism relatively able (mean (SD) IQ at 3 years = 89.9 (25.6) & in mid-childhood = 107.2 (19.2)) so it is not possible to generalise our findings to the wider population of children diagnosed with autism in clinical settings. However, this is a well-characterised sample of children selected in early infancy on the basis of familial risk and without a selection bias for gender.

#### **414.055** (Poster) Non-Inferiority of a Rapid 5-Item Version of the Social Responsiveness Scale for the Identification of Autism Spectrum Disorder

**M. Eliasziw<sup>1</sup>, A. Bowling<sup>2</sup>, T. Kral<sup>3</sup>, S. Magaña<sup>4</sup>, L. Sikich<sup>5</sup>, H. Stanish<sup>6</sup>, D. Tybor<sup>7</sup>, L. G. Bandini<sup>8</sup>, C. Curtin<sup>9</sup> and A. Must<sup>1</sup>,**  
(1)Tufts University School of Medicine, Boston, MA, (2)School of Health Sciences, Merrimack College, North Andover, MA, (3)University of Pennsylvania School of Nursing, Philadelphia, PA, (4)Steve Hicks School of Social Work, University of Texas at Austin, Austin, TX, (5)Department of Psychiatry and Behavioral Sciences, Duke Center for Autism and Brain Development, Durham, NC, (6)Department of Exercise and Health Sciences, University of Massachusetts- Boston, Boston, MA, (7)Public Health and Community Medicine, Tufts University, Boston, MA, (8)Eunice Kennedy Shriver Center, University of Massachusetts Medical School, Worcester, MA, (9)University of Massachusetts Medical School, Waltham, MA

---

#### Background:

Identifying individuals with autism spectrum disorder (ASD) using a screening questionnaire is valuable in research studies and in clinical settings when a medical diagnosis is unavailable. In this regard, it is common to use the validated 65-item parent-completed Social Responsiveness Scale (SRS). Although shortened 16-item and 11-item versions have been proposed, their

derivations have been limited in their ability to account for potentially important socio-demographic, familial, environmental, and community characteristics that may differ between children with and without ASD.

#### Objectives:

The aim of the present study was to derive a shortened version of the parent-completed SRS from a large sample of sibling dyads.

#### Methods:

The Simons Simplex Collection Version 15.3 was used to create sibling dyads comprising a child with a clinically confirmed diagnosis of ASD and a full sibling without ASD within the same family, all between the ages of 4-18 years. The full sibling without ASD was chosen to be closest within 5 years of age to the child with ASD. Areas under Receiver Operating Characteristics (AUROC) curves were used to estimate accuracy [ranging from 0.5 (chance) to 1.0 (perfect)] and to compare the rapid 5-item version to the 65-item SRS using a 95% two-sided confidence interval and a prespecified non-inferiority margin of -0.005 points.

Results: The sample consisted of 1596 sibling dyads. The mean (sd) age of the children with and without ASD was 9.3 (3.3) and 9.2 (3.6) years, respectively ( $p=0.55$ ). Children with ASD were significantly more likely to be male than their siblings (87% vs 47%,  $p<0.001$ ). Eighty percent were of White race. The rapid 5-item version comprised three social communication items (16.Avoids eye contact or has unusual eye contact; 22.Plays appropriately with children his or her age; 35.Has trouble keeping up with the flow of a normal conversation) and two autistic mannerisms items (24.Has more difficulty than other children with changes in routine; 28.Thinks or talks about the same thing over and over). The relationship between the rapid 5-item version and the 65-item SRS was near perfect (Pearson correlation=0.95) and both had near-perfect accuracy. The AUROC was 0.993 (95% CI: 0.991 to 0.996) for the rapid 5-item version and 0.992 (95% CI: 0.990 to 0.995) for the 65-item SRS. The resulting difference of 0.001 (95% CI: -0.001 to 0.003;  $p=0.46$ ) supported non-inferiority of the rapid 5-item version. Using a cut-point of 4 or higher (corresponding to a median-split of a scale ranging from 0 to 15), the rapid 5-item version had sensitivity=97.6%, specificity=96.2%, predictive value positive=96.3%, and predictive value negative=97.6%.

#### Conclusions:

From this unique data resource that accounts for shared family environments, the rapid 5-item version of the SRS has been shown to have near-perfect accuracy and to be non-inferior to the 65-item SRS. In research settings where participants are often overburdened by the volume of questions, the rapid 5-item version can be administered in under one minute and may be considered to replace the commonly used query asked of parents, "Has your child ever been diagnosed with autism spectrum disorder?"

**414.056** (Poster) Normative Sample of the Alsolife Skills Assessment System and Comparisons to Children with Autism  
**B. Wang<sup>1</sup>**, X. Bai<sup>2,3</sup>, Z. Zhu<sup>2,3</sup>, X. Li<sup>2,3</sup> and F. Y. Lin<sup>1</sup>, (1)ALSOLIFE, Beijing, China, (2)Key Laboratory of Mental Health, Institute of Psychology, Chinese Academy of Sciences, Beijing, China, (3)University of Chinese Academy of Sciences, Beijing, China

Background: Research has supported the success of applied behavior analysis (ABA) in teaching children with autism spectrum disorder (ASD) in a variety of domains. However, given the critical shortage of ABA therapists in China, many parents of young children with ASD must prepare themselves to teach their children at home settings. To form a home-based ABA therapy, parents need a comprehensive assessment to evaluate all aspects of child development to generate a tailored educational plan to meet the child's unique needs and strength. The purpose of ALSOLIFE skills assessment system (ALSOLIFE Assessment) is to provide a free online tool for caregivers who wish to work with their preschool children with ASD at home settings. It comprises 6 skill-domains covering 22 skill subdomains (Fig 1) including various key skill sets across early childhood period. It has been tested with satisfied reliability and validity, but an evaluation of normative sample data will further strengthen the utility of ALSOLIFE Assessment.

Objectives: To examine typical child development across the 6 skill-domains and repertoires of the ALSOLIFE Assessment, we conduct the current study for providing a normative sample of the ALSOLIFE Assessment and a subsequent comparison to children with ASD.

Methods: We administered the ALSOLIFE Assessment to 376 neurotypically developing children (228 boys and 148 girls) with the ages ranged from 0.9 to 10.92 years from 29 of 34 provinces of China. To match age and sex with the normative sample, a total of 391 children (237 boys and 154 girls) diagnosed with ASD age from 1.5 to 9.85 were selected to participate in our study.

Results: There was a strong relationship between the ALSOLIFE Assessment total scores and ages in the normative sample ( $r = 0.77, p < 0.001$ ), and a cubic regression provided a strong fit for the data ( $R^2 = 0.82, p < 0.001$ ). In ASD sample, the results also showed a significant correlation between the ALSOLIFE Assessment total scores and ages ( $r = 0.64, p < 0.001$ ), while  $\beta$  value of cubic function didn't achieve the significant level ( $R^2 = 0.434, p = 0.089$ ) (Fig 2). For the normative sample, the children, by age of five, achieved full scores in two of six domains in skills repertoires of the ALSOLIFE Assessment: cognitive skills and social interaction skills. Then academic skills, social regulation skills and life skills arrived at the ceiling one year later. The living skills domain was the latest to be mastered completely by age seven (Fig 3).

Conclusions: The present data suggest that ALSOLIFE Assessment would be an useful tool offering present level information for practitioners at home settings.

#### 414.057 (Poster) Objective Assessment of Sensory Reactivity in Adnp Syndrome

C. F. Layton<sup>1</sup>, T. Levy<sup>1</sup>, S. M. Lurie<sup>1,2</sup>, N. Benrey<sup>1,2</sup>, J. Zweifach<sup>1</sup>, M. A. Rowe<sup>3</sup>, L. Tang<sup>4</sup>, S. B. Guillory<sup>1</sup>, D. Halpern<sup>1</sup>, I. Giserman-Kiss<sup>5</sup>, M. P. Trelles<sup>1</sup>, J. H. Foss-Feig<sup>1</sup>, T. Tavassoli<sup>6</sup>, J. D. Buxbaum<sup>7</sup>, S. De Rubeis<sup>8</sup>, A. Kolevzon<sup>1</sup> and P. M. Siper<sup>1</sup>, (1)Seaver Autism Center for Research and Treatment, Department of Psychiatry, Icahn School of Medicine at Mount Sinai Hospital, New York, NY, (2)Ferkau Graduate School of Psychology, Yeshiva University, Bronx, NY, (3)Department of Radiology and Biomedical Imaging, University of California, San Francisco, San Francisco, CA, (4)David Geffen School of Medicine at UCLA, Los Angeles, CA, (5)Neurodevelopmental and Behavioral Phenotyping Service, National Institutes of Mental Health, Bethesda, MD, (6)Centre for Autism, School of Psychology & Clinical Language Sciences, University of Reading, Reading, United Kingdom, (7)Department of Psychiatry, Icahn School of Medicine at Mount Sinai, New York, NY, (8)The Mindich Child Health and Development Institute, Icahn School of Medicine at Mount Sinai, New York, NY

**Background:** Sensory reactivity symptoms are prominent in individuals with autism spectrum disorder (ASD) and are incorporated into the Diagnostic and Statistical Manual of Mental Disorders, 5<sup>th</sup> Edition criteria for ASD. Sensory patterns include hyperreactivity (over-responsiveness), hyporeactivity (under-responsiveness), and sensory seeking, which can occur across multiple sensory modalities. There is a growing body of literature describing sensory symptoms in individuals with syndromic ASD, however, few studies have prospectively examined sensory symptoms using a battery of standardized assessments.

**Objectives:** To describe the sensory reactivity phenotype in children and adolescents with pathogenic variants in *activity dependent neuroprotective protein (ADNP)*. ADNP syndrome represents one of the most common single-gene causes of ASD.

**Methods:** One hundred seventy-eight individuals between the ages of 2 and 17 years old received a battery of standardized observations, caregiver interviews, and questionnaires measuring sensory reactivity. The Sensory Assessment for Neurodevelopmental Disorders (SAND), Short Sensory Profile (SSP), Autism Diagnostic Observation Schedule, 2<sup>nd</sup> Edition (ADOS-2), and the Autism Diagnostic Interview-Revised (ADI-R) were administered to all participants. Participants included 22 individuals with ADNP syndrome (10 female,  $M_{age}=7.72$ ), 109 with idiopathic ASD (iASD) (16 female,  $M_{age}=6.48$ ), and 47 controls (26 female,  $M_{age}=5.90$ ).

**Results:** All participants with ADNP syndrome presented with mild-to-profound ID and only half met DSM-5 criteria for ASD. All participants displayed clinically significant sensory symptoms on at least one measure and 91% (20/22) displayed sensory reactivity abnormalities on every measure. A distinct sensory phenotype was identified characterized by high levels of sensory seeking across tactile, auditory, and visual domains. On the SAND, mean total scores were  $>3$  SDs higher than TD norms ( $p < .0001$ ) and similar to overall iASD sensory abnormalities. Sensory seeking was  $>2$  SDs higher than the TD controls across visual, tactile, and auditory domains ( $p < .0001$ ), and approximately 1 SD higher than iASD in tactile and auditory domains ( $p < .0001$ ). ASD diagnosis and severity did not impact sensory symptoms identified by the SAND, SSP, or ADOS-2, indicating that the sensory phenotype in ADNP is generalizable across the syndrome, rather than driven by a subset with ASD. Cognitive functioning, adaptive behavior, age, and sex did not impact SAND or ADOS-2 scores, both of which capture direct observation of symptoms. Cognitive functioning, adaptive behavior, and age were correlated with several SSP scales, suggesting that the higher the cognitive or adaptive level and older the individual, the fewer abnormal sensory responses parents reported.

**Conclusions:** These findings demonstrate that sensory symptoms were present across individuals with ADNP syndrome regardless of age, sex, cognition, adaptive skills, and most importantly, irrespective of ASD diagnosis. Sensory symptoms, particularly seeking, appear to span the range of individuals with ADNP syndrome and can be quantified using existing standardized instruments. The SAND appears to be the most robust sensory assessment, independent of functioning level or age, unlike the SSP. The sensory domain may represent a relevant target for treatment in ADNP clinical trials, and clinically, can inform treatment recommendations based on an individual's unique sensory preferences.

**414.058** (Poster) Observed Sensory Modulation Behaviors and Their Relationship to Parent- and Child-Reports in Children and Adolescents with Autism Spectrum Disorder

**S. Ramappa**<sup>1,2</sup>, **J. Jung**<sup>2</sup>, **R. Chu**<sup>2</sup>, **K. K. Cummings**<sup>1</sup>, **G. Patterson**<sup>1</sup>, **M. Dapretto**<sup>2</sup>, **S. Y. Bookheimer**<sup>2</sup> and **S. A. Green**<sup>2</sup>, (1)University of California, Los Angeles, Los Angeles, CA, (2)Dept of Psychiatry and Biobehavioral Sciences, University of California, Los Angeles, Los Angeles, CA, (3)Growing Healthy Children Therapy Services, Inc., Rescue, CA, (4)Semel Institute of Neuroscience and Human Behavior, University of California, Los Angeles, Los Angeles, CA

---

**Background:**

Individuals with Autism Spectrum Disorders (ASD) often exhibit sensory modulation atypicalities (Leekam et al., 2007; Miller et al., 2017). Sensory modulation challenges include Sensory Over-Responsivity (SOR): exaggerated negative responses to aversive sensory input, Sensory Seeking (SS): craving a higher level of sensory input, and Sensory Under-Responsivity (SUR): reduced responses to sensory input (McCormick et al., 2015). Currently, the vast majority of ASD sensory modulation studies use parent-report questionnaires, and there is a strong need to develop standardized observational assessments of sensory processing challenges, particularly those that can be used across a wide range of ages, including adolescents.

**Objectives:**

To investigate how an observed behavioral assessment of sensory processing atypicalities differentiated ASD compared to typically-developing (TD) school-aged children and adolescents, as well as to examine correlations between observed behavior and parent- and child-report of sensory symptoms.

**Methods:**

Forty-one ASD and 33 age- and performance-IQ-matched TD participants, aged 8-17 years participated in the Sensory Processing 3-Dimensional (SP3-D) Assessment (Mulligan et al., 2019). This study examined responses to the tactile, visual, and auditory sensory modulation items. Sensory stimuli were designed to be ecologically valid (e.g., bright flashing lights, musical instruments, scratchy materials). Participants' responses to the sensory stimuli were then scored as typical or atypical for each item using standardized scoring, based on showing any aversive response/avoidance (SOR), difficulty disengaging (SS), or lack of expected negative response (SUR). Participants and parents completed the SP3-D Inventory (Miller et al., 2017) to report on participants' SOR, SS, and SUR.

**Results:**

Compared to TD participants, the ASD group had more atypical SOR ( $t(72)=-2.49, p=0.02$ ) and SS ( $t(72)=-2.48, p=0.02$ ) responses across visual, tactile, and auditory domains on the SP3-D Assessment. Within both ASD and TD groups, child-reported SS was moderately correlated with visual and auditory seeking on the SP3-D assessment ( $r=0.33, p=0.04$ ;  $r=0.38, p=0.02$ ). There were no significant correlations between parent-reported and observed sensory processing. For both diagnostic groups, younger children showed greater SS and SOR observed scores. Within the adolescents only (13 to 17-year-olds), diagnostic group differences were found in tactile SOR ( $t(43)=-2.467, p=0.018$ ) but not in SS, potentially indicating that seeking decreases with age more than SOR does for the ASD group.

**Conclusions:**

Here, we showed that the SP3-D Assessment of SOR and seeking behaviors differentiated ASD and TD diagnostic groups across a large age range of youth with cognitive skills in the normal range. Within an adolescent-only sample, SOR, particularly in the tactile domain, revealed the strongest diagnostic group differentiations, consistent with reports that tactile stimuli are among the most bothersome for individuals with ASD (Tomchek & Dunn, 2007). Additionally, the low correlations between questionnaire reports and direct observations are consistent with previous literature (Tavassoli et al., 2019); this further highlights the importance of combining questionnaires and observed data to form a more complete understanding of individuals' sensory processing. Results suggest the SP3-D assessment may provide further insight into SOR over and above child- and parent-reports, but future research is needed to determine how questionnaire and direct assessment data can best be combined.

**414.060** (Poster) Online Administration of the ADOS for Research in Response to the Pandemic

**I. M. Eigsti**<sup>1</sup>, **R. P. Thomas**<sup>1</sup>, **A. Mohan**<sup>1</sup>, **M. J. Stabile**<sup>1</sup>, **M. F. Dieckhaus**<sup>1</sup>, **J. Crutcher**<sup>2</sup>, **E. Taverna**<sup>3</sup> and **D. A. Fein**<sup>1</sup>, (1)Psychological Sciences, University of Connecticut, Storrs, CT, (2)NIMH, Bethesda, MD, (3)Department of Psychological Sciences, University of Connecticut, Storrs, CT

---

**Background:** Coronavirus-related restrictions present novel barriers to research and have led to the use of online data collection methods. In addition, there is a need for telehealth diagnostic tools to serve individuals in remote locations and with few expert service providers. Adult diagnosis is increasingly in demand (Howlin & Moss, 2012). To address these clinical service gaps, it is critical to develop online methods to reliably capture ASD symptomatology. Two prior studies compared in-person versus remote assessments; however, both required in-person staff support at the client site, as well as special technology.

**Objectives:** This study evaluates the reliability and validity of an online administration of the ADOS-2 Module 4 assessment, implemented without specialized equipment or on-site clinical or technical staff.

**Methods:** Twenty-nine adults ages 19-32 years with and without a history of autism spectrum disorder (ASD) completed a videoconference session during which the adapted version of the ADOS-2 was administered; they also completed the Autism Spectrum Quotient (AQ) via Qualtrics as a measure of self-reported ASD symptomatology. Parents or caregivers completed the Vineland Adaptive Behavior Scales and the Achenbach Adult Behavior Checklist to provide parental impressions of the participant's current social and communicative functioning. The ADOS-2 was reviewed and scored by trained clinicians.

Modifications to the ADOS included: a gaze calibration procedure; online presentation of scanned versions of the Cartoons and Picture Description tasks; sending of Tuesday books and the Creating a Story objects by snail mail, in advance; and omission of the optional Construction and Break activities.

**Results:** The videoconference sessions went smoothly; problems were infrequent and easily resolved. Inter-rater reliability in scoring the ADOS-2 was "substantial" ( $k = .67$ ). ADOS item-based analyses indicated reliabilities ranging from .67 to 1.0, with an average of .86. Items that were expected to yield low reliability given prior research (Eye contact; Repetitive mannerisms) were, in fact, highly reliable. Correlational analyses of the ADOS with the AQ ( $r(24) = .52^{**}$ ), VABS (Communication,  $r(22) = -.79^{***}$ ; Socialization,  $r(22) = -.65^{***}$ ), and Achenbach (Friends scale,  $r(23) = -.70^{***}$ ) suggested that the online ADOS-2 results showed significant convergence with other assessments of ASD-relevant symptoms and characteristics.

**Conclusions:** The on-line ADOS-2 was highly reliable, and correlated highly with parent-report measures of socialization, communication, and friendships. It also correlated highly with the individual's autism scale self-report (AQ), suggesting that participants' own assessments of their autistic traits were consistent with clinician impressions. Altogether, the substantial reliability of scores, together with the convergence of results with external measures, suggests that this method is effective for ascertaining ASD behaviors in a verbal adult population. While any online assessments must be used with caution, the approach described here has sufficient validity and reliability to fill current urgent clinical and research needs.

**414.061 (Poster) Pain Anticipation and Empathy for Pain Towards Social and Non-Social Agents in Adults with ASD: A Novel Psychophysiology Artificial Neural Networks Based Study**  
*J. De Angelis<sup>1</sup>, P. Ricciardelli<sup>2</sup> and E. Grossi<sup>3</sup>, (1)Psychology, University of Milano-Bicocca, Milano, Italy, (2)Psychology, University of Milano - Bicocca, Italy, Milano, Italy, (3)Autism Research Unit, Villa Santa Maria Foundation, Tavernerio, Italy*

---

**Background:**

Although abnormal pain sensitivity has become one of the diagnostic criteria for Autism Spectrum Disorder (ASD), this area is still under-investigated. Specifically, a very few studies focused on the anticipatory components characterizing pain experience related to self and others in ASD.

**Objectives:**

The present study was aimed at investigating psychophysiological responses in adults with High Functioning Autism (HFA) when observing a painful stimulus approaching (pain anticipation) their own skin (self-condition), another participant skin (other social agent condition) or a robotic hand (other non-social agent condition).

**Methods:**

Skin Conductance Responses (SCR) were measured in a group of adult participants with ASD diagnosis and a control group of participants without any psychiatric or neurological diagnosis. The experimental sessions consisted of a naturalistic paradigm where the participants observed a painful (sterilized needle) or a neutral (cotton bud) stimulus that could approach their own skin, the skin of another person or the hand of a robot (Figure 1). Data were analysed by implementing a new Machine Learning

approach combining predictive modelling (i.e. Artificial Neural Networks) and Auto-Contractive Maps, that is an emerging data mining approach able to detect connectivity associations among variables through an artificial adaptive system.

Results:

The predictive model was 91% accurate and able to differentiate ASD participants from control group participants. Two distinct patterns were found for each group. Specifically, ASD individuals exhibited a lower physiological activation than controls when the noxious stimulus (needle) approached their skin after repeated stimulations. Interestingly, ASD participants showed a higher response when the robotic hand was approached by the painful stimulus, whereas no differences related to the human social agent between the two groups emerged.

Conclusions:

These results can contribute to clarifying the psychophysiological mechanisms underlying pain experience in ASD individuals. Implications for the study of the self-injury phenomenon, often observed in ASD, will be discussed.

**414.062 (Poster) Parent Concerns of Infants at Familial Risk for Autism during the COVID-19 Pandemic**

**G. MacNaughton<sup>1</sup>, A. Tran<sup>2</sup> and S. Jeste<sup>3</sup>, (1)UCLA Semel Institute, Los Angeles, CA, (2)David Geffen School of Medicine at UCLA, Los Angeles, CA, (3)University of California, Los Angeles, Los Angeles, CA**

---

Background: A diagnosis of autism spectrum disorder (ASD) in an older sibling increases the risk of developing ASD in infant siblings (HR; 15-20%). Parental concerns can help determine if their children should be monitored and screened. Caretakers of HR infants may be particularly sensitive to developmental red flags given they have older children with ASD. Prospective studies among HR infants showed that parent concerns at 12 and 24 months predicted later ASD diagnoses. The COVID-19 pandemic poses new challenges for families of children with neurodevelopmental disabilities, including the suspension of in-person learning and navigating intervention access. Despite these hardships, caretakers can now closely observe their HR infants. Given the value of parent concerns and the unique situation that the pandemic has placed upon families, we investigated their intersection.

Objectives: To examine parent concerns of HR infants before and during the COVID-19 pandemic and assess their agreement with a validated developmental screening tool.

Methods: Parents of HR infants reported concerns about development and behavior at 18-months ( $n=31$ ; male=15, female=16) as part of a longitudinal study. A coding system using inductive analysis categorized responses into (1) ASD-related (restrictive and repetitive behaviors [RRBs], speech/language, social, unspecified ASD), (2) General (motor/sensory, medical, behavior/temperament, general development), and (3) Total Concerns (the sum of ASD-related and General). Two blinded research members coded the data and discrepancies were discussed to reach consensus. The Modified Checklist for Autism in Toddlers, Revised, with Follow-up (M-CHAT-R/F) screened for delays and ASD. Infants were grouped as “pre-COVID” ( $n=13$ ) or “COVID” ( $n=18$ ) to evaluate concerns at each respective time point.

Results: The majority of parents during COVID (78%, 14/18) and nearly half pre-COVID (46%, 6/13) disclosed concerns about their HR infants at 18 months (see Figure 1). Of ASD-related concerns, the COVID group most commonly reported worries about speech/language (56%, 9/16) and the pre-COVID group reported equally high proportions of speech/language and RRBs concerns (36%, 5/14). Regarding general concerns, motor/sensory were highest for both groups (COVID: 47%, 8/17; pre-COVID: 71%, 5/7). Parents in the COVID group reported a greater proportion of general concerns than the pre-COVID group;  $\chi^2(2, 31)=3.90, p<.05$ . No differences in ASD-related or total concerns were observed, although the latter approached significance. ASD-related concerns and MCHAT-R/F scores had a significant moderate positive correlation across time points (see Figure 2);  $r(29)=.675, p<.001$ .

Conclusions: During COVID-19, parents of 18-month-old HR infants predominantly expressed worries in speech/language and motor/sensory domains. Findings indicate that parents are highly attuned to their infants' development and may be recognizing more subtle delays as they are with their infants more often during COVID-19 restrictions. Furthermore, concerns across time points were in agreement with a developmental screening measure, highlighting their potential clinical validity. Caretakers' ability to accurately detect early delays in their infants could assist in receiving evaluations and services during the pandemic. Higher-powered studies should further investigate the nature and value of parent concerns of HR infants, especially during this unprecedented time when access to diagnostic assessments is limited.

**414.063** (Poster) Parental Experiences with Early Identification and Initial Care of Their Child with Autism. a Mixed-Method Design

**M. Snijder**<sup>1,2</sup>, **I. Langerak**<sup>3</sup>, **S. Kaijdoe**<sup>4</sup>, **J. K. Buitelaar**<sup>5</sup> and **I. J. Servatius-Oosterling**<sup>1</sup>, (1)Karakter Child and Adolescent Psychiatry University Centre, Nijmegen, Netherlands, (2)Radboud University Medical Centre, Donders Institute for Brain, Cognition and Behavior, Nijmegen, Netherlands, (3)Karakter, kinder-en jeugdpsychiatrie, Nijmegen, Netherlands, (4)Karakter Child and Adolescent Psychiatry University Center, Nijmegen, Netherlands, (5)Department of Cognitive Neuroscience, Donders Institute for Brain, Cognition and Behaviour, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands

---

**Background:**

Due to multiple benefits, early identification of autism spectrum disorder (ASD) has been deemed a priority over the last years. The experiences of parents regarding the diagnostic process of ASD are well documented (Boshoff et al., 2018; Crane et al., 2016), but less is known about their experiences with the process of early identification and initial care. Since early identification generally starts with parents expressing their concerns regarding their child's development, it is highly important that their experiences and perspectives of the process are better understood.

**Objectives:**

The current study aims to explore parental experiences with the process of early identification and received initial care for their child with ASD.

**Methods:**

A mixed-method design was conducted. First, an online survey was completed by 45 parents (39 birthmothers, 6 birthfathers). They were asked to share their initial concerns of their child having ASD and their search for adequate care. Participants rated on a five-point Likert scale (with 1 being *not concerned* and 5 being *very concerned*) how severe initial concerns were for mothers, fathers and first line healthcare professionals. A paired samples t-test was conducted to compare the severity of concerns between parents and professionals. Also, the average time delay between initial concerns and receiving an ASD diagnosis was calculated, together with the average number of visited healthcare professionals. Next, an additional focus group (n=10) was held to gain more in-depth insights into perceived barriers and improvement strategies for early identification and initial care. Grounded theory was used to analyze the focus group data (Glaser & Strauss, 2017).

**Results:**

Results indicated that a) parents seemed to report a higher severity of initial concerns (M=3.64, SD=.89) than first line healthcare professionals (M=2.55, SD=1.10,  $t(41), p < .001$ ). Specifically, mothers (M=3.89, SD=.98) compared to fathers (M=3.27, SD=1.03), experienced the most severe concerns ( $t(42), p=.001$ ); b) there was an average delay of 26 months between initial concerns (M=22, SD=12.96) and receiving an ASD diagnosis for their child (M=48, SD=15.35); c) parents visited a wide range (0-6) of healthcare professionals before their child's diagnosis, with an average of 2.5; d) parents experienced the following barriers during the process of early identification and initial care: limited professional knowledge & expertise, limited personal attention to parental needs, obstacles in the healthcare system (e.g. inflexibility, waiting lists and fragmentation of care); e) parents suggested the following improvement strategies: additional training to improve professional's knowledge & expertise on the early symptoms of ASD and have attention to parental needs by acknowledging parental concerns instead of dismissing them. Parents also suggested strategies to target the obstacles in the healthcare system by improving the collaboration between first line healthcare and specialized mental healthcare.

**Conclusions:**

Taken together, these findings indicate that the process of early identification and initial care can be challenging for parents. Overall, there seems to be a risk that parents initial concerns can be dismissed during initial care, contributing to an overall delay in the early identification of ASD. Implication of findings will be discussed.

**414.064** (Poster) Parental Knowledge in Screening for Autism Spectrum Disorder

**J. A. Rankin**<sup>1</sup>, **T. S. Tomeny**<sup>2</sup> and **A. M. Birnschein**<sup>2</sup>, (1)Department of Psychiatry, University of Pennsylvania, Perelman School of Medicine, Philadelphia, PA, (2)Psychology, The University of Alabama, Tuscaloosa, AL

---

Background: Parent-report screening tools (e.g., the Modified Checklist for Autism in Toddlers – Revised; M-CHAT-R; Robbins et al., 2014) are widely used to aid timely diagnosis of autism spectrum disorder (ASD), which is associated with improved outcomes for children with ASD (e.g., Charman & Baird, 2002). Whereas some parents notice symptoms of ASD as early as 14 months of age, many parents first notice symptoms much later (Chawarska et al., 2007), leading to delays in age of first diagnosis (Baio et al., 2018). When rating ASD symptoms, parents tend to display some inaccuracy (Baranek, 1999), and this inaccuracy may vary across different items that measure different aspects of ASD (Hampton & Strand, 2015). Low knowledge about ASD among parents may contribute to inaccuracy in recognizing symptoms of ASD (Daniels & Mandell, 2014).

**Objectives:** This study sought to test whether parents accurately identify atypical behaviors when shown behaviors characteristic of ASD and to understand how parental knowledge of ASD symptoms relates to parents' abilities to accurately identify these behaviors.

**Methods:** 288 parents ( $M_{\text{age}} = 34$ ,  $SD_{\text{age}} = 8$ ; 52% Female; 58% White) of children 18-30 months old participated. Parents completed measures of child development knowledge, ASD knowledge, and parental self-efficacy. Next, parents viewed videos (~5 minutes each) of two children with ASD (one scored 'Moderate' on the ADOS-2 and one scored 'Severe') and rated each child's behavior on a modified version of the M-CHAT-R. Ratings were compared to two clinicians' ratings of the same children for accuracy. Item response theory assessed whether parents accurately identified behaviors characteristic of ASD and how difficult each behavior was for parents to rate accurately. Structural equation modeling (SEM) examined which factors related to parental accuracy.

**Results:** Parental accuracy ranged from 38% to 97% across items. 79% of items yielded a negative IRT item difficulty parameter, with no difficulty parameters greater than 0.380, suggesting that most items were classified as Easy or Very Easy difficulty (Baker & Kim, 2017). SEM results indicated that accuracy in identifying "moderate" symptoms of ASD ( $R^2 = .218$ ) was related to greater Parent Knowledge ( $\beta = .184$ ,  $p = .004$ ), greater number of children raised ( $\beta = .158$ ,  $p = .020$ ), and greater parental self-efficacy ( $\beta = .202$ ,  $p = .005$ ). Accuracy in identifying "severe" symptoms of ASD ( $R^2 = .647$ ) was related to greater Parental Knowledge ( $\beta = .463$ ,  $p < .001$ ), less parental education ( $\beta = -.263$ ,  $p < .001$ ), and greater parental self-efficacy ( $\beta = .513$ ,  $p < .001$ ).

**Conclusions:** This study found that the majority of behaviors characteristic of ASD assessed during the screening process were easy or very easy for parents to correctly identify. Greater parental knowledge of child development norms and knowledge of ASD helped parents to accurately identify symptoms of ASD, particularly when these symptoms were severe. Results of the current study help to highlight a fundamental challenge in screening, wherein more severe symptom presentations of ASD may be easier for parents to identify, while milder, less severe symptom presentations of ASD may be more difficult for parents to identify.

#### **414.065 (Poster) Parenting Stress in Mothers and Fathers of Children Who Have Autism Spectrum Disorder or Intellectual Disability**

**S. Patel<sup>1</sup>**, **M. Rivard<sup>2</sup>**, **C. Mello<sup>3</sup>** and **D. Morin<sup>4</sup>**, (1)Psychology, Université du Québec à Montréal, Montreal, QC, Canada, (2)Psychology, Université du Québec à Montréal, Montréal, QC, Canada, (3)Applied Psychology, The Pennsylvania State University, University Park, PA, (4)Université du Québec à Montréal, Montréal, QC, Canada

---

**Background:** A large body of literature has demonstrated that parents who have a child with a developmental disability such as autism spectrum disorder (ASD) or intellectual disability (ID) experience higher levels of stress compared to parents of typically developing children (Hayes & Watson, 2012). Some characteristics that contribute to parental stress include problem behaviors, autism symptom severity, and lower adaptive functioning. Other stressors that can also impact aspects of the family include financial difficulty and trouble accessing services (Mello et al., 2019). Thus, developmental disabilities have repercussions for both children and their parents. However, much of the research has focused on mothers in the family only, with less attention devoted to fathers and both parents. Stress in both parents is necessary to address, because the couple who has a child with a developmental disability is particularly disadvantaged; these stressors can negatively affect couples' relationships and partner satisfaction, ultimately leading to divorce (Bluth et al., 2013).

**Objectives:** Therefore, the current study aimed to (1) provide a descriptive comparison of mother and father stress upon examination of family demographics and characteristics and (2) investigate how mother and father stress are associated with each other when taking into account children's clinical profiles.

**Methods:** Participants included fifty-nine mothers and fathers from Quebec, Canada, who recently received an ASD or ID diagnosis for their child ( $M_{\text{age child}} = 4.29$  years). They completed measures assessing family demographics (e.g., education, income, employment, number of children, immigration), parenting stress (Parenting Stress Index; Abidin, 2012), and child intellectual functioning (Wechsler Preschool and Primary Scale of Intelligence-IV; Wechsler, 2012), adaptive behavior (Adaptive Behavior Assessment System-II; Harrison & Oakland, 2003), behavioral and emotional problems (Child Behavior Checklist; Achenbach, 1991), and symptom severity (Childhood Autism Rating Scale; Schopler et al., 1980).

**Results:** Although mothers' and fathers' stress did not differ within families, one-way ANOVAs demonstrated that they were each significantly linked to different family characteristics. Furthermore, correlations between parent and child variables demonstrated significant associations between mother stress, father stress, and child characteristics. To assess these relations

further, parent and child variables were entered into hierarchical multiple regression models. The results showed that mothers and fathers accounted for unique variance in each other's stress above and beyond family-level and child-level predictors.

Conclusions: Findings are discussed in terms of orienting services for the entire family; for instance, in addition to tending to their children's needs, parents may also be able to support each other in their own difficulties. The results from the current study demonstrate that mothers and fathers seem to have different types of stressors, thus working together may help couples manage and alleviate the stress that they experience when raising a child with a developmental disability.

**414.066** (Poster) Pediatrician Referral Practices for Early Self-Injury in Young Children with Intellectual and Developmental Disabilities

**J. Fodstad**<sup>1,2</sup>, **J. Mehringer**<sup>3</sup> and **N. Scheive**<sup>1</sup>, (1)Indiana University School of Medicine, Indianapolis, IN, (2)Indiana University Health Physicians, Indianapolis, IN, (3)Indiana University Purdue University - Indianapolis, Indianapolis, IN

---

Background: Self-injurious behavior (SIB) is a class of non-suicidal behavior defined as repetitive physical acts performed on one's body that may inflict tissue damage (e.g., head banging, face slapping, and hair pulling).<sup>1</sup> It is most commonly used to gain attention, avoid undesirable situations, or act as a form of communication. Children with intellectual and developmental disabilities (IDD) demonstrate SIB at higher rates. When SIBs emerge in young children, families commonly view their primary care pediatrician (PCP) as one of the first points of contact for support and assistance.

Objectives: The goal of this analysis is to consider current referral practices and recommendations of PCP's who evaluate children with IDD exhibiting SIB. Utilizing a chart review, we examined the frequency and quality of PCP recommendations for children with IDD and SIB to investigate primary care SIB management from the time of initial concern to specialty referral as recommended by the American Academy of Pediatrics (AAP).

Methods: Two hundred and fifty children meeting study criteria (i.e., 10 - 59 months of age; had an ICD-10 developmental disability in their pediatric primary care electronic health record (EHR); and documented parent concern of SIB in at least two separate clinical notes) were randomly selected. The following data was extracted from the EHR: patient age at first parent SIB concern, ethnicity, and ICD-10 primary diagnosis. Clinical notes were reviewed prior to and after parents' first SIB concern was documented until the patient was referred to an appropriate specialist, the SIB resolved, or until the last recorded pediatrics primary care note during the chart review (conducted 3/2020 – 6/2020). Other data extracted were: if a referral was made, if an SIB-related injury beyond general redness (e.g., swelling, laceration, bleeding, etc.) had occurred, and SIB-specific recommendations provided by the PCP. When documented, a list of SIB-specific recommendations was tabulated.

Results: The majority of the sample (mean<sub>age</sub> = 27.7 months; SD = 12.4 months) were white (65.2%), male (75.2%), had delayed speech (57.2%), and engaged in headbanging (82.4%). No child experienced a SIB-related significant injury. Only two children had a clear remission of SIB. Out of the 250 children whose parents expressed concerns regarding early SIB, only 8.0% (n = 20) were referred by their PCP to an appropriate specialist per AAP guidelines. Across those 20 children, the average time from first parent concern to initiation of a SIB-specific and appropriate referral was 6.7 months (SD = 5.1 months). No specific recommendations to address SIB were provided to 157 (62.8%) children. For the other 93 (37.2%) children, SIB recommendations were present but varied widely.

Conclusions: Outcomes from the data suggest that only an extremely small portion (8%) of young children with delays and early SIB received AAP recommended intervention via referral to subspecialty providers by their PCP. More research should be done with larger samples or with more well-developed data collection paradigms in an attempt to gain a better understanding of PCP practices for evaluation and treatment of early SIB in this patient population.

**414.067** (Poster) Phenotypic Sex Differences and Sex Ratio in Latin-American Children with Autism

**A. Torres** and **C. Nava**, *Psychological Science, University of Texas Rio Grande Valley, Edinburg, TX*

---

Background:

Latin-American children are under-represented in autism research dealing with identification of sex differences in the expression of symptoms. Researchers have identified that adaptive function manifest differently in cross-cultural samples with ASD. Furthermore, it is not strongly predicted by the autism symptom severity in Asian children. This contrasts with the findings in white American children, where adaptive impairment is a direct function of standardizing autism symptom severity. This is critical because both severity and adaptive profiles are utilized for diagnostic, service referral, and intervention programming.

Objectives:

The purposes of this study were to identify the symptom severity, adaptive function, and intellectual profiles of Latin-American children; and to identify the relationship between autism symptom severity and adaptive function in a clinical Venezuelan children population with ASD after controlling for age and intelligence.

#### Methods:

One-hundred and three children from a clinical sample in Maracaibo, Venezuela were included in this study. Ages ranged from three to seven years,  $X=4.6$  (1.4). ASD symptom severity was measured by the Autism Diagnostic Observation Schedule (ADOS), adaptive function via the Vineland Adaptive Behavior Scale (VABS), and intelligence by the Raven Matrices, which measure non-verbal intelligence to control for cultural and linguistic factors. A psychologist confirmed ASD diagnosis as per the diagnostic criteria of the DSM-V-TR. The final sample revealed a boy: girl ratio of 3.91:1. All measures were administered in Spanish.

#### Results:

Independent samples T-test revealed not-significant sex differences in autism symptom severity, adaptive function, and intellectual profiles. Four multiple regression models were designed and used global symptom severity, intelligence, and age as predictors to each of the four domains of adaptive function as per the VABS. Symptom severity was not a significant predictor for adaptive function.

#### Conclusions:

This study echoes with research identifying no sex differential in autism, specifically in pre-school and early-school aged children. This sample's sex ratio was similar to that from the CDC's 2020 general population. autism sex ratio. These findings also supplement the limited cross-cultural research identifying a weak or nonexistent relationship between autism symptom severity and adaptive function in Asian children. The overall findings indicate that culture could play a role in the manifestation in the ASD profile or their parent interpretations. Females with ASD typically report lower cognitive profiles compared to boys. In this study, that was not the case, indicating that such differences could be better accessed with non-verbal IQ, which controls language and cultural influences, or with a comprehensive measure of cognitive profile. This is the first study to provide a comprehensive profile of children with autism from Latin-America. Nonetheless, future research should address these scales' psychometric validity; further research is needed to formulate an ASD evaluation process that controls for sex and cultural differences in children with ASD.

#### **414.068** (Poster) Practitioners' Experiences in Assessing Females with Autism

*N. C. Freeman<sup>1</sup> and P. Paradis<sup>2</sup>, (1)Faculty of Education, Monash University, Monash University, VIC, Australia, (2)Krongold Clinic, Monash University, Monash University, Clayton, VIC, Australia*

---

**Background:** The process of obtaining a diagnosis among females is likely to be a different, more protracted process than for males. Several explanations have been suggested to explain this phenomenon, including the social camouflage theory which delays identification, a lack of assessment/screening measures that are sensitive to the female phenotype, and a higher potential for misdiagnosis or missed diagnosis.

**Objectives:** To explore the training received, assessment practices and diagnostic taxonomies used, and confidence in assessment and diagnosis when assessing autism in females among practitioners in Australia.

**Methods:** 135 practitioners completed an online survey and seven psychologists participated in a semi-structured interview conducted via Zoom.

**Results:** Speech pathologists were more likely to report receiving no training in their course around diagnosing autism, but most practitioners reported that diagnosing autism in females specifically was rarely addressed (74.2%). Practitioners said their practice in the assessment of females was most significantly influenced by the current diagnostic criteria (87.9%), the reliability/validity of the assessment tools they use (78.5%), and professional development they have attended in the last 5 years (71.3%). Almost all practitioners used the DSM-5. The most common assessment components used were conducting an interview with the parents and a standardised autism assessment. The ADOS was the most commonly used tool, with only one practitioner saying they would only use the ADOS for assessing males. Psychologists and speech pathologists were more confident than paediatricians in diagnosing adult females, but confidence levels were similar across clinicians for other age groups. In the interviews, the main themes that emerged were: the female phenotype; the assessment process; missed diagnoses and misdiagnoses; applying the diagnostic criteria; and the need for more training.

Conclusions: While the female autism phenotype is gaining traction in research, the theory-practice gap is still evident. While most practitioners reported receiving training in diagnosing autism, the notion that gender differences may exist was often not addressed and subsequently shaped the practices of many practitioners in their early years. While practitioners reported that more recent professional development offerings have influenced their assessment practice, interviewees emphasized that finding relevant training was difficult. The interviewees identified that the current assessment tools available are less sensitive in detecting traits associated with the female phenotype. While the survey identified the ADOS as the most widely used tool, several interviewees described how they modified the protocol when assessing females. While it is positive that practitioners felt fairly confident in their assessment practices, the identified need for more training and more valid assessment tools for females that can be used “as is” (not modified) suggests that there is still scope for improvements in these areas to minimise misdiagnosis and missed diagnoses.

**414.069** (Poster) Predicting Diagnosis of Autism Spectrum Disorder Using Health Claims Data in Young Children  
**Y. H. Chen<sup>1</sup>, Q. Chen<sup>1</sup>, L. Kong<sup>2</sup> and G. Liu<sup>2</sup>,** (1)Industrial and Manufacturing Engineering, The Pennsylvania State University, State College, PA, (2)Penn State College of Medicine, Hershey, PA

---

Background: Early diagnosis and intervention are keys to improve long-term outcomes of children with autism spectrum disorder (ASD). Universal screening has been advocated to improve early ASD identification, but could be challenging to implement widely in practice due to limited clinical resources of screening and diagnostic evaluations. Pre-identifying high-risk individuals for a risk-based screening could utilize clinical resources more effectively; however, there lacks a systematic approach for assessing ASD risk of young children prior to the screening in pediatric care settings.

Objectives: To predict the ASD risk in children between 18- and 30-month-old using medical insurance claims data.

Methods: Using the 2005-2016 MarketScan® database, we retrospectively created a study cohort of young children with and without ASD. The inclusion criteria of ASD subjects included: (1) at least 2 outpatient or 1 inpatient ASD diagnoses (ICD-9 codes 299/ICD-10 codes F84); and (2) continuous enrollment during age 3-30-month-old. For non-ASD subjects, we required continuous enrollment from age 3-60-month-old to exclude possible ASD subjects that remain undiagnosed due to limited follow-up time (**Figure 1**). We extracted variables of demographics (gender, age, etc.), number of emergency department (ED) visits, and number of diagnosis and procedure encounters up to 24-month-old to predict risk of ASD diagnosis. For better clinical interpretability, we aggregated the diagnosis and procedure codes using Clinical Classification System. We employed two machine learning models, Lasso logistic regression (LR) and random forest (RF), which were trained on a balanced sample of the cohort (N=20,000, ASD:non-ASD=1:1) and tested on an independent sample with the same prevalence of ASD in the general population (N=16,123, ASD:non-ASD=1:54). To evaluate the prediction performance, we estimated sensitivity, specificity, positive predictive value (PPV), and the area under receiver operating characteristic curve (AUROC). We also compared the risk prediction at different post-birth window at the end of 18- and 30-month, respectively.

Results: We identified 12,743 ASD subjects and 25,833 non-ASD subjects in total. At the age of 24-month, our prediction models achieved similar performance with AUROC of 0.752 (95% Confidence Interval [CI]: 0.745-0.759) by LR and 0.766 (0.759-0.773) by RF (**Table 1**). When the sensitivity target was 50%, the LR prediction model showed the specificity of 83.1% (82.1-84.2%) and PPV of 5.2% (4.9-5.5%), equivalent to 3.1 times of the baseline ASD risk in general population; the RF model showed a higher specificity of 95.5% (95.0-96.0%) and PPV of 12.1% (11.1-13.1%). As the sensitivity threshold increased, specificity and PPV decreased in both models. Comparing the ASD prediction models at ages of 18, 24, and 30-month-old, we found that the prediction accuracy increased as more claims data were available for model training at an older age. Both models identified clinically meaningful variables such as gender, ED visits, upper respiratory infections and otitis media as key predictive factors.

Conclusions: Our study demonstrated the feasibility and promising performance of predicting ASD diagnosis using machine learning models and healthcare claims data. Our findings highlighted the potential of risk-based screening strategies in a more targeted manner. Further research in determining the effective risk cut-off is warranted.

**414.070** (Poster) Psychometric Analysis and Measurement Invariance of a Measure of Challenging Behavior in Infants and Toddlers with Autism Spectrum Disorder  
**T. L. Benninger<sup>1</sup>, A. Witwer<sup>2</sup> and M. Norris<sup>1</sup>,** (1)Child Development Center, Nationwide Children's Hospital, Westerville, OH, (2)The Ohio State University, Columbus, OH

---

Background: Individuals diagnosed with Autism Spectrum Disorder (ASD) often present with high rates of challenging behavior. Similar to school-aged children, many early-identified children present with challenges such as emotional dysregulation and

behavior problems. While previous research has adeptly described the occurrence of challenging behaviors in adolescents and school-aged children, there is inadequate information available on young children with ASD.

**Objectives:** This study examines novel psychometric elements of a commonly used measure of challenging behavior, the Child Behavior Checklist (CBCL) in a group of young children diagnosed with ASD.

**Methods:** Charts from 496 children aged 18-48 months with and without a diagnosis of ASD were reviewed. Psychometrics of the CBCL were analyzed including internal consistency, factor structure, and measurement invariance. The current study examines the previously established hierarchical factor structure of the CBCL with 2 higher-order factors (internalizing and externalizing), each with respective lower order factors (subscales). Measurement invariance (MI) was then evaluated, comparing 'non-ASD' and 'ASD' groups. MI is typically assessed through multigroup confirmatory factor analyses, which examines changes in various goodness-of-fit indices as increasing constraints are imposed on the models.

**Results:** Internal consistency values were strong for externalizing, internalizing and total problems subscales for the CBCL in the both groups. Results from the CFA indicated acceptable fit for the tested model with 6 first-order factors and 2 second-order factors. All three levels of measurement invariance were tested for each subscale. The Emotional Reactivity, Anxious/Depressed, Withdrawn, and Aggressive Behavior subscales achieved scalar invariance, while the Attention Problems subscale achieved metric invariance and Somatic Complaints subscale did not achieve configural invariance.

**Conclusions:** The CBCL had strong internal consistency in both ASD and non-ASD samples, congruous with scores from the normed sample, implying reliability among the subscales and higher-order factors. This study is one of the first to evaluate the factor structure of the CBCL in a large, well-characterized sample of young children with ASD. Standardized item loading values indicated that the existing factor structure had good convergent validity. Good model fit indicates the CBCL constructs of challenging behavior in young children with ASD is consistent with the nature of the previously conceptualized constructs. These findings support the use of the CBCL in a clinical setting to assess level of challenging behavior in young children with ASD. With regard to MI, a sufficient level of invariance was established for the Emotionally Reactive subscale, Anxious/Depressed subscale, Withdrawn subscale, and Aggressive Behavior subscale, implying the subscales measure the constructs in similar ways that the resulting scores can be compared across groups. Due to the lack of scalar invariance on two subscales, using only item level data is appropriate when comparing children with and without ASD on the Somatic Complaints, and Attention Problems subscales. Overall, results demonstrate support for the construct validity of the CBCL in young children with ASD. In conclusion, the CBCL can be considered a reliable instrument for identifying challenging behavior in young children with ASD. This information can then be used to inform intervention planning and direct treatment goals.

**414.071 (Poster)** Relationship between Social Impairment and Sensory Patterns Assessed with the Italian Sensory Profile 2 in Children with Autism Spectrum Disorders

**I. Basadonne<sup>1</sup>, C. Iannaccone<sup>1</sup>, R. Atzei<sup>2</sup>, R. Tancredi<sup>3</sup> and P. Venuti<sup>1</sup>,** (1)Department of Psychology and Cognitive Science, University of Trento, Rovereto, Italy, (2)NPM Bambini in Movimento SCS, Firenze, Italy, (3)IRCCS Stella Maris Foundation, Pisa, Italy

**Background:** Given the high prevalence of sensory peculiarities in Autism Spectrum Disorders (ASD), the availability of a standardized and agile tool for their assessment is crucial. In Italy, this was missing until our recent publication of the Italian adaptation of Dunn's Child Sensory Profile 2 (SP-2), a questionnaire for parents that results in the evaluation of sensory processing patterns, sensory channels, and related behaviors. Since each individual's sensory processing patterns support or interfere with functional participation in everyday contexts, a relationship between sensory peculiarities and social impairment in ASDs has been hypothesized. Although evidence was reported, there are still no conclusive results on what sensory patterns and specific sensory channels are actually involved. Furthermore, possible effects of different functioning levels have not been explored.

**Objectives:** The aim of this study was to test the association between sensory patterns/sensory sections of the Italian Child SP-2 and total score and subscales of the Social Responsiveness Scale (SRS) in a group of high and low functioning Italian children.

**Methods:** Mothers of 40 ASD children (mean age 6.49 years  $\pm$  2.07, 22 high- and 18 low-functioning) completed the Child SP-2 and the SRS. T-tests on the differences in SP-2 scores between the high- and low-functioning subgroup were conducted. Pearson correlation was calculated between sensory patterns or sensory sections and SRS scores. Linear regression models with SRS total score or subscales as dependent variable and sensory patterns and functioning level as independent variables were tested. Moreover, a linear regression model for the SRS total was explored with the sensory sections as independent variables. A stepwise procedure was run on all regression models. A Bonferroni correction for multiple comparisons was applied to all analyses.

Results: 80% of the participants had at least one sensory pattern and 77.5% at least one sensory section with a higher than normal score. The high-functioning group showed lower scores for the pattern *Registration* ( $p = 0.045$ ) and the section *Movement* ( $p = 0.046$ ) than the low functioning group. *Registration* correlated positively with the total SRS score ( $p = 0.003$ ), *Social Cognition* ( $p = 0.015$ ) and *Mannerisms* ( $p=0.00002$ ) and was the only independent variable reported in the corresponding reduced models ( $p < 0.01$ ). The pattern *Seeking* was the only variable selected with the stepwise procedure for the *Social Awareness* subscale ( $p = 0.0035$ ), with which it correlated positively ( $p = 0.0021$ ). The total SRS score also correlated positively with the sensory section *Movement* ( $p = 0.033$ ), reported as the only variable in the reduced model ( $p = 0.021$ ).

Conclusions: Italian ASD children tested with the new Italian Child SP-2 showed sensory peculiarities. The patterns with a high sensory threshold seem to affect social responsiveness, probably due to the difficulties to detect social cues either because of a passive self-regulation behavior (*Registration*) or an excessive engagement in providing themselves with more sensory input (*Seeking*). *Movement* appears the most involved sensory section. A possible effect of functioning levels on the relationship between sensory and social aspects in ASDs should be further investigated.

**414.072 (Poster)** Reliability and Validity of a Denver Developmental Screening Test Complemented Autism Screening Checklist in Chinese ASD Population

Z. H. Ma<sup>1</sup>, X. Li<sup>2</sup>, H. Wang<sup>2</sup> and F. Y. Lin<sup>3</sup>, (1)ALSOLIFE, Beijing, China, (2)Peking University Sixth Hospital, National Clinical Research Center for Mental Disorders, Beijing, China, (3)ALSOLIFE, Beijing, China

---

**Background:**

Autism Spectrum Disorder (ASD) is a neurodevelopmental disorder with core symptoms of abnormal functioning in social interaction and communication, and restricted, repetitive behavior. Early screening, early diagnosis, and early intervention are of great importance for ASD children. However, the ability in early screening of ASD in mainland China is still limited to some extent: first, the primary care physicians in community hospitals are not well prepared to recognize early signs of ASD; second, most early screening tools for autism are introduced and adapted from other countries, therefore having some problems in localizing and popularizing, as those tools may be not well suited for local population or primary care physicians may have limited access to those tools.

**Objectives:**

Based on Denver Developmental Screening Test (DDST) which is widely used by primary care physicians in community hospitals in mainland China, referring to Diagnostic and Statistical Manual of Mental Disorders 5th edition (DSM-5) Autism Spectrum Disorder (ASD) criterion, widely used ASD screening tools, and rich clinical experiences, we developed a DDST Complemented Autism Screening Checklist, which is performed by physicians and takes about 10 minutes to finish. The checklist contains 13 items in total, which are divided into three subscales (social, communication and restricted and repetitive behaviors/RRB). The current study examined the psychometric properties of the tool and intended to promote the ASD screening in mainland China.

**Methods:**

This study included 15 patients diagnosed with ASD (aged 2.1-7.3 years) and 10 patients diagnosed with Intellectual Disability (aged 0.8-8.2 years) according to the DSM-5 criteria at an early intervention center in Beijing from September 2020 to October 2020. Child and adolescent psychiatrists gave diagnosis and examined all participants with the DDST complemented Autism Screening Checklist. Discriminative validity, criterion validity and internal consistency of the tool were examined.

Results: The Cronbach's  $\alpha$  of the total score of the autism screening checklist was 0.864 ( $P < 0.01$ ). For discriminative validity, the total scores of the autism screening checklist in autism group ( $8.2 \pm 2.62$ ) were significantly different with the total scores in mental retardation group ( $5.0 \pm 2.26$ ). For criterion validity, ROC curve was drawn taking clinical diagnosis as gold standard. Area under ROC curve (AUC) was 0.817 ( $P < 0.01$ , Figure 1). According to the rule of the greatest Youden's index, when the cut off value was set as 5, the sensitivity was 0.933, and the specificity was 0.6.

**Conclusions:**

The DDST complemented Autism Screening Checklist has good validity and fair reliability. For criterion validity taking clinical diagnosis as gold standard, the tool has high sensitivity and fair specificity. To optimize our Autism Screening Checklist, we would further modify items and factors to improve the internal consistency, include interrater and test-retest data, and enlarge our

sample.

**414.073 (Poster)** Reliability and Validity of the Alsolife Skills Assessment System in Chinese Families of Children with Autism Spectrum Disorders

**X. Bai<sup>1,2</sup>, B. Wang<sup>3</sup>, Y. Guo<sup>4</sup>, Z. Zhu<sup>1,2</sup>, X. Li<sup>1,2</sup> and F. Y. Lin<sup>3</sup>,** (1)Key Laboratory of Mental Health, Institute of Psychology, Chinese Academy of Sciences, Beijing, China, (2)University of Chinese Academy of Sciences, Beijing, China, (3)ALSOLIFE, Beijing, China, (4)Peking University Sixth Hospital, Beijing, China

---

**Background:** To improve the transition to adulthood for individuals with autism spectrum disorders (ASD) in China, a novel intervention conception named “ALSO” is proposed with an emphasis that “for children with ASD, current interventions should be guided by future needs in adulthood, and future goals in adulthood must be practiced in current interventions.” Therefore, ALSO sets “Occupational and independent-living skills” in early adulthood as the ultimate goal in individualized education for children with ASD, and proposes that “Occupational and independent-living skills” (O) in early adulthood could be achieved via training on “Academic and cognitive skills” (A), plus “Living and life skills” (L), plus “Social interaction and social regulation skills” (S) from early intervention to adolescent education for individuals with ASD. This intervention conception can be summarized as “A+L+S=O” and is therefore abbreviated “ALSO”. To facilitate implementing ALSO, an ALSOLIFE skills assessment system (ALSOLIFE Assessment) was developed after seven years’ interdisciplinary research. The ALSOLIFE Assessment comprises six skill-domains, which include 22 skill subdomains covering 511 skills (Fig 1). ALSOLIFE Assessment aims to assist caregivers in evaluating skills for children with ASD as the basis for individualized education in home life during the preschool period, and is free for life to the families of the children with ASD.

**Objectives:** Although more than 100,000 caregivers of children with ASD have used the ALSOLIFE Assessment to assist their children’s early intervention in home context, the validation of the ALSOLIFE Assessment is still unknown. Assessment is the basis for IEP, it is important to know the reliability and validity of the ALSOLIFE Assessment and whether its scoring is validation compared to other well validated assessment systems for children with ASD (e.g., PEP-3 or VB-MAPP). To explore the answers for these questions, we conducted this study to comprehensively examine the reliability and validity of the ALSOLIFE Assessment in children with ASD in China.

**Methods:** A sample of 1,050 children diagnosed with ASD by DSM-5 was randomly recruited from 31 provinces of China. The ages of the enrolled children with ASD ranged from 1.52 to 10.43 years (mean = 4.46±1.52), and the sex ratio was 5.40:1 (886 boys and 164 girls). Their primary caregivers were invited to use the ALSOLIFE Assessment to evaluate the ability of their children. The VB-MAPP and PEP-3 were also administered to some of the children in the sample to determine the criterion-related validity.

**Results:** Items analysis found that the content validity of the ALSOLIFE Assessment met psychometric requirement after reduction from 511 to 464 items. Exploratory factor analysis of ALSOLIFE Assessment scoring data yielded six factors, and confirmatory factor analysis verified that the best fitting model is a bifactorial model with six group factors. The ALSOLIFE assessment total score significantly predicted the VB-MAPP and PEP-3 scores. The reliability tests indicated strong internal consistency, test-retest reliability, and inter-rater reliability of the overall ALSOLIFE Assessment as well as each of the six underlying components.

**Conclusions:** The reliability and validity of the revised ALSOLIFE skills assessment system (464-items) satisfied psychometric requirements.

**414.074 (Poster)** Role of Provider Concern during Primary Care Screening for Early Identification of ASD

**A. T. Wieckowski<sup>1</sup>, R. K. Ramsey<sup>2</sup>, K. L. Coulter<sup>3</sup>, Y. Algor<sup>4</sup>, V. Ryan<sup>4</sup>, S. Y. Eldeeb<sup>1</sup>, L. B. Adamson<sup>5</sup>, A. C. ---

**Background:** Pediatric providers identify ASD risk in toddlers through the complementary processes of standardized screening and surveillance, the latter captured by provider indication of concern. The contributions of each strategy to ASD detection warrant a closer look. In this project, we evaluate the added value of provider-indicated concern during primary care screening in early identification of ASD.

**Objectives:** This study aimed to 1) evaluate rates of provider-indicated concern when providers are simply encouraged to indicate concern compared to when they are required to do so, and 2) evaluate the Positive Predictive Value (PPV) when screening or concern, or both indicates ASD risk.

**Methods:** Participants were children screened for ASD during primary care check-ups ( $n=6,204$ , aged 14.8 to 22.17 months), during two multi-site studies. Parents completed the Modified Checklist for Autism in Toddlers, Revised, with Follow-Up (M-CHAT-R/F; Robins, Fein, & Barton, 2009). In addition, for each participant, providers had the option to indicate whether or not they had ASD concerns. In one study, providers were encouraged, but not required to indicate concern ( $n=4,274$ ;  $M=18.52$  months,  $SD=0.87$ ). In the other study, providers were required to indicate whether they have an ASD concern before they accessed M-CHAT-R/F results ( $n=1,930$ ;  $M=18.76$  months,  $SD=0.87$ ). Children at risk for ASD either through screen result or provider concern ( $n=562$ ) were invited for an ASD evaluation; 268 children attended the evaluation and were classified as ASD or non-ASD. PPV (likelihood that positive result is a true ASD case) was calculated by dividing true positive ASD cases by all screen positive cases.

**Results:** Providers were equally likely to indicate concerns for ASD whether they were required or just encouraged to do so (2.9% vs. 2.6%;  $\chi^2(1, N=6204) = 0.41, p = .525$ ). Combined across both studies, PPV was .628 when both screener and provider concern indicated ASD risk, compared to .500 for concern only, and .426 for screener only; overall these were significantly different ( $\chi^2(2, N=268) = 9.17, p = .010$ ). Pairwise comparisons of PPV indicated screener only was significantly lower than concern only or both ( $\chi^2(1, N=248) = 9.17, p < .01$ ), but not for both vs. concern only or for screener vs. concern ( $ps > .29$ ).

**Conclusions:** Requiring providers to indicate whether they are concerned a child may have ASD in order to access the M-CHAT-R/F results did not change the rate of endorsement of ASD concern, suggesting that when providers have ASD concerns, they indicate them irrespective of the prompt level (required vs. encouraged). Our results also highlight the benefit of providers indicating concern for ASD, as a combined method of incorporating standardized screening and provider surveillance resulted in highest likelihood that a positive result is a true ASD case. Consistent with the recommendation of the American Academy of Pediatrics, early detection of ASD risk during well-child visits should therefore incorporate both screening and surveillance. Further studies are needed to explore types of concerns indicated by the providers, in order to identify symptoms providers are observing that augment those identified by screening measures.

**414.075 (Poster)** Scatter on Stanford-Binet 5th Edition Routing Subtests Reduces Predictive Validity of Abbreviated Battery IQ in a Clinical Sample of Youth with Ndds

*K. G. Stephenson, J. Horack and E. Butter, Nationwide Children's Hospital, Columbus, OH*

---

**Background:** Scattered cognitive profiles are thought to be common in children with ASD and there is some concern that significant scatter between various cognitive subdomains decreases the validity of global IQ scores. Despite this apprehension, research suggests that the presence of scatter in subdomains does not invalidate FSIQ scores, particularly with Wechsler Intelligence Scales. However, this question has not been investigated with the Stanford-Binet 5<sup>th</sup> Edition (SB-5) abbreviated battery IQ (ABIQ), which is commonly used in research and clinical applications as an estimate of cognitive ability. Given that the ABIQ is based on administration of only the two routing subtests, it is possible that the ABIQ is more susceptible to an attenuation of validity due to significant scatter.

**Objectives:** To determine whether scatter among SB-5 routing subtests impacts the validity of the ABIQ in predicting FSIQ. We hypothesized that scatter would not significantly impact ABIQ.

**Methods:** The sample included 1679 youth (21% female) ages 6-16 ( $M=9.1, SD=2.9$ ) who presented for evaluation at a large children's hospital who had a clinical diagnosis of ASD and/or ADHD. Participants completed a full SB-5. Two groups were formed based on presence (56.3%) or absence (43.7%) of ASD diagnosis. Using multiple regression, predictors of FSIQ included ABIQ, scatter between routing subtests, and their interaction. We tested both linear and curvilinear (quadratic) effects of ABIQ.

**Results:** There were no group differences in scatter [ $t(1656.3)=-1.88, p=.06, d=.09$ ]. Both linear and quadratic regression models were significant. The quadratic model fit the data best [ $F(5,1672)=1555, p<.001, R^2=.82$ ]. All predictors were significant. Scatter was a significant moderator, such that higher scatter was associated with an increasing *overestimation* of FSIQ, particularly at moderate values of ABIQ (e.g., 80-115; see Fig. 1). There were no differences in these effects between the two groups.

**Conclusions:** Results suggest that, on average, ABIQ overestimates FSIQ when there is significant scatter between routing subtests, especially when ABIQ is in the average range. The use of the SB-5 ABIQ in research and clinical applications, without consideration of scatter on routing subtests, is potentially problematic.

**414.076** (Poster) Screening for ASD with Telehealth Rapid Interactive Screening Test for Autism in Toddlers (RITA-T)  
**R. Choueiri<sup>1</sup>, M. Ravi<sup>2</sup> and W. Garrison<sup>3</sup>,** (1)University of Massachusetts Memorial Children's Medical Center, North Worcester, MA, (2)UMass Children's Hospital, Worcester, MA, (3)Pediatrics, Developmental and Behavioral Pediatrics, University of Massachusetts Medical School, Worcester, MA

---

Background:

Amidst the COVID-19 pandemic, telehealth and remote video evaluations have been propelled to the forefront. As we continue to develop guidelines to best evaluate ASD via telehealth, it has become important to identify and test tools and measures that will allow the remote early identification of young children at high risk for ASD. There are no empirically validated telehealth ASD screening measure for those 18-36 months. The in-person RITA-T (*Rapid Interactive screening Test for Autism in Toddlers*) has been shown to demonstrate similar cut-off scores for those 18-24 months and 24-36 months. It has a proven record of effective training, broad and affordable access to providers, and a targeted focus on socio-developmental constructs relevant to ASD that are observable in very young children.

Objectives:

To validate a modified version of the RITA-T as a telehealth tool for those 18-36 months, and to identify a cut off score to differentiate between those with ASD and those with non-ASD.

Methods:

We have developed a modified telehealth RITA-T and we have been validating it remotely. This project is ongoing. Thus far, 30 toddlers have been enrolled in the study. Of those, 10 had received the interactive RITA-T, and all were identified in the high-risk range for ASD. Parents had no concerns for ASD in another 10 of those toddlers, and the remaining 10 were referred for concerns of ASD and with a positive score on the MCHAT-R/F. Ages in the study varied between 18 and 34 months with a mean of 28 months. The telehealth RITA-T includes modified activities and behavioral prompts the parent is instructed to complete with the toddler. These prompts mirror the validated items drawn from the RITA-T. The modified telehealth RITA-T has a maximum score of 20 (vs. 30 for the RITA-T). After consent was obtained, a trained research assistant instructed the families regarding each prompt, and then scored the test. Parents engaged readily in this project, and results show they were able to perform each prompt successfully. The diagnostic remote evaluation then included history, observation of play and structured prompts and any available previous testing. Children in the study were also evaluated using current DSM-5 criteria and the Childhood Autism Rating Scale- 2.

Results:

Those children with an eventual diagnosis of ASD had a score higher than 10 on the telehealth RITA-T. Those with a non-ASD diagnosis (typically developmental delays in speech and language) had a score of less than 9. All 10 toddlers who previously scored in the high-risk range for ASD on the interactive RITA-T, had a score higher than 10 on the modified telehealth version.

Conclusions:

In the wake of COVID-19 and the rapid development of remote telehealth evaluations and diagnosis, we report on promising results and our current work validating a modified telehealth version of the RITA-T. It is likely that this method can continue to be used and applied efficiently after the COVID-19 crisis subsides in those areas where obstacles to identification lead to significant delays in diagnosis and intervention.

**414.077** (Poster) Screening for Depression in Young Adults with Autism Spectrum Disorder  
**A. Sirsikar<sup>1</sup> and I. M. Eigsti<sup>2</sup>,** (1)University of Connecticut, Storrs, CT, (2)Psychological Sciences, University of Connecticut, Storrs, CT

---

Background: Autism spectrum disorder (ASD) is a neurodevelopmental condition that is characterized by increased symptoms of depression (Hedley *et al.*, 2018); depression in ASD is significantly underdiagnosed (Bitsika, 2015). High rates of undetected depression in ASD could suggest that the comorbid presentation of depression is unique, that there is somewhat reduced insight into symptoms, or that screening tools fail to capture critical symptoms in ASD (Hill & Frith, 2004).

**Objectives:** In this study, we tested the convergence of self- and parent-reported symptoms of depression in young adults with ASD, as compared to an age-matched typically developing (TD) university sample.

**Methods:** Individuals with a confirmed ASD diagnosis ( $n=112$ ; 61 females) and TD undergraduates ( $n=387$ ; 262 females), ages 18-24 years, completed the Beck-Depression Inventory-II (BDI-II) and the Autism Questionnaire (AQ). Only individuals who endorsed paying close attention to the task were included. In addition, only TD students with AQ scores under 26 were included; final sample,  $n=107$  ASD and  $n=255$  university students. Some parents completed the Adult Behavior Checklist (ABCL) to report symptoms of depression:  $n=40$  (ASD group) and  $n=52$  (TD group). There was no difference between participants who did versus did not have parental measures,  $p's > .08$ . Analyses tested absolute rates and convergence of self- and parent-reported depression symptoms in ASD versus TD groups. We contrasted the contributions of somatic versus affective items to BDI scores, to test whether the ASD group had differential reporting of physical versus emotional symptoms. Exploratory analyses tested effects of gender on convergence.

**Results:** Participants with ASD reported significantly more symptoms of depression,  $p < .001$ , Fig. 1A. Both groups reported significantly more somatic than affective symptoms,  $p < .001$ , Fig. 1B; the interaction of group and symptom type was not significant,  $p = .35$ . Child and parent depression scores were significantly correlated in *both* ASD,  $r(40) = .85$ , and TD,  $r(52) = .82$ , groups,  $p's < .0001$ , Fig. 1C/D. Child-parent concordance in the ASD group was significantly correlated for both men  $r(40) = .88$ ,  $p < .001$  and women,  $r(31) = .72$ ,  $p = .003$ ; there were too few TD men to test gender differences.

**Conclusions:** Young adults with ASD reported significantly more symptoms of depression compared to their TD peers, consistent with findings that autism severity is associated with loneliness and depression (Hedley *et al.*, 2018). Alexithymia, characterized by difficulty recognizing emotions from internal bodily states, is frequent in ASD (Hill & Frith, 2004), and prompted an examination of whether somatic symptoms might be more readily reported in our ASD sample. However, both groups reported more somatic than affective symptoms, with no group difference. Strong parent-child concordance for *both* ASD and TD groups was consistent with prior work (Ozsivadjian *et al.*, 2014). While women with autism, particularly those with cognitive abilities in the typical range, are often misdiagnosed (Lai *et al.*, 2017), and might be expected to camouflage symptoms, findings suggest similar parent-child concordance in males and females. Overall, the current results suggest that the BDI-II may be adequate for probing depression symptoms in ASD.

#### **414.078 (Poster) Sex Differences in Universal Autism Screening Using the M-CHAT in Primary Care**

**L. K. Steinbeck, C. J. Zampella, L. S. Cubit, M. Drye, M. Fecher, L. A. Wang, K. E. Wallis, J. S. Miller and W. Guthrie, Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA**

**Background:** Universal autism screening is essential for timely referrals for assessment and access to intervention; however, there is growing evidence for sex differences in screening accuracy. Our evaluation of large-scale universal screening at the Children's Hospital of Philadelphia (CHOP; Guthrie *et al.*, 2019) using the Modified Checklist for Autism in Toddlers (M-CHAT; Robins *et al.*, 2001) revealed positive predictive value that was significantly higher in boys (20%) than girls (8%), suggesting greater false positives for girls. Given well-documented discrepancies in diagnostic rates and how symptoms present across sexes, this study sought to examine sex differences in item-level performance on the M-CHAT.

**Objectives:** Examine the extent to which individual M-CHAT items differentially predict ASD diagnosis among girls and boys, in a large sample of children screened for ASD in primary care and followed until age 4-6 years using data from the electronic health record (EHR).

**Methods:** Universal screening of children aged 16-30 months was conducted using the M-CHAT at CHOP primary care clinics. Children were identified within the EHR for inclusion if the M-CHAT was completed between ages 16-30 months, and the child presented to primary care for follow-up at age  $\geq 4$  years. Diagnostic outcomes were abstracted from EHR records from pediatricians and ASD specialists within CHOP. The final cohort included 20,375 children, with an overall ASD prevalence rate of 2.2% (3.4% in boys, 1.0% in girls).

**Results:** Across children who did and did not go on to have ASD, parents of boys endorsed several items more frequently than parents of girls (items 4-7, 9, 13-15, 17, 19-21, 23 after controlling for multiple comparisons). Individual logistic regressions testing for sex differences (i.e., significant interaction between sex and M-CHAT item score in predicting ASD diagnosis) identified five differentially predictive items. Girls with the following items endorsed were significantly more likely to be diagnosed with ASD than boys: pretend play, response to name, response to joint attention, receptive language (5, 14, 15, 21); however, the latter two items did not survive Benjamini-Hochberg corrections for multiple comparisons. In contrast, responsive social smile (12) was significantly more predictive of ASD in boys than girls.

Conclusions: Using the M-CHAT in a clinical setting, important sex differences in how early ASD symptoms predict later diagnosis were revealed, with specific patterns behind differential prediction varying across items. Responsive social smile was a better predictor in boys, likely because this item was rarely endorsed in girls (3% and .5% in ASD and non-ASD groups) compared to boys (25% and 13% respectively). Conversely, girls with ASD were more likely to not respond to their name compared to boys (17% vs. 8%). Difficulty with pretend play was endorsed relatively evenly across girls and boys with ASD (26% vs. 28%), but was rarer in girls without ASD vs. boys (1% vs. 3%). Sex differences in early socialization experiences, developmental expectations, and/or thresholds for parental concerns may have contributed to these findings, warranting future research. Continued examination of sex differences in autism screening may inform sex-specific screening methods for improved accuracy.

**414.079 (Poster) Sex Differences in the ADOS-2 in ASD Verbal Youth**

*H. Rea<sup>1,2</sup>, S. J. Webb<sup>3</sup>, M. Santhosh<sup>4</sup>, R. A. Øien<sup>5</sup>, K. D. Riley<sup>6</sup> and F. Shic<sup>1</sup>, (1)Center for Human Development and Disability, University of Washington, Seattle, WA, (2)Psychiatry and Behavioral Sciences Department, University of Washington, Seattle, WA, (3)Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA, (4)Center for Child Health, Behavior and Development, Seattle Children's Research Institute, Seattle, WA, (5)The Arctic University of Norway, Tromsø, NORWAY, (6)Seattle Children's Research Institute, Seattle, WA*

---

**Background:** Autism spectrum disorder (ASD) assessments require research with females to account for sex and gender differences in presentation and ascertainment. Social and behavioral differences between males and females with ASD include increased use of compensatory strategies (e.g., rote-memorization and repetition) for females, in part because females with ASD show relative strengths in awareness of deficits and aspects of social understanding (Lai et al., 2011). Females' social deficits may be apparent later in development, as female social demands increase in intensity and complexity in adolescence (Kopp & Gillberg, 2011). Observers may also be more likely to miss or misunderstand female ASD behaviors because the formation and validation of diagnostic criteria and assessments are largely based on males (Koenig & Tsatsanis, 2005). In one study on sex differences on the ADOS-2 module 3, females showed less atypicality on some individual items (i.e., excessive interests, hyperactivity items) and less direction of facial expressions. However, there were no differences in overall calibrated severity scores in analyses when IQ was not controlled (Ratto et al., 2018). As most research on sex and gender differences in ASD assessments used the DSM-IV and original ADOS (e.g., Tillman et al., 2018), follow-up is needed.

**Objectives:** To conduct exploratory logistic regressions predicting sex by ADOS-2 item.

**Methods:** 229 participants (age 8 to 17 years 11 months;  $M_{age} = 12.78$ ) completed the ADOS-2 module 3 or 4 as part of a multisite NIMH study on sex differences in ASD. Youth had a prior clinical diagnosis and most ( $n=186$ ) met CPEA research criteria for ASD (Kau & Cooper, 2013). Sex was defined as sex assigned at birth ( $n = 99$  females).

**Results:** A forward stepwise logistic regression was conducted to predict sex from individual ADOS items and interactions of items. Positive coefficients (see Table 1) indicate increased likelihood of being male. Individuals who showed less gesture use and/or had less reciprocal communication were more likely to be male. However, the interaction of less reciprocal social communication and less eye contact predicted increased likelihood of being female. Individuals who asked for less information were also more likely to be female. The model had 69.4% accuracy distinguishing between males and females with ASD. The area under the curve was 0.65 (95% CI: 0.59-0.71).

**Conclusions:** Findings indicate that items on the ADOS-2, primarily those relating to content and quality of verbal and nonverbal communication, distinguish between sex. Some interactions emerged that need to be validated but suggest that items that typically predict being male are predictors of being female when in conjunction with other behaviors and vice versa. These findings may inform screening and assessment, as providers may need to consider combinations of atypical behaviors when assessing girls with ASD.

**414.080 (Poster) Telehealth Evaluation of Autism Spectrum Disorder during COVID-19: Comparative Outcomes from Implementation of the Tele-ASD-PEDS**

*R. McNally Keehn<sup>1</sup>, C. James<sup>1</sup>, Q. Tang<sup>2</sup>, A. Paxton<sup>1</sup> and B. Enneking<sup>1</sup>, (1)Pediatrics, Indiana University School of Medicine, Indianapolis, IN, (2)Biostatistics, Indiana University School of Medicine, Indianapolis, IN*

---

**Background:** The COVID-19 pandemic has exacerbated longstanding barriers to accessing diagnostic evaluations for young children at risk for autism spectrum disorder (ASD) and demanded rapid development of novel diagnostic approaches. Telehealth has been implemented as a widespread clinical solution during the pandemic, safely allowing for continuity of ASD diagnostic and evaluation services. Although research has explored telehealth ASD diagnostic models with promising results, extant studies

have largely focused on homogenous samples of high-risk children, employ a strict research evaluation protocol, and/or do not allow for comparative between-group analysis.

**Objectives:** To examine clinic-wide outcomes of telehealth evaluation for young children at-risk for ASD. Specifically, we sought to 1) compare child-, clinician-, and caregiver-reported outcomes between ASD diagnostic evaluations that did and did not include administration of the TELE-ASD-PEDS, and 2) determine associations between TELE-ASD-PEDS and clinical best-estimate ASD diagnosis.

**Methods:** In response to the COVID-19 pandemic, the Riley Child Development Center (RCDC), a large Midwestern academic medical center neurodevelopmental evaluation clinic, transitioned the evaluation model for all children  $\leq 48$  months of age referred for ASD assessment from face-to-face to telehealth evaluation. Clinicians were trained in the TELE-ASD-PEDS, a novel caregiver-led, clinician-coached remote ASD observational assessment tool, and those clinicians employed this tool in their evaluation protocol. Children referred to the clinic were assigned to clinicians randomly by a clinic scheduling team. Clinicians completed a survey after each evaluation consisting of questions related to diagnosis, diagnostic certainty, and satisfaction with telehealth. Caregivers were asked to complete a satisfaction survey for their child's evaluation experience.

**Results:** Since May 2020, 57 children (mean age: 32.0 months; SD: 8.2) received an evaluation with the TELE-ASD-PEDS, and 24 children (mean age: 35.3 months; SD: 8.2) received evaluation without an ASD observational tool. No between-group demographic differences in child age, insurance type, race/ethnicity, family income, or caregiver education were found (all  $p > .10$ ). Clinicians were able to provide a definitive diagnosis more frequently (93%) in evaluations using the TELE-ASD-PEDS, as compared to those that did not use an observational tool (54%;  $p = .0001$ ). Similarly, clinicians rated diagnostic certainty as somewhat/completely certain in 79% of evaluations using the TELE-ASD-PEDS (compared to 58% of those without an observational tool). 91% of clinicians were satisfied with the information obtained for evaluations using the TELE-ASD-PEDS (compared to 75% of those without an observational tool). Overall, caregiver satisfaction ratings were high across both groups with no significant between-group differences. TELE-ASD-PEDS categorical risk aligned with clinician best-estimate diagnosis in 63% of ASD diagnostic outcomes and 50% of non-ASD outcomes.

**Conclusions:** Use of the TELE-ASD-PEDS as part of a telehealth ASD evaluation protocol is associated with significantly improved ability to provide a diagnosis, moderate concordance with clinician best-estimate diagnosis, and appears to result in higher clinician ratings of diagnostic certainty and some indices of satisfaction. Overall, caregivers were highly satisfied with telehealth ASD diagnostic evaluation. Together, our findings suggest that deployment of telehealth ASD evaluation services has the potential to address access barriers to high-quality diagnostic services during the COVID-19 pandemic and beyond.

**414.081 (Poster)** The Feedback Session of an Autism Assessment: A Scoping Review of Clinical Practice Guideline Recommendations

**E. Pattison<sup>1</sup>, A. Ure<sup>2</sup>, S. Mittiga<sup>1</sup>, G. Werninghaus<sup>3</sup>, K. Williams<sup>4</sup> and N. C. Freeman<sup>1</sup>,** (1)Faculty of Education, Monash University, Monash University, VIC, Australia, (2)Department of Paediatrics, Monash University, Clayton, VIC, Australia, (3)Australian Catholic University, Melbourne, VIC, Australia, (4)Department of Paediatrics, Monash University, Melbourne, VIC, Australia

**Background:** Clinical practice guidelines exist to assist clinicians with all elements of an autism assessment, including the feedback of results and diagnosis to families. The feedback session can be the interface between the assessment process and a period of understanding, support and intervention for families. To date, reviews of autism assessment guidelines have not examined recommendations for providing feedback.

**Objectives:** The objective of this scoping review was to assess the quality and content of recommendations for delivering feedback within internationally published clinical practice guidelines. Specifically, it aimed to examine how feedback should be conducted and what information should be provided to families.

**Methods:** We systematically searched multiple electronic databases and government websites for autism assessment guidelines. The Appraisal of Guideline Research and Evaluation Second Edition was used to assess the quality of each included guideline. A content analysis was conducted of each guideline's recommendations for feedback of results and diagnosis.

**Results:** Seventeen guidelines fit inclusion criteria. Five did not provide recommendations for feedback. The majority of recommendations for feedback were based on the expert opinions of the individual guideline's development groups. Five guidelines used expert consensus to form recommendations and only one reported using a formal method of reaching consensus. Details of feedback recommendations were tabled and related to who should attend, the timing and mode of delivery, how the clinician should conduct themselves and what should be discussed. Recommendations from different guidelines did not often

contradict each other, however inconsistencies did exist, and recommendations emphasised as important in some guidelines were omitted from others.

Conclusions: Considerable variations were observed between autism assessment guideline's recommendations for feedback. The majority of recommendations were created based on the expert opinions of the respective guideline development groups and the limited empirical research that exists within this area. These factors likely contribute to the variability in recommendations. There is evidently a need for further research into this important element of the autism assessment process.

**414.082 (Poster)** The Impact of Demographic Variables and Comorbidities on the Timing of ASD Diagnosis and Access to Services: Data from a Large National Survey

**J. E. Goldblum<sup>1</sup>**, **O. Putnam<sup>2</sup>** and **C. Harrop<sup>3</sup>**, (1)Department of Psychology and Neuroscience, University of North Carolina at Chapel Hill, Chapel Hill, NC, (2)Department of Allied Health Sciences, University of North Carolina at Chapel Hill, Chapel Hill, NC

---

Background: Female, BIPOC (Black, Indigenous, and People of Color), and low-income children with Autism Spectrum Disorder (ASD) are understudied and underserved in their access to timely ASD diagnoses (Bargiela et al. 2016, Nowell et al. 2015). Under-identification, diagnostic disparity, and diagnostic lag delay the start of vital early intervention services, necessary for overall wellbeing and functioning (Zwaigenbaum et al. 2015).

Objectives: Using large-scale national data, we investigated the interplay of assigned sex at birth, race, income, and co-occurring conditions in the prediction of age at ASD diagnosis and frustration in access to services. Our research will contribute to a greater understanding of ASD identification in US children.

Methods: Survey data from 1,245 parents of ASD children from the 2017-2018 National Survey of Children's Health (CAHMI) were analyzed (79% male, 21% female; 67% white, 13% Hispanic, 13% Multiracial/Other, 6.6% Black;  $M_{age} = 11.45$  years,  $SD_{age} = 4$  years). CAHMI surveys are completed by caregivers of youth across the United States. Data for each year come from 1 child per household. Generalized linear models were used to analyze study questions.

Results: The distributions of diagnostic age varied by assigned sex: a higher proportion of males were diagnosed under the age of three [ $X^2(1, 1245) = 8.37, p = .003$ ] and more females were diagnosed over the age of five [ $X^2(1, 1245) = 17.74, p < .000$ ]. When accounting for urban vs. rural, race, and sex, children in families with lower incomes were diagnosed later ( $\beta = -0.09, p < 0.01, R^2 = 0.002$ ). Assigned sex, metro vs. rural status, income and age of diagnosis predicted co-occurring conditions; after accounting for race, males ( $\beta = 0.06, p < 0.05, R^2 = 0.1$ ), living in a rural area ( $\beta = 0.07, p < 0.02, R^2 = 0.1$ ), from lower income families ( $\beta = -.08, p < 0.001, R^2 = 0.1$ ), and with a younger age of ASD diagnosis ( $\beta = -.07, p < 0.04, R^2 = 0.1$ ) had a higher number of co-occurring conditions. With regards to family frustration in accessing services, children with co-occurring conditions (anxiety, depression, ADHD, behavioral disorder, speech disorder, intellectual disorder, and developmental disorder) significantly predicted family frustration in access to services ( $\beta = 0.35, p < 0.000, R^2 = 0.11$ ), after accounting for sex, race, age of ASD diagnosis, metro vs. urban, "working poor", and income level.

Conclusions: Our research supports previous findings that disparities in age at ASD diagnosis exist by sex and demographic variables and predict rates of co-occurring conditions. Greater numbers of co-occurring conditions predicted higher parent reported frustration in access to services. Notably, low-income level was the most common predictor of later age at ASD diagnosis, higher service-access frustration, and higher numbers of co-occurring conditions. Targeted work is required to increase timely ASD diagnosis and access to services in low-income families.

**414.083 (Poster)** The Impact of Diagnosis Scale – Revised (IODS-R)

**S. Arnold<sup>1,2</sup>**, **Y. Huang<sup>1,2</sup>**, **J. Higgins<sup>1,2</sup>**, **J. Hwang<sup>3</sup>**, **A. L. Richdale<sup>2,4</sup>**, **J. N. Trollor<sup>1,2</sup>** and **L. P. Lawson<sup>2,4</sup>**, (1)Department of Developmental Disability Neuropsychiatry, UNSW, Sydney, NSW, Australia, (2)Cooperative Research Centre for Living with Autism (Autism CRC), Brisbane, QLD, Australia, (3)University of New South Wales, Sydney, NSW, Australia, (4)Olga Tennison Autism Research Centre, La Trobe University, Melbourne, VIC, Australia

---

Background:

Health professionals frequently communicate what can be life changing diagnoses. The Impact of Diagnosis Scale (IODS) has been developed in relation to Borderline Personality Disorder (Courtney & Makinen, 2016) but as yet no measurement tool exists to determine the psychological impact of receiving a diagnosis of autism. Autism is increasingly diagnosed in adulthood,

however, the few studies that explore self-reported impact of receiving a diagnosis have been primarily qualitative. A standardised measure to examine the impact of receiving an autism diagnosis in adulthood is needed.

#### Objectives:

Our aim was to develop an impact of diagnosis scale suitable for autistic adults by revising the IODS developed for Borderline Personality disorder.

#### Methods:

Following a promising trial of a co-produced, preliminary revision of the IODS (Arnold et al., 2020), the research team and autistic advisors developed an expanded pool of 46 items, scored on 7-point Likert scale, within 6 hypothesised domains; “Service Access, Well-being, Self-acceptance and self-understanding, Diagnostic process, Accuracy of diagnosis, Relating with others”. Participants were drawn from the Autism CRC Australian Longitudinal Study of Autism in Adulthood (ALSAA). Scale reduction processes were applied to data from 108 formally diagnosed autistic adults aged 25+ years.

#### Results:

Following iterative rounds of exploratory factor analysis using principal factors with promax rotation, 22 items were retained across 4 domains. Domains showed acceptable internal consistency and were named “Well-being” ( $\alpha = .87$ ), “Clinician support” ( $\alpha = .82$ ), “Self-understanding” ( $\alpha = .75$ ) and “Service Access” ( $\alpha = .76$ ). Overall internal consistency was good ( $\alpha = .81$ ). Mean scores reiterated themes from preliminary findings, of a generally positive “Well-being” ( $M=5.27, SD=1.41$ ), “Self-understanding” ( $M=6.36, SD=.75$ ), and “Clinician support” ( $M=5.76, SD=1.17$ ), though poor “Service access” ( $M=3.34, SD=1.46$ ).

Qualitative data reiterated previous findings of Self-Understanding, Identity and Acceptance, Support and Services, Valence of Response, Relationships and Camouflaging. Regarding adulthood autism diagnosis many “spent my entire life thinking... there was something wrong”. For most diagnosis “was a relief” and “changed my life” or even “saved my life”. However, for some it was the “worst decision”, “very difficult emotionally”, going as far as saying “I am still devastated”.

#### Conclusions:

The IODS-R adds new understanding to the experience of receiving an autism diagnosis in adulthood. It is unique in quantitatively measuring the self-reported impact of receiving a diagnosis. More post- diagnosis support is needed for autistic adults. The IODS-R may prove useful for evaluating diagnostic services.

#### **414.084** (Poster) Toward Earlier Screening for ASD: A New Factor Structure of the First Years Inventory (FYIv3.1)

**G. T. Baranek<sup>1</sup>, J. Sideris<sup>2</sup>, Y. J. Chen<sup>1</sup>, E. Crais<sup>3</sup> and L. R. Watson<sup>3</sup>,** (1)Chan Division of Occupational Science and Occupational Therapy, University of Southern California, Los Angeles, CA, (2)Frank Porter Graham Child Development Institute, Chapel Hill, NC, (3)Department of Allied Health Sciences, University of North Carolina at Chapel Hill, Chapel Hill, NC

Background: Early screening for ASD risk in the community is critical to increasing families’ access to early intervention. Yet, few autism-specific screening tools have been developed and tested for the general population of infants <18 months. The First Year(s) Inventory (Baranek et al., 2003; Reznick et al., 2007) showed promise for detecting ASD risk in a community sample of 12-month-olds. Of note, the sensory reactivity/regulation domain added specificity and prediction accuracy over the social-communication domain alone (Turner-Brown et al., 2013; Ben-Sasson and Carter, 2013), likely because sensory features emerge in infancy prior to full ASD manifestations (Canu et al., 2020). A new version of the FYI (v3.1), with clinical utility for a wider age range, is available but requires empirical validation of the factor structure (to include items tapping sensory reactivity/regulation and social-communication domains) with a new sample.

Objectives: This study aimed to (a) validate the factor structure of the new FYIv3.1 with a large community sample of infants, and (b) determine correlations among factors and age.

Methods: Participants (N=6,427) were parents of infants (6-16 months) recruited from the community through state birth records. FYIv3.1 surveys were collected online and by mail. This cross-sectional study applied factor analytic models to determine the optimal number of underlying constructs. Exploratory structural equation models and confirmatory factor analyses (CFA) were run allowing for evaluation of the reliability of the proposed structure, the match between items and constructs, and the

relationships of these factors to each other, as well as to age. All 69 items were scored for frequency of specific child behaviors using five response categories (“Never” to “Always”). Given the ordinal variables and the planned missingness (due to two different forms-A/B with 27 overlapping items), we used robust maximum likelihood estimation. We specified the model to have at least three items per factor and no cross-loadings.

Results: The exploratory models suggested five to nine oblique factors. Review by the clinical/research team resulted in the retention of seven factors that were retested by CFA:

1) Communication, Imitation & Play (CIP), 2) Social Attention & Affective Engagement (SAE), 3) Sensory Hyperresponsiveness (Hyper), 4) Sensory Hyporesponsiveness (Hypo), 5) Self-regulation in Daily Routines (SReg), 6) Sensory Interests, Repetitions, Seeking Behaviors (SIRS), and 7) Motor Coordination and Milestones (Motor). The 7-factor model had good fit (SRMR=.05); >90% of items had standardized factor loadings >.30. Inter-factor correlations ranged from <.01 to .75 (Table 1). Age was moderately correlated with CIP and Motor.

Conclusions: These results provided support for a theoretically sound, clinically distinct, and empirically validated 7-factor model underlying the new FYIv3.1. Two factors represented aspects of social-communication, four represented aspects of sensory reactivity/regulation, and one represented motor development. As expected, social-communication and motor were more related to age than were aspects of sensory reactivity/regulation. Future directions for research about the new FYIv3.1 include assessment of differential item function (across age, prematurity status, and SES) as well as determination of optimal scoring algorithms/cutoffs for screening based on ASD clinical outcomes later in life.

**414.086 (Poster)** Unveiling Autism in Girls: Efficacy of Girls’ Questionnaire for Autism Spectrum Conditions (GQ-ASC) As a Screening Tool for Five to Twelve-Year-Old Girls in Malta.

*M. Mifsud, TAASC, Birkirkara, Malta*

---

Background: This explorative study offers novel information about the efficiency of the Girls’ Questionnaire for Autism Spectrum Conditions (GQ-ASC, Attwood, Garnett & Rynkiewicz, 2011) as a screening tool for five to twelve-year-old females in Malta. The GQ-ASC contains 54 questions relating to play, friendships, social situations, abilities, interests, sensory profiles and mental health. This tool is still being piloted and to date, there are no cut off scores for this age range. Nevertheless, it is suggested that the higher the score, the higher the indication of autism symptomology (Ormond et al., 2018; Minds and Hearts, n.d).

Objectives: This study aimed to explore whether the GQ-ASC is an effective tool to screen for autism in five to twelve-year-old females in Malta, with and without intellectual impairment. It also investigated whether there is a relationship between poor mental health symptoms and risk of autism in females; and whether a multidisciplinary assessment impacts assessment conclusions in comparison to stand-alone assessments. Additionally, the researcher explored the age of diagnosis for females in Malta and initial parental concerns with respect to their daughters’ development.

Methods: Data were collected through parent-reported online questionnaires which included the GQ-ASC and additional questions. Parents of females aged five to twelve years were recruited via state and private assessment clinics and social media (n=29 parents of females assessed for autism; n=39 parents of neurotypical females). The study used quantitative methodology to examine the relationship between GQ-ASC scores for females assessed for autism and neurotypical females. Statistical analysis was used to investigate the relationship between GQ-ASC scores for assessed females and the independent variables: IQ; diagnosis and mental health symptoms. Similarly, statistical tests were used to analyse the impact of multidisciplinary assessment on diagnostic conclusions or lack thereof; and the age when females are diagnosed. The statistical analyses involved the two independent sample t-test, one-way ANOVA, the Tukey post-hoc test and cross-tabs. Furthermore, qualitative methodology was used to explore the initial concerns of parents of females assessed for autism through thematic analysis.

Results: The GQ-ASC was found to be a discriminant screening tool particularly for females without intellectual impairment and for females experiencing symptoms related to depression, anxiety and/or panic attacks. Females assessed for autism had statistically significant higher GQ-ASC scores (n=29, M=138) in comparison to neurotypical females (n=39, M= 124). This study found that multidisciplinary assessments may offer more conclusive results than stand-alone assessments. In Malta, most females are assessed by six years; and initial parental concerns tally with current diagnostic criteria.

Conclusions: This is the first study to compare GQ-ASC mean scores of assessed and neurotypical females aged between five and twelve years. A cut-off score of 124 is being proposed for females within this age range. While a larger scale study is required to support the findings of this research, this does not discount the novel and valid contribution offered by this research supporting the GQ-ASC as a discriminant screening tool for autism in five to twelve-year-old females in Malta.

**414.087 (Poster)** Use of Child Behavior Checklist in Toddlers with Autism

**L. Y. Zhao<sup>1</sup>, F. F. Wang<sup>1</sup>, X. Li<sup>2</sup>, J. Liu<sup>2</sup> and G. Q. Han<sup>1</sup>,** (1)Peking University Sixth Hospital, Beijing, China, (2)Peking University Sixth Hospital, National Clinical Research Center for Mental Disorders, Beijing, China

---

**Background:** Emotional and behavioral problems are common comorbidity of autism. The emotional and behavioral problems in toddlers with autism and the use of the CBCL as a screening tool for ASD are not explored adequately in China.

**Objectives:** To investigate the emotional and behavioral problems in toddlers with autism and explore efficacy of Child Behavior Checklist (CBCL) (version for 2-3 years children) for screening of autism in toddlers.

**Methods:** A total of 200 toddlers aged 2 to 3 years (2.68±0.5 years old) continuous diagnosed by experienced child psychiatrists of the research group from outpatient department of Peking University Sixth Hospital during 2016 to 2018, meeting criteria of autistic disorder (AD) in Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition (DSM-IV) were enrolled to our study. 200 typically developing(TD) children (2.72±0.5 years old) according to the ratio of 1:1 matched with autistic group in gender and age from Kindergartens in Beijing were included from 2016 to 2018. All subjects were evaluated by Achenbach Child Behavior Checklist (CBCL, 2 to 3 years old) and some of them were rated with Autism Behavior Checklist (ABC) at the same time. Scores of CBCL (2 to 3 years old) and positive rate of CBCL (2 to 3 years old) factors were compared between the two groups. Data were also analyzed with the Logistic regression model and the Spearman correlation to assess the validity of the CBCL in screening children with autism.

**Results:** The total score, scores of subscales (internalization and externalization subscales) and scores of each factor of CBCL (social withdrawal, depression, somatic complaints, sleep problems, aggressive behavior and destructive behavior) in AD group were higher than those in TD group (P<0.001). The positive rate of each factor of CBCL (2 to 3 years old) in AD group was higher than that of TD group (P<0.05). Using Logistic regression analysis, the withdrawn factor has the highest OR value for the diagnosis of autism(OR=1.34, P<0.001). The results also showed that the Spearman Correlation coefficients were 0.41 and 0.33 between the score of CBCL internalization subscale, social withdrawal factor and ABC total score (P<0.001). The internalization subscale and social withdrawal factor yielded the better discrimination between the two groups using 14 and 8 as a boundary score respectively. The Area Under the Curve (AUC), sensitivity and specificity were 0.88, 0.77, 0.81 for internalization subscale and 0.87, 0.75, 0.76 for social withdrawal factor separately.

**Conclusions:** Toddlers with autism have more emotional and behavioral problems than typically developing children. The internalization subscale and social withdrawal factor of CBCL (2 to 3 years old) could differentiate toddlers with ASD from typical toddlers effectively.

**414.088 (Poster)** Using M-CHAT to Screen for Autistic Spectrum Disorder in Toddlers from Ethnic Minorities in Israel: Experiences and Perspectives of Public Health Nurses

**O. Kerub<sup>1</sup>, I. Menashe<sup>2</sup>, G. Meiri<sup>3</sup>, N. Davidovitch<sup>4</sup> and E. J. Haas<sup>5</sup>,** (1)Ben-Gurion University, Ministry of Health, Be'er Sheva, Israel, (2)National Autism Research Center, Beer Sheva, Israel, (3)Preschool Psychiatric Unit, Soroka University Medical Center, Beer Sheva, Israel, (4)Ben-Gurion University in the Negev, Ministry of health, Be'er Sheva, Israel, (5)Ministry of Health, Beer Sheva, Israel

---

**Background:**

The prevalence of autistic spectrum disorder (ASD) is rising sharply. Disparities in the diagnosis of ASD, especially at young ages for whom intervention is most likely to be effective, among ethnic populations in Israel have been reported elsewhere. One of the largest gaps observed is between the Jewish and Bedouin populations in southern Israel.

In order to address this issue, the southern district Ministry of Health collaborated with Soroka University Medical Center, leading a project to improve early detection of children with ASD using the M-CHAT administered by public health nurses in maternal and child health centers. Children who screened positive are further examined by a specialist nurse and, if appropriate, referred for a specialist examination at Soroka University Medical Center.

**Objectives:**

To examine the perspectives of public health nurses regarding the factors influencing the potential use of the M-CHAT screening tool.

## Methods:

A qualitative research method based on interpretive theory was used. 56 public health nurses participated in seven focus groups conducted through structured interviews.

## Results:

In reviewing the transcripts, four topic clusters came up. These four clusters were transformed into open codes. Within each of these four open codes, a number of sub-topics were identified that were labeled as axis codes.

### (1) Potential benefits of using a specific screening tool:

A. Using general developmental milestones to detect developmental delay versus using M-CHAT. B. Enhancing professionalism. C. Raising confidence in professional decision-making.

### (2) Challenges that arise from using M-CHAT:

A. Use of the term autism. B. Technical difficulties. C. Lack of time and work force. D. Lack of parental awareness.

### (3) Unique aspects related to cultural and social characteristics of the patients:

A. Traditional and patriarchal cultural barriers. B. Language barriers. C. Parental suppression of information and stigma.

### (4) Strategies that could further promote the screening process:

A. Empowering parents as part of the diagnostic process. B. Adapting the screening tool culturally. C. Adjustment of the layout of the examination room. D. Professional development of the nurses. E. Separating the developmental visit at the age of 18 months from other preventive visits such as vaccines.

## Conclusions:

The present study revealed several key benefits and challenges of using M-CHAT to screen for autism in children from the Bedouin population as perceived by public health nurses. Using the tool, the nurses, developed additional ways of assessing their patients and were empowered in making professional decisions.

The nurses emphasized the difficulty of navigating administrative and technical barriers, time and work force constraints and cultural barriers of patients and families.

Given these challenges and the need for effective use of the screening tool, a policy is required to define the time and resources required to implement this important screening tool in children from ethnic minorities.

**414.089** (Poster) Using Machine Learning to Enhance Autism Screening with the Social Communication Questionnaire: A Cross-Cultural Approach

B. Mitchell<sup>1</sup>, Y. Korkontzelos<sup>2</sup> and T. Karaminis<sup>3</sup>, (1)Department of Computer Science, Birmingham, United Kingdom, (2)Department of Computer Science, Edge Hill University, Ormskirk, United Kingdom, (3)Department of Psychology, Edge Hill University, Ormskirk, United Kingdom

---

## Background:

Machine learning has recently been employed to enable improvements in the detection of autistic symptomatology using screening instruments. Trained on existing screening data from individuals who have completed the diagnostic process, machine-learning algorithms can discover intricate patterns that underlie the categorisation of individual responses into diagnostic categories. This knowledge can subsequently be applied to predict autistic symptomatology in new unseen data with higher sensitivity and specificity than the cutoff-based algorithms that typically accompany screening instruments.

Machine learning approaches to autism offer a promising framework, however, they have so far been limited to data from English-speaking cultures. This bias, which coincides with a more general bias in autism research towards the study of the condition within statistically prominent cultures, hinders the usage of computational screening methods in languages and cultures in which autism is less well understood and in which fewer diagnostic data are available.

Objectives:

In this study, we applied machine learning methodologies to a cross-cultural dataset, which included parental responses to the English and the Greek versions of the Social Communication Questionnaire (SCQ), a parent-report screening instrument based on the Autism Diagnostic Interview gold-standard assessment. Our first aim was to examine the effectiveness of different machine learning methodologies in two target languages. Our second aim was to examine the diagnostic performance of machine learning algorithms that have been trained on data from one language and tested on data from the other language, as well as algorithms trained and tested on pooled data from the two languages.

Methods:

To address our first aim, we trained representative machine learning algorithms on the English (N = 332 individuals, 104 autistic, mean age: 6-20 years old ) and the Greek data (N = 162 individuals, 62 autistic, age range 4-26 years old) and assessed their diagnostic performance in unseen data from the two target languages (with stratified 10-fold cross-validation method). To address our second research aim, we trained machine learning algorithms on English (Greek) data and assessed their diagnostic performance in Greek (English) data. We also performed experiments in which machine learning algorithms were trained and tested on pooled English and Greek data.

Results:

For both English and Greek, several machine learning algorithms outperformed SCQ's default cutoff-based algorithm in detecting autism. Furthermore, the same types of machine-learning algorithm achieved the best performance in the English and the Greek SCQ data (see Table 1). Our results also suggest that gains from machine learning transferred from English to Greek and vice-versa, and held for the experiments with the pooled dataset (see Table 2).

Conclusions:

Our findings suggest that machine learning can be applied cross-culturally and enable improvements in autism screening. Our results also suggest that machine learning methodologies are potentially transferable across cultures. This implies that large-scale datasets from prominent cultures could support screening for autism with computational methods in cultures that are underrepresented in autism research. Our current work involves using machine learning to understand cross-cultural differences in the identification and the diagnosis of autism.

**414.090** (Poster) Using Word Embeddings to Detect Autism Based on Language Data from an Assessment of Cognitive Ability  
*N. NNamoko<sup>1</sup>, Y. Korkontzelos<sup>2</sup> and T. Karaminis<sup>3</sup>, (1)Department of Computer Science, Edge Hill University, Ormskirk, United Kingdom, (2)Department of Computer Science, Edge Hill University, Ormskirk, United Kingdom, (3)Department of Psychology, Edge Hill University, Ormskirk, United Kingdom*

---

Background:

Word embeddings are a powerful resource from computational linguistics; they are grounded on the distributional hypothesis, according to which words with similar meanings tend to occur in similar contexts. Broadly speaking, word embeddings enable the representation of meanings of words or sentences in a multi-dimensional Euclidean space capturing semantic regularities. For example, the meaning of the word CUP will be represented as a vector in a, say, 300-dimensional space. Importantly, CUP will fall closer to MUG and MILK than to JACKET and TREE.

Recent studies have employed word embeddings to characterise the linguistic profiles of autistic children in structured interactions within diagnostic assessments for autism (e.g., ADOS-2: Goodkind et al., 2018; Prud'hommeaux, Van Santen, & Gliner, 2017). This research has offered new insights into the unique ways with which autistic children use language and showed the potential of word embeddings to support the diagnosis of autism from language data.

## Objectives:

In this study, we use word embeddings to characterise the linguistic profiles of autistic children in the Wechsler Abbreviated Scales of Intelligence (WASI-II; Weschler, 2011), a general-purpose assessment of cognitive ability (rather autistic symptomatology per se). Our first aim is to use word embeddings to account for language ability in the WASI-II Vocabulary task, in which participants are asked to describe what a list of target words mean. Our second aim is to train machine learning classifiers on Vocabulary-task data from autistic and typical children represented with word embeddings, and evaluate their ability to distinguish between responses of autistic and neurotypical children.

## Methods:

To address our first aim, we represented sample responses provided in the WASI-II's scoring manual in a multidimensional space using word embeddings (Word2vec and GloVe). We then examined whether the distances between the target word and the sample responses in the multidimensional space were consistent with the gold-standard scoring of the sample responses. To address our second aim, we applied machine learning classifiers to a dataset with the WASI-II responses from 50 typical and 25 autistic children, aged 6-14 years old, represented in a multidimensional Euclidean space.

## Results:

Our results showed that the distances between the target word and the sample responses in the multidimensional space were consistent with the gold-standard scoring in 81% of the cases. The best classification results on the human data were obtained when a Support Vector Machine with a linear kernel was trained on the dataset represented with the GloVe word embeddings (see Table 1). Diagnostic performance (see Table 1) was moderate and varied considerably across individual WASI-II items (mean sensitivity = 37.25, range = 8.70-100).

## Conclusions:

Our preliminary results suggest that word embeddings can be used to characterise language ability and also detect autistic symptomatology using WASI-II responses with moderate success. Our current work aims to implement methods that take into account age and gender.

### 414.091 (Poster) Using the Big Data Approach to Clarify the Structure of Restricted Repetitive Behaviors across the Most Commonly Used Autism Spectrum Disorder Measures

*M. Uljarevic<sup>1</sup>, B. Jo<sup>2</sup>, T. W. Frazier<sup>3</sup>, L. Scahill<sup>4</sup>, E. Youngstrom<sup>5</sup> and A. Y. Hardan<sup>6</sup>, (1)Department of Psychiatry and Behavioral Sciences, School of Medicine, Stanford University, Stanford, CA, (2)Department of Psychiatry and Behavioral Sciences, Stanford University, Stanford, CA, Stanford, CA, (3)Psychology, John Carrol University, Cleveland, OH, (4)Marcus Autism Center, Atlanta, GA, (5)University of North Carolina at Chapel Hill, Chapel Hill, NC, (6)Psychiatry & Behavioral Sciences, Stanford University, Stanford, CA*

**Background:** Despite the mounting evidence suggesting that restricted and repetitive behaviors (RRB) in autism spectrum disorder (ASD) are not a unitary construct but encompass several distinct domains, the ability of commonly used diagnostic and quantitative ASD measures to assess these domains separately has not been systematically evaluated. By conflating distinct constructs, overly broad domain scores can cloud the understanding of RRB trajectories, the recognition of associations with other clinical domains and hinder understanding of neurobiological mechanisms. Given the wide use of measures such as the Social Responsiveness Scale-2 (SRS-2), the Social Communication Questionnaire (SCQ), and the Autism Diagnostic Observation Schedule (ADOS) across research and clinical contexts, and their availability in several large-scale databases that also include neuroimaging and genetic data, rigorous psychometric evaluation of the ability of these instruments to capture different RRB constructs is needed.

**Objectives:** The main objective of the current investigation was to conduct a psychometric evaluation of the ability of the SRS-2, the SCQ, the ADI-R and the ADOS to capture different RRB constructs.

**Methods:** Exploratory Structural Equation Modeling (ESEM) was conducted using individual item-level data from the SRS-2, SCQ, ADI-R and the ADOS. Data were obtained from five existing publicly available databases. For the SRS-2, the final sample consisted of N= 16761 individuals ( $M_{age}=9.43$ ,  $SD=3.73$ ; 18.5% female); for the SCQ, of N= 15840 ( $M_{age}=7.99$ ,  $SD=4.06$ ; 18.1% female); for the ADI-R, of N= 8985 ( $M_{age}=8.86$ ,  $SD=4.68$ ; 19.4% female); and for the ADOS, of N= 6314 ( $M_{age}=12.29$ ,  $SD=6.79$ ; 17.7% female).

**Results:** The three-factor structure provided the most optimal and interpretable fit to data for all measures (comparative fit index  $\geq .983$ , Tucker Lewis index  $\geq .966$ , root mean square error of approximation  $\leq .028$ ). Repetitive-motor behaviors (RMB), insistence on sameness (IS) and unusual (UI) and/or circumscribed interests (CI) factors emerged across all instruments. No acceptable fit was identified for the ADOS. The three-factor model performed well across sex and age. Associations with age, cognitive functioning, internalizing and externalizing symptoms suggested somewhat distinctive patterns. Higher RMB ratings across all scales and UI ratings across the SCQ and ADI-R were associated with younger age and lower verbal IQ (VIQ) and non-verbal IQ (NVIQ). IS scores across all measures and CI scores on the SRS-2 were directly correlated with age and to a lesser degree but in the same direction with VIQ and NVIQ. Child Behavior Checklist (CBCL) internalizing T scores were strongly positively associated with the SRS-2 and ADI-R IS scores. CBCL externalizing T scores were positively associated with IS and CI scores across all measures.

**Conclusions:** Reported findings demonstrate the capacity and the limitations of the SRS-2, SCQ and ADI-R to measure RRB in individuals with ASD. These measures were not specifically developed to capture distinct RRB domains, however, they are widely used in research and clinical practice and have been collected in several large datasets that are available to the research community. Reported findings also highlight the directions for future measurement development.

**414.092 (Poster)** Using the Brief Observation of Social Communication Change (BOSCC) to Measure Changes in Social Communication of Minimally Verbal Children

**C. K. Toolan<sup>1</sup>, A. Holbrook<sup>1</sup>, S. Freeman<sup>2</sup>, T. Paparella<sup>3</sup> and C. Lord<sup>1</sup>,** (1)University of California, Los Angeles, Los Angeles, CA, (2)Child Psychiatry, UCLA Medical Center, Los Angeles, CA, (3)University of California Los Angeles, Los Angeles, CA

---

Background:

The Brief Observation of Social Communication Change (BOSCC) provides a standardized and efficient method of measuring changes in social communicative behaviors in children with ASD, observed in naturalistic environments. The BOSCC can detect significant change in minimally verbal children's social communication behaviors over time (Grzadzinski et al., 2016; Kitzerow et al., 2016), using coders blinded to treatment status and timepoint. This study is a replication of initial BOSCC studies using a pre-post design. Additionally, we will use this data to determine the feasibility of the online BOSCC coding platform that is currently in beta.

Objectives:

- 1) Use preliminary BOSCC data to examine change in social communication behaviors over time in minimally verbal children undergoing intensive intervention.
- 2) Examine correlates of change in BOSCC scores.
- 3) Examine the relation between BOSCCs that are hand-coded vs. coded using an online coding platform.

Methods:

Participants included 25 minimally verbal children (Mage=46.39 months, SD=13.89) enrolled in a center-based comprehensive intensive partial hospitalization program for young children with ASD.

The BOSCC is a 12-minute videotaped play interaction between an individual and play partner blind to treatment status. BOSCCs were completed at entry and exit (10 weeks of program enrollment) by research assistants. The BOSCC coding includes 15 items coded on a 6-point scale. Items are categorized into two domains: social communication (SC) and restricted and repetitive behaviors (RRBs), as well as a core total. Due to COVID-19, BOSCC coding training and reliability meetings were conducted remotely. Following training, BOSCCs were hand-coded by coders blind to timepoint. Online coding is in progress and results will be available by May 2021.

At entry, participants completed the Mullen Scales of Early Learning and Vineland Adaptive Behavior Scales. Parents also completed the Child Behavior Checklist (CBCL) and Social Responsiveness Scale-2 (SRS) at entry and exit.

Results:

Remote training of coders resulted in strong interrater reliability (% agreement  $\pm 1$  point=.904; ICC<sub>SC</sub>=.975; ICC<sub>RRB</sub>=.982; ICC<sub>Total</sub>=.985)

Children demonstrated significant improvements in BOSCC SC between entry (Md<sub>entry</sub>=30.00) and exit (Md<sub>exit</sub>=25.50; Wilcoxon signed-rank Z=-2.34, p=.019, ES=-.331), but not in RRBs or total scores.

Entry communication scores on the Vineland related to change on BOSCC SC (B=-.097, R<sup>2</sup>=.214; p=.046). Children demonstrated significant improvements on the CBCL (p=.012) and SRS (p=.036) total scores between entry and exit; changes were not related to changes on the BOSCC SC domain.

#### Conclusions:

Consistent with previous studies examining the BOSCC, the BOSCC detects subtle changes in observed social communication due to a brief intervention period in minimally verbal children with ASD. These changes in social communication behavior provide different information than parent-reported change in social skills and behavioral problems. The BOSCC presents the potential to provide data that is truly blinded, though a limitation of this study is the lack of a control group. The online platform represents an opportunity to streamline the training process, coding process, and to increase accessibility to a wider audience of clinical researchers.

#### 414.093 (Poster) Utility of Electronic Measures of Cognition in the Age of COVID-19

**B. Britvan<sup>1</sup>, T. Levy<sup>1</sup>, H. Grosman<sup>1</sup>, I. Gisserman-Kiss<sup>2</sup>, J. Zweifach<sup>3</sup>, D. Halpern<sup>3</sup>, M. P. Trelles<sup>3</sup>, A. Kolevzon<sup>3</sup>, S. Bishop<sup>4</sup>, J. D. Buxbaum<sup>5</sup> and P. M. Siper<sup>3</sup>,** (1)Seaver Autism Center, Department of Psychiatry, Icahn School of Medicine at Mount Sinai Hospital, New York, NY, (2)Neurodevelopmental and Behavioral Phenotyping Service, National Institutes of Mental Health, Bethesda, MD, (3)Seaver Autism Center for Research and Treatment, Department of Psychiatry, Icahn School of Medicine at Mount Sinai Hospital, New York, NY, (4)University of California San Francisco, San Francisco, CA, (5)Department of Psychiatry, Icahn School of Medicine at Mount Sinai, New York, NY

---

**Background:** In order to reduce risk of exposure to COVID-19, many researchers are now required to conduct data collection remotely. Measuring cognitive ability in autism spectrum disorder (ASD) research is critical to the diagnostic process. The use of personal protective equipment limits the validity of in-person IQ testing and therefore examining the utility of web-based measures of cognition is of great interest to the field.

**Objectives:** To examine the accuracy of two electronic measures of cognition in predicting IQ on an examiner-administered assessment in individuals with ASD and their immediate family members.

**Methods:** Ninety-two individuals completed this study including 19 probands (10.68 years $\pm$ 4.9), 46 parents (46.5 $\pm$ 7.0), and 27 siblings (11.56 $\pm$ 4.8). Participants completed (1) the Wechsler Abbreviated Scales of Intelligence, Second Edition (WASI-II) administered by a clinician, (2) an electronic version of the Peabody Picture Vocabulary Test, Fourth Edition (e-PPVT-4), and (3) an online Visual Reasoning test (VR) developed by TestMyBrain.org. The majority of participants completed their assessments within the same day and a laptop computer with a standard mouse was used for electronic measures. Data collection occurred prior to COVID-19.

#### Results:

Measures were completed by all participants, with the exception of one proband who was unable to complete the VR test. Mean scores in probands on the WASI-II FSIQ-4 standard score, e-PPVT-4 standard score, and VR z-score were 90.21 $\pm$ 23.6, 87.58 $\pm$ 23.4, and -0.85 $\pm$ 1.18, respectively. On the same measures, mean scores in parents were 112.37 $\pm$ 11.1, 103.78 $\pm$ 9.9, and 0.3 $\pm$ 0.78, respectively, and 115.78 $\pm$ 11.1, 109.19 $\pm$ 11.0, and 0.7 $\pm$ 0.99 in siblings. Mean scores were significantly lower in probands relative to both parents and siblings on the WASI-II (p=.001; p<.001), e-PPVT-4 (p=.008; p=.001), and VR (p=.007; p=.010). There was no significant difference between parent and sibling scores (p's>.05).

Pearson's correlation coefficients indicated that WASI-II FSIQ-4 standard scores were significantly correlated with both e-PPVT-4 standard scores (r=0.789, p<.001) and VR z-scores (r=0.694, p<.001). However, only 28.3% of participants' e-PPVT-4 standard scores fell within the 95% confidence interval of their WASI-II FSIQ-4 standard scores. When the sample was divided based on scores one standard deviation below the mean (i.e., SS $\geq$ 85 and Z-score $\geq$ -1), the e-PPVT-4 accurately predicted 97.6% of participants, and the VR accurately predicted 84.5% of participants. Among participants whose WASI-II FSIQ-4 scores were below 85 (all were probands), classification accuracies for the e-PPVT-4 (n=8) and VR (n=7) were 62.5% and 85.7%,

respectively. For probands with WASI-II standard scores above 85 (n=11), 90.9% were correctly classified on the e-PPVT-4 and 81.8% on the VR. The e-PPVT-4 and VR accurately classified 97.8% and 84.8% of parent scores, and 100% and 85.2% of sibling scores, respectively.

**Conclusions:** Correlations between electronic measures of cognition and the WASI-II suggest all three assessments are measuring the same construct. However, variability at the individual level indicates that the electronic measures do not provide adequate estimates of a specific IQ score. The electronic measures may be useful to understand cognitive capacity of individuals with and without ASD at a group level, although additional measures should be explored to provide more reliable individual estimates of IQ.

**414.094 (Poster)** Utility of the Modified Anxiety Dimensional Observation Scale (M-Anx-DOS) in Preschoolers with Autism Spectrum Disorder

**A. L. Hogan<sup>1</sup>**, K. D. Smith<sup>1</sup>, N. Mian<sup>2</sup>, C. J. Black<sup>1</sup>, C. E. Knott<sup>3</sup>, C. G. Moser<sup>4</sup>, K. Hills<sup>5</sup>, A. Fairchild<sup>1</sup>, A. S. Carter<sup>6</sup> and J. Roberts<sup>1</sup>. (1)Department of Psychology, University of South Carolina, Columbia, SC, (2)University of New Hampshire, Manchester, NH, (3)Psychology, University of South Carolina, Columbia, SC, (4)Communication Sciences & Disorders, University of South Carolina, Columbia, SC, (5)University of South Carolina, Columbia, SC, (6)Department of Psychology, University of Massachusetts Boston, Boston, MA

---

**Background:** Co-occurring anxiety affects ~50% of individuals with autism spectrum disorder (ASD) and results in greater impairments and poorer quality of life than ASD alone. However, little is understood about how anxiety manifests early in childhood in ASD, particularly in children with intellectual disability, in part due to the paucity of measures designed to assess anxiety symptoms in very young children with ASD. Improved observational measurement and a better understanding of anxiety in young children with ASD is critical to the development of prevention programs, which have been shown to be highly effective at mitigating the long-term impacts of anxiety in typically developing (TD) children.

**Objectives:** In the present study, we modified the Anxiety Dimensional Observation Scale (Anx-DOS), an existing observational measure of anxiety symptoms in young children and examined its reliability and validity in preschool-aged children with ASD and comorbid intellectual disability.

**Methods:**

This study included 48 children with ASD (41 male, 7 female; M(SD) age=43.96(7.12) months) and 31 typically developing controls (24 male, 7 female; M(SD) age=43.62(11.64) months). Of the children with ASD, 81.3% (n=39 out of 48), had an IQ < 70. The Modified Anx-DOS (M-Anx-DOS) included five presses designed to elicit anxiety-related behavior: Spider, Auditory Startle, Mystery Jar, Maternal Separation, and Stranger Approach. Each press was coded offline from video for a variety of behaviors, including fear arousal, exaggerated startle, physical avoidance, and proximity seeking, and a global anxiety rating was also assigned. Cronbach's alpha was computed to examine internal consistency within each press. Intra-class correlations (ICCs) were utilized to investigate inter-rater reliability. Convergent validity was investigated via Pearson correlations with the Preschool Anxiety Scale (PAS) subscales. Predictive validity was evaluated via binary logistic regression models predicting clinical best estimate anxiety diagnoses. The proportion of children with at least one anxiety diagnosis was marginally higher in the ASD group (47.83%) than the TD group (29.03%),  $\chi^2(1)=2.72, p=.099$ .

**Results:** All presses showed good internal consistency, with alphas ranging from .70 to .92. ICCs ranged from .81 to 1.00, reflecting strong inter-rater reliability. In the ASD group, several Anx-DOS press scores were associated with social, separation, and generalized anxiety symptoms on the PAS,  $r_s \geq .26, p_s < .05$ . When groups were combined, the Anx-DOS press scores were a marginally significant predictor of anxiety diagnosis,  $\chi^2(5)=9.55, p=.089$ , with sensitivity of .39 and specificity of .87. When run separately, the model was non-significant in the ASD group,  $\chi^2(5)=2.89, p=.717$  (sensitivity=.55; specificity=.67), but significant in the TD group,  $\chi^2(5)=20.28, p=.001$ , (sensitivity=.67; specificity=.96).

**Conclusions:** The M-Anx-DOS exhibited strong reliability and convergent validity in preschool-aged children with ASD. Interestingly, the M-Anx-DOS predicted clinical best estimate anxiety diagnoses in the TD group, but not the ASD group. These findings suggest that while the M-Anx-DOS may be effective at eliciting anxiety symptoms in very young children with ASD, it may not correspond as closely with categorical anxiety diagnoses. This may reflect the challenges inherent in assigning anxiety diagnoses in young children with ASD, particularly those with intellectual disability.

**414.095 (Poster)** Utilizing the CBCL As an ASD Screener and Outcome Measure for a Social Skill Intervention in Autistic Adolescents

Background:

Autistic adolescents' social challenges contribute to lower quality and quantity of friendships, greater loneliness, and victimization (Adams et al., 2016; Kasari et al., 2011; Mazurek & Kanne, 2010). Furthermore, common comorbidities (i.e. depression, anxiety) increase social challenges, increasing the possibility for autistic individuals to experience detrimental outcomes (Bellini, 2004; Mazurek & Kanne, 2010). As the prevalence rates of Autism Spectrum Disorder (ASD) increase (Baio et al., 2018), it is imperative to explore potential screeners, functioning to screen individuals at high-risk for an ASD diagnosis and suggest further evaluation. The Child Behavioral Checklist (CBCL; Achenbach & Rescorla, 2001) provides one such potential ASD screener and intervention outcome evaluation for the *Program for the Evaluation of the Enrichment of Relational Skills (PEERS®; Laugeson & Frankel, 2010)*.

Objectives:

The purpose of the present study was twofold. First, in light of prior discrepant research findings (e.g., Bölte et al., 1999; Havdahl et al., 2016; Mazefsky et al., 2011), a replication of CBCL subscale score examination for differences between two adolescent ASD and age-controlled, IQ-matched typically developing (TD) samples was conducted. Second, this study investigated the outcomes of *PEERS® for adolescents* via the CBCL scales to examine the use of a broadband measure of behavior to quantify widespread intervention outcomes.

Methods:

122 participants aged 11-16 ( $M=13.55$ ; 93.9 % male) were recruited and enrolled in the current study and placed within the following conditions: Experimental (EXP;  $n=56$ ), Waitlist (WL;  $n=53$ ) Control (TD;  $n=13$ ). EXP and WL conditions were randomly assigned for autistic individuals without a cognitive disability ( $IQ>70$ ). All groups completed self- and parent-report questionnaires, including the CBCL, at two timepoints: pre- and post- intervention (*PEERS® for adolescents*). Aim one utilized a Multivariate Analysis of Variance (MANOVA) to examine group differences (EXP vs. WL vs. TD) on CBCL Syndrome scales scores (Anxious/Depressed, Withdrawn/ Depressed, Social Problems, Thought Problems, Attention Problems, and Aggressive Behavior scales). Aim two examined a Group (EXP vs WL) by Time (pre- vs. post-intervention) repeated measures MANOVA conducted on the aforementioned scales.

Results:

Results for aim one indicated elevated scores for the CBCL present in ASD EXP and WL groups as compared to TD groups on the Anxious/Depressed, Withdrawn/Depressed, Social Problems, Somatic Problems, and Attention Problems subscales (Wilks' Lambda = .594,  $F(16, 224) = 4.168$ ,  $p < .001$ ; see Table 1). Results of the second aim showed a significant effect of Time x group (Wilks' Lambda = .884,  $F(6,102) = 2.242$ ,  $p = .045$ , Partial  $\eta^2 = .116$ ). Follow-up univariate tests showed significant decreases in the Social Problems and Withdrawn/Depressed mean scores for the EXP group (See Table 2).

Conclusions:

Findings support prior research indicating the CBCL as a potential screener for ASD in adolescents by the identification of a unique scale elevation pattern. Furthermore, outcomes provide additional support for the efficacy of *PEERS® for adolescents* in ameliorating social challenges and collateral symptoms. Findings implications include the importance for further evaluation of the CBCL as an ASD screener, and the need for greater dissemination of social skills interventions.

**414.096 (Poster)** Validating an Adaptive Age Equivalent and Adaptive Developmental Quotient Using the National Database for Autism Research (NDAR)

**L. Hamrick<sup>1</sup>, B. Kelleher<sup>1</sup>, T. Halligan<sup>2</sup>, W. S. Neo<sup>1</sup>, T. F. Protho<sup>1</sup> and N. Witthuhn<sup>3</sup>, (1)Psychological Sciences, Purdue University, West Lafayette, IN, (2)Child Study Center, Yale University School of Medicine, New Haven, CT, (3)University of Oregon, Eugene, OR**

---

Background: Estimates of developmental functioning are critical for contextualizing other developmental skills and behaviors. Gold-standard evaluations of developmental level are typically conducted in highly-standardized contexts but are not always feasible due to financial or behavioral constraints. Adaptive skills are associated with developmental level (Perry, Flanagan, Geier, & Freeman, 2009) and can be accurately assessed remotely via parent report. Thus, adaptive skills may serve as a proxy for estimating developmental functioning when in-person testing is not possible. However, no quantitative methods exist for translating adaptive skills to estimates of developmental functioning.

Objectives: We evaluate the convergent and divergent validity of two new metrics—the adaptive age equivalent (AAE) and the adaptive developmental quotient (ADQ)—that can be calculated from parent-report data using the Vineland Adaptive Behavior Scales, 3<sup>rd</sup> Edition (Vineland-3) and may serve as developmental functioning proxies.

Methods: Our sample included 403 children with autism spectrum disorder (ASD) aged 17-166 months from the National Database Autism Research (NDAR). We included participants with raw scores for each of the seven primary subdomains of the Vineland-3: Receptive Language (RL), Expressive Language (EL), Personal Skills (PER), Interpersonal Skills (IP), Play & Leisure (PL), Fine Motor (FM), Gross Motor (GM). For each subdomain, we calculated a developmental quotient (DQ) score by (1) converting raw scores to age equivalent (AE) scores and (2) dividing the AE score by chronological age. We conducted two separate exploratory factor analyses (EFA) for the AE and DQ scores. Subdomains that loaded  $>|.40|$  onto the first factor were averaged to create AAE and ADQ scores. We then explored associations with convergent and divergent measures, listed in Table 2. We hypothesized that AAE and ADQ scores would demonstrate at least medium associations with convergent validity measures ( $r \geq .50$ ) and smaller associations ( $r < .30$ ) with divergent validity measures.

Results: Analyses were conducted in R using psych and lavaan packages. EFAs demonstrated that five subdomains loaded onto the first factor for the AAE model and three subdomains loaded onto the first factor for the ADQ model (Table 1). We conducted Pearson's partial correlations of AAE and ADQ with each validity measure, covarying for chronological age. Results partially supported our hypotheses for convergent validity (Table 2), with AAE and ADQ demonstrating medium-to-large associations ( $r$ 's  $> .57$ ) with chronological age and the Mullen Scales of Early Learning, whereas associations with other convergent measures were small ( $r$ 's  $< .32$ ). Results supported our hypotheses for divergent validity; AAE and ADQ demonstrated significant but small associations with executive functioning, ASD symptomatology, and repetitive behaviors ( $r$ 's  $< .28$ ).

Conclusions: Our findings suggest adequate validity of AAE and ADQ scores and support their use for approximating developmental level for children with ASD. Convergent analyses suggest that AAE and ADQ metrics may be better suited as proxies for developmental skills (e.g., language, motor) as opposed to cognitive ability (e.g., fluid reasoning, verbal comprehension), consistent with the types of skills primarily captured by the Vineland-3. This study represents an important step towards overcoming barriers to research on early development by establishing valid metrics of developmental level that can be obtained remotely.

#### 414.098 (Poster) Validation of the Autism Detection in Early Childhood-Japanese (ADEC-J)

*H. Kawashima<sup>1</sup>, C. Dissanayake<sup>1</sup>, D. Hedley<sup>1</sup>, E. Kezuka<sup>2</sup> and M. Okuno<sup>3</sup>, (1)Olga Tennison Autism Research Centre, La Trobe University, Melbourne, VIC, Australia, (2)Gunma Prefectural Women's University, Gunma, Japan, (3)Gunma University of Health and Welfare, Gunma, Japan*

---

Background: In Japan, universal 18-month health check-ups at Public Health Centers provide an opportunity to screen children aged 18–24 months for developmental concerns, including autism. However, children who are detected as having developmental concerns and referred for follow-up services are rarely assessed further, thereby delaying formal diagnosis. Although research emphasizes the importance of autism screening as part of follow-up services, the use of standardized autism screening instruments within these services is rare. This is likely due to a lack of well validated autism screening instruments available in Japanese.

Objectives: To compare the screening properties of a new Japanese version of the Autism Detection in Early Childhood (ADEC-J), a brief, play-based Level 2 autism screening tool designed for young children (up to 3-years), with the Autism Diagnostic Observation Schedule-Second Edition (ADOS-2) in young Japanese children classified as high or low likelihood for a developmental disability based on service use.

Methods: Participants were 60 Japanese children (31 male,  $M_{age}=28.87$  months,  $SD=7.13$ ) who were assessed with the ADEC-J, ADOS-2 (Japanese version), the New Kyoto Scale of Psychological Development, and the Social Maturity Scale-Third Edition. The use of follow-up services at their local Public Health Center was utilized as an index of high likelihood for a developmental disability ( $n=29$  children). Two children had existing diagnoses of autism and two were suspected as having autism. The

administrators of the ADEC-J and ADOS-2 were blind to participants background, group status, and any diagnostic information, as well as each other's assessment results.

Results: Children in the high-likelihood group scored significantly higher on both the ADEC-J and ADOS-2, and significantly lower on developmental and adaptive skills, compared to the low-likelihood group. The ADEC-J scores were significantly and highly correlated with the Social Affect, Total, and Comparison Scores of the ADOS-2 ( $r = .80-86, p < .001$ ), and moderately correlated with the Restricted and Repetitive Behavior scores ( $r = .64, p < .001$ ). One of the children with an autism diagnosis and two suspected cases met cut-off scores on both the ADEC-J and ADOS-2. One older (41 months) child with autism met criteria on ADOS-2 but not ADEC-J.

Conclusions: The findings of high ADOS-2 scores and low developmental and adaptive skills in children using Public Health Center follow-up services in Japan suggests the presence of autism and possible developmental delays; yet many children did not have any formal diagnosis suggesting the need for developmental pediatric assessments in this population to identify, or rule out, autism and other conditions. The newly developed ADEC-J was strongly correlated with the ADOS-2 and was effective in identifying autism in young children indicating the promise of this tool for use in Japan. Our findings support its introduction as part of the developmental assessment of children identified with developmental concerns as part of routine screening throughout the public health network.

**414.099** (Poster) Validation of the Autism Diagnostic Observation Schedule with Open-Access Data

**H. Baker-Harvey**<sup>1</sup>, **S. Schwartz**<sup>2</sup> and **H. Tager-Flusberg**<sup>3</sup>, (1)Boston University, Boston, MA, (2)Graduate Program for Neuroscience, Boston University, Boston, MA, (3)Department of Psychological and Brain Sciences, Boston University, Boston, MA

---

Background: The Autism Diagnostic Observation Schedule (ADOS) has been the gold-standard for autism diagnosis for many years. However, the algorithm items for the ADOS-G (Lord et al., 2000) were initially validated on only 223 samples, and later revised based on a new validation set of 1,630 assessments for the ADOS-2 (Gotham et al., 2007) that were then validated on an independent sample of 1,282 assessments (Gotham et al., 2008).

Objectives: We sought to validate the ADOS algorithm items using a large set of open-access data and to investigate the potential predictive value of a singular set of core autism items, accurately differentiating between autism and no autism across age and language level.

Methods: Data from the ADOS-2 Modules 1-3 were downloaded from the NIMH Data Archive (NDAR). After removing invalid or missing data, 10,042 assessments remained. Assessments were from children aged 17 months to 192 months, labeled as either having autism ( $n = 6558, \text{Age} = 87 (SD = 45)$  months) or not ( $n = 3487, \text{Age} = 60 (SD = 37)$  months). We selected the 18 ADOS items that were common across the three modules and collapsed data across modules. Item values were ordinal, with ratings between 0 and 3. Exploratory and confirmatory factor analyses were conducted to identify how items covaried and grouped into either one, two, or three-factor constructs. Logistic regression models were then conducted using the ADOS items selected from these factor models to predict autism diagnosis. Specificity and selectivity of the logistic regression models were based on 20% of the data after training the models on an initial 80% of the data.

Results: Factor analyses provided statistical support for both a single-factor model combining core autism features and a two-factor model with constructs similar to what the ADOS-2 has previously defined as "Social Affect" (SA) and "Repetitive and Restricted Behavior" (RRB) domains (**Table 1**). In the single-factor model, core features were a significant predictor of diagnosis (log likelihood = -4022.4,  $p < 0.001$ ). In the two-factor model, SA and RRB were significant predictors of diagnosis (log likelihood = -4121.1,  $p < 0.001$ ; SA: log likelihood = -4162.6,  $p < 0.001$ ; RRB: log likelihood = -5189.2,  $p < 0.001$ ). Furthermore, logistic models using single- and two-factor model items to predict autism diagnosis performed with a sensitivity of ~93% and specificity of ~88% (**Table 2**).

Conclusions: Analyses validated a two-factor model of the ADOS with a substantially larger sample size from open-access repository data and demonstrate the potential predictive value of a single-factor algorithm that captures core features of autism across language level modules.

**414.100** (Poster) Validity of the Boscc across Settings and Interaction Partners

**J. Kitzrow**, **C. Lemler**, **S. Kleber**, **Z. Kim**, **K. Teufel** and **C. M. Freitag**, Autism Research and Intervention Center of Excellence Frankfurt, Department of Child and Adolescent Psychiatry, Psychosomatics and Psychotherapy, University Hospital Frankfurt, Goethe University, Frankfurt, Germany

---

**Background:** The *Frankfurt Early Intervention Program for preschool children with ASD (A-FFIP)* is a manualized low-intensive therapist-delivered and parent-supported early intervention program, which is currently studied for efficacy by a German multi-center randomized controlled trial (target sample N = 134 preschool-aged children at four study sites). The primary outcome measure is the *Brief Observation of Social Communication Change (BOSCC)* with an unknown administrator. Several additional secondary outcome measures as well as mediating mechanisms are studied. The BOSCC is a relatively new instrument and has mainly been used to code parent-child interactions. Additionally, the ADOS\_BOSCC was developed to allow coding of more standardized situations with an unknown tester. The Early social communication scales (ESCS) are widely used in early intervention trials and might also be appropriate for recoding with the BOSCC. To date (1) the usage of an ESCS\_BOSCC has not been studied, and (2) no study has directly compared BOSCC scores of four different settings with different interaction partners.

**Objectives:** To (1) present psychometric properties of the BOSCC coding based on selected ESCS video-scenes, and (2) to compare BOSCC scores derived from parent-child interaction scenes (DCMA) and interactions with unknown testers (BOSCC, ADOS-2, ESCS).

**Methods:** Cross-sectional data of N = 30 minimally verbal children, aged 2-5.5 years old are reported. The BOSCC coding system was applied to four different 12-minute video scenes: DCMA, BOSCC, ADOS-2, and ESCS. (1) Score distributions, Cronbach's alpha, confirmatory factor analyses and consensus are reported; (2) repeated measures ANOVAs were performed to elicit differences between the different settings.

**Results:** (1) Psychometric properties of the ESCS\_BOSCC were satisfying. (2) There was a significant difference in the BOSCC total scores by setting ( $F=5.74, p=.005, \eta^2=.175$ ) and the domain scores (social communication (SC):  $F=7.76, p<.001, \eta^2=.223$ ; restrictive and repetitive behavior (RRB):  $F=5.57, p=.002, \eta^2=.171$ ). Children showed less RRBs in the parental interaction but had higher SC scores, compared with the other more standardized situations with an unknown tester. Regarding the situations with an unknown administrator most RRBs were noticed in the free-play interaction, least RRBs in the highly structured setting of the ESCS, whereas SC scores were comparable over the three settings involving an unknown tester.

**Conclusions:** The BOSCC is a feasible instrument that may be used with different settings to measure autism symptoms. Based on our study, validity of BOSCC scoring based on ESCS scenes was satisfying. To compare study results, existing ESCS videos can be recoded with the aim to capture more autism-symptom related behaviors. Also, this study highlights the importance of being aware about influencing factors when choosing specific BOSCC settings and interaction partners. Specific interventions might improve social-communication skills during parent-child interaction, but more global measures and standardized settings show greater degrees of generalization that differ from the behaviors shown in parent-child interactions. The results on the varying RRB-scores show setting related behaviors that need to be taken into account for when interpreting study findings.

#### **414.101 (Poster) Variability and Change in Autism Symptom Severity Trajectories across Childhood**

**E. Waizbard-Bartov<sup>a</sup>, E. Ferrer<sup>a</sup>, B. Heath<sup>a</sup>, S. J. Rogers<sup>a</sup>, C. W. Nordahl<sup>b</sup>, M. Solomon<sup>a</sup> and D. G. Amaral<sup>b</sup>, (1)UC Davis, Davis, CA, (2)Department of Psychiatry and Behavioral Sciences, The Medical Investigation of Neurodevelopmental Disorders (MIND) Institute, UC Davis School of Medicine, University of California Davis, Sacramento, CA**

**Background:** Autism symptom severity in an individual can change across childhood. However, the prevalence of change is still not well understood. Several publications have documented small groups of children that increased or decreased in symptom severity across childhood. But, we previously found that nearly half of the autistic children experienced significant change in symptom severity during early childhood, suggesting change might be more common than previously portrayed (Waizbard-Bartov et al., 2020).

**Objectives:** Symptom severity trajectories were evaluated for a group of 183 autistic children (128 boys, 55 girls) at three time points across childhood: beginning of early childhood (T1; approximately age 3), end of early childhood (T3; approximately age 6), and during middle childhood (T4; approximately age 11).

**Methods:** Autism symptoms were measured using the Autism Diagnostic Observation Schedule-2 (ADOS-2) and symptom severity was quantified using the Calibrated Severity Scores (CSS). Symptom trajectories were modeled using Latent Change Score models and Mixture Models. Symptom severity change was also evaluated using the Reliable Change Index, to determine the amount of change (in CSS) between measurement points that could be considered significant change in severity.

**Results:** The ADOS trajectory for all participants taken together indicated a small decrease in severity during early childhood (T1-T3; 3-6 years of age) followed by a small increase in severity during middle childhood (T3-T4; 6-11 years of age). However, symptom severity change demonstrated large individual differences between children, and subgroups were identified that demonstrated a common change tendency across childhood. Two groups of children consistently decreased in severity across

childhood: one group (20.5% of the sample) decreased from high to moderate severity levels and the other (5%) from moderate to minimal severity levels, no longer meeting diagnostic criteria for autism. A third group (27.4%) experienced a large increase in symptom severity. Symptom severity change also differed across developmental phases; children who decreased in severity during early childhood tended to increase in severity during middle childhood, and vice versa (Figure A). The two core domains, Social Affect (SA) symptoms and Restricted, Repetitive Behaviors (RRB), showed opposite change patterns; during middle childhood, SA severity increased for a large proportion of children while most children decreased in RRB severity. Girls demonstrated a stronger tendency to decrease in symptom severity than boys, which became more evident through childhood and led to girls having lower scores with age (Figure B).

Conclusions: Up to 48% of children experienced symptom severity change, either decrease or increase in severity, during different periods of childhood. Symptom severity change was highly variable and characterized by three types of differences: individual differences between children, differences within children across time and differences between the core domains. These differences balanced out in the combined ADOS trajectory for all children, creating a stable presentation across time that did not reflect the extent of change occurring in the individuals that constituted the sample. Determining what biological and social factors contribute to the varying trajectories of autism severity during childhood will be a fertile area for research in the future.

**414.102 (Poster)** Verification of New Screening Tools for Neurodevelopmental Disorders in 5-Year-Old Children, Including the Use of Web Systems

**A. Terui<sup>1</sup>, M. Saito<sup>1</sup>, M. Adachi<sup>2</sup>, Y. Sakamoto<sup>1</sup>, A. Osato<sup>3</sup>, T. Mikami<sup>3</sup> and K. Nakamura<sup>1,3</sup>,** (1)Department of Neuropsychiatry, Graduate School of Medicine, Hirosaki University, Hirosaki, Japan, (2)Department of Clinical Psychological Science, Hirosaki University, Hirosaki, Japan, (3)Research Center for Child Mental Development, Graduate School of Medicine, Hirosaki University, Hirosaki, Japan

Background: Early intervention for neurodevelopmental disorders (NDD) requires early detection, but the spread of Covid-19 makes it difficult to perform developmental screening for infants and young children. In addition, long-term epidemiological studies are needed on the impact of COVID-19 on NDD. We created the NDD screening algorithm for 5-year-old children in 2014, and then started using it as multiple questionnaires. This system, which began to be used as a Web system in 2019, can still be used even under the spread of COVID-19 infection.

Objectives: This study reports the results, including the verification of the Web system in 2019.

Methods: In 2013, we created an algorithm for NDD risk group extraction from multiple questionnaires filled out by parents and teachers of 954 5-year-olds, detailed examinations of 156 people, and DSM-5 diagnostic data. We conducted 965 children in 2014, 1004 in 2015, 1031 in 2016, 967 in 2017, and 1040 in 2018 to verify the usefulness of the algorithm. The verification method is as follows. First, we compared the proportion of risk children under the old and new algorithms for each year. Next, we compared changes in the proportion of children who underwent detailed examinations who were diagnosed with NDD and needed assistance and those who were below the diagnostic criteria but needed observation. Finally, the sensitivity and specificity of the old and new standards were calculated.

Results: According to the new algorithm, the rate of children at risk of NDDs in all 5-year-olds of the year was 18.6% in 2014, 20.0% in 2015, 17.4% in 2016, 16.4% in 2017, 17.1% in 2018 and 17.6% in 2019 compared with 23.8% in 2013 (fig.1). The ratio of NDD risk group extraction was lower in the new algorithm than in the old one. In addition, despite the decline in the number of children at risk, the proportion of children diagnosed with NDD among those who underwent detailed examination increased to 72.7% in 2014, 62.1% in 2015, 73.1% in 2016, and 80.2% in 2017, 69.2% in 2018 and 69.7% in 2019 compared with 47.8% in 2013 (fig.2). We were able to prove that about 90% of children, including those in the need for observation (NDD gray zone), needed follow-up and intervention support in each year. In the algorithm we created, the sensitivity of NDD diagnosis was 79.8% and the specificity was 99.1%. The sensitivity of follow-up judgment was 89.1% and the specificity was 98.8%.

Conclusions: This study proved that the algorithm we created can efficiently detect developmental disorders in preschool children. This web screening system is expected to have a high level of participation even under COVID-19 infection and will be beneficial to children and parents in need of support for primary school enrollment.

**414.103 (Poster)** Virtual Diagnostic Evaluation of Young Children for Autism Spectrum Disorder: The Observation of Play Screener: Home Edition

**R. E. Nickel, OHSU, Eugene, OR**

Background: The Corona virus pandemic resulted in the shutdown of face-to-face diagnostic services for young children with suspect Autism Spectrum Disorder (ASD). The shutdown significantly delayed referral of young children with ASD to the limited treatment services available and connecting families with online resources on ASD.

Objectives: Develop a valid and reliable virtual play assessment as part of a virtual diagnostic evaluation of young children referred with suspect ASD.

Methods: The virtual diagnostic evaluation was conducted during two 1 hour virtual visits (by Zoom) scheduled 2 weeks apart. During the first visit, a structured interview based on DSM 5 criteria for ASD (\_\_\_\_, unpublished) is conducted with parents and developmental/medical history is completed. Prior to the second visit parents are requested to create and upload videos of 3 or 4 household routines for review. During the second visit, a structured virtual play assessment is conducted, the Observation of Play Screener: Home Edition (OOPS:HE, \_\_\_\_\_, 2020), and surface physical exam for minor anomalies and birth marks and observation of gross motor skills are obtained. Parents are sent a description of OOPS:HE prior to the second virtual visit including a list of recommended toys and the 12 structured activities (Recipe for Success: A Structured Play Observation with Your Child). The examiner prompts the parent to complete all of the activities with their child during the session.

The OOPS:HE was developed for use with children 12-36 months of age and has 20 items arranged in three sections: Social Communication (SC), Social Emotional Reciprocity and Relationships (SERR), and Restricted and Repetitive Behaviors (RRB). The test items for the SC and SERR sections are behaviors typically seen in toddlers. They are spontaneous behaviors you observe (e.g., to-and-fro vocalizations, seeking contact with parent, use of words and gestures), and the toddler's responses to specific activities of the play session (e.g., response to name being called, requesting, rolling a ball back, imitation). The test score is the number of items failed (not present) for SC and SERR sections plus the number of RRB items present. The examiner also circles whether a diagnosis of ASD is definite, probable, possible or not present.

Results: 20 children have completed the virtual diagnostic evaluation to date, all save one OOPS:HE sessions were adequate technical quality. Ages ranged from 16 months to 3 years, OOPS:HE scores ranged from 2 to 20, 8 rated as definite ASD (mean score 16), 6 probable ASD (mean score 13), and 5 no ASD (mean score 3). The rating of OOPS:HE (probable, definite ASD) agreed in all cases with the results of the DSM interview. 19 families submitted home videos of which 14 were sufficient quality. Results were consistent with the OOPS:HE. Children are now being scheduled into child development clinic for further assessment to confirm their diagnosis and review progress.

Conclusions: Preliminary results support the ability of parents to conduct a virtual play assessment with their child. Continuing research on virtual diagnostic evaluations of young children with suspect ASD is needed.

**414.104** (Poster) Visual and Tactile Sensory Experiences of Children with ASD: Voices of Those with Autism from Their Autobiographies grant No. T73MC29073 from the Health Resources and Services Administration.

*P. Towle<sup>1</sup> and N. Turygin<sup>2</sup>, (1)Westchester Institute for Human Development, Valhalla, NY, (2)Behavioral Psychology, Westchester Institute for Human Development, Valhalla, NY*

---

Background:

The Diagnostic and Statistical Manual, 5<sup>th</sup> Edition (DSM-5, APA 2013) incorporated sensory symptoms as a new diagnostic criterion for autism spectrum disorder (ASD) under the Restricted and Repetitive Behaviors (RRB) domain. This resulted in research and clinical challenges resulting from the lack of an established construct definition and the dearth of corresponding instruments (Cascio et al., 2016; Schaaf & Lane, 2015). Much of the recent research in the area of RRBs and sensory symptoms used psychophysical and brain imaging methods (Gliga et al., 2018; Haartsen, et al., 2019). There is also the need to understand the perspective of those experiencing these symptoms. As many autistic individuals who are verbal, insightful, and have written about their lives, autobiographical material may be an important complementary resource for information about sensory experiences. This study systematically recorded quotes from such autobiographies to perform a content analysis of these statements.

Objectives:

To examine the experience and contexts of sensory symptoms involving vision and touch as described in autobiographies of those with ASD.

Methods:

Nine conventionally-published autobiographies were identified through internet and online book-selling sources. One autobiography was excluded because it was written entirely through facilitated communication, which as been shown to be unreliable. Two readers read each book and extracted quotes using a standardized recording form. Quotes that described either visual or tactile experiences from the childhood period were identified by consensus of research assistants, and then confirmed by the lead authors. The sensory behavior was classified as either Seeking (wanting to experience it, often repeatedly) or Avoiding (finding the experience aversive). In addition to recording the quote in this way, any elaborated information was classified into three areas: phenomenology (e.g., “it felt like my skin was on fire); associated behavior (“when she tried to take my hand, I jerked it away.”); and explanations for “why” the author did the behavior (“I found it very relaxing,” “...it would help me cope with the overstimulation.”).

The results were then tabulated in terms of percentages of similar descriptions and themes in the area of description (type of behavior), phenomenology, behavior, and explanations.

Results:

The most common type of visual behavior was in the Seeking area of wanting to create repetitive visual experiences. Explanations for these often centered around being relaxing or pleasurable. A second visual Seeking type was that of using peripheral vision to experience the sight in a more comprehensible way. The most common Avoiding visual experiences involved fluorescent or excessively bright lights. In the area of touch, Avoiding behavior was more commonly described, and its phenomenology often involved reported experiences of painful and/or overstimulating touch. The most common Seeking behavior related to touch was towards full-body deep pressure, and secondarily towards stroking or feeling carpet, hair, or fabric.

Conclusions: Autobiographical statements from autistic individuals about their sensory experiences in childhood in the areas of vision and touch showed consistency in description, phenomenology, associated behavior and offered subjective explanations for behaviors. Therefore, these descriptions may be valuable as complementary information to more controlled investigations.

**414.105** (Poster) What's behind the Mask? Evaluating Methods of Measuring Camouflaging  
*B. Hannon, L. Hull and W. Mandy, (1)Cambridgeshire & Peterborough Foundation NHS Trust, Peterborough, United Kingdom, (2)University College London, London, United Kingdom of Great Britain and Northern Ireland*

---

Background:

In recent years there has been increasing interest in the measurement of camouflaging or masking strategies (hiding of and compensating for autistic characteristics) used by autistic people. Several different methods of measurement have been developed, however until now there has no evaluation or direct comparison of these different methods. Researchers therefore have little guidance when choosing which methods are most appropriate for their studies.

Objectives:

To evaluate established methods of measuring camouflaging in autism, and to compare three such methods in an autistic adolescent sample.

Methods:

Methods of measuring camouflaging were identified through systematic review and evaluated using COSMIN criteria by two independent reviewers. Two of these methods (self-report questionnaire and a ‘discrepancy’ approach) and a newly developed method (informant-report questionnaire) were applied to a sample of 59 autistic adolescents (29 female, mean age 14.5 years, mean IQ 100.6), in addition to a parent-reported measure of social skills.

Results:

Evaluation using COSMIN criteria revealed that the most commonly used measures of camouflaging appear to be the most psychometrically rigorous, providing evidence of good structural validity, and some indication of reliability. In the adolescent sample, self-report and informant-report measures, and informant-report and discrepancy measures, were strongly positively correlated ( $r = .47$  and  $r = .46$  respectively). None of the measures were significantly correlated with participants’ social skills.

Conclusions:

Researchers should be aware of the strengths and limitations of the methods available to measure camouflaging. Different methods of measuring camouflaging are related to each other but distinct from social skills, suggesting that they each tap into a similar underlying construct of 'camouflaging'. Where participants are not able to report on their own behaviours, informant-report and discrepancy methods can be used to identify camouflaging behaviours.

**414.106 (Poster)** Youth at Low Risk for Receipt of an ASD Diagnosis: Identification of Predictor Variables to Improve Screening and Triage

*X. D. Hu<sup>a</sup> and K. Nowell<sup>b</sup>, (1)University of Missouri, Columbia, MO, (2)Thompson Center for Autism & Neurodevelopmental Disorders, Columbia, MO*

---

**Background:** Given the increased demand on diagnostic assessment services, families seeking evaluations for autism spectrum disorder (ASD) are facing extremely long waitlists and corresponding delays in diagnosis. To address this crisis, a potential strategy is to maximize efficiency of services by using scores from screening instruments to triage youth referred for ASD diagnostic evaluations to specific clinics based on their level of risk. However, evidence suggests psychometric properties of screening instruments may vary depending on a variety of child and family factors (Rosenberg et al., 2018). Thus, it is important that other indicators be identified to supplement screening measures such that youth at risk for receipt of an ASD diagnosis are triaged to the most appropriate diagnostic services.

**Objectives:** We aimed to characterize a sample of youth referred to a low-risk ASD diagnostic clinic. Secondly, we aimed to explore predictor variables from commonly administered measures that may be associated with receipt of an ASD diagnosis.

**Methods:** Data were extracted from an on-site database for 233 youth (79% male; *M* age = 7.17 yrs., range: 3-19 yrs.) who were referred for an ASD diagnostic evaluation at a specialist center serving individuals with autism and neurodevelopmental disorders. Youth included in this study were at low risk for receipt of an ASD diagnosis based on SCQ scores (< 12) and triaged to an interdisciplinary clinic designed specifically for this population. Descriptive statistics were used to characterize the sample, and logistic regression analysis was used to examine a model with ASD diagnosis as a dichotomous dependent variable. Predictor variables included the following: demographic variables (i.e., household income, gender, and race), *Social Communication Questionnaire* (SCQ) scores, *Adaptive Behavior Assessment System-Third Edition* (ABAS-3) domain scores (i.e., Conceptual, Social, Practical), and *Child Behavior Checklist* (CBCL) subscale scores.

**Results:** Of the sample, 44.2% (74% male; *M* age = 7.14 yrs.) received an ASD diagnosis. The binomial logistic regression model was significant ( $\chi(14) = 50.36, p < .001$ ) and resulted in the following additional pertinent findings: SCQ scores were not predictive of an ASD diagnosis (Odds = 1.049,  $p = .590$ ); the ABAS-3 Social domain score was significantly *negatively* related to receipt of an ASD diagnosis (Odds = .940,  $p = .004$ ); the CBCL: Withdrawn/Depressed subscale (Odds = 1.139,  $p = .005$ ) and CBCL: ADHD subscale score (Odds = 1.173,  $p = .003$ ) were predictive of an ASD diagnosis. Specifically, the model indicated that for every standard deviation increase in withdrawn/depression scores or ADHD score, the odds that a child get an ASD diagnosis increased by 13.9% or 17.3% while accounting for the effects of all variables in the equation.

**Conclusions:** Results suggest that, in this sample of youth, scores from the SCQ were not helpful in differentiating youth who ultimately received an ASD diagnosis. However, there appear to be other predictors from commonly administered measures that could be used in conjunction with other data to appropriately triage youth to ASD diagnostic clinics. Limitations, clinical applications, and future directions will be discussed.

**414.107 (Poster)** • Validation of a New Digital Tool, the Pirates Autism Assessment App, to Aid Screening of Primary School Children Referred with Possible Autism for Formal Diagnostic Assessment

*W. Farr<sup>a</sup> and I. Male<sup>b</sup>, (1)Sussex Community NHS Trust, Haywards Heath, United Kingdom, (2)Mid Sussex Child Development Team, Sussex Community NHS Trust, Haywards Heath, United Kingdom*

---

Background:

With increasing demand and waiting times for autism diagnostic assessment, we need to improve the timeliness of diagnostic assessment (National Health Service (NHS) England Long Term Plan 2019). Digital tools which are task-specific and adapted for inclusive use can engage children across the neuro-diverse spectrum positively; and have potential to deliver more efficient diagnostic pathways. We present the results of a validation study of a novel autism assessment app (Pirates). This includes tests of Theory of Mind, Affect Recognition, Fantastic Stories and Understanding of Idiom presented in a pirate adventure game format. This can be played with the child, alongside history taking and school information, at initial clinical assessment of a child referred for possible autism.

#### Objectives:

- Determine if children diagnosed with autism perform differently to Neurotypical (NT) children using the Pirates app.
- Establish sensitivity and specificity.

#### Methods:

Following statistical advice, and NHS ethical approval, we aimed to recruit 120 children (60 autism, 60 NT) attending mainstream primary school (age 4 to 11). With written informed consent children played on the app with a researcher, and responses to each question were recorded. From this a score was calculated based on number of errors (if no errors, score 28, each error scores +1 to total, so max score 56 (28 errors)). Statistical significance tested by unpaired T-test.

#### Results:

Children with autism (N=51, study closed early as unable to assess children during Covid) made a larger number of errors (mean score 35) than NT (n=59) (score 31  $p<0.000001$ ). Number of errors decreased in both groups with age, reflecting that developmental skills such as Theory of Mind improve with the age of the child: NT key stage one (KS1) (<90 months) mean score 32, key stage two (KS2) (over 90 months) 31, and in autism group KS1: score 37, KS2: 34. From this, cut-offs between likely autism and likely NT were determined according to age. Using these cut-offs overall sensitivity was 75%, specificity 86%, improving to 77% and 94% for KS1 age group. It was also observed that playing with the child using the app gave additional helpful information about their social interaction, e.g. whether they responded socially to shared humour during some scenarios, or needed reminders to listen to the question before pressing buttons “impulsively”. Previous published pilot work has shown high acceptability with parents and children, and suggests digital-clinical interaction typically takes 10-15 minutes to complete, fitting well into a standard 60-90 minute initial paediatric developmental assessment.

#### Conclusions:

The Pirates app shows promise as a tool that can be used alongside initial clinical assessment including history taking and information from school, to determine whether full, detailed, diagnostic assessment is required. In some cases, it may support an early and shortened diagnostic pathway of the child at the initial stage of the diagnostic process. By improving early decision making, including increasing confidence in deciding whether or not a child needs to proceed to full diagnostic assessment, this could help improve the timeliness of diagnostic assessment, and reduce service delivery costs.

## Early Development (< 48 months)

### ORAL SESSION — EARLY DEVELOPMENT (< 48 MONTHS)

#### Oral 308 - Assessment & Social Development

**308.001** (Oral) Screening for ASD in Toddlers Born Premature: Psychometric Properties of the M-CHAT-R/F

*K. D. Kelly<sup>1</sup>, T. Hamner<sup>1</sup>, G. Perez Liz<sup>1</sup>, S. E. Nanovic<sup>1</sup>, K. Feehan<sup>2</sup>, B. Garvin<sup>2</sup>, R. Turchi<sup>2</sup>, D. A. Fein<sup>3</sup> and D. L. Robins<sup>1</sup>, (1)A.J. Drexel Autism Institute, Drexel University, Philadelphia, PA, (2)St. Christopher's Hospital for Children, Philadelphia, PA, (3)Psychological Sciences, University of Connecticut, Storrs, CT*

**Background:** Medical advances have contributed to higher rates of survival for infants born preterm, yet these children remain at increased risk for cognitive and behavioral disabilities (Peralta-Carcena et. al., 2017). Early work suggests infants born premature show increased rates of positive screens on autism spectrum disorders (ASD) screening measures (13-14%; Gray et. al., 2014; Guy et. al., 2015). However, diagnostic outcomes in toddlers born premature are not well understood, in part because the process from screening to diagnosis is often not completed (Monteiro et. al., 2019), which may be due to both family and provider/system factors. A better understanding of ASD screener performance in children born premature is critical to informing early detection and intervention.

**Objectives:** This study explores the association between gestational age and screening results, evaluation completion, and diagnostic outcomes.

**Methods:** Across three toddler screening studies, seventy primary care practices screened for ASD using the Modified Checklist for Autism in Toddlers, Revised, with Follow-Up (M-CHAT-R/F; Robins et al., 2009). A total of 8352 toddlers (50.28% male) met inclusion criteria: screened during a toddler well-visit and parent-reported gestational age. Participants were classified using WHO-defined categories of prematurity (extremely [EP] <28 weeks; very [VP] 28-32 weeks; moderately [MP] 32-37 weeks), or as full term (FT>37 weeks). Children identified as at risk from screening or provider/caregiver concern were invited for a diagnostic evaluation (see Table 1).

**Results:** More severe categories of prematurity were related to higher rates of positive M-CHAT-R/F screens ( $\chi^2(3, N = 8352) = 285.96, p < .001$ ). Evaluation attendance ranged from 71.58% (FT) to 89.01% (MP) but did not vary considerably between groups ( $p = .14$ ). The M-CHAT-R/F showed decreasing sensitivity by gestational age category with highest sensitivity for those in EP and VP groups. Conversely, specificity increased by gestational age category, with highest specificity in the MP and FP groups (see Table 2). Diagnostic outcomes revealed ASD prevalence of 14.63% in EP, 2.06% in VP, 2.86% in MP, and 1.46% in FT children, and global developmental delay (GDD) prevalence of 13.41% in EP, 8.27% in VP, 2.55% in MP, and 0.65% in FT children.

**Conclusions:** Findings suggest a higher screen-positive rate for infants born preterm that increases with more severe categories of prematurity. Despite a presumed history of medical involvement, those with prematurity did not attend evaluations at higher rates; thus, there is a need to examine potential barriers to follow-up and to provide support for evaluation referral/completion, especially in high-risk groups. Overall, the EP group evidenced increased rates of both ASD (14.63%) and GDD (13.41%), suggesting a unique, elevated risk related to disrupted developmental trajectories associated with prematurity. Lower specificity in more severely premature groups observed in this study indicates that future research should explore tailored scoring of screeners to improve psychometrics to aide in differentiating ASD risk for this group. This increased risk demonstrates that it is crucial for providers to implement universal screening in vulnerable groups and refer for developmental diagnostic evaluations when concerns arise to promote early intervention.

**308.002** (Oral) Testing the Accuracy and Clinical Value of Novel Tools for Tele-Assessment of ASD in Young Children  
*L. Corona<sup>1</sup>, A. S. Weitlauf<sup>1</sup>, J. F. Hine<sup>1</sup>, A. F. Berman<sup>1</sup>, A. Miceli<sup>2</sup>, A. Nicholson<sup>3</sup>, C. Stone<sup>3</sup>, N. A. Broderick<sup>3</sup>, S. Francis<sup>3</sup>, P. Juárez<sup>4</sup>, A. Vehorn<sup>5</sup>, L. Wagner<sup>5</sup> and Z. Warren<sup>6</sup>, (1)Vanderbilt University Medical Center - Treatment and Research Institute for Autism Spectrum Disorder, Nashville, TN, (2)Vanderbilt Kennedy Center, Vanderbilt University Medical Center, Nashville, TN, (3)Vanderbilt University Medical Center, Nashville, TN, (4)Vanderbilt University, Pleasant View, TN, (5)Vanderbilt University Medical Center - Treatment and Research Institute for Autism Spectrum Disorder, Nashville, NY, (6)Vanderbilt University Medical Center- Treatment and Research Institute for Autism Spectrum Disorder, Nashville, TN*

**Background:** Telemedicine offers tremendous potential for addressing healthcare disparities related to early accurate identification of ASD in traditionally underserved communities. Telemedicine consultation potentially can alleviate time, travel, and geographic burdens for many families that often drastically limited access to services; speed entry into appropriate care; empower parents and medical providers to take a more active role in care; reduce wait times at specialty clinics; and help ensure that for those families for whom further assessment is recommended, the associated waits and expense are truly necessary. Our preliminary work suggests that telemedicine consultation in rural pediatric clinics can potentially rapidly, accurately identify large percentages of young children as with ASD with high levels of family and provider satisfaction, but this work to date was been powerfully constrained by the fact that no specific tools explicitly developed for telemedicine consultation of early ASD were available (i.e. preliminary work required both an expert clinician and a trained technician utilizing traditional assessment within community practice setting).

**Objectives:** In the current work we set out to conduct a rigorous initial evaluation and comparison of two telemedicine assessment tools (*TELE-STAT* and *TELE-ASD-PEDS (TAP)*) that could allow parents or naïve providers in remote locations to complete an ASD risk assessment under in via telemedicine consultation with an expert psychologist.

**Methods:** As part of an ongoing trial (ClinicalTrials.gov: NCT03847337), we will present interim results of young children (n=77; ages 18-36 months) randomized to evaluation with either *TELE-STAT* or the *TELE-ASD-PEDS*. We rigorously evaluated the ability of these to facilitate accurate telemedicine supported diagnostic decision making in comparison to blinded comprehensive evaluations.

**Results:** Interim analyses revealed a total accuracy of telemedicine based classification across all tools and processes ranging from 86-95%. Some 42 of 44 children [*ADOS-2 CSS* of 8.83 (*SD*=1.42), *MSEL: M* = 54.88 (*SD*=11.58), & *VABS-3 ABC: M* = 56.03 (*SD*=10.85)] were accurately classified (i.e. ASD / Other concerns) via assessment processes utilizing the TAP by psychologist with expertise in ASD assessment. Trial completion and full data analyses are anticipated by conference date.

**Conclusions:** Parent-mediated administration of the telemedicine tools for ASD assessment yielded a very high level of agreement regarding ASD risk classification with blinded gold-standard evaluation. Although promising, this work was limited by its reliance on (1) controlled laboratory settings, standardized materials, and researcher-provided technology as well as (2) a sample of clinically referred children with high levels of concern for ASD, recruited from a single site, and evaluated by expert providers. Future work should (a) evaluate in-home use in a broader community sample with novel groups of diagnostic clinicians and (b) rigorously evaluate value, impact, and disparity/harm for those underserved and under-resourced families most likely affected by existing barriers to traditional evaluation.

**308.003 (Oral)** Infants with Later ASD Have Less Night Sleep, and This Relates to Emerging Developmental Differences in Social Attention

**J. Begum Ali<sup>1</sup>, L. Gosse<sup>2</sup>, G. Pasco<sup>3</sup>, T. Charman<sup>4</sup>, M. H. Johnson<sup>1</sup> and E. J. Jones<sup>1</sup>,** (1)Centre for Brain and Cognitive Development, Birkbeck, University of London, London, United Kingdom, (2)Centre for Brain and Cognitive Development, Birkbeck University of London, London, United Kingdom, (3)Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (4)Department of Psychology, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom

---

**Background:** Sleep is a crucial aspect of development (Field, 2017). Infant sleeping patterns have been shown to be related to later attentional abilities, executive functioning, temperament and self-regulation (Williams et al., 2016). Sleep problems have been implicated in neurodevelopmental disorders, such as Autism Spectrum Disorder (ASD) and Attention Deficit Hyperactivity Disorder (ADHD), persisting from early development to adulthood (Rydzewska et al., 2020). Further, sleep duration is related to ASD symptom severity (Veatch et al., 2017); as such it is important to examine sleep in development and its relation to emerging attentional abilities in ASD.

**Objectives:** In this study, we report sleep findings from a prospective longitudinal infant sibling study (infants with an elevated likelihood of developing ASD, ADHD, ASD+ADHD or neither).

**Methods:** We assessed sleep using two parent report measures; the Sleep and Settle Questionnaire (Matthey, 2001) and the Infant Behaviour Questionnaire Revised (Putnam et al., 2014) at 5, 10 and 14 months of age from a sample of 151 infants. From a factor analysis, a primary factor of 'Night Sleep' emerged which encapsulated night sleep duration, night awakening frequency and night sleep onset duration; with higher scores indicating better sleep. Infants also took part in a number of eye-tracking (ET) tasks, at the above time points, that measured social attention.

**Results:**

Infants with an elevated likelihood of ASD had less Night Sleep than those without a family history of ASD [ $F(1, 133) = 10.08, p = .002, \eta^2 = .07$ ; Figure 1]; sleep did not vary by familial likelihood of ADHD [ $F(1, 133) = .17, p = .68, \eta^2 = .001$ ] or ASD\*ADHD-L [ $F(1, 133) = .03, p = .87, \eta^2 = .0$ ]. Children with a 36 month ASD-Outcome also had less Night Sleep than those without ASD [ $F(1, 109) = 4.6, p = .03, \eta^2 = .04$ ]; this varied by Age [ $F(2, 166) = 9.68, p < .001, \eta^2 = .1$ ] such that the ASD group had less Night Sleep at 14-months. [ $t(96) = 4.1, p < .001, d = 1.46$ ], but not at 5 [ $t(72) = .49, p = .62, d = .16$ ] or 10-months [ $t(98) = 1.41, p = .16, d = .47$ ].

To investigate the relationship between sleep and social attention, we conducted several cross lagged structural equation models. We found that higher levels of Night Sleep at 10 months were associated with higher attentiveness to a social ET task at 14 months ( $\beta = .27, p = .03$ ) and more time spent looking to the face during a Face Popout task at 14-months ( $\beta = .23, p = .01$ ). However, interestingly, we found the opposite pattern at earlier timepoints; *lower* levels of Night Sleep at 5-months were associated with greater looking to the face at 10-months ( $\beta = -.28, p = .01$ ; see Figure 2).

Conclusions:

Our findings show that infants at an elevated likelihood of ASD, and those who go on to have ASD, demonstrate decreased levels of Night Sleep, which relates to later social attention. However, this relationship differs across developmental time.

### **308.004 (Oral) Quantifying Latent Social Motivation and Its Developmental Associations with Joint Attention and Language in Infants at High and Low Risk for Autism Spectrum Disorder (ASD)**

**I. C. Stallworthy<sup>1</sup>, N. Marrus<sup>2</sup>, D. Berry<sup>3</sup>, S. Davis<sup>4</sup>, J. J. Wolff<sup>5</sup>, K. Botteron<sup>6</sup>, S. R. Dager<sup>5</sup>, A. M. Estes<sup>6</sup>, H. C. Hazlett<sup>7</sup>, L. Zwaigenbaum<sup>8</sup>, R. T. Schultz<sup>9</sup>, J. Piven<sup>10</sup>, J. T. Ellison<sup>4</sup> and J. R. Pruett<sup>11</sup>,** (1)Institute of Child Development, University of Minnesota, Minneapolis, MN, (2)Washington University School of Medicine, St. Louis, MO, (3)Institute of Child Development, University of Minnesota, Twin Cities, Minneapolis, MN, (4)University of Minnesota, Minneapolis, MN, (5)Radiology, University of Washington, Seattle, WA, (6)Speech and Hearing Sciences, University of Washington, Seattle, WA, (7)\*co-senior author, University of North Carolina, Chapel Hill, NC, (8)University of Alberta, Edmonton, AB, Canada, (9)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (10)\*Co-senior author, University of North Carolina, Chapel Hill, NC, (11)\*Co-senior author, \*\*For the IBIS Network, Washington University School of Medicine, St. Louis, MO

Background:

Social motivation –the psychobiological predisposition for preferential social orienting, seeking social contact, and maintaining social interaction –is hypothesized to contribute to the development of social communication and the ontogeny of ASD (Chevallier et al., 2012). However, the lack of early social motivation measures has constrained the ability to delineate associations between social motivation, other social abilities affected in ASD (e.g., joint attention), and ASD-related outcomes. Recent work supports psychometric validity of early childhood social motivation measures (e.g., Phillips et al., 2019) and the influence of social motivation on language in toddlers with ASD (Su et al., 2020). Here, we use a latent factor model of novel infant social motivation measure and examine associations between early social motivation, joint attention, and language skills in a sample of typically and atypically developing children with varying familial ASD liability.

Objectives:

- To derive a latent factor model of social motivation that exhibits measurement invariance –a psychometric property important for making meaningful substantive comparisons (Bauer, 2017) –across age, ASD risk, and sex.
- To use factor scores from this model to examine developmental associations between early social motivation and joint attention behaviors and their contribution to language outcomes in infants at high (HR) and low (LR) familial risk for ASD.

Methods:

534 HR and LR infants (n=229 females; n=214 LR, n=68 ASD) were assessed at ages 6, 12, and 24 months in the Infant Brain Imaging Study and assigned a 24-month clinical best estimate diagnosis.

Six and 12-month items with strong face validity for social motivation were identified from well-established parent-report measures (Infant Behavior Questionnaire-Revised, Vineland Adaptive Behavior Scales, Macarthur-Bates Communicative Development Inventory, First Year Inventory). The Dimensional Joint Attention Assessment (Elison et al., 2013) indexed 12-

month response to joint intention (RJA), while item 7 from the Communication and Symbolic Behavior Scales indexed 12-month initiation of joint attention (IJA). The Mullen Scales of Early Learning indexed 24-month receptive and expressive language.

Moderated Nonlinear Factor Analysis (MNLFA; Bauer, 2017) was used to generate latent social motivation scores adjusting for item measurement non-invariance across age, ASD risk, and sex. Using path analyses, associations between social domains – 6- and 12-month social motivation, 12-month RJA, and 12-month IJA – and 24-month receptive and expressive language were examined.

#### Results:

Latent social motivation scores were continuously distributed (Figure 1). Preliminary path model results indicated that neither 6- nor 12-month social motivation was associated with 24-month language outcomes (Figure 2). Twelve-month social motivation was concurrently associated with RJA ( $p=0.018$ ) and IJA ( $p=0.004$ ). Both 12-month IJA and RJA were significantly associated with 24-month receptive ( $p_{IJA}=0.001$ ;  $p_{RJA}=0.024$ ) and expressive language ( $p_{IJA}=0.002$ ;  $p_{RJA}=0.038$ ).

#### Conclusions:

This study offers a novel measurement invariant latent modeling approach to quantifying infant social motivation, its interrelationships with other social domains, and influence of these domains on language. Social motivation functions concurrently with 12-month RJA and IJA, which, consistent with prior research, associates with 24-month language outcomes. This approach, by more precisely modeling the developmental interdependencies of these domains, may inform the developmental science of ASD and timing of interventions.

## POSTER SESSION — EARLY DEVELOPMENT (< 48 MONTHS)

### Poster 415 - Early Development (< 48 months) Posters

**415.001** (Poster) A Prospective Study of Anxiety and Perceptual Sensitivity As Early Markers for Restricted and Repetitive Behaviors in Infants with Typical and Elevated Likelihood of Autism Spectrum Disorder.

*N. Narvekar<sup>1</sup>, V. Carter Leno<sup>2</sup>, G. Pasco<sup>3</sup>, M. Johnson<sup>4</sup>, E. J. Jones<sup>5</sup> and T. Charman<sup>6</sup>, (1)IoPPN, King's College London, London, United Kingdom, (2)King's College London, Institute of Psychiatry, Psychology and Neuroscience, London, United Kingdom, (3)Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (4)Department of Psychology, University of Cambridge, Cambridge, United Kingdom, (5)Centre for Brain and Cognitive Development, Birkbeck, University of London, London, United Kingdom, (6)Department of Psychology, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom*

#### Background:

Autism Spectrum Disorder (ASD) is defined by its observable manifestations in social and communication impairments (SCI) and restricted and repetitive behaviours (RRB). Evidence indicates that RRBs are associated with anxiety and atypical sensory features (e.g., differences in perceptual sensitivity). Studies of children with autism do not clarify the order of emergence of these traits, therefore creating a need for longitudinal prospective studies. Identifying which early markers relate to later manifestations of ASD is important for understanding causal paths to symptom development. Prospective studies of infant-siblings of children with ASD, of whom ~20% will go on to develop ASD themselves, have provided important insights into early developmental trajectories associated with a later diagnosis of ASD. The current study uses this prospective longitudinal infant-sibling design to investigate whether infant traits of early anxiety and perceptual sensitivity relate to later manifestations of RRBs and SCIs.

#### Objectives:

To examine the longitudinal relations between Fear/Shyness and Perceptual Sensitivity at 9, 14 and 24-months and RRB and SCI at 36-months.

#### Methods:

As part of the British Autism Study on Infant Siblings (BASIS: <http://www.basisnetwork.org>), 247 infant-siblings participated in a longitudinal study. All elevated-likelihood (EL) participants (N=170) had at least one older-sibling with a diagnosis of ASD whereas all typical-likelihood (TL) participant (N=77) had no known immediate family members with a diagnosis of ASD. Parents rated infant's traits of early anxiety and perceptual sensitivity using the Infant Behavior Questionnaire (IBQ; Fear and Perceptual Sensitivity subscales) at 9 and 14-months, and the Early Childhood Behavioral Questionnaire (ECBQ; Shyness and Perceptual Sensitivity subscales) at 24-months, RRBs and SCIs were assessed using subscales of the parent-rated Social Responsiveness Scale (SRS-2) at 36-months. Longitudinal cross-lag structural equation models tested 1) bidirectional pathways between fear/shyness and perceptual sensitivity between 9-24 months and 2) predictive pathways from fear/shyness and perceptual sensitivity at 9-24 months and RRBs and SCIs at 36-months.

#### Results:

Results found significant auto-regressive pathways (e.g., within-domain continuity) for both fear/shyness and perceptual sensitivity between 9-14 and 14-24 months (Figure 1). Cross-lagged paths indicated that higher levels of fear at 14-months were associated with higher levels of perceptual sensitivity at 24-months. All other cross-lagged associations were not significant (all  $p \geq 0.20$ ). The cross-lagged auto-regressive model provided a good fit to the data ( $\chi^2(2) = 3.87, p = 0.144$ ; CFI = 0.993, RMSEA = 0.062). Both higher levels of shyness and perceptual sensitivity at 24-months were significantly associated with heightened levels of both RRB and SCI symptoms at 36-months (Figure 2). There was a significant positive correlation between RRB and SCI symptoms at 36-months.

#### Conclusions:

Relative stability was found over time in both fear/shyness and perceptual sensitivity, indicating some developmental continuity of the traits. At a trait level, early infant manifestations of anxiety (e.g., fear/shyness) and perceptual sensitivity precede and relate to later RRBs and SCIs in toddlerhood. This demonstrates novel developmental pathways to later emerging RRBs but also calls into questions theories that argue that these domains specifically underlie RRBs rather than the broader range of behaviours which are associated with ASDs.

#### 415.002 (Poster) ASD-Related Characteristics in Infancy in Relation to Autonomic Functioning

S. Soker-Elimaliah<sup>1,2</sup> and J. B. Wagner<sup>1,2</sup>, (1)The Graduate Center, City University of New York, New York, NY, (2)College of Staten Island, City University of New York, Staten Island, NY

Background: The autonomic nervous system (ANS) is responsible for maintaining homeostasis and includes sympathetic and parasympathetic influences. Differences in ANS activity have been found in ASD, including heightened sympathetic activity (e.g., Hirstein et al., 2001) and reduced parasympathetic activity (e.g., Bal et al., 2010). Furthermore, recent work with infants at high risk for ASD (HRA; by virtue of an older sibling with ASD) and low-risk control infants (LRC) has found that atypical parasympathetic activity in the first year of life across both groups predicted elevated ASD-related characteristics at 36 months (Nyström et al., 2018).

Objectives: The current study will examine both sympathetic and parasympathetic activity in infancy as it relates to concurrent measures of ASD-related characteristics in HRA and LRC.

Methods: Participants included 21 infants ( $M_{age} = 10.16$  months,  $SD = .66$  months, Range = 6.13–19.10 months; HRA:  $n = 3$ ; LRC:  $n = 18$ ). As part of a larger testing session, heart rate (HR), respiration, and skin conductance (SC), a measure of sympathetic processing, were recorded using a Biopac MP150WSW system during a 5-minute baseline period as infants sat on their parent's lap quietly engaged with silent toys and bubbles. At the end of the session, the Autism Observation Scale for Infants (AOSI; Bryson et al., 2008) was conducted to assess ASD-related characteristics. Using MindWare software, HR and SC data were divided into five 60-second segments, and responses were averaged across all segments. Respiratory sinus arrhythmia (RSA), a measure of high-frequency heart rate variability associated with the parasympathetic system, was also calculated with a respiration frequency range of .24–1.04 Hz (see Bar-Haim et al., 2000), and RSA segments with peak respiration in this range were averaged. AOSI total score was used as a measure of ASD-related characteristics, with higher scores reflecting more ASD-related traits.

Results: Correlational analyses showed that AOSI scores were positively correlated with SC ( $r(19) = .53, p = .014$ ; see Figure 1) and negatively correlated with RSA ( $r(19) = -.44, p = .047$ ; see Figure 2). This suggests that elevated ASD-related characteristics are associated with higher sympathetic and lower parasympathetic activity in infancy. These results remained the same with and without the inclusion of HRA infants. Because age was significantly negatively correlated with the AOSI ( $p = .038$ ), analyses

were also repeated with age partialled out. After accounting for age, the association between AOSI scores and SC remained significant ( $r(17) = .68, p = .002$ ), but the relationship between AOSI and RSA became marginal ( $r(17) = -.43, p = .068$ ).

**Conclusions:** The current study is among the first to examine both sympathetic and parasympathetic functioning alongside ASD-related characteristics in HRA and LRC infants. Consistent with research on ANS function in children with ASD (e.g., Bal et al., 2010; Hirstein et al., 2001), infants with elevated ASD-related traits showed heightened sympathetic activity and reduced parasympathetic activity. These results held with and without the inclusion of HRA, suggesting that individual differences in ANS activity could relate to variability in ASD-related characteristics more broadly during infancy.

**415.003 (Poster) Associations between Child Sensory Reactivity Patterns and Caregiver Responsiveness**

**E. Campi<sup>1</sup>, J. Sideris<sup>1</sup>, A. McConnell Hatch<sup>1</sup>, A. Masuda<sup>1</sup>, E. Crais<sup>2</sup>, L. R. Watson<sup>2</sup> and G. T. Baranek<sup>1</sup>,** (1)Chan Division of Occupational Science and Occupational Therapy, University of Southern California, Los Angeles, CA, (2)Department of Allied Health Sciences, University of North Carolina at Chapel Hill, Chapel Hill, NC

---

**Background:** Caregiver responsiveness has been shown to predict outcomes for children with and at risk for autism spectrum disorder (ASD), especially in verbal development (Edmunds, Kover, & Stone, 2019; Haebig, McDuffie, & Weismer, 2013; McDuffie & Yoder, 2010). Many factors influence caregiver responsiveness, including children's sensory and communicative behaviors (Edmunds, Kover, & Stone, 2019; Kindard et al., 2017). Caregivers tend to talk less and use more play actions when children demonstrate sensory hyporeactive patterns and limited communication (Kinard et al. 2017). Despite evidence for the impact of caregiver responsiveness on development, there is limited research on caregiver responsiveness to children's sensory-related cues and factors that influence that responsiveness.

**Objectives:** This poster aimed to examine the association between infant sensory reactivity and caregiver responsiveness to sensory reactivity cues. We hypothesized that hyporeactivity and hyperreactivity scores will be negatively associated with caregiver responsiveness.

**Methods:** Participants were a community sample of 63 11-16-month-old infants (M=13 months; 63.5% elevated likelihood for ASD; 68% male; 87% White) and their caregivers (68% biological mothers; 70% with at least a college degree). Risk status (elevated likelihood for ASD) was measured via the First Years Inventory v3.1- Lite, a screening tool for ASD (Baranek, Watson, Crais, Turner-Brown, & Reznick, 2014). Sensory processing was measured via the Sensory Processing Assessment (SPA; Baranek, 1999), a semi-structured observational tool that measures hyporeactivity; hyperreactivity; and sensory interests, repetitions, and seeking (SIRS) behavior patterns. Caregiver responsiveness was measured with a behavioral rating scheme applied to recordings of caregiver-child interaction during 4 contexts: free play, an anticipatory game, a snack, and a caregiving activity. Scores ranged from 1 (unresponsive) to 7 (highly responsive), with one rating assigned per context. Caregiver responsiveness scores across all contexts were averaged to compute a single mean score. Hierarchical linear regression was performed to analyze the associations between sensory reactivity patterns and caregiver responsiveness, with hyporeactivity entered first, followed by hyperreactivity, then SIRS. Sample size will be approximately 75 participants prior to the conference.

**Results:** Children at elevated likelihood for developing ASD differed from children with lower likelihood on hyporeactivity, SIRS, and caregiver responsiveness ( $p < .05$ ). However, interactions between risk group and sensory patterns and differences in correlations across risk groups were non-significant and not included in the final models. See Table 1 for correlations among variables. Hyporeactivity demonstrated the only main effect; see Table 2 for regression results.

**Conclusions:** The association between hyporeactivity and caregiver responsiveness may be due to caregivers having difficulty noticing and responding to hyporeactivity, which often presents as more subtle behaviors than the other sensory reactivity patterns. The loss of association with hyporeactivity after the addition of SIRS could be due to the potential shared effect of SIRS behaviors and hyporeactivity on caregiver responsiveness. Further research is needed in a larger, more diverse sample to understand the manner in which child sensory reactivity patterns and other child features affect caregiver responsiveness.

**415.004 (Poster) Associations of Brain Injury and Race on Autism Diagnosis and Severity**

**L. Nichols<sup>1</sup>, A. T. Wieckowski<sup>2</sup>, J. Zavadak<sup>3</sup>, G. Vivanti<sup>4</sup>, L. B. Adamson<sup>5</sup>, D. A. Fein<sup>5</sup> and D. L. Robins<sup>2</sup>,** (1)A.J. Drexel Autism Institute, Philadelphia, PA, (2)A.J. Drexel Autism Institute, Drexel University, Philadelphia, PA, (3)Drexel University School of Medicine, Philadelphia, PA, (4)Psychology, Georgia State University, Atlanta, GA, (5)Psychological Sciences, University of Connecticut, Storrs, CT

---

**Background:**

Incidence of brain injury during the early developmental period has been associated with deficits characteristic of neurodevelopmental disorders, such as autism spectrum disorder (ASD; Singh, Turner, & Ngyuen, 2016). These deficits extend to intellectual functioning (Barlow et al., 2005). Within ASD, racial differences in intellectual functioning and symptom severity are notable with children of color often exhibiting higher symptom severity and greater intellectual deficits than White children (Baio et al., 2014). Less is known about the interaction of race on the association between brain injury and ASD diagnosis.

Objectives: The present study examined 1) if race was associated with incidence of brain injury among those at risk for ASD and 2) if the association of race and injury was associated with ASD symptom severity.

Methods:

This sample consists of 950 children (419 White, 531 Children of Color (CoC) including 270 Black, 50 Asian, see Table 1; 205 with ASD, 354 with developmental delay (DD), see Table 2) in a multi-site study referred for diagnostic evaluations after a positive screen on the Modified Checklist for Autism in Toddlers, Revised, with Follow-Up (M-CHAT-R/F) or pediatric provider concern for ASD. Parents completed a history questionnaire that collected information on gestational age at birth, pregnancy and labor complications, and brain injuries, as well as demographic information. Diagnostic evaluations included the Autism Diagnostic Observation Schedule, Second Edition (ADOS-2), Mullen Scales of Early Learning (MSEL), and Vineland Adaptive Behavior Scales (VABS-II). Children were considered brain-injured if they had a history of a specific brain injury or had their umbilical cord wrapped around their neck at birth and were treated in the neonatal intensive care unit. Children were considered to have a probable brain injury if they were born severely premature (<32 weeks).

Results:

Chi-square analysis indicated a significant association between brain injury and a diagnosis of DD, but not ASD, in both racial groups ( $\chi^2(4, N=950)=17.02, p=.002$ ). Specifically, brain injuries and probable brain injury in CoC was associated with DD, and probable brain injury in White children was associated with DD. Regarding symptom severity and developmental delays, MANOVA analyses indicated a significant main effect of race, but no main or interacting effects of injury, on VABS-II composite scores ( $F(56, 588)=1.82, p=.049$ ). There were no main or interacting effects of injury and race on ADOS-2 or MSEL composite scores. Post-hoc analyses revealed that CoC demonstrated higher VABS-II scores than White children ( $F(1, 588)=6.37, p=.012$ ).

Conclusions:

Early-life brain injury appeared to be associated with developmental delays, but not specifically with ASD symptomology. This association is apparent in both racial groups with evidence of a stronger association within CoC. Autism symptom severity was unrelated to brain injury. However, race was associated with developmental outcomes such that in our sample, White children demonstrated greater deficits in adaptive functioning than CoC. Race did not interact with injury to predict ASD symptom severity. Of note, this study relied on parent report of history. Thus, future research should include review of medical records.

**415.005 (Poster)** Behavioural Reactions to a Task Intended to Elicit Fear in Infants at High Risk for Autism Spectrum Disorder  
*M. Susko<sup>1</sup>, V. L. Armstrong<sup>2</sup>, J. A. Brian<sup>3</sup>, S. E. Bryson<sup>1</sup>, A. Kushki<sup>1</sup>, L. A. Sacrey<sup>4</sup>, L. Zwaigenbaum<sup>5</sup> and I. M. Smith<sup>7</sup>,*  
*(1)Dalhousie University, Halifax, NS, Canada, (2)IWK Health Centre, Halifax, NS, Canada, (3)Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (4)Bloorview Research Institute, Toronto, ON, Canada, (5)Autism Research Centre, Glenrose Rehabilitation Hospital, Edmonton, AB, CANADA, (6)University of Alberta, Edmonton, AB, Canada, (7)Dalhousie University / IWK Health Centre, Halifax, NS, CANADA*

Background: Compared to typically developing peers, children at risk for or diagnosed with autism spectrum disorder (ASD) exhibit more negative affect and avoidance behaviours (Clifford et al., 2012; Garon et al., 2008), and express fear differently (Evans et al., 2005; Macari et al., 2018; Turner & Romanczyk, 2012). To explore these differences, we examined behavioural reactions of infants at high familial risk for ASD to stimuli that typically elicit fear in older children.

Objectives: (1) To determine whether 18-month-olds' behavioural reactions to tasks intended to elicit fear differ between typically developing infants and infants at high familial risk for ASD. (2) To determine if behavioural reactions at 18 months are related to ASD symptoms at 24 months in infants at risk for ASD.

Methods: Participants include 32 high-risk infants (HR; younger sibling of a child with ASD; 18 females) and 19 low-risk infants (LR; no family history of ASD; 7 females). At 18 months, infants were shown two masks that commonly elicit fearful responses

in older children. Reactions were video-recorded and coded offline using Noldus Observer. Approach (yes/no) and avoidance (intensity: low (0) to high (2)) behaviours were coded in 5-second intervals. Crying and freezing durations were recorded, and gaze aversions and smiles were coded as point events (frequency). At 24 months, infants were assessed with the Autism Diagnostic Observation Schedule 2<sup>nd</sup> ed. – Toddler module (ADOS-T). A 2 x 2 repeated measures ANOVA was conducted on each dependent variable, with group as a between-subject factor and mask as a within-subject factor. Pearson correlations were used to examine associations between coded behaviours and ADOS-T scores.

Results: A significant main effect of group emerged for smiling ( $F(1, 49) = 5.10, p = .03$ ) with LR infants ( $M = .71, SD = 1.08$ ) smiling more frequently than HR infants ( $M = .28, SD = .83$ ). Approach, avoidance, and gaze aversions were positively correlated with 24-month ADOS-T scores. Increased approach behaviour was associated with more severe symptoms in the Social-Affect domain ( $r = .34, p = .02$ ). Higher avoidance intensity was related to more severe Restricted and Repetitive behaviour (RRB) symptoms ( $r = .34, p = .02$ ). Gaze aversion increased with total ASD symptom severity ( $r = .32, p = .03$ ), with this relationship being driven by symptoms in the Social-Affect domain ( $r = .36, p = .01$ ).

Conclusions: Consistent with previous research, findings suggest that LR infants smile more often than HR infants (Filliter et al., 2015). Findings also demonstrate that increased levels of approach, avoidance, and gaze aversion at 18 months are related to ASD symptoms at 24 months in HR infants. Atypical responses to stimuli that typically elicit fear in children may be seen in infants with higher levels of ASD symptoms. A better understanding of the nature and implications of these differences may inform early detection and intervention in ASD.

**415.006 (Poster) Brainstem Integrity Dissociated with Linguistic Competence in Young Children with Autism**

L. Yu<sup>1,2</sup>, A. Yi<sup>3</sup>, B. Lai<sup>1,2</sup>, J. Zhang<sup>1,2</sup>, N. Li<sup>1,2</sup>, L. Ban<sup>1,2</sup>, J. Xin<sup>3</sup> and S. Li<sup>3</sup>, (1)School of Psychology, South China Normal University, Guangzhou, China, (2)Autism Research Center, South China Normal University, Guangzhou, China, (3)Department of Children Rehabilitation, Foshan Chancheng Central Hospital, Foshan, China

**Background:** Delayed auditory brainstem response (ABR) latencies were observed in infants younger than 3 months who later diagnosed with autism (Cohen et al., 2013; Miron et al., 2016). Others have found that such abnormality can persist into childhood, although with considerable heterogeneity (Talge et al., 2018). ABR latency delay has also been linked with language delay in young children with suspected autism (Roth et al., 2012). These work provide compelling evidence for the role of subcortical brain structures in early emergence and language impairment of autism. However, it is still unclear to what extent brainstem integrity might regulate developmental progression in young children with and without autism and what specific elements it implicates.

**Objectives:** The current research aimed to verify whether ABR latency was abnormal in young children who developed autism in comparison with clinical controls who did not develop autism. The results were expected to help make inferences about specific developmental processes to target for understanding brainstem-behavior relationships in young children with neurodevelopmental disorders.

**Methods:** Click-ABRs were recorded from a total of 87 children admitted to Pediatric Rehabilitation Unit. The age at the ABR testing was on average 31 month, ranging from 14 to 55 months. Developmental outcomes were assessed using the Gesell Developmental Schedule concurrently or shortly after the ABR testing at age 14~57 months. The mean time interval between ABR and Gesell was 18 days (0~5 months). Thirty-five of these children were diagnosed with autism. The remaining 52 were diagnosed with developmental language disorder (DLD). The two groups were matched on age at ABR testing and age at Gesell assessment. Pearson correlation was performed for the latency of ABR Wave V and each Gesell subscale.

**Results:** The Wave V latency in the autism group (mean = 5.74 ms) did not differ from the DLD group (5.73 ms). Neither group showed age-related latency changes. The two groups differed on language and sociability but not on adaptation, gross motor, or fine motor on the Gesell, that the autism group scored lower for language and sociability ( $p < 0.01$ ). Language was the only measure that was significantly correlated with latency, that faster Wave V was associated with better language in the DLD group ( $r = -0.29^*$ ) but not in the autism group.

**Conclusions:** We showed that Wave V latency of click-ABR largely stabilized after age 14 months in the children with neurodevelopmental disorders. The weak but significant relationship between Wave V and language in the DLD group provides supporting evidence for the role of the ascending subcortical pathways in scaffolding early linguistic competence. The results also suggested that compared to DLD peers, the young autistic children experienced extra language and social challenges. However, their language impairment appeared to be somewhat dissociated from general brainstem integrity under 5 years of age. Future work may tap more sophisticated brainstem functions in relation to language outcomes, i.e., speech encoding, in autism during early critical periods.

**415.007 (Poster) Caregivers Training Groups: Viable Alternative for Public Health in Brazil?**

*M. L. Nogueira<sup>1</sup>, M. L. Carvalho<sup>1</sup>, L. B. J. Souza<sup>1</sup>, V. C. Schneider<sup>1</sup>, K. F. Vieira<sup>1</sup> and A. Hatem Pereira<sup>2</sup>, (1)Universidade Federal de Minas Gerais, Belo Horizonte, Brazil, (2)FHEMIG, Belo Horizonte, Brazil*

---

**Background:** Prevalence studies show that, in the United States, the rate of children with Autism Spectrum Disorder (ASD) is 1 in 54, and it's a scientific consensus that early intensive intervention relates to positive prognosis in later years. Although lacking large statistical research, a pilot study in Brazil points that there are around 40 thousand people with ASD in a city nearby São Paulo, one of the most populated cities in the world. Many studies have evaluated the efficiency of parents/caregivers conducted stimulation, showing that stimulation programs implemented by the family lead to positive results for the child as well as the parents. Given the high prevalence of children with autism, it is important to highlight that expensive treatment costs and socioeconomic vulnerability in Brazil can limit the access of many families to quality treatment, which considerably affects the child's development, may increase the families' stress levels and interfere with their sense of self-efficacy as parents

**Objectives:** To evaluate the efficacy of parents/caregivers training groups as a viable alternative for the Brazilian public health context.

**Methods:** The groups consisted of 10 on-site weekly meetings with 3 to 5 families of children from 0 to 4 years old, diagnosed, or with suspicion of ASD diagnosis. The meetings were facilitated by a senior psychology student and were based on the methodological design suggested in the Early Start Denver Model, as well as themes more relevant to the Brazilian reality, and 2 extra meetings suggested by the groups. Pre and post-tests were used to measure changes in parental stress (Parental Stress Scale); Self-efficacy (Parental Self-Efficacy Scale in the Management of Asperger's Syndrome); family involvement (Family Involvement Questionnaire), and the ESDM Checklist Curriculum conducted with the children. Training strategies consisted of videomodeling, roleplay, online monitoring through WhatsApp groups, and analysis of the video content brought by the parents/caregivers, in which they implement the methods discussed in the meetings. Selfcare activities were also suggested every week. These on-site groups are the first step in a research that seeks to develop an app for parental training, in which public healthcare professionals and university students can monitor the family's progress in training and implementing stimulation programs at home. For this case study we analyzed the data of 3 families: 2 mothers and 1 father, randomly selected.

**Results:** Post-test results showed that the children had significant improvements only in Self Independence skills, suggesting that the training might not replace an intensive intervention program. However, the post-test scales indicated a great reduction in parental stress and increase in self-efficacy; they also organized their daily routines better, dedicated more time to take the children to public places; were more involved in school-related tasks such as homework and dialoguing with teachers, and finally, had an increase in efficacy when managing the children's behaviors.

**Conclusions:**

The study indicated that parents had an overall better elaboration of the autism diagnosis, given how the parents had a significant reduction in the discomfort related to the children's behaviors.

**415.008 (Poster) Developmental Profiles and Associated Rates of ASD in Early Intervention: A Confirmatory Latent Profile Analysis**

*M. Troxel<sup>1</sup>, R. C. Sheldrick<sup>2</sup>, A. Eisenhower<sup>3</sup> and A. S. Carter<sup>1</sup>, (1)Department of Psychology, University of Massachusetts Boston, Boston, MA, (2)Boston University School of Public Health, Boston, MA, (3)University of Massachusetts Boston, Boston, MA*

---

**Background:**

Part C Early Intervention (EI) is a US federal program that seeks to support children ages zero to thirty-six months who demonstrate delays in developmental functioning, including children with autism spectrum disorders (ASD). The Battelle Developmental Inventory, Second Edition (Newborg, 2005) is frequently used in EI to assess the developmental functioning of children across five domains—Communication, Cognitive, Motor, Adaptive and Personal/Social—yet relatively little is known about child developmental profiles given their domain scores and how profiles are associated with ASD.

**Objectives:** This study will aim to replicate and extend findings from the only known study (Elbaum & Celimli-Aksoy, 2017) that has conducted a latent profile analysis of child developmental profiles measured by the Battelle for children in Part C EI.

**Methods:** Children included in this study (N=28,983) were a subset of those enrolled in one of twelve Part C EI agencies in the state of Massachusetts between 2011-2019 and completed a Battelle assessment. A confirmatory latent profile analysis, using the

five Battelle domains as indicator variables, was conducted in Mplus. Children were assigned to their most likely class given posterior probabilities. Associations between class membership and child ASD diagnosis were investigated in Stata.

Results: Over half of the sample was male (61.6%). The average age was 15.48 months at the time of assessment, and over half of the sample was non-White or White Latinx (53.9%). Six percent of children had a record of an ASD diagnosis. Confirmatory latent profile analyses yielded a close replication of previous findings from Elbaum et al., 2017, such that a four-class model demonstrated the best and most parsimonious fit to the data. Furthermore, entropy and the pattern of profiles (see Figure 1) were consistent with those in the previous study. Two classes, one indicative of larger delays (Class 1, 13.9% of total sample) and one indicative of milder delays (Class 3, 30.5%), demonstrate a primary delay in communication relative to the other domains. The other two classes, also differentiated by overall level of delay (Class 2, 7.5%; Class 4, 48.1%), demonstrate relatively level functioning across domains. Average child age and ASD status differed significantly by assigned class (see Table 1). The greatest proportion (29.9%), and approximately half (49.2%), of children with ASD diagnoses were assigned to Class 1, which is differentiated from the other classes by its primary and severe communication delay. Approximately one quarter of children with an ASD diagnosis were assigned to Classes 3 and 4 (23.0% and 24.1%, respectively). These findings differ from those of Elbaum et al.

#### Conclusions:

Using latent profile analyses and a significantly larger sample, we replicated previous findings regarding pattern of developmental profiles of children in EI. Findings suggest that the observed patterns may hold true across geographic regions in the U.S. In this study, children who ultimately received an ASD diagnosis were most likely to be assigned to Class 1, which included approximately half of all ASD cases. This suggests that this profile may contribute to earlier identification of children at greater risk for ASD.

#### **415.009** (Poster) Differences in Temperament during Early Childhood in Children at Familial Risk for Autism with Low Versus High Parent Reported Autism, ADHD and Anxiety Symptoms

**T. Bazelmans<sup>1</sup>, R. Arthur<sup>2</sup>, M. H. Johnson<sup>3</sup>, E. J. Jones<sup>3</sup>, T. Charman<sup>4</sup> and & The BASIS Team<sup>5</sup>, (1)King's College London, Institute of Psychiatry, Psychology and Neuroscience, London, United Kingdom, (2)Kings College London, London, United Kingdom, (3)Centre for Brain and Cognitive Development, Birkbeck, University of London, London, United Kingdom, (4)Department of Psychology, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (5)Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom**

---

Background: Temperament, the way someone reacts and regulates their behaviour, has been associated with social behaviours and behavioural problems as well as neurodevelopmental disorders, such as autism, ADHD and anxiety. Less is known about how individual differences in temperamental trajectories in early childhood relate to later distinct neurodevelopmental outcomes.

Objectives: We compare parent-reported Surgency, Negative Affect (NA) and Effortful Control (EC) of children between 4 months and 10 years to see if trajectories differ between groups who show low versus elevated symptoms of neurodevelopmental disorders in mid-childhood. The cohort consists of children at elevated likelihood of autism because of an older diagnosed sibling. High co-occurrence of neurodevelopmental disorders means they are more likely to show symptoms of ADHD and anxiety.

Methods: 52 typical likelihood and 81 elevated autism likelihood children were seen at multiple timepoints as part of an ongoing longitudinal study. Parents completed the infant (4, 8, 14 months), early childhood (24 months) and children's (mid-childhood, 7-10 years) behaviour questionnaires to measure temperament. Children were assigned to low versus elevated mid-childhood symptom groups based on their T-scores on the Social Responsiveness Scale for autism ( $\geq 60$ ), Spence Children's Anxiety Scale for anxiety ( $\geq 60$ ) and Conners for ADHD ( $\geq 65$  on either Inattentive or Hyperactivity subscale) symptoms. Nine mixed models were run (3 neurodevelopmental outcomes x 3 temperament constructs). The effect of time may be affected by the version of the questionnaire and is not considered. Post-hoc comparisons are Bonferroni corrected.

Results: Thirty children had elevated symptoms of *autism*, 37 of *ADHD* and 21 of *anxiety*. *Autism*: Groups did not differ on overall Surgency. The interaction between time and group was significant ( $p=.027$ ), but groups did not differ at any timepoint. For EC, there was a significant group and interaction effect ( $p<.001$ ). The elevated-autism group had lower EC, which became significant from 14 months and increased over time. The elevated-autism group showed increased NA ( $p<.001$ ), but the interaction with time was not significant. *ADHD*: Groups did not differ on overall Surgency, but there was an interaction effect ( $p<.001$ ). The elevated-ADHD group had higher Surgency at mid-childhood. The group and interaction effect of EC and NA were both significant ( $p<.001$ ). The elevated-ADHD group had lower EC from 8 months and the difference increased over time. NA became significantly higher in the elevated-ADHD group from 14 months. *Anxiety*: There were no differences in Surgency.

Children with elevated anxiety had lower EC ( $p=.041$ ) and the interaction effect was significant ( $p=.027$ ). Scores differed at 14 months and mid-childhood. For NA, the group and interaction effects were significant ( $p<.001$ ). The elevated-anxiety group had higher scores on NA at all timepoints, except 4 months.

Conclusions: Children with elevated symptoms of autism, ADHD or anxiety in mid-childhood show similar temperamental profiles, but the time of onset differs. Lower levels of EC emerge first in the ADHD group, whereas higher NA is first evident in the autism and anxiety groups. The next step is to see how patterns differ between neurodevelopmental disorders considering their co-occurrence, using structural equation models.

**415.010** (Poster) Distinguishing Symptoms of ASD from Global Developmental Delay on Screening and Diagnostic Instruments  
**R. P. Thomas<sup>1</sup>**, S. Milan<sup>1</sup>, L. R. Naigles<sup>1</sup>, D. L. Robins<sup>2</sup>, M. Barton<sup>1</sup>, L. B. Adamson<sup>3</sup> and D. A. Fein<sup>1</sup>, (1)Psychological Sciences, University of Connecticut, Storrs, CT, (2)A.J. Drexel Autism Institute, Drexel University, Philadelphia, PA, (3)Psychology, Georgia State University, Atlanta, GA

---

Background: Autism spectrum disorder (ASD) can be reliably diagnosed in children before their second birthday (e.g., Klin et al., 2015). However, cognitive impairment or delay in young children may impair diagnostic clarity in distinguishing children with ASD from those with other neurodevelopmental disorders, such as global developmental delay (GDD; Gardner et al., 2018; Thurm et al., 2019).

Objectives: This study attempts to distinguish symptoms primarily related to cognitive delays from those more highly related to ASD by comparing children who have ASD with cognitive impairment (ASD-low-MA) and children with GDD on an ASD screener (M-CHAT-R/F) and a diagnostic observational instrument (ADOS-2 Toddler Module).

Methods: Participants were drawn from studies of the Modified Checklist of Autism in Toddlers (M-CHAT-R/F; Robins et al., 2014) in Connecticut, Pennsylvania, and Georgia. The current sample includes all children ( $n=30$ ) between 15-26 months with ASD-low-MA, defined as meeting criteria for ASD, with Mullen Scales of Early Learning (Mullen, 1990) language and cognitive age equivalents below 12 months. A subset of children with GDD ( $n=30$ ) was selected to match the ASD-low-MA group as closely as possible on Mullen Expressive Language age equivalents (Table 1). Mullen Visual Reception (VR) was about one month higher in the GDD group ( $t(58)=2.04$ ,  $p = .046$ ) and the distribution of race was also significantly different ( $\chi^2(1, N = 54) = 6.03$ ,  $p = .014$ ) (Table 1).

Results: The groups did not differ in total M-CHAT-R/F scores, which have a maximum of 20 at-risk items (Table 1). Chi-squares were used to identify differences between groups on M-CHAT-R/F and ADOS-2 items, with Holm-Bonferroni corrections for multiple comparisons. We then regressed out VR age equivalents to see if group differences on specific items were partly attributable to developmental delays (Table 2). Three M-CHAT-R/F items discriminated the groups: The ASD-low-MA group was less likely to *follow a point*, *imitate others*, and *show interest in other children* than the GDD group; these held after controlling for VR. Eighteen ADOS-2 items were more likely to be endorsed in ASD-low-MA children; all except 'pointing' survived VR regression (Table 2).

Conclusions: On the ASD screener, items that differentiated the groups were in the social behavior domain. The remaining M-CHAT-R/F items may not be particularly specific to ASD in toddlers who are also globally delayed. The ADOS-2 successfully captured ASD symptomatology even in children with mental ages below 12 months. Behaviors in all ASD diagnostic domains (social interaction, communication, repetitive behaviors, sensory and restricted interests) differentiated the diagnostic groups, suggesting that even very delayed children with ASD show classic symptoms, and that the ADOS-2 Toddler Module can be used with very young and delayed children. Furthermore, almost all significant group differences on both instruments survived regressing out VR, suggesting that these behaviors are strongly indicative of ASD and not of developmental delays. Future research should confirm these findings with a larger sample and explore whether the race by diagnostic group discrepancy is replicated and, if so, factors that might contribute to this finding.

**415.011** (Poster) Early Development of Emotional Self-Regulation: Differences in Behavioural Dynamics at 9-Months Due to Premature Birth in a Longitudinal Birth Cohort

**Y. W. Chua<sup>1</sup>**, L. Ginnell<sup>2</sup>, V. Ledsham<sup>2</sup>, C. Tachtatzis<sup>3</sup>, I. Andonovic<sup>3</sup>, J. Boardman<sup>4</sup>, P. Rowe<sup>5</sup>, S. Fletcher-Watson<sup>5</sup> and J. Delafield-Butt<sup>1</sup>, (1)Faculty of Humanities and Social Sciences, Laboratory for Innovation in Autism, University of Strathclyde, Glasgow, United Kingdom, (2)University of Edinburgh, Edinburgh, United Kingdom, (3)Department of Electronic and Electrical Engineering, University of Strathclyde, Glasgow, United Kingdom, (4)MRC Centre for Reproductive Health, University of Edinburgh, Edinburgh, United Kingdom, (5)Department of Biomedical Engineering, University of Strathclyde, Glasgow, United Kingdom

## Background:

Preterm infants are at risk of inattention, social and emotional difficulties and the severity of symptoms can result in diagnoses of ADHD, anxiety or Autism Spectrum Disorder (ASD) (Johnson and Marlow 2011). Early difficulties with emotion regulation are common in ASD, often manifesting as tantrums and “meltdowns” in childhood (Mazefsky & White., 2014). Studying how preterm birth affects early development of socioemotional processing across cognitive, motor and attentional systems to regulate emotions has the potential to understand the developmental processes that might implicate emotion regulation difficulties in ASD.

## Objectives:

The objective of this study is to investigate in 9-month-old term and preterm infants, using the well-established still-face paradigm, differences in the dynamics of emotional self-regulation (ER) behaviours.

## Methods:

131 term and preterm infants (born at <33 weeks gestation age (GA)) participating in Theirworld Edinburgh Birth Cohort Study (Boardman et al., 2020) and followed up at 9-months were included in this study. Videos of infants participating in an extended ‘still-face’ paradigm were obtained, which comprised three 2-min episodes of normal playful interactions with their caregiver, alternating with two 2-min still-face episodes (SF1 and SF2), where their caregiver draws a neutral expression and stops interacting. Infant’s ER behaviours (eg. self-comforting, object exploration behaviours), previously reported in the still-face literature, were coded second-by-second to obtain a categorical time series for SF1 and SF2. Using Recurrence Quantification Analysis (RQA) (Webber & Zbilut., 2014), each time series (120 samples) was processed for measures quantifying how ER behaviours occur, recur or persist over each 2min still-face episode. Recurrence Rate (RR), Laminarity (LAM), Trapping Time (TT) and Entropy (catH), respectively indicating the rate of recurrences of behavioural states, periods of state stability, length of persisting states and patterns in which the same state was revisited, were analysed using mixed-effects models with prematurity and still-face episode as predictors. Analyses were conducted in R (v3.6, crqa and lmer packages).

## Results:

As the study is ongoing, this abstract reports on a subset of data coded and processed to date. In this subset of 40 infants (25 male, 15 female), 26 infants were born at term age (mean GA 39.5 weeks, range 36.0-41.0) and 14 were born preterm (mean GA 29.8 weeks, range 27.0-31.0 weeks). Compared to term infants, we found weak evidence that infants born preterm showed lower LAM (Effect=-3.40%, CI=-6.84 – 0.05), lower RR (Effect=-4.11%, CI=-8.85% – 0.63%) and lower catH (Effect = -0.16, CI = -0.34 – 0.03), but no evidence of differences in TT (Effect=-0.72, CI=-2.33 – 0.88).

## Conclusions:

We found trends towards developmental differences in the dynamic structure and patterns of ER behaviours at 9-months due to premature birth. In particular, reduced entropy (catH) indicates greater similarity in the patterns of self-regulatory behaviours. Differences in dynamics highlights the importance of coordinating of neural subsystems for socioemotional processing during development, providing a novel perspective on how altered motor and socio-cognitive development in ASD might influence the activity of the emotion regulation system as a whole. Full analyses are anticipated in March 2021.

### **415.013** (Poster) Early Patterns of Social Visual Engagement in Preterm and Full-Term Toddlers with Autism Spectrum Disorder

*E. McQueen, H. Tokish, A. Rudrabhatla, L. A. Edwards, H. Walum, W. Jones, A. Klin and C. Klaiman, Marcus Autism Center, Children's Healthcare of Atlanta and Emory University School of Medicine, Atlanta, GA*

---

Background: Preterm toddlers are at higher risk for neurodevelopmental abnormalities that could lead to atypical developmental trajectories (Soul & Spence, 2020, Woodward et al., 2006). For example, preterm toddlers (pre-36 weeks gestational age (GA)) are at a higher risk for autism spectrum disorder (ASD) compared to their full-term counterparts (Guy et al., 2015). It is estimated that the prevalence rate for ASD in preterm toddlers is 7%, while it is 1.85% (1:54) in the general population (Agrawal et al., 2018, Maenner et al., 2020). Past developmental social neuroscience studies have shown that there are disruptions in patterns of

early social visual engagement (SVE; collected using eye-tracking technology) in toddlers with ASD (Klin et al., 2013). Full term infants later diagnosed with ASD show atypical gaze patterns to faces, with declines in eye-looking over the first 2 years of life. These gaze patterns may also be related to developmental outcomes such as language ability and social disability. Given the increased prevalence of ASD in preterm toddlers, here we investigate whether atypical patterns of SVE—and the adaptive value of SVE for language and social development—differ for preterm and full-term ASD toddlers.

**Objectives:** This study aims to quantify patterns of SVE in preterm and full-term toddlers with ASD, in order to elucidate shared and/or unique mechanisms of atypical development in these populations.

**Methods:** Participants were preterm (GA<36 weeks) toddlers with ASD (n=30, M<sub>age</sub>(SD)=25.12 (5.23) months) and a chronological age-matched sample of full-term (GA>36 weeks) ASD toddlers (n=134, M<sub>age</sub>(SD) = 24.99 (5.09) months). Receptive and expressive language was assessed with either the Mullen or Bayley-III. Social ability was measured with the ADOS-2. Eye-tracking data were collected while children viewed naturalistic videos of social interactions; these data were quantified as percentage of time spent visually fixating on facial ROIs (i.e. eye and mouth regions).

**Results:** There were no differences in patterns of visual fixation to eye and mouth regions between the full-term and preterm groups ( $r_{eye}=0.663$ ,  $p_{mouth}=0.439$ ). However, the adaptive value of these fixation patterns differed between groups: full-term ASD toddlers' eye-and mouth- looking were positively associated with receptive ( $r_{eye}=-0.357$ ,  $p<0.001$ ;  $r_{mouth}=-0.367$ ,  $p<0.001$ ) and expressive ( $r_{eye}=0.373$ ,  $p<0.001$ ;  $r_{mouth}=0.286$ ,  $p<0.01$ ) language age equivalences. In contrast, in preterm ASD toddlers, eye- looking was associated with receptive (but not expressive) age-equivalent language scores ( $r_{eye}=0.398$ ,  $p=0.040$ ); mouth- looking was not associated with language ability in preterm toddlers. Full-term ASD toddlers' fixation to eyes and mouth was also negatively associated with total ADOS scores ( $r_{eye}=-0.315$ ,  $p<0.001$ ;  $r_{mouth}=-0.268$ ,  $p<0.01$ ), while this only held true for eye- looking in preterm toddlers ( $r_{eye}=-0.543$ ,  $p<0.01$ ).

**Conclusions:** Preliminary analyses indicate that preterm and full-term toddlers with ASD allocate similar levels of visual attention to facial regions when viewing scenes of naturalistic social interactions. However, the adaptive value of attending to these facial regions may differ between them. These results point to potential differences in the social learning mechanisms underlying language development and social interactions in the first years of life, in these subgroups of children with ASD.

#### **415.014 (Poster) Early Sleep Differences in Young Infants with Autism Spectrum Disorder**

**M. Foster<sup>1</sup>, A. Federico<sup>1</sup>, C. Klaiman<sup>2</sup>, A. Klin<sup>2</sup> and J. Bradshaw<sup>1</sup>,** (1)University of South Carolina, Columbia, SC, (2)Marcus Autism Center, Children's Healthcare of Atlanta and Emory University School of Medicine, Atlanta, GA

---

#### **Background:**

Sleep-wake cycles change dramatically in the first year of life, characterized by decreasing daytime sleep and increasing nighttime sleep. At approximately two months of age, increased melatonin production promotes circadian rhythm development, leading to the onset of asymmetry in daytime vs. nighttime sleep. Individuals with ASD experience disrupted sleep patterns in childhood that may be a direct consequence of abnormal melatonin production (Rossignol & Frye, 2011). It is unclear, however, how sleep patterns may differ for infants with ASD in the first six months of life, during a time of significant neurodevelopment and consolidation of the circadian rhythm.

#### **Objectives:**

The current study uses parent report in the context of a prospective longitudinal design to examine differences in early sleep patterns between infants who are later diagnosed with ASD and typically developing (TD) infants.

#### **Methods:**

Participants (n=42) were enrolled in a longitudinal infant sibling study prior to 6 months of age and were determined to be TD (n=30) or diagnosed with ASD (n=12) at 24 months. Beginning at 1 week of age, caregivers completed a sleep diary every month until 6 months. From this report, we investigated trajectories of daytime and nighttime sleep duration (i.e., total hours asleep) and examined associations between early sleep trajectories and autism severity at 24 months.

#### **Results:**

Linear mixed-effects models were used to compare the relationship between age and sleep duration across diagnostic groups. As expected, nighttime sleep significantly increased over time while daytime sleep significantly decreased from birth to 6 months for both groups. The groups did not differ in trajectories of nighttime sleep, but a significant interaction was observed for daytime sleep ( $F(1,101) = 6.59, p = .012$ , see Figure). Infants later diagnosed with ASD and TD infants exhibited a similar decline in daytime sleep from birth to 3 months, but beginning at about month 4, this decline was significantly less for the ASD group. By six months of age, infants with ASD were sleeping nearly 1.5 hours more than TD infants during the day. Daytime sleep duration at six months was significantly associated with autism severity (ADOS CSS,  $r = .598, p < .001$ ), but not measures of language or cognition (Mullen: Expressive Language  $r = -.031, p = .886$ , Visual Reception  $r = .097, p = .6505$ ).

#### Conclusions:

The results of this study suggest that sleep differences in infants later diagnosed with ASD emerge between 4-6 months of age. Previous literature indicates that melatonin levels rapidly increase in infancy between three to six months, such that infants become better able to sustain wakefulness in the day and experience uninterrupted sleep at night (McGraw et al., 1999; Kennaway et al., 1992). Findings of this study point the possibility of early differences in melatonin production that may disrupt sustained wakefulness during the day for infants with ASD. These potential differences in circadian rhythm development may occur very early in life for children with ASD. Additional research is needed to examine neurodevelopmental differences in early infant sleep and their relationship to clinical outcomes.

#### **415.015 (Poster) Early Temperament Profiles in Infants at High Risk for ASD and ADHD**

**G. Kadlaskar<sup>a</sup>, S. Ozonoff<sup>b</sup> and M. Miller<sup>c</sup>,** (1)Department of Psychiatry & Behavioral Sciences, University of California, Davis, MIND Institute, Sacramento, CA, (2)Psychiatry and Behavioral Sciences, University of California at Davis, MIND Institute, Sacramento, CA, (3)Psychiatry and Behavioral Sciences, University of California, Davis, MIND Institute, Sacramento, CA

Background: Autism spectrum disorder (ASD) and attention-deficit/hyperactivity disorder (ADHD) likely share developmental pathways. Early atypical temperament profiles may distinguish individuals with later diagnoses of ASD and/or ADHD from those developing typically. Variations in temperament profiles such as negative affect and effortful control are observed in older children with ASD (Mallise, 2020) and, to some extent, in ADHD (DePauw, 2011). Longitudinal studies suggest associations between early temperament differences and later ASD and ADHD symptomatology. Given the potential for overlapping risk factors, questions remain regarding early shared and distinct temperament profiles that may distinguish these groups.

Objectives: To examine similarities and differences in parent-reported temperament profiles at 12 and 18 months in infants at high and low risk for ASD and ADHD.

Methods: Participants included infants with a family history of ASD (older sibling with ASD;  $n=97$ ), ADHD (older sibling/parent with ADHD;  $n=46$ ), and low-risk comparison infants (no family history of ASD/ADHD;  $n=40$ ). Parents completed the Infant Behavior Questionnaire-Revised (IBQ-R; Gartstein & Rothbart, 2003) at 12 months and the Early Childhood Behavior Questionnaire (ECBQ; Putnam, 2006) at 18 months. At 36 months, participants were classified into one of the three outcome groups: ASD (*DSM-5* diagnosis;  $n=22$ ), ADHD Concerns (elevated ADHD symptoms based on parent or teacher report, and/or examiner observation;  $n=26$ ), and a Comparison group (non-ASD/non-ADHD Concerns;  $n=114$ ). A series of one-way ANOVAs with planned contrasts were conducted to examine group differences for each temperament subscale.

Results: At 12 months (IBQ-R), there were main effects of outcome group for the rate of recovery from distress ( $p=.004$ ), sadness ( $p=.02$ ), and vocal reactivity ( $p=.03$ ) subscales. The ADHD Concerns outcome group exhibited a reduced rate of recovery from distress ( $p=.001$ ) and higher sadness ( $p=.007$ ) relative to the Comparison group, as well as reduced vocal reactivity relative to both the Comparison ( $p=.01$ ) and ASD ( $p=.04$ ) groups. At 18 months (ECBQ), there were main effects for high-intensity pleasure ( $p=.01$ ), positive anticipation ( $p=.001$ ), and sadness ( $p=.001$ ). The ASD group showed reduced high-intensity pleasure relative to the Comparison group ( $p=.005$ ) while the ADHD Concerns group exhibited reduced positive anticipation relative to both the Comparison ( $p<.001$ ) and ASD ( $p=.02$ ) groups. Both the ASD ( $p=.005$ ) and ADHD Concerns ( $p=.003$ ) groups scored higher on sadness relative to the Comparison group.

Conclusions: Relative to the Comparison group, infants developing concerns for ADHD exhibited differences in temperament profiles at both 12 and 18 months, while differences among infants developing ASD were restricted to 18 months. Children with ASD and ADHD Concerns showed variations in distinct temperament domains, except for sadness which was seen in both groups at 18 months. Results partially support previous research showing variable temperament profiles in ASD during early development (Mallise, 2020). Findings are consistent with the limited body of research suggesting temperament differences among infants at risk for ADHD (Auerbach, 2008; Miller, 2019). A combination of shared and distinct temperament profiles may

be present among infants developing ASD and ADHD symptoms, with possible differences in developmental trajectories. Further research is needed to examine associations between temperament domains and dimensional symptoms.

**415.016 (Poster)** Effects of Mechanism of Genetic Transmission of Autism on Clinical Characteristics of Infants and Toddlers with Emerging Autism Symptoms

**T. Cohenour<sup>a</sup>, A. Gulsrud<sup>a</sup> and C. Kasari<sup>a</sup>,** (1)University of California, Los Angeles, Los Angeles, CA, (2)UCLA Semel Institute for Neuroscience & Human Behavior, Los Angeles, CA

---

**Background:** Genetic factors account for a substantial share of liability to autism spectrum disorder (ASD), and influence symptom expression among affected individuals. The genetic architecture of autism, and the relative contribution of inherited familial genetic factors versus spontaneous, non-familial genetic factors, is thought to differ among individuals with ASD from multiplex (multiple affected family members) and simplex (one affected family member) families (Leppa et al., 2016). Differences in symptom severity and incidence of intellectual disability among multiplex and simplex individuals with ASD have been reported (e.g., Robinson et al., 2014), suggesting that mechanism of genetic transmission (i.e., familial, as in multiplex ASD, or non-familial, as in simplex ASD) may influence behavioral phenotypes. However, the extent to which such differences are observable among infants and toddlers with *emerging* autism symptoms remains unclear.

**Objectives:** Evaluate the association between mechanism of genetic transmission and clinical presentation among infants and toddlers with emerging autism symptoms.

**Methods:** This study used data collected for two larger autism intervention studies for infants and toddlers showing behavioral signs of ASD (P50-HD055784-5843, P50-HD055784-8487, PI: Kasari). Participants ( $N=121$ , 22.3% female) were between 12-36 months of age at enrollment ( $M=20.9$  months). Three groups were formed: multiplex (MPX,  $n=29$ ; at least one sibling with ASD), simplex younger siblings (SPX-Sib,  $n=38$ ; at least one typically-developing older sibling and no family history of ASD), and simplex first-borns (SPX-FB,  $n=54$ ; no older siblings and no family history of ASD). Scores from baseline assessments (ADOS-2, Mullen) were used to address study aims.

**Results: Cognitive Ability.** A MANCOVA revealed significant group differences in cognitive ability (Pillai's Trace=.102,  $F_{(4,222)}=2.99$ ,  $p=.020$ ) after controlling for age, sex, and cohort. Univariate follow-up analyses found significant group differences in both dependent variables (Nonverbal DQ and Verbal DQ,  $p's<.05$ ). See Figure 1 for results of univariate tests and pairwise comparisons. **Language Delay.** The majority of children (71.8%) presented with expressive language delay (Mullen Expressive Language T-score  $\leq 35$ ). SPX-Sib children were more likely to present with language delay than MPX children ( $p=.014$ , OR=6.57) after controlling for age, sex, cohort and Nonverbal DQ. **Autism Symptomatology.** A MANCOVA revealed significant group differences in core autism symptoms (Pillai's Trace=.098,  $F_{(4,230)}=2.97$ ,  $p=.020$ ), after controlling for age, sex, and cohort. Follow-up univariate tests found significant group differences on both dependent variables (ADOS-2 Social Affect and RRB scores,  $p's<.05$ ). In separate analyses, ANCOVA revealed group differences in ADOS-2 calibrated severity score ( $p=.006$ ) after controlling for age, sex, and cohort. See Figure 2 for results of univariate tests and significant pairwise comparisons.

**Conclusions:** Results reveal clinically-meaningful differences in behavioral phenotypes of simplex and multiplex infants and toddlers. Children from multiplex families demonstrated stronger cognitive skills and less severe autism symptoms than those from simplex families. These findings suggest that multiplex-simplex differences previously reported in older children are observable in the first years of life, and before autism symptoms fully emerge. Future work is needed to probe *biological mechanisms* (e.g., genetic, neural) and *environmental factors* (e.g., family context) driving phenotypic differences, and examine the effects of familial genetic risk on developmental trajectories.

**415.017 (Poster)** Emotional Availability in Mother-Child and Father-Child Dyads

**A. Bentenuto<sup>1</sup>, S. Perzollini<sup>1</sup>, G. Bertamini<sup>1</sup>, C. Zaupa<sup>2</sup>, N. Mazzone<sup>2</sup> and P. Venuti<sup>1</sup>,** (1)Department of Psychology and Cognitive Science, University of Trento, Rovereto, Italy, (2)University of Trento, Trento, Italy

---

**Background:**

A positive and reciprocal parent-child interaction is crucial for child development. The growing literature highlighted that both mothers and fathers play a fundamental role for the early development for children with typical and atypical development (Flippin & Crais, 2011, Cabrera, & Tamis-LeMonda, 2013; Flippin, & Watson, 2015, Cano, Perales, & Baxter, 2019). As for typically developing children, in the case of Autism Spectrum Disorder (ASD) the majority of previous studies about parenting primarily focused on mothers. In fact, the affective quality of fathers in interaction with their children needs further investigation since they may have a specific role on child development, as suggested in previous studies (Cabrera, & Tamis-LeMonda, 2013).

## Objectives:

The aim of this study was to compare mothers' and fathers' interactive behaviors with their children with ASD, to identify common characteristics, specific differences and the differential impact of child's variables on parents' interactive skills.

## Methods:

This study involved  $n=76$  children with ASD (M chronological age=43.67 months, SD=11.22; M mental age=41.85 months, SD=11.38; 11 females), with their mothers (M chronological age=37.96 years, SD=5.69) and with their fathers (M chronological age=41.21 years, SD=6.94), for a total of 152 parent-child interactions. The relationship between parent and child was evaluated using the Emotional Availability Scales (EAS, Biringen et al., 2008). Data was collected during a 10-min play session, in which parents were asked to play with her or his child, as they typically would do in the home context. Inferential statistics and linear mixed effect models have been applied to investigate cross-sectional differences between mothers and fathers while interacting with their child.

## Results:

There were no significant differences between mothers and fathers in the mean levels of Sensitivity, Structuring, Non-intrusiveness and Non-hostility. The scores fall in the moderate to good range. Also, there were no differences neither in the mean level of child Responsiveness nor in the mean level of Involvement of the child considering mothers and fathers. We further investigated if parent gender, child's cognitive level and symptoms severity could predict Adult and Child EA Scales. Results highlighted that Adult EA scales of both mothers and fathers seem not to be predicted by the child's cognitive functioning nor symptom's severity. Interestingly, concerning the child's scales, symptoms severity, but not cognitive functioning, resulted to be a significant predictor for both Responsiveness ( $b=-0.645$ ,  $p<0.001$ ) and Involvement ( $b=0.5150$ ,  $p<0.01$ ) with both the parents.

## Conclusions:

Similar levels of Emotional Availability (EA) might constitute a positive foundation on which to build early-parents child interventions. Further, understanding the specific role of father's may have important service delivery implications for effectively involving parents in play-based early interventions for children with ASD. It is also important to understand if and how mothers' and fathers' involvement may differentially impact on treatment outcomes and child's gains over time. Finally, considering non-optimal adult EA strengthens the importance of involving caregivers into the therapeutic setting.

### **415.018** (Poster) Examining Profiles of Mental Health Symptoms and Neurodevelopment Among Younger Siblings of Youth with Autism Spectrum Disorder

---

**Background:** Siblings of youth with Autism Spectrum Disorder (ASD) are at increased risk for developing ASD, as well as impairments in cognition, emotion regulation, and social development. Previous research has identified clear heterogeneity in these domains, though investigation of early profiles of behavioral and mental health symptoms has been limited.

**Objectives:** The current study utilized data from the Early Autism Risk Longitudinal Investigation (EARLI) to examine how younger siblings at high familial risk clustered based on parent-reported mental health and adaptive behavior rating scales.

**Methods:** We conducted a latent profile analysis (LPA) using the DSM-oriented subscales of the Child Behavior Checklist (CBCL) and the subscales of the Vineland Adaptive Behavior Scales (VABS), collected at the sibling's 36-month follow-up visit. We identified the best-fitting model using fit statistics and clinical judgement. Latent profile regression was used to determine the association between profile membership and the sibling's diagnosis at 36 months, sex assigned at birth, and maternal anxiety and/or depression during pregnancy.

Results: The sample included 170 younger siblings at high familial risk from the EARLI study (mean age = 36 months +/- 3 months, 54% Male) and resulted in a 4-profile model. Profile 1 (n = 20, 12%) labelled “Moderate Developmental Problems,” was characterized by elevated levels on the CBCL pervasive developmental problems subscale and clinically significant language and motor impairment on the VABS. Profile 2 (n = 36, 21%) labelled “Typically Developing”, was characterized by normative scores on all subscales. Profile 3 (n = 95, 56%) was labelled “Mild Developmental Problems”, as the siblings in this group had mild motor and language delays on the VABS. Profile 4 (n = 19, 11%) was labelled “Mental Health and Developmental Problems” given that siblings in this group had elevated scores on the CBCL affective, pervasive developmental, and oppositional defiant subscales and impaired motor and language skills on the VABS. Younger siblings with an ASD diagnosis were most likely to belong to the “Moderate Developmental Problems” profile compared to the “Typically Developing” ( $\chi^2 = 10.77, p < .01$ ) or the “Mild Developmental Problems” ( $\chi^2 = 8.93, p = .01$ ) profiles. Males were more likely to belong to the “Moderate Developmental Problems” profile than the “Typically Developing” ( $\chi^2 = 21.21, p < .001$ ) or “Mild Developmental” ( $\chi^2 = 22.47, p < .001$ ) profiles than females. Siblings whose mother had a history of anxiety or depression were more likely to be in the “Mental Health and Developmental Problems” profile than any other profile (vs. Profile 1:  $\chi^2 = 7.65, p < .01$ , Profile 2:  $\chi^2 = 17.18, p < .001$ , Profile 3:  $\chi^2 = 23.00, p < .001$ ).

Conclusions: Younger siblings of youth with ASD show differential profiles of mental health and neurodevelopmental impairments at 36 months, and these profiles are associated with child- and maternal-specific factors. These profiles further our understanding of borderline and clinically impairing phenotypic expression among non-typically developing siblings, as well as help to identify siblings who may be in need of cognitive, emotional, and/or social early intervention services.

**415.019 (Poster)** Examining the Relationship between Parent-Child Interactions and Social Communication Skill Acquisition in Early Intervention Settings

**M. M. Chemotti<sup>1,2</sup>, J. A. Ko<sup>2</sup>, K. S. Dickson<sup>1</sup>, S. R. Rieth<sup>2</sup> and A. C. Stahmer<sup>3</sup>,** (1)Child and Adolescent Services Research Center, San Diego, CA, (2)San Diego State University, San Diego, CA, (3)UC Davis MIND Institute, University of California, Davis, Sacramento, CA

---

**Background:** Parent-mediated interventions for young children focus on parents learning and practicing techniques to support their child in the home and other community settings. Active parent engagement in services is best practice for young children with social communication challenges (Zwaigenbaum et al., 2015), but parents can often struggle to learn and use complex interventions with full fidelity (e.g., Stahmer et al., 2019). As such, it may be helpful to identify key components or strategies used by parents that are positively related to child progress. Examining parent behaviors used to promote social communication skills during participation in early intervention programs can support identification of possible relationships between parents’ use of certain techniques and child progress. This information may help identify key areas to target for parent support within the context of parent-mediated intervention.

**Objectives:** This study explored the relationship between use of certain parent behaviors during parent-child interactions and child progress on a proximal measure of social communication skills after three months of early intervention.

**Methods:** In this community-based early intervention study, Part C providers delivered services to 24 parent-child dyads. Children averaged 23.16 months (SD = 5.03) of age, were 71% male, and 46% Hispanic/Latinx. A total of 100% of participating parents were biological mothers. Child social communication skills were evaluated via provider report at intake and after three months of treatment, using the revised Social Communication Checklist (SCC-R; Wainer et al., 2017). The SCC-R is a 70-item checklist covering four primary domains: social engagement, expressive communication, receptive communication, and imitation/play. SCC-R total scores were calculated for all participants. Parent behavior was evaluated using the Parent Interactions with Children: Checklist of Observations Linked to Outcomes (PICCOLO; Roggman et al., 2013) at the conclusion of treatment. Trained observers scored the PICCOLO via video-recorded parent-child interactions to examine parenting behaviors of Affection, Responsiveness, Encouragement, and Teaching. Multiple regression was used to test if parenting behaviors observed with the PICCOLO at the conclusion of treatment were significantly related to change in child social communication scores on the SCC-R across three months of early intervention.

**Results:** Results demonstrated that the PICCOLO Teaching domain significantly predicted change in children’s social communication scores ( $\beta = .54, p < .05$ ), but the Affection, Encouragement and Responsiveness domains were not significantly related. The ability to detect significant relationships within this analysis was likely impacted by the high collinearity of parenting behaviors as measured by the PICCOLO (VIF values from 1.25 to 1.97).

**Conclusions:** The current exploration provides preliminary evidence on the importance of encouraging parent teaching behaviors related to children’s social communication skill acquisition. Teaching, as defined by the PICCOLO, involves creating stimulating parent-child interactions by sharing conversation (e.g., expanding words and sounds; labeling objects and actions) and play (e.g.,

extending what the child is doing; suggesting activities). Building upon current teaching behaviors could be a future area of focus within parent-mediated interventions for young children with social communication challenges.

**415.020 (Poster)** Exploring Face Inversion Effects and Attentional Biases in Infants at High Risk for ASD

**C. Brittenham<sup>1</sup>, J. B. Wagner<sup>2,3</sup>, H. Tager-Flusberg<sup>4</sup> and C. A. Nelson<sup>5</sup>,** (1)*The Graduate Center, City University of New York, New York, NY*, (2)*College of Staten Island, City University of New York, Staten Island, NY*, (3)*The Graduate Center, City University of New York, New York, NY*, (4)*Department of Psychological and Brain Sciences, Boston University, Boston, MA*, (5)*Developmental Medicine, Boston Children's Hospital, Boston, MA*

---

**Background:** Decades of research have debated whether visual processing abilities in ASD result from enhanced featural processing, configural processing deficits, or both (Simmons & Todorova, 2018). In typically-developing infants, faces are processed configurally by the second half of the first year (Scott & Nelson, 2006), seen also by increased attention to the left side of the face (Guo et al., 2009). Configural processing can be disrupted through face inversion (Freire et al., 2000), though in ASD these effects are diminished (Falck-Ytter, 2008), as are biases to the left side of the face (Dundas et al., 2012a). By 11 months, infants at high risk for ASD (HRA; by virtue of an older sibling with ASD) also differ from low-risk control infants (LRC) in attention to the left and right sides of upright faces (Dundas et al., 2012b), and the current study will expand on past research to look at face inversion effects and left vs. right face attention in HRA and LRC infants at 6, 9, and 12 months.

**Objectives:** The current aim is to evaluate patterns of visual scanning to faces in infancy that could reflect similarities and differences in configural and featural processing between HRA and LRC.

**Methods:** Participants included 53 6-month-olds (HRA:  $n=23$ ; LRC:  $n=30$ ), 57 9-month-olds (HRA:  $n=22$ ; LRC:  $n=35$ ), and 62 12-month-olds (HRA:  $n=20$ ; LRC:  $n=42$ ). Infants viewed 12 upright and 12 inverted faces, each for 3.5 sec, while a Tobii eye-tracker captured visual attention. Analyses examined looking to the face overall, and to the left and right sides of the face.

**Results:** A repeated-measures ANOVA with orientation (upright,inverted) as the within-subjects factor and group (HRA,LRC) and age-months (6,9,12) as the between-subjects factors, revealed an orientation\*group interaction for attention to the face,  $F(1,166)=4.797, p=.03$ . Groups showed non-significant trends in the opposite direction for attention to upright vs. inverted faces, with LRC looking longer to upright than inverted ( $p=.12$ ) and HRA looking longer to inverted than upright ( $p=.074$ ; see Figure 1). A second ANOVA added face-region (left,right) as a within-subjects factor and found an orientation\*face-region\*age-months\*group interaction,  $F(1,166)=3.364, p=.037$ . Follow-up ANOVAs for each age were conducted, and an orientation\*face-region\*group interaction at 12 months was found ( $p=.049$ ; see Figure 2), with different patterns of attention to the left and right side depending on orientation for each group.

**Conclusions:** The current study found differences in face inversion effects and attention to the left and right sides of faces between HRA and LRC in the first year of life. LRC showed a trend towards more attention to upright than inverted faces, while HRA showed the opposite pattern. When examining side biases in attention, differences in looking to the left vs. right for upright and inverted faces varied most for LRC and HRA at 12 months. More work is needed to understand whether these differences might indicate enhanced featural or disrupted configural processing in HRA. Future work will include infant diagnostic outcomes to further understand how these measures of visual processing might also differentiate HRA later receiving an ASD diagnosis.

**415.021 (Poster)** Factors Associated with Toileting Resistance in Preschool-Aged Children with Autism Spectrum Disorder and Other Developmental Delays/Disabilities

**L. Wiggins<sup>1</sup>, S. Hepburn<sup>2</sup>, C. Nadler<sup>3</sup>, A. M. Reynolds<sup>4</sup>, S. Rosenberg<sup>5</sup> and J. Zubler<sup>6</sup>,** (1)*Centers for Disease Control and Prevention, Atlanta, GA*, (2)*Colorado State University, Fort Collins, CO*, (3)*Children's Mercy Kansas City, Kansas City, MO*, (4)*University of Colorado School of Medicine, Aurora, CO*, (5)*University of Colorado Anschutz Medical Campus, Aurora, CO*, (6)*Eagle Global Scientific, Atlanta, GA*

---

**Background:** Most typically developing children achieve daytime continence by 3 years of age. Some studies suggest that children with autism spectrum disorder (ASD) achieve continence later than children in the general population (POP) and those with other non-ASD developmental delays (DD). Factors associated with toileting resistance in adolescents/adults with ASD include intellectual disability, behavior problems, gastrointestinal (GI) issues, and ASD diagnostic symptoms. There is little literature on factors associated with toileting resistance in preschool-aged children with ASD compared to other children.

**Objectives:** (1) Compare toileting resistance among children ages 3–5 years who were classified as ASD, DD, and POP in a multi-site community-based study and (2) identify behavior problems and GI issues associated with toileting resistance in children with ASD and DD.

**Methods:** Families of children ages 2–5 years were enrolled in the Study to Explore Early Development Phase-2 (SEED-2) from 2012 to 2016. Mothers were first asked to complete an ASD screen. Children who did not demonstrate risk on the ASD screen completed the Mullen Scales of Early Learning (MSEL) and were defined as DD or POP. Others were additionally asked to complete the Autism Diagnostic Observation Schedule and Autism Diagnostic Interview – Revised to determine ASD status. MSEL scores of 70 points or less defined intellectual disability (ID).

Mothers self-reported education and race/ethnicity and completed the Child Behavior Checklist 1½–5 years (CBCL) including whether the child rarely or sometimes/often resisted toilet training in the last 3 months. CBCL scales for anxiety, attention deficits/hyperactivity, and oppositional problems defined behavior problems in this study. Mothers also completed a child health history form including whether the child rarely or sometimes/often had specific GI issues within the past year (Table 1).

**Results:** Children ages 3–5 years with complete CBCL data and classified with ASD (n=746), DD (n=768), or as POP (n=701) were included. Children with ASD were significantly more likely to resist toilet training sometimes/often (49.1%) than DD (23.7%) or POP (8.4%) children ( $\chi^2=308.2$ ,  $p<.001$ ) (Table 1). They were also significantly more likely to have behavior problems and GI issues than DD or POP children (Table 1). Constipation was the most frequent GI issue reported for children with ASD (35.7% vs. 23.0% [DD] and 15.8% [POP]). After adjusting for child sex and ID and maternal education and race/ethnicity, logistic regression analyses found that attention deficits/hyperactivity (OR=1.6; 95%CI=1.1,2.3), constipation (OR=1.7; 95%CI=1.2,2.5), and diarrhea (OR=1.6; 95%CI=1.1,2.5) were significantly associated with toileting resistance in children with ASD. Oppositional behaviors (OR=2.6; 95%CI=1.4,4.6) and diarrhea (OR=2.5; 95%CI=1.5,4.6) were significantly associated with toileting resistance in children with other DD (Table 2).

**Conclusions:** Our study suggests a significantly higher proportion of children with ASD (i.e., one-in-two) resist toilet training, compared with other children. Addressing factors associated with toileting resistance in the preschool years may help tailor interventions that could prevent toileting problems later in life. Our results support the need to identify and treat constipation and diarrhea and co-occurring attention deficits/hyperactivity when toilet training young children with ASD.

#### **415.022** (Poster) Gross Motor Development and Its Relation to Language Skills in Infants at Low and High Familial or Screen Risk for ASD

**D. Huaracha**<sup>1,2</sup>, **A. B. Choi**<sup>3</sup>, **H. Tager-Flusberg**<sup>4</sup> and **C. A. Nelson**<sup>3</sup>, (1)Harvard College, Cambridge, MA, (2)Boston Children's Hospital, Boston, MA, (3)Developmental Medicine, Boston Children's Hospital, Boston, MA, (4)Department of Psychological and Brain Sciences, Boston University, Boston, MA

---

#### Background:

Infants who later develop autism spectrum disorder (ASD) show early gross motor problems, including delays in motor milestones (Lloyd et al., 2013; Ozonoff et al., 2008). Also, significant differences in gross motor development between infants at high and low familial risk for ASD have been reported (Bhat et al., 2012), albeit mixed findings (Iverson et al., 2019). What remains unknown is whether a non-familial risk group of infants (i.e., those who fail a developmental screener at 12 months) show differences in gross motor development. Moreover, it remains unclear whether the relation between early gross motor and language development, found in typically developing populations, extends to infants at high familial or screen risk for ASD.

#### Objectives:

To investigate whether infants in three groups – (1) infants at low risk of ASD due to having no older siblings with autism and having passed a 12-month screener (Low-Risk Controls, or LRC), (2) infants at familial risk for ASD due to having at least one older sibling with autism (High-Risk for Autism, or HRA), and (3) infants at developmental risk for ASD based on early behavioral differences detected on a 12-month screening instrument (High-Risk Screeners, or HRS) - differ in gross motor development between 12 and 24 months and to examine whether gross motor skills are related to language skills in the three groups.

#### Methods:

The Communication and Symbolic Behavior Scales (Wetherby & Prizant, 2002) was used at 12 months to identify infants for inclusion in the HRS group. Infants from each group (LRC:  $n = 120$ ; HRA:  $n = 72$ ; HRS:  $n = 49$ ) were administered the Mullen Scales of Early Learning (MSEL; Mullen, 1995) at 12, 18, and 24 months to measure gross motor and language skills. Because data were not normally distributed, nonparametric tests were used to test group differences in gross motor scores across HRA,

HRS, and LRC groups. Spearman's correlations were used to examine associations between concurrent gross motor and language scores at each age.

#### Results:

The HRS group had significantly lower gross motor scores than the HRA group at 12 and 24 months ( $p < .05$ ). The HRS group also had significantly lower gross motor scores than the LRC group at 12 and 18 months ( $p < .05$ ). There were significant, positive correlations between gross motor and receptive language scores in the LRC group at 12, 18, and 24 months ( $r_s = .23-.48$ ,  $p < .05$ ). However, there were no robust associations between gross motor and language scores in the HRA and HRS groups.

#### Conclusions:

Infants in the HRS group had significantly lower gross motor scores compared to infants in the HRA and LRC groups in the first two years of life. The association between gross motor and language skills was significant only in the LRC group, suggesting that the gross motor-language relation may be robust in typically-developing infants, but not those who are at high familial risk for ASD or those who fail a developmental screener.

#### **415.023 (Poster)** Individual and Parental Factors Affecting Behavior and Emotional Problems of Italian Toddlers with Low-Functioning Autism Spectrum Disorder

**A. Bacherini<sup>1</sup>, R. Iglizzi<sup>2</sup>, G. Rebecchini<sup>1</sup>, R. Cagiano<sup>2</sup>, A. Mancini<sup>2</sup>, R. Tancredi<sup>2</sup>, F. Muratori<sup>3</sup> and G. Balboni<sup>1</sup>,** (1)Department of Philosophy, Social and Human Sciences and Education, University of Perugia, Perugia, Italy, (2)IRCCS Stella Maris Foundation, Pisa, Italy, (3)Department of Clinical and Experimental Medicine, University of Pisa, Pisa, Italy

Background: The expression of behavior and emotional problems (BEP) in toddlers with low-functioning Autism Spectrum Disorders (ASD) may be associated to several individual and parental factors, to consider for a complete picture of the child. Parents' socio-cultural level (SCL) is relevant for the development of children. It is composed by three dimensions: (1) socio-economic status (SES), with educational level, type of job and income as indicators; (2) cultural capital, with participating, consuming and expert using as dimensions; and (3) social capital, with bonding and bridging as indicators (Bordieau, 1986; Bornstein & Bradley, 2003).

Objectives: The present study aimed to examine whether the BEP of 148 Italian toddlers aged from 18 to 37 months old ( $M = 30.84$ ,  $SD = 4.62$ ; 82% males) with low-functioning ASD are affected by individual and parental factors.

Methods: As individual factors, toddlers' age, birth order, development level (Griffiths Mental Development Scale; Griffiths, 1996; Luiz et al., 2006), autistic symptomatology (ADOS-2; Lord et al., 2012), and adaptive behavior (Vineland-II; Sparrow et al., 2005) were considered. As parental factors, both parents' age, years of education, occupational prestige, cultural capital (Scale of Cultural Capital; Balboni et al., 2019), and social capital (Personal Social Capital Scale; Chen et al., 2009) were investigated. Toddlers' BEP were assessed with the CBCL 1½-5 (Achenbach & Rescorla, 2000) (see Table 1). First, Pearson's correlation coefficients were calculated to examine the relationships among individual and parental factors. Then, only those individual and parental factors which resulted statistically significantly correlated with BEP were entered at Step 1 and at Step 2, respectively, as independent variables in hierarchical regression models with each CBCL syndrome or DSM-oriented scale as dependent variable. For each factor found to significantly affect BEP, the  $f^2$  effect size was computed (Cohen, 1988).

Results: Correlations' results showed that toddlers' development level, socio-affective autistic symptomatology and adaptive behavior were related with the majority of CBCL scales, while toddlers' age, birth order, restricted-repetitive behaviors autistic symptomatology, mothers' age, both parents' years of study, occupation, consuming and expert using cultural capital, and bonding and bridging social capital were associated only with specific CBCL scales. Regressions' results showed that higher levels of BEP are affected by higher toddlers' age, birth order and socio-affective autistic symptomatology, and by lower adaptive behavior, restricted-repetitive behaviors autistic symptomatology, mothers' age, both parents' bonding social capital, and fathers' expert using cultural capital. Among all factors, only toddlers' adaptive behavior affected the majority of CBCL scales and with the highest power, showing moderate and large effect sizes for some CBCL scales, while all other individual and parental factors affected only specific CBCL scales and with small effect sizes.

Conclusions: Already at early age, the expression of BEP of toddlers with ASD is influenced by parents' SCL as well as specific individual factors (i.e. adaptive behavior, birth order, restricted-repetitive behaviors autistic symptomatology). Hence, measuring all these individual and parental factors may be useful for several clinical purposes, like planning individualized interventions focused on better children's quality of life and inclusion in the community.

**415.024 (Poster)** Investigating Associations between Older Siblings' ASD and ADHD Traits and Infant Siblings' Temperament  
**H. Halkola<sup>1</sup>, A. Pickles<sup>2</sup>, J. Begum Ali<sup>3</sup>, A. Gui<sup>4</sup>, G. Pasco<sup>5</sup>, M. H. Johnson<sup>6</sup>, T. Charman<sup>6</sup>, E. J. Jones<sup>3</sup> and &. The BASIS Team<sup>1</sup>,**

---

#### Background:

Autism spectrum disorder (ASD) and attention deficit/hyperactivity disorder (ADHD) are both highly heritable conditions. Having an older sibling with ASD increases the likelihood of developing autism symptoms and dimensional variation in proband symptomology has been shown to be a predictor of familial ASD recurrence risk. Similarly, people that have a relative with ADHD are more likely to develop ADHD themselves. Previous prospective studies have indicated that perceptual sensitivity and fear/shyness in infancy could be possible early predictors for later ASD traits, while activity level and infant attentional temperamental traits (duration of orientating, attentional focus/shifting) might predict later ADHD traits. However, there is a lack of prospective studies investigating how proband traits of ASD and ADHD are associated with early infant developmental traits in their younger siblings.

#### Objectives:

To investigate the associations between older siblings' ASD and ADHD traits and early childhood predictors of ASD, ADHD and anxiety in infant siblings at typical and elevated likelihood of ASD and/or ADHD.

#### Methods:

The study included 411 infant participants (male = 213, female = 198) and their older siblings with ASD (n=250), ADHD (n=31), both (n=21) or neither (n=106) from the British Autism Study of Infant Siblings (BASIS) and Studying Autism and ADHD Risks (STAARS) studies. Parents completed the Infant Behavior Questionnaire (IBQ) for the infant sibling at 8-months and 14-months and the Early Childhood Behavior Questionnaire (ECBQ) at 24-months. Perceptual sensitivity and fear/shyness were used as possible early predictors for ASD, while activity level, duration of orientation and attentional shifting/focus were used for ADHD.

For the proband ASD traits, parents completed the Social Communication Questionnaire Lifetime version (SCQ Lifetime) (n=329), and the Conners 3 questionnaire (n=198) for ADHD traits, from which the subscales for inattention and hyperactivity/impulsivity were used. Latent growth curve models were used in statistical analysis.

#### Results:

##### *ASD*

Older siblings' higher SCQ scores (more symptoms) were associated with higher initial infant fear and its decline over time (figure 1). The model for older siblings' SCQ scores and infant perceptual sensitivity ( $\chi^2(2) = 4.43, p = .109; CFI = .985, RMSEA = .055$ ) showed that higher proband SCQ scores associated with infants' lower stable perceptual sensitivity ( $\beta = -.013, p = .045$ ), but there was no significant change over time.

##### *ADHD*

Older siblings' higher levels of inattention were associated with higher initial infants' activity levels, but not with the change (slope) over time (figure 2). Proband hyperactivity/impulsivity did not associate with infants' activity level. Neither inattention nor hyperactivity/impulsivity were associated with infants' attentional measures.

#### Conclusions:

This is one of the first studies investigating proband trait association with infant sibling temperament. The results show that older siblings' ASD and ADHD traits do associate with their infant siblings' temperamental developmental trajectories, although the

pattern was different across the different constructs. As these temperamental traits might be early predictors for later emergence of ASD and ADHD, futures studies should explore how proband traits might relate to their infant sibling's later development.

**415.025 (Poster)** Investigating Attention to Non-Social and Social Stimuli and Underlying Mechanisms of Language Development in a Prospective ASD and ADHD Infant-Sibling Study

*M. A. Agyapong<sup>1</sup>, M. H. Johnson<sup>2,3</sup>, T. Charman<sup>4</sup>, E. J. Jones<sup>2</sup> and &. The BASIS-STAARS Team<sup>1,2</sup>, (1)Department of Psychology, Institute of Psychiatry, Psychology & Neuroscience, King's College London, London, United Kingdom, (2)Centre for Brain and Cognitive Development, Birkbeck, University of London, London, United Kingdom, (3)Department of Psychology, University of Cambridge, Cambridge, United Kingdom, (4)Department of Psychology, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom*

---

**Background:**

Neurodevelopmental disorders like autism spectrum disorder (ASD) and attention deficit hyperactivity disorder (ADHD) are diagnosed in early childhood and frequently co-occur. It is important to understand the early mechanisms that could contribute to later difficulties in these disorders through prospective studies. One important component in early learning is how the social relevance and temporal structure of events influences attention. Infant's attention to particular frequencies may shape their arousal and attention to social contexts like language. Here we explore patterns of attention to different temporal frequencies in social and non-social contexts in infants with first-degree relatives with and without ASD and/or ADHD.

**Objectives:**

To investigate attention to temporal structure (i.e. information presented at different frequencies) in a prospective study of infants at typical-likelihood (TL) and elevated-likelihood (EL) of ASD and/or ADHD due to family history.

**Methods:**

This study included 93 five-month old infants (51 males) from the British Autism Study of Infant Siblings, Studying Autism and ADHD Risks (STAARS; [www.staars.org](http://www.staars.org)). 25 TL controls, 42 EL-ASD, 14 EL-ADHD and 12 EL-ASD+ADHD infants completed an eye-tracking paradigm ('Frequency Task'). Ten-second videos of non-social stimuli (checkerboard pairs) and of social stimuli (face pairs) were presented to the infants. Three trials were presented for each condition, respectively. In both non-social and social conditions, each stimulus in the pair alternated at a different frequency; either low (1Hz), mid (6Hz; i.e. the frequency of human syllabic speech) or high (10Hz) frequency.

**Results:**

Infants showed a side bias for stimuli presented on the right of the screen; therefore, this was included as a covariate along with age in days. There were no group differences in looking time. There was an effect of frequency ( $F(2, 922.62) = 80.80, p < .001$ ) with infants showing a looking preference for low<mid<high frequency stimuli. There were no differences in the overall amount of looking at social and non-social stimuli. However, there was a significant interaction between stimulus type and frequency ( $F(2, 912.04) = 21.90, p < .001$ ). Infant's looking patterns to non-social stimuli were more modulated by temporal frequency than for social stimuli (see Figure 1).

**Conclusions:**

Typical-likelihood and elevated-likelihood for ASD and/or ADHD infants showed similar modulation of attention by temporal frequency and social content. Infants did not show a consistent preference for 6Hz stimuli over 1Hz and 10Hz, suggesting they were not perceptually tuning in to the frequency of human syllabic speech. The study also provides behavioural evidence of content-related modulation as preference for faces or checkerboards varied by frequency. These fundamental processes appear similar in very early development of infants with elevated-likelihood for neurodevelopmental disorders. Future work will take a longitudinal approach to explore attention to temporal structure in these infants, and its relation to later language and ASD outcomes.

**415.026 (Poster)** Joint Engagement Experiences Are Associated with Communication Skills and Autism Severity in Toddlers with ASD.

**A. Browngoehl**<sup>1</sup>, A. Zitter<sup>1</sup>, A. T. Wieckowski<sup>1</sup>, K. Suma<sup>2</sup>, R. Bakeman<sup>3</sup>, L. B. Adamson<sup>3</sup> and D. L. Robins<sup>1</sup>, (1)A.J. Drexel Autism Institute, Drexel University, Philadelphia, PA, (2)University of Georgia, Athens, GA, (3)Psychology, Georgia State University, Atlanta, GA

---

**Background:** Joint engagement is positively associated with communication outcomes concurrently and prospectively in toddlers with autism spectrum disorder (ASD; Adamson et al., 2009, 2019; Bottema-Beutel, 2014). However, there is heterogeneity in communication skills and symptom severity across the autism spectrum that impact early intervention approaches (Kim et al., 2016; Wiggins et al., 2012) and long-term outcomes. Play with others, such as parents, is an opportunity for children to further develop their social and communication skills (Pierucci, 2015).

**Objectives:** The present study explores the relation between joint engagement experiences for toddlers with ASD during parent-child play and their communication and socialization abilities, and ASD severity.

**Methods:** Toddlers (18–32 months at evaluation,  $M = 23.85$ ,  $SD = 3.45$ ;  $n = 103$ ) with ASD were recruited from an early detection study. Participants were included if they completed all measures, no more than two months apart. In one session, toddlers participated in a joint engagement study, producing video of 15-minute, semi-structured parent-child interaction using the Communication Play Protocol (CPP; Adamson et al., 2016). Videos were reliably rated using three 7-point rating items from the Joint Engagement Rating Inventory (JERI; Adamson et al., 2020). Total Joint Engagement (TJE) describes overall quantity of joint engagement; Scaffolding assesses caregiver's support and furtherance of child's interactional experiences; and Fluency & Connectedness (F&C) characterizes flow of the interaction. In a separate session, the Mullen Scale of Early Learning (MSEL; Mullen, 1995), Vineland Adaptive Behavior Scale- 2nd Edition (VABS-II; Sparrow et al., 2016), and Autism Diagnostic Observation Schedule, Second Edition (ADOS-2; Lord et al., 2012) were collected. Correlations examined associations between the three JERI items and measures of communication (MSEL Expressive and Receptive Language developmental quotients [DQ; age equivalent/chronological age\*100]), socialization (VABS-II Socialization Standard Score), and ASD severity (ADOS-2 Total Calibrated Severity Score).

**Results:** Communication scores were significantly and positively correlated with all three JERI items (Table 1; all  $r > .21$ ;  $p < .038$ ). Socialization results revealed significant small positive correlations with Scaffolding ( $p = .048$ ) and F&C ( $p = .043$ ), but no association was found for TJE. A small significant negative correlation between ASD severity and Scaffolding ( $p = .028$ ) and F&C ( $p = .050$ ) exists, but not for TJE.

**Conclusions:** Results indicate that for toddlers with ASD, parents' scaffolding and the flow during parent-child interactions are associated with children's communication and socialization abilities and with ASD severity. Additionally, the time a child with ASD is in joint engagement during these interactions is associated with their communication abilities. One manifestation of deficits in quality of interactions among toddlers with ASD is difficulty engaging in reciprocal play. Our findings suggest that variability in the quality of interaction these toddlers experience reflects in part heterogeneity in their language skills and autism severity. These findings present an opportunity to inform early intervention and parent-mediated therapy by focusing on maximizing children's time spent in joint engagement, parents' support of child's activities, and balance and flow of interaction in dyadic play, which may affect future outcomes for children with ASD.

**415.027 (Poster)** Language Abilities in Children with Autism and Language Development in the First Two Years of Life in Their High-Risk Siblings

---

**Background:** A recent report found that quantitative variation in language abilities and autism traits in children with autism spectrum disorder (ASD) may help inform the development of their high-risk younger siblings (Girault et al., 2020). Younger siblings of children with ASD have been shown to exhibit altered trajectories of language development as early as 12 months of age (Estes et al., 2015), which may serve as a target for intervention. Here we examine how the language abilities of older ASD siblings (probands) may inform language development in their high-risk siblings from 6 to 24 months of age.

**Objectives:** In this study, we assessed the predictive utility of proband language abilities for developmental trajectories of expressive (EL) and receptive (RL) language in high-risk (HR) siblings in the first two years of life.

**Methods:** Three hundred and eighty-four proband-sibling pairs were included in this study; 89 were concordant for ASD (i.e. both diagnosed with ASD). Proband EL and RL was evaluated using the Vineland Adaptive Behavior Scale and ASD trait level was measured with the Social Communication Questionnaire (SCQ). Sibling language abilities were evaluated at 6, 12, and 24 months using the Mullen Scales of Early Learning and the Vineland. Additional measurements of language were captured using the Communication and Symbolic Behavioral Scales (CSBS) and MacArthur-Bates Communicative Development Inventories (MCDI) at 12 and 24 months.

**Results:** Pearson correlation estimates revealed proband Vineland RL was significantly correlated with 24-month RL scores of HR siblings who developed ASD (HR-ASD) on the Vineland ( $r = 0.43$ ,  $q = 0.016$ ) and Mullen ( $r = 0.41$ ,  $q = 0.016$ ), and the number of phrases understood on the MCDI ( $r = 0.41$ ,  $q = 0.031$ ). Proband Vineland EL scores were significantly correlated with HR-ASD sibling EL scores on the Mullen at 24-months ( $r = 0.39$ ,  $q = 0.029$ ). We found no associations between proband language abilities and HR sibling language at 6 or 12 months (**Figure 1**). Proband SCQ was not associated with sibling language development at any timepoint. Longitudinal mixed models adjusted for age, sex, and study site identified significant associations between proband and sibling Vineland RL and EL scores (**Figure 2**). Given that a subset of HR siblings negative (HR-Neg) for ASD have been shown to exhibit language delay (Ozonoff et al., 2014), we also tested whether proband categorical language delay (Vineland EL or RL score  $<10$ ) predicted sibling categorical language delay (Mullen EL or RL t-score  $<35$ ). Regardless of diagnostic outcome, proband language delay significantly predicted language delay in siblings at 24-months (OR = 2.26, 95% CI 1.29 to 4.08,  $p = 0.005$ ).

**Conclusions:** These results extended previous work to reveal that ASD proband language abilities explain significant variation in HR sibling language skills at 24-months, but not before, among siblings who develop ASD. Language delay in probands was predictive of language delay in HR siblings at 24-months regardless of diagnostic outcome. This suggests that HR siblings of children with ASD and language delay should be monitored closely in the first two years of life.

**415.028 (Poster)** Longitudinal Trajectories of Social Visual Engagement Distinguish between Language Profiles at Two Years in Autism Spectrum Disorder

**E. Kushner<sup>1</sup>, S. Koirala<sup>2</sup>, D. Parmaksiz<sup>3</sup>, S. Yuan<sup>4</sup>, W. Jones<sup>5</sup>, S. Shultz<sup>5</sup>, A. Klin<sup>5</sup> and L. A. Edwards<sup>5</sup>, (1)Emory University, Marcus Autism Center, Atlanta, GA, (2)Department of Pediatrics, Emory University School of Medicine, Marcus Autism Center, Atlanta, GA, (3)Marcus Autism Center, Atlanta, GA, (4)Emory University School of Medicine, Marcus Autism Center, Atlanta, GA, (5)Marcus Autism Center, Children's Healthcare of Atlanta and Emory University School of Medicine, Atlanta, GA**

**Background:**

Language outcomes among individuals with Autism Spectrum Disorder (ASD) are highly variable, ranging from those who remain minimally- and non-verbal to those who develop fully functional speech (Tager-Flusberg, Paul, & Lord, 2005). Language skill in early childhood is one of the strongest predictors of functional success for children with ASD, yet our understanding of the heterogeneity of communicative development remains limited (Mawhood, Howlin, & Rutter, 2000). Eye-tracking measures of Social Visual Engagement (SVE) have previously been used to differentiate children with ASD from typically developing children and identify mechanisms of social disability within ASD (Jones & Klin, 2013). Little work has explored how trajectories of SVE might differentiate children with ASD who present heterogeneously. These trajectories may elucidate mechanisms of variable language outcome and provide preliminary SVE predictors of language among children with ASD.

**Objectives:**

Prior studies have described two meaningful subgroups of children with ASD: those with significant language impairments and those with more typical language acquisition (Tek et al., 2014). This project aimed to model and compare developmental trajectories of SVE in these two subgroups, across the first two years of life.

**Methods:**

50 male infants later diagnosed with ASD were followed prospectively from birth until age two years. SVE measures (quantified as percentage of time spent fixating on different Regions Of Interest (ROIs): eyes, mouth, body, and objects) were collected a maximum of 12 times ( $M=6.84, SD=2.8$ ) between birth and 2 years. Children were assessed for developmental functioning at 2 years using the Mullen Scales of Early Learning. Those who received T-scores greater than 1 SD below the mean in either the

Expressive or Receptive Language sub-scales were classified as ASD-Typical Language (ASD-TL(N=34)), while those with T-Scores less than 1 SD below the mean in either language sub-scale were classified as ASD-Language Delayed (ASD-LD(N=16)). Functional data analysis was utilized to model longitudinal trajectories of SVE in both language groups.

#### Results:

Despite individual heterogeneity, results indicate differential trajectories of SVE between children with ASD with and without language delays at 2 years ( $F=2.85, p=0.09$ ) reaching trending significance. In ASD-LD children, eye-looking declines across the first 2 years, whereas in ASD-TL group, eye-looking appears to initially increase (2-6 months) and remains comparatively high thereafter. Conversely, in the ASD-LD group, mouth-looking appears to increase more rapidly and stay elevated, reaching a plateau at 18 months, whereas ASD-TL children show more gradual increases in mouth-looking from 2-18 months, after which this behavior appears to decline (18-24 months).

#### Conclusions:

Previous studies have shown reduced eye-looking in ASD compared to typically developing children, and also showed an association between the extent of decline in eye-looking that a child's outcome level of social disability (Jones & Klin, 2013). Here, in a larger sample of infants with ASD, results show that decline in eye-looking also appears to be associated with outcome levels of language function and highlights heterogeneity in outcomes across the Autism Spectrum. Trajectories of SVE may both predict and suggest mechanisms by which children with ASD develop heterogeneous functional outcomes, such as language.

#### 415.029 (Poster) Maternal Depressive Symptom Trajectory and Brain and Behavioral Development in Infants at High and Low Risk for Autism

**A. B. Choi**<sup>1,2</sup>, C. L. Wilkinson<sup>1</sup>, G. Sideridis<sup>3</sup>, H. Tager-Flusberg<sup>4</sup> and C. A. Nelson<sup>1</sup>, (1)Developmental Medicine, Boston Children's Hospital, Boston, MA, (2)Harvard Graduate School of Education, Cambridge, MA, (3)Developmental Medicine, Boston Children's Hospital/Harvard Medical School, Boston, MA, (4)Department of Psychological and Brain Sciences, Boston University, Boston, MA

Background: Children of depressed mothers are more likely to have atypical frontal brain activity and develop internalizing and externalizing behavior problems than children of nondepressed mothers (Dawson et al., 1999; Barker et al., 2012). Although a large body of research documents the relations between maternal depression and various developmental outcomes in typically developing children, it remains unknown whether similar associations are found in infant siblings of children with autism spectrum disorder (ASD).

Objectives: We aim (1) to identify trajectories of depressive symptoms in mothers of high-risk infant siblings later diagnosed with ASD, high-risk infants not diagnosed with ASD, and low-risk infants between 6 and 24 months of age and (2) to examine the associations between trajectory class and infants' brain and behavioral development.

Methods: Participants were 142 parent-infant dyads (high-risk:  $n=85$ , low-risk:  $n=57$ ). Maternal depressive symptoms were measured using CESD-R when their infants were 6-, 12-, 18-, and 24-months old. Infants' baseline EEG and socio-emotional behaviors (measured using ITSEA) were collected at 24 months. Frontal EEG asymmetry, a trait marker of vulnerability to depression (Coan & Allen, 2004), was calculated from subtracting the left hemisphere alpha power from the right hemisphere alpha power. ASD outcomes were assessed using ADOS and clinical best estimate at final visit.

#### Results:

(1) Using latent class growth curve analysis, we identified three trajectories of maternal depressive symptoms. Mothers with "high-decreasing" symptoms (7%) started out with a high level of depressive symptoms at 6 months (intercept=30), but the level significantly decreased over time ( $b=-5.52, p<.001$ ). Mothers with "mid-increasing" symptoms (49%) initially reported a moderate level (intercept=12), but the level significantly increased over time ( $b=1.06, p=.041$ ). Finally, mothers with "low-decreasing" symptoms (44%) started out with a low level at 6 months (intercept=4), and the level significantly decreased over time ( $b=-0.61, p=.001$ ). There were no associations between trajectory class and the infant's ASD risk or eventual diagnosis.

(2) Using ANOVAs, we found significant differences in alpha asymmetry at 24 months ( $F(2,75)=3.35, p=.041$ ) among trajectory classes (Figure 1). Infants whose mothers had "high-decreasing" symptoms had significantly lower asymmetry scores ( $M=-0.10, SE=0.17$ ), indicating reduced relative left hemisphere power, compared to infants whose mothers had "low-decreasing" symptoms ( $M=0.00, SE=0.12; p=.037$ , Bonferroni). There was no effect of group or interaction effect between class and group.

There were significant differences in internalizing behaviors at 24 months among trajectory classes ( $F(2, 92)=4.48, p=.014$ ) as well as the groups ( $F(2,92)=3.39, p=.038$ ). Infants whose mothers had “mid-increasing” symptoms had significantly higher internalizing behaviors ( $M=52.21, SE=1.39$ ) than infants whose mothers had “low-decreasing” symptoms ( $M=46.91, SE=1.38; p=.024$ , Bonferroni; Figure 2). High-risk infants not diagnosed with ASD had significantly higher internalizing behaviors ( $M=52.98, SE=1.44$ ) than low-risk infants ( $M=46.48, SE=1.48; p=.006$ ; Bonferroni). There was no interaction effect between class and group.

Conclusions: Maternal depressive symptom trajectories were associated with in 24-month alpha asymmetry and internalizing behaviors in infants at high and low risk for ASD, suggesting a need to examine not just child-level factors but also family-level factors to understand brain and behavioral development of high- and low-risk infants.

**415.030** (Poster) Multimodal Pathways into Sustained Attention during Dyadic Toy Play for Children with and without Autism  
**J. R. Yurkovic<sup>1</sup>**, G. Lisandrelli<sup>1</sup>, R. Shaffer<sup>2</sup>, K. Dominick<sup>3</sup>, E. Pedapati<sup>3</sup>, C. A. Erickson<sup>3</sup>, C. Yu<sup>4</sup> and D. P. Kennedy<sup>1</sup>,  
(1)Psychological and Brain Sciences, Indiana University, Bloomington, IN, (2)Division of Developmental and Behavioral Pediatrics, Cincinnati Children's Hospital Medical Center, Cincinnati, OH, (3)Cincinnati Children's Hospital Medical Center, Cincinnati, OH, (4)Psychology, University of Texas at Austin, Austin, TX

---

Background: Sustained attention (SA) is the ability to maintain attention on a stimulus for an extended amount of time and has been linked to positive language and cognitive development for both typically developing (TD) children and children with autism spectrum disorder (ASD) (Bakeman & Adamson, 1984; Johansson et al., 2015; Yu et al., 2019). The use of head-mounted eye-trackers has broadened our understanding of the mechanisms underlying SA in both children with and without ASD. First, *parent social attention and action* relates to extended SA (Suarez-Rivera et al., 2019; Yu & Smith, 2016; Yurkovic et al., 2020). Second, *child manual action* frequently results in hand-eye coordination which constrains and supports the child's attention (Bambach et al., 2017; Yu & Smith, 2017a, 2017b; Yurkovic et al., 2020).

Objectives: It remains an open question how these mechanisms may be utilized to enter SA. We aim to determine if pathways into SA impact the duration of SA moments and if different pathways are more likely to achieve SA.

Methods: Thirteen TD dyads and 17 ASD dyads contributed data. Parents and children engaged in toy play while wearing head-mounted eye-trackers (Figure 1a). We operationalized SA as a child look to an object lasting  $\geq 3$  seconds. We computed the proportion of the 5 seconds preceding SA where each of the following behaviors were directed towards the target of SA: child look, child touch, parent look, parent touch, and parent naming (Figure 1b).

Results: An unsupervised clustering approach (*k*-means) was used to characterize four specific pathways into SA (Figure 1c,d). The four pathways can be characterized as spontaneous (1a), parent-led (1b), joint hand-eye coordination (2a), and child touch led (2b). The groups utilized the pathways at a similar rate ( $\chi^2(1, N=412)=1.40, p=0.70$ ). A linear mixed effects model on duration revealed no main effect of pathway ( $F(3,404)=0.21, p=0.89$ ) and a trending group by pathway interaction effect ( $F(3,404)=2.46, p=0.06$ ) on SA duration. We next analyzed the success of each pathway by assigning all of the short looks ( $<3$ s) to one of the pathways based on the 5 seconds preceding the look (Figure 2b). Pathway 1a (“spontaneous”) is the most utilized and least successful pathway for achieving SA ( $\chi^2(1, N=4227)=115.92, p<0.001$ ). This result is maintained when SA from TD and ASD children are analyzed separately. Additionally, Pathway 2a (“joint hand-eye coordination-led”) is more successful than Pathway 1b (“parent-led”) overall and for the TD group, but not for the ASD group. Surprisingly, children with ASD are more effective at utilizing Pathway 1b (“parent-led”) than their TD peers.

Conclusions: TD children and children with ASD utilize similar pathways at a similar rate to enter into SA moments. Notably, for both groups, the pathway into SA does not impact the “quality”, or duration, of SA. However, pathways differ in “quantity”, or their likelihood of achieving SA. This understanding of the mechanisms that parents and children can use to support the child's attention during play may provide key insights into the co-development of social and attentional processes in both typical and atypical populations.

**415.031** (Poster) Parental Needs of Children in Early Intervention for Autism Spectrum Disorder in Brazil  
**M. L. Nogueira<sup>1</sup>**, N. W. da Silva<sup>2</sup>, M. L. Carvalho<sup>1</sup> and A. Hatem Pereira<sup>3</sup>, (1)Universidade Federal de Minas Gerais, Belo Horizonte, Brazil, (2)private, Mariana, Brazil, (3)FHEMIG, Belo Horizonte, Brazil

---

Background: Many recent and scientifically relevant approaches understand that children with Autism Spectrum Disorder (ASD) require early, specialized and intensive intervention. Early intervention programs point to positive outcomes regarding the

children's self-independence and their families' well-being, considering their individual potential. Scientific literature also show that even low-intensity interventions with parents and caregivers, focused on interaction and play strategies with their young children with ASD, able to result in immediate effects on the child's social behaviors and communication. Those studies rely on well-designed clinical trials with randomized control groups. However, how those programs affect the family is yet to be measured.

**Objectives:** The present study sought to understand the needs of the parents of children with ASD undergoing early intervention in the Brazilian context.

**Methods:** An online assessment for parents and caregivers of children, ranging from 0 to 60 months, old, with confirmed or suspected ASD diagnosis, was applied. This assessment was released and shared on social media, mainly Instagram and whatsapp, and had 150 answers spread across 23 of 27 of Brazilian states, and 3 answers from Brazilian families living in Portugal and Germany.

**Results:** The results showed significant lack of proper service, support, and quality scientifically knowledge regarding autism and intervention programs. We identified that the main barriers were therapy costs (57,3%); low service availability (44%). 64,7% of the participants reported financial issues and 63,3% had to reduce their work hours. Internet is the main source of information for the families (76,7%), while health professionals are sought by only 10%. Most participants evaluate their own knowledge on developmental domains as average.

98% of answers were given by mothers, which highlights issues shown in literature, where mothers are protagonists of care, generating great stress. Children undergoing early intervention averaged between 2 and 3 years old, starting intervention between 12 and 24 months, a great improvement when compared to a 2017 study, that indicated access to intervention at 6 years old. This was possible because healthcare institutions, the Unified Health System (SUS) and political fields have worked towards sharing the importance of early screening, diagnosis, and treatment for ASD.

Finally, in the open question "what is early intervention in your opinion and understanding?", most participants demonstrated some understanding of neuroplasticity; many responses indicated expectation of cure and spectrum correction, which shows that neurodiversity paradigm is still an issue in Brazil.

**Conclusions:** Access to early intervention is still limited in Brazil, and information and support is even more restricted, even for those who have access to intervention; they still face lack of proper service and programs. 84% of the sample had a higher education level, indicating a socioeconomic bias. Thus, we still need to confirm the findings through another type of public access (such as the application of the same questionnaire in public health; primary, for example). The situation is even more critical specially on north and northeast states or in cities that are not capital ones. Further research is required.

**415.032 (Poster)** Parents of Children with and without Autism Coordinate Object Labeling with Child Behaviors during Dyadic Play

**J. R. Yurkovic<sup>1</sup>, G. Lisandrelli<sup>1</sup>, R. Shaffer<sup>2</sup>, K. Dominick<sup>3</sup>, E. Pedapati<sup>3</sup>, C. A. Erickson<sup>3</sup>, C. Yu<sup>4</sup> and D. P. Kennedy<sup>1</sup>,**  
(1)Psychological and Brain Sciences, Indiana University, Bloomington, IN, (2)Division of Developmental and Behavioral Pediatrics, Cincinnati Children's Hospital Medical Center, Cincinnati, OH, (3)Cincinnati Children's Hospital Medical Center, Cincinnati, OH, (4)Cognitive Science Program, Indiana University, Bloomington, IN

---

**Background:** Parents of typically developing (TD) children scaffold their child's language learning environment by coordinating object labeling utterances with their child's behavior (Suanda et al., 2016). Specifically, children learn words in contexts where their visual attention to toys is coordinated with their manual actions (hand-eye coordination), thereby reducing visual clutter and providing a clear target for the label (Yu & Smith, 2012). The ability to integrate visual and motor information during play is also positively related to language abilities in children with ASD (Hellendoorn et al., 2015), a disorder characterized by social deficits and language delays.

**Objectives:** It remains an open question if children with ASD are exposed to a similar rate of object labeling compared to TD children, and if labeling occurs during informative hand-eye coordination moments.

**Methods:** Data were collected from 24-48mo children and their parents (ASD: n=17, TD: n=14). Of note, the ASD group was significantly delayed in both expressive and receptive language (Mullen Scales of Early Learning Developmental Quotient: 39.9 (SD=±17.9)); 45.0 (17.2), respectively). Dyads played together with 24 toys while wearing head-mounted eye-trackers. Child gaze was calibrated offline, and targets of gaze and manual action were then coded. Parent speech during play was divided into utterances, defined as speech moments separated by at least 400ms of silence. These utterances were fully transcribed to find moments where parents labeled the toys. Parent perception of child vocabulary size was also recorded using the MacArthur-Bates Communicative Development Inventories (MCDI).

Results: There was no difference between groups in the number of parent labels per minute (ASD: 5.43 (0.68); TD: 4.51 (0.67);  $t(29)=0.95$ ,  $p=0.35$ ). The rate of parent labeling was correlated with MCDI in children with ASD but not TD children (ASD:  $r(16)=0.68$ ,  $p=0.01$ ; TD:  $r(13)=-0.22$ ,  $p=0.46$ ). Further, parents of children with ASD used almost three fewer words per labeling utterance than parents of TD children (ASD: 4.85 (0.33); TD: 7.45 (0.53);  $t(29)=-4.37$ ,  $p<0.01$ ). Parents in both groups labeled toys most frequently during child hand-eye coordination. Interestingly, parents labeled toys during both hand-eye coordination moments that are informative (child looking at and touching the labeled toy) (ASD: 31%; TD: 24%) and misleading (child looking at and touching another toy) (ASD: 30%; TD: 22%). There were no differences between groups (informative:  $t(28)=1.29$ ,  $p=0.21$ ; misleading:  $t(28)=0.35$ ,  $p=0.14$ ).

Conclusions: Parents in both groups utilized informative child hand-eye coordination moments, suggesting that children with ASD are exposed to similar rates of learning moments as their TD peers. Parents in both groups also frequently labeled toys during misleading moments, possibly resulting from parents redirecting their child's attention or scaffolding combinatorial play (playing with multiple toys together). Despite similarities in the rate and context of labeling, parents of children with ASD used fewer words per labeling utterance than parents of TD children. This is likely an adaptive behavior to reduce the complexity of speech and support child engagement. Child language abilities have been shown to improve following interventions that coach adults to use fewer utterances and words during play with the child (Kasari et al., 2008).

**415.033 (Poster)** Quantifying Social Visual Engagement in Preterm Toddlers with and without Autism Spectrum Disorder  
*H. Tokish, E. McQueen, A. Rudrabhatla, C. Klaiman, H. Walum, W. Jones, A. Klin and L. A. Edwards, Marcus Autism Center, Children's Healthcare of Atlanta and Emory University School of Medicine, Atlanta, GA*

---

Background: Compared to full-term infants, preterm infants born before 36 weeks gestational age are at a higher risk of atypical neurodevelopmental outcomes such as autism spectrum disorder (ASD) (Joseph et al., 2017; Limperopoulos et al., 2008). While the community prevalence of ASD is 1 in 54 (1.85%), the ASD prevalence in preterm children is approximately 7% (Agrawal et al., 2018; Maenner et al., 2020). Although preterm infants face a disproportionately high risk of ASD, their unique medical needs and developmental delays can create barriers to the early identification of ASD.

Measures of social visual engagement (SVE)—collected via eye-tracking technology—quantify how children visually explore, engage with, and learn from their surrounding world at different stages of development. Past research suggests that SVE is disrupted in ASD, which may lead to a cascade of developmental effects associated with the core symptoms of the disorder (Jones & Klin, 2013; Klin et al., 2009). Patterns of SVE may also shed light on typical and atypical neurodevelopment in preterm populations, with implications for effective early detection and intervention. However, SVE has not been extensively studied in preterm populations.

Objectives: This study quantifies patterns of SVE to social stimuli close to the earliest point of diagnosis in preterm toddlers with diagnoses of ASD and non-ASD developmental disorders (DD), as well as preterm toddlers who are not showing developmental delays (TD).

Methods: Participants ( $n=47$ ) were toddlers with a gestational age below 36 weeks and diagnoses of ASD ( $n=19$ ), DD ( $n=9$ ), or TD ( $n=19$ ). Eye-tracking data were collected between ages 12 and 28 months ( $M_{age}=22.24$ ) during viewing of naturalistic videos of social interactions. Data were quantified as the percentage of time participants spent fixated on regions of interest (ROIs) within the stimuli (Eyes, Mouth, Body, and Object regions). Toddlers were later diagnosed by expert clinicians upon review of gold-standard assessments.

Results: Significant ROI by diagnosis interactions were found (Eyes, Mouth, Body:  $F(4, 88)=3.248$ ,  $p=0.016$ ; Eyes, Mouth, Object:  $F(4, 88)=4.227$ ,  $p=0.004$ ). Post hoc comparisons revealed that preterm ASD and TD toddlers allocated significantly different proportions of visual attention to all ROIs: Eyes ( $t(36)=-2.787$ ,  $p=0.008$ ), Mouth ( $t(36)=-3.318$ ,  $p=0.002$ ), Body ( $t(36)=2.336$ ,  $p=0.025$ ), and Object ( $t(26.01)=2.528$ ,  $p=0.018$ ). Preterm ASD toddlers also differed significantly from DD toddlers in visual attention to Eyes ( $t(26)=-2.839$ ,  $p=0.009$ ), Mouth ( $t(26)=-2.209$ ,  $p=0.036$ ), and Object ( $t(26)=2.476$ ,  $p=0.020$ ) regions. TD and DD toddlers did not differ significantly in allocation of visual attention to any ROI. Overall, preterm toddlers with ASD looked significantly less at eyes and mouths and more at bodies and objects than TD and DD preterm toddlers.

Conclusions: Preliminary results suggest that SVE patterns may distinguish ASD from TD and DD in preterm toddlers, who are at heightened risk for neurodevelopmental disorders. These findings are similar to previous research with full-term ASD toddlers, indicating the ability to diagnostically differentiate ASD in preterm toddlers despite their increased diagnostic complexities. Future analyses will explore whether SVE may elucidate mechanisms of development and disability across severity within the preterm population (e.g. between extremely preterm versus moderately preterm subgroups).

**415.034 (Poster)** Screen Time in 18 and 24-Month-Olds at Increased Risk for ASD and ADHD

*M. M. Hill<sup>1</sup>, A. M. Iosif<sup>2</sup> and M. Miller<sup>1</sup>, (1)Psychiatry and Behavioral Sciences, University of California, Davis, MIND Institute, Sacramento, CA, (2)Public Health Sciences, University of California Davis, Davis, CA*

---

**Background:** Screen time has been associated with various aspects of child development. This may be particularly relevant to children at increased risk for atypical development such as those with a family history of Autism Spectrum Disorder (ASD) or Attention-Deficit/Hyperactivity Disorder (ADHD). Prior research documents negative associations between greater screen time and increased ASD symptoms in community samples (Heffler et al., 2020), as well as ADHD symptoms and lower receptive and expressive language among 36-month-olds with a family history of ASD or ADHD (Hill, et al., 2020).

**Objectives:** To examine associations between screen time, ASD symptoms, ADHD symptoms, and language development between 18 and 24 months of age in a sample including children at increased familial risk for ASD or ADHD.

**Methods:** Participants included 116 children with a family history of ASD ( $n = 49$ ), ADHD ( $n = 34$ ) or no family history of either disorder ( $n = 33$ ). Standardized evaluations at 18 and 24 months of age included the Mullen Scales of Early Learning (MSEL) Receptive (RL) and Expressive Language (EL) subscales, the Autism Diagnostic Observation Schedule, Second Edition (ADOS-2), and the Behavioral Rating Inventory for Children (BRIC), which is a measure of observed ADHD-relevant behaviors (inattention, hyperactivity, impulsivity). Parents reported average daily hours of television and/or video viewed by the child at both 18 and 24 months.

**Results:** Multivariable regression analysis showed a significant effect of outcome group on screen time at both 18 months,  $F(2, 114) = 6.11, p = .003$  and 24 months,  $F(2, 86) = 3.38, p = .04$  (adjusting for maternal education and child sex). The ASD-risk group engaged in significantly more screen time than the low-risk group (estimated difference, 0.65 at 18 months, 0.66 at 24 months [i.e., 39-40 min],  $p = .004$  and  $.01$ , respectively). Multivariable regression analysis adjusting for maternal education and child sex revealed that higher screen time at 18 months was associated with higher ASD symptom severity scores at 24 months ( $p < .001$ ); the association with 24-month BRIC scores was non-significant but trend-level ( $p = .08$ ). After adjusting for maternal education, child sex, and baseline/18-month BRIC and ADOS-2 comparison scores, higher screen time at 18 months was also associated with lower RL scores at 24 months ( $p = .03$ ); the association between 18-month screen time and 24-month EL was non-significant.

**Conclusions:** Children with a family history of ASD engaged in more screen time at both 18 and 24 months of age than those in the low-risk group. Greater screen time at 18 months also predicted higher ASD symptom severity and lower receptive language scores at 24 months across all groups; there was a trend-level relationship between 18-month screen time and 24-month ADHD-relevant behaviors. This suggests an association between screen time, greater accumulation of ASD symptoms, and decreased receptive language acquisition over time even when accounting for the influence of baseline ASD symptoms. There was no association between screen time and expressive language skills. Future longitudinal studies incorporating 36-month categorical outcomes are needed to further explore these findings.

**415.035 (Poster)** Sex Differences in the Adaptive Value of Social Visual Engagement in Preterm Toddlers with Autism Spectrum Disorder

*A. Rudrabhatla, E. McQueen, H. Tokish, C. Klaiman, H. Walum, W. Jones, A. Klin and L. A. Edwards, Marcus Autism Center, Children's Healthcare of Atlanta and Emory University School of Medicine, Atlanta, GA*

---

**Background:**

Males are four times more likely than females to be diagnosed with autism spectrum disorder (ASD). Although much remains unknown, past research points to sex-based phenotypic differences in the expression of ASD. For example, in full-term toddlers at high risk for ASD, females have been shown to exhibit stronger expressive and receptive language functioning than males (Messinger et al., 2015). In studies using measures of social visual engagement (SVE), collected via eye-tracking, full-term females at high risk for ASD showed increased attention to faces relative to males, which was associated with improved socio-communicative functioning (Chawarska et al., 2016).

Compared to full-term infants, preterm infants, born before 36 weeks gestational age, are at higher risk for atypical neurodevelopmental outcomes such as ASD (Joseph et al., 2017; Limperopoulos et al., 2008). However, degree of prematurity is a more salient risk factor for ASD in preterm females than preterm males (Allen et al., 2020). Past work suggests that in general, male preterm infants are at higher risk for less favorable outcomes than females (Yaari et al., 2018), who demonstrate more developmentally-appropriate language and cognitive functioning than males (Skiöld, 2014). Sex-based phenotypic differences have not yet been studied in preterm infants and toddlers with ASD.

#### Objectives:

This study explores sex differences in the cognitive development, language development, social functioning, and SVE of a cross-sectional cohort of preterm toddlers with ASD.

#### Methods:

Chronologically (CA) and gestationally (GA) age-matched male (N=21, M<sub>CA</sub>=27.42months, M<sub>GA</sub>=32.21weeks) and female (N=13, M<sub>CA</sub>=28.81months, M<sub>GA</sub>=32.19weeks) preterm toddlers with ASD were evaluated with the Mullen Scales of Early Learning (MSEL) or Bayley-III, and the Autism Diagnostic Observation Schedule (ADOS-2). Participants were also eye-tracked while passively viewing videos of toddlers engaged in naturalistic peer interactions. ASD diagnoses were confirmed by clinical best estimate procedures from expert clinicians blind to eye-tracking. MSEL or Bayley-III expressive and receptive language age equivalents were used as measures of language functioning, and MSEL visual reception or Bayley-III cognitive age equivalents were used as measures of cognition. ADOS-2 Social Affect (SA) and Restricted and Repetitive Behavior (RRB) scores were examined separately as measures of social disability. Eye-tracking (SVE) data was quantified as the percentage of time toddlers spent visually fixating on regions-of-interest (ROIs) within videos (i.e. face, body, and object/background). We tested for sex differences in language, cognition, social disability, and SVE. Spearman correlations examined associations between SVE and developmental measures.

#### Results:

Male and female preterm toddlers with ASD did not significantly differ in receptive language, expressive language, cognition, indices of social disability, or face-, body- or object-looking (all  $p > .160$ ). However, face-looking positively predicted receptive language ( $r = .682, p = .021$ ), and negatively predicted SA ( $r = -.685, p = .020$ ) in preterm ASD females, but not males. Additionally, body-looking predicted higher SA scores ( $r = .667, p = .025$ ) and object-looking predicted higher RRB scores ( $r = .669, p = .024$ ) in preterm ASD females, but not males.

#### Conclusions:

Our exploratory analyses found no sex-based differences in receptive language, expressive language, cognition, indices of social disability, or SVE in preterm toddlers with ASD. However, our results suggest that SVE may have differential adaptive value for male and female preterm toddlers with ASD.

#### **415.036 (Poster) Social Visual Engagement Predicts Developmental Stability of Quantitative Autistic Traits**

**K. Lineback<sup>1</sup>, N. Marrus<sup>2</sup>, A. L. Glowinski<sup>3</sup>, A. Klin<sup>4</sup>, W. Jones<sup>4</sup> and J. N. Constantino<sup>2</sup>, (1)Washington University School of Medicine in St. Louis, St. Louis, MO, (2)Washington University School of Medicine, St. Louis, MO, (3)Washington University in St. Louis, St. Louis, MO, (4)Marcus Autism Center, Children's Healthcare of Atlanta and Emory University School of Medicine, Atlanta, GA**

#### Background:

Prospective studies have demonstrated that autism spectrum disorder (ASD), a highly heritable neurodevelopmental disorder, is often preceded by atypical development across multiple heritable domains. Characterizing how early variation in ASD endophenotypes relates to the emergence of core autistic traits is crucial for elucidating ASD's ontogeny and advancing early risk assessment. Here, we focused on developmental associations between two ASD endophenotypes, social visual engagement (SVE), preferential attention to social stimuli, and reciprocal social behavior (RSB), an indicator of quantitative autistic traits (QATs), both of which are robust recurrence predictors of ASD. We examined these associations in general population toddler twins, an approach which maximized detectable variation for resolving inter-relationships across the continuum of familial liability for ASD.

#### Objectives:

To assess relationships between RSB and SVE in toddlers, including testing whether interactions between RSB and SVE influence developmental stability of RSB, and by extension, QATs.

#### Methods:

An epidemiologic toddler twin sample (n=129; monozygotic=29 pairs; dizygotic=34 pairs; 3 unmatched twins) from the general population was longitudinally assessed from ages 18 to 48 months. At 18 months, RSB was quantified with the “Video-referenced Rating Scale of Reciprocal Social Behavior,” a downward extension of the Social Responsiveness Scale (SRS), a validated instrument indexing QATs as deficits in RSB. 18-month SVE was quantified as percent fixation for eye- and mouth-looking in an established eye-tracking paradigm featuring child-friendly videos of social interactions. At 36 or 48 months, RSB outcome was measured with the SRS. Generalized estimating equations (GEE) accounting for twin relatedness tested contributions of 18-month RSB, 18-month SVE, and their interaction to 36/48-month RSB outcome. Twin concordances were evaluated using intraclass correlation coefficients (ICCs).

#### Results:

18-month eye- and mouth-looking were inversely correlated ( $r=-0.86$ ,  $p<.01$ ), and 18-month-olds looked more at mouths than eyes (55% versus 24%). Separate GEE models for mouth- and eye-looking identified relationships between 1) 36/48-month RSB outcome and 18-month RSB and 2) the interaction between 18-month RSB and 18-month SVE (Table 1). 18-month RSB accounted for 34.3% variance in later RSB (i.e., QATs), while the interaction of 18-month RSB and SVE contributed an additional 4% variance for mouth-looking and 3% variance for eye-looking. Lower mouth-looking and higher eye-looking corresponded to a stronger association (i.e., greater developmental stability) of RSB across age (Figure 1). When comparing identical twin concordances for RSB outcome in groups divided by high versus low levels of fixation, higher concordances were observed for participants with low versus high mouth-looking [ $ICC_{\text{low mouth}}=0.99(0.97,0.99)$ ;  $ICC_{\text{high mouth}}=0.71(0.25,0.89)$ ] and high versus low eye-looking [ $ICC_{\text{high eyes}}=0.99(0.98,0.99)$ ;  $ICC_{\text{low eyes}}=0.76(0.41,0.89)$ ], a distinction not observed for 18-month RSB.

#### Conclusions:

18-month SVE moderated the stability of QATs during toddlerhood, when ASD arises. Higher identical twin concordances for 36/48-month RSB stratified by earlier levels of SVE suggests potential overlap between heritable factors underlying SVE and developmental consolidation of QATs. These findings imply a mechanism whereby interactions between distinct ASD endophenotypes may contribute to stabilization of QATs, consistent with ASD’s complex genetic architecture. Developmental surveillance tracking multiple endophenotypes may be key for improving early identification and interventions.

#### **415.037 (Poster)** The Sensory Assessment for Neurodevelopmental Disorders: Infant and Toddler Version

**P. M. Siper<sup>1</sup>, J. Bragg<sup>2</sup>, C. F. Layton<sup>3</sup>, M. Rowe<sup>1</sup>, J. Zweifach<sup>1</sup> and T. Tavassoli<sup>5</sup>,** (1)Seaver Autism Center for Research and Treatment, Department of Psychiatry, Icahn School of Medicine at Mount Sinai Hospital, New York, NY, (2)Neonatology, Mount Sinai Medical Center, New York, NY, (3)Seaver Autism Center, Department of Psychiatry, Icahn School of Medicine at Mount Sinai Hospital, New York, NY, (4)UCSF, San Francisco, CA, (5)Centre for Autism, School of Psychology & Clinical Language Sciences, University of Reading, Reading, United Kingdom

**Background:** The Sensory Assessment for Neurodevelopmental Disorders (SAND) is a newly developed measure that has been validated for use in children ages 2-10 years. Combining a clinician-administered observation and corresponding caregiver interview, the SAND demonstrates high internal consistency, inter-rater, test-retest reliability, and good convergent validity. Literature from studies of high risk infant siblings indicates that parent-reported sensory symptoms differentiate infants who go on to develop ASD as early as six months of age, often before core symptoms of autism emerge. To date, there are no clinician-administered assessments for infants and toddlers under 24 months of age. Early identification of sensory reactivity differences during infancy and toddlerhood may improve access to treatment.

**Objectives:** To develop and test the feasibility of the SAND: Infant and Toddler Version in a high-risk cohort of infants and toddlers under 24 months of age.

**Methods:** The SAND: Infant and Toddler Version was developed by adapting examples within the original SAND interview to be more appropriate for a younger population and to account for typical sensory behaviors during this early period of development. The observation and all scoring remains the same between versions. Twelve infants/toddlers ages 8-20 months ( $M=15$ ,  $SD=4.9$  months) presenting to Mount Sinai’s NICU follow up program participated in this study. Convergent validity was examined between the SAND: Infant and Toddler Version and the Infant/Toddler Sensory Profile (I/T SP). The SAND quantifies sensory symptoms in hyperreactivity, hyporeactivity, and seeking domains across visual, tactile, and auditory sensory modalities. Higher SAND scores indicate a greater number of sensory symptoms. The I/T SP is a caregiver questionnaire that measures sensory processing patterns in children birth to 36 months. Lower SP scores indicate a greater number of symptoms.

Results: All participants successfully completed the SAND observation and interview. SAND: Infant and Toddler Version total score was significantly correlated with the I/T SP total score ( $r=-.816, p=.002$ ). Observed scores ( $r=-.647, p=.031$ ) and reported scores ( $r=-.878, p<.001$ ) were also significantly correlated. In addition, I/T SP Low Registration scores were significantly correlated with overall hyporeactivity domain scores ( $r=-.808, p=.001$ ) and reported scores ( $r=-.826, p=.001$ ), but not observed scores. SAND hyperreactivity domain scores were significantly correlated with SP sensation avoiding scores ( $r=-.678, p=.022$ ).

Conclusions: Administration of the SAND: Infant and Toddler Version was successful in all participants. Correlations between the SAND and the I/T SP were driven by the caregiver interview, which is consistent with findings from validation studies of the original SAND and suggests that the clinical observation provides useful information about sensory reactivity that is not captured solely by caregiver report. Studies are ongoing to further examine the psychometric properties of the SAND: Infant and Toddler Version in both high- and low-risk samples. Ultimately, establishing methods for early detection of potentially modifiable sensory processing differences may improve longer-term outcomes.

**415.038 (Poster)** Validity of the Toddler Autism Symptom Inventory (TASI) in White and Black/African American Children  
**K. L. Coulter<sup>1</sup>, M. Moreno<sup>1</sup>, M. Barton<sup>1</sup>, D. L. Robins<sup>2</sup> and D. A. Fein<sup>1</sup>, (1)Psychological Sciences, University of Connecticut, Storrs, CT, (2)A.J. Drexel Autism Institute, Drexel University, Philadelphia, PA**

**Background:** Despite work showing no racial differences in age of first concern (Jang et al., 2014), racial disparities in detection of autism spectrum disorder (ASD) persist. Standardized screening reduces these disparities (Herlihy et al., 2014), but Black/African American children are still diagnosed 1.5 years later than White children (Constantino et al., 2020). Early detection of ASD facilitates early intervention, which optimizes long-term outcomes.

Parent and clinician factors, including bias and culture may play a role in these disparities (Donohue et al., 2019). Some differences in symptom expression have been reported; ethnic minority children diagnosed with ASD are more likely to demonstrate impaired expressive language and emotional lability than White children (Becerra et al., 2014).

Diagnostic evaluations of ASD integrate information from multiple sources, including direct observation and caregiver report. It is important to assess these measures for bias or differential validity for different racial or ethnic groups, so that children in specific groups are not excluded from access to diagnosis and treatment.

**Objectives:** Determine whether any differences exist in caregiver responses of Black/African American and White families to a novel semi-structured interview for children age 12-36 months.

**Methods:** Children ( $n=294$ ) 12 to 36 months old were referred for evaluation after a positive screen or pediatrician concern. Evaluations included observational measures of autism symptoms (ADOS-2) and developmental testing (Mullen Scales of Early Learning Composite, ELC). Caregivers were administered the Toddler Autism Symptom Inventory (TASI; [mchatscreen.com/tasi](http://mchatscreen.com/tasi)), a 40 item semi-structured interview designed to elicit caregiver report of toddler autism symptoms. Children were assigned diagnoses of ASD, another developmental delay (DD), or typical development/no diagnosis (TD/ND). Caregivers reported their child's race; 52% of the sample was White ( $n=153$ ), while 23% was Black/African American ( $n=69$ ); the remainder reported other racial identities.

**Results:** Significant differences were found in mean developmental level, diagnoses, SES, and TASI score (Table 1). More Black children were diagnosed with DD, while more White children were diagnosed TD/ND; percent of ASD diagnoses was not different between groups. Black/African American children scored lower than White children on ELC, although a regression indicated that this was explained by annual income. Similarly, regression analyses demonstrated that although race predicted TASI score ( $R^2=.029, p=.011$ ), race was no longer a significant predictor ( $B=-.346, p=.728$ ) after inclusion of ELC and SES in the model ( $p's<.002$ ; overall model  $R^2=.169$ ).

Validity of the TASI cutoff score is comparable in both racial groups (Table 2). Sensitivity and specificity are greater than .9 and .7, respectively, for both groups. Area under the curve in ROC analyses was approximately .9 for both groups. Examination of item-level responses between racial groups revealed *no differences* (Bonferroni adjusted  $\alpha=.00125$ ) in percent endorsement of any TASI question (Table 2).

**Conclusions:** Caregiver responses to a novel semi-structured interview reveal that the TASI cutoff for ASD risk is valid for both Black and White children. Results suggest no significant differences between the two groups in ASD symptom expression in toddlers aged 12-36 months.

**415.039 (Poster)** White Matter Microstructure and Language Abilities in Infants at High Familial Risk for Autism Spectrum Disorder

**Background:** Autism spectrum disorder (ASD) is a highly heritable (~80%) neurodevelopmental disorder. Approximately 20% of infants who have an older sibling diagnosed with ASD develop ASD themselves (Ozonoff et al., 2011). An additional 28% of infants who do not have ASD diagnoses display other developmental concerns including language delays (Ozonoff et al., 2014). To date, studies have demonstrated atypical patterns of white matter development in various fiber tracts spanning the brain in infants who later develop ASD (Wolff et al., 2012). While white matter microstructure has been shown to relate to language development in the first two years of life in typical development (Girault et al., 2019), these associations are unexplored in ASD.

**Objectives:** In this study, we examined white matter circuitry in relation to language development in high-risk infant siblings and controls at 24 months.

**Methods:** Data come from the Infant Brain Imaging Study. A total of 76 controls (low familial risk for ASD and negative for a diagnosis; LR-Neg) and 225 familial high-risk (HR) siblings with diffusion weighted images (DWIs) and language assessments at 24 months were included. 47 HR siblings received a clinical best estimate ASD diagnosis at 24 months (HR-ASD) and 178 HR infants were negative for ASD (HR-Neg). Measures of language include Receptive Language (RL) and Expressive Language (EL) from the Mullen Scales of Early Learning (MSEL). Nonverbal Developmental Quotient (NVDQ) calculated from the fine motor and visual reception domains on the MSEL was also included to test for specificity of findings to language. Fiber tractography was performed and tract-average fractional anisotropy (FA) values were generated for analyses. Tracts of interest included the bilateral arcuate, uncinate, and inferior longitudinal fasciculus (ILF) as well as the genu, splenium, and body of the corpus callosum. To determine whether white matter FA in tracts of interest at 24 months is related to language abilities at the same age and test whether this association differs by group we implemented multiple linear regression for each fiber tract adjusting for age, sex, and study site.

**Results:** Linear models revealed significant positive associations between FA in the left arcuate tract and RL ( $b=0.73$ ,  $t=4.93$   $p<0.0001$ ) and EL ( $b=0.52$ ,  $t=3.08$   $p=0.0023$ ) in the HR-ASD group that differed compared to the control group (**Figure 1A-B**). FA in the right arcuate tract was also significantly associated with RL ( $b=0.51$ ,  $t=3.62$   $p=0.00035$ ) and EL ( $b=0.35$ ,  $t=2.17$   $p=0.03$ ) in the HR-ASD group (**Figure 1C-D**). Associations between language scores and bilateral arcuate FA did not differ between the HR-Neg and LR-Neg groups. The association between FA in left arcuate tract and NVDQ in the HR-ASD group ( $b=0.38$ ,  $p=0.02$ ) was relatively weaker than that observed with RL or EL. No associations were observed between FA in the right arcuate tract and NVDQ in the HR-ASD group ( $b=0.24$ ,  $p=0.11$ ). No associations were found between FA in the other tracts analyzed and language or non-verbal abilities.

**Conclusions:** Findings highlight the key role of left and right arcuate white matter microstructure in language development in high familial risk infants who develop ASD.

**415.040 (Poster)** Associations between Socioeconomic Variables and Local Cortical Gyrification in Language Regions in Preschoolers with Autism Spectrum Disorder

**L. Olson<sup>1,2</sup>**, B. Chen<sup>1,2</sup>, I. A. Martindale<sup>2</sup>, M. C. Arcadio Arce<sup>2</sup>, J. S. Kohli<sup>1,2</sup>, A. C. Linke<sup>2</sup>, C. Ibarra<sup>2</sup>, S. R. Peña<sup>2</sup>, E. Mendez<sup>2</sup>, R. A. Müller<sup>1,2</sup>, R. A. Carper<sup>1,2</sup> and I. Fishman<sup>1,2,3</sup>, (1)Joint Doctoral Program in Clinical Psychology, SDSU/UC San Diego, San Diego, CA, (2)Brain Development Imaging Laboratories, San Diego State University, San Diego, CA, (3)SDSU Center for Autism and Developmental Disorders, San Diego State University, San Diego, CA

**Background:** Although language delay is no longer a diagnostic criterion for autism spectrum disorder (ASD), many individuals with ASD show delayed language development, which is often the first sign suggesting the possible presence of ASD. Socioeconomic status (SES) is associated with language and brain development in early childhood in typical development (e.g.,

Johnson et al., 2016). Our previous work has shown that SES variables positively correlate with language skills in young children with autism, over and above the effect of diagnosis on language skills (Olson et al., 2020). Less is known regarding associations between SES and indices of cortical maturation in brain regions supporting language in ASD. One such feature of brain maturation that has shown associations with SES in typically developing children is local gyrification (Jednorog et al., 2012), representing the folding of the cerebral cortex, which mainly occurs during prenatal and early postnatal life.

**Objectives:** To examine associations between socioeconomic variables and local gyrification in language-related brain regions in preschoolers with ASD.

**Methods:** T1-weighted anatomical MRI was acquired in 37 toddlers with ASD (mean age: 39.0±13mo., range: 17-66 months; 27 males) during natural sleep. Clinical best estimates of ASD diagnoses were established according to DSM-5 criteria, supported by the ADOS-2 and the Autism Diagnostic Interview, Revised. FreeSurfer v.5.3.0 was used for cortical surface reconstruction and to calculate local gyrification index (LGI) in language-related regions of interest in each hemisphere using the Desikan-Killiany atlas (8 ROIs total: bilateral superior temporal gyrus, transverse temporal gyrus/primary auditory cortex, inferior frontal gyrus: pars opercularis, and inferior frontal gyrus: pars triangularis). Data quality was inspected by two independent raters. SES variables included Maternal Educational Level, Income-to-Needs Ratio, Median Income in the postal code area, and Neighborhood Adversity Index (PCA-derived index of neighborhood SES variables from 2019 census data). Multiple linear regression models were used to examine associations between SES variables and LGI in language regions. Total brain volume, age, and sex were used as nuisance regressors, and retained in models when significantly associated with LGI outcome measures.

**Results:** Both Income-to-Needs Ratio and Neighborhood Advantage Index were positively associated with LGI in the left superior temporal gyrus (STG;  $r_s > 0.35$ ,  $p_s < 0.05$ ; see Figure 1a,b). Median Income (derived based on postal code) was positively associated with left hemisphere transverse temporal gyrus LGI ( $r = 0.36$ ,  $p = 0.04$ ; see Figure 1c).

**Conclusions:** Findings suggest that, in young children with ASD, local gyrification in auditory/language regions (transverse temporal gyrus, superior temporal gyrus) is higher with increased access to social and economic resources (i.e., increased family income, neighborhood advantage). These associations indicate that factors associated with low SES in autism may impact patterns of cortical maturation in areas that subservise language function very early in development. These findings highlight the need for targeted early intervention and effective implementation strategies for children with ASD from low-resource households and communities, and for policies designed to improve access to resources for these young children and their families.

**416.001** (Poster) Low Dose Amitriptyline for Repetitive Behaviors and OCD in Autism Spectrum Disorder: Three Illustrative Cases.

*J. A. Hellings<sup>1</sup> and Z. Abbass<sup>2</sup>, (1)Psychiatry, University of Missouri Kansas City and Truman Behavioral Health, Kansas City, MO, (2)Psychiatry, University of Missouri- Kansas City, Kansas City, MO*

Background: Autism spectrum disorder (ASD) prevalence has increased markedly over recent decades, but treatment studies are seriously lacking. Although selective serotonin reuptake inhibitors (SSRIs) are the most commonly prescribed medications in ASD, evidence is largely lacking for their use while side effects are common. Two studies of fluoxetine were negative in youth with ASD, along with a negative multisite randomized controlled trial of citalopram for repetitive behaviors. Amitriptyline is a tricyclic antidepressant (TCA) with established action, unlike any other TCA or SSRI of increasing phosphorylation of TrkB, the receptor for BDNF by which it regulates multiple neurotrophic actions in the brain, including in the hippocampus. Empirical observations suggest amitriptyline superiority clinically, although it is not universally tolerated and should still be used with caution. Amitriptyline has less overdose risk of in ASD since most such individuals don't self-administer medications.

Objectives: To review and discuss three illustrative cases of treatment-resistant patients with ASD, severe repetitive behaviors and OCD, as well as ADHD and various levels of intellectual disability, all of whom were prescribed amitriptyline. Amitriptyline treatment outcomes will be described in each, in terms of dosing, concomitant medications, symptom outcomes and improvements in function. Previous medications tried will also be discussed.

Methods: We reviewed in detail the charts of the three cases (2 females and 1 male), and extracted demographic data including age, gender, disabilities, challenging behaviors, diagnoses, amitriptyline dosing and any side effects, including any dose reductions made.

Results: Cases included a 15-year-old WF and a 16-year-old WF both of whom were legally blind. Both had severe ASD and repetitive behaviors as well as behavioral rigidity, while the 15-year-old had more severe intellectual disability. The third was a 27-year-old WM with severe ASD and Mild ID, OCD, and ADHD. All manifested significant self-injury on presentation. All had failed trials of SSRIs, stimulants and alpha agonists, along with side effects. Each case will be discussed in detail. All responded to low dose amitriptyline (Case 1: 25mg daily at bedtime plus risperidone 1mg, Case 2: 25mg bid plus buspirone 10mg bid, and Case 3: monotherapy with 25mg bid plus 50mg at bedtime), and all were Much Improved on the Clinical Global Impressions scale. The 15-year-old who had more severe intellectual disability required amitriptyline reduction from 25 mg bid to 25 mg daily, due to behavioral activation following an initial improvement, however her response was then recaptured. All cases also showed improved cognitive abilities and communication in addition to repetitive behavior improvements.

Conclusions: Low dose amitriptyline significantly improved repetitive behaviors and functioning as well as communication in the 3 individuals with ASD described. The female with more severe intellectual disability and ASD became activated after her initial response to 25mg twice a day, but response was recaptured with dose reduction to 25 mg daily at bedtime. Based on its mechanism of action, and empirical observations that amitriptyline may improve repetitive behaviors and other core ASD symptoms as well as cognition, further studies are warranted.

## Education

### ORAL SESSION — EDUCATION

#### Oral 323 - Factors in Effective Education

##### **323.001** (Oral) Supporting Paraprofessionals Use of Ebps with Autistic Elementary School Children

**S. L. Odom<sup>1</sup>, A. Sam<sup>2</sup> and J. R. Steinbrenner<sup>3</sup>,** (1)Frank Porter Graham Child Development Institute, University of North Carolina at Chapel Hill, San Diego, CA, (2)Frank Porter Graham Child Development Institute, Carrboro, NC, (3)Frank Porter Graham Child Development Institute, University of North Carolina at Chapel Hill, Chapel Hill, NC

**Background:** In U.S. schools, evidence-based instructional practices are increasingly delivered by paraprofessionals to autistic children. However, in most states paraprofessionals are not required to have training related to autism or in the implementation of EBPs (Russel et al., 2015). AFIRM for PARAs (AFP) is a professional development program design to train paraprofessionals to use EBPs with elementary aged autistic students. It consists of online training about EBPs and coaching by the supervising teacher. The EBPs were reinforcement (R+), prompting (P), time delay for prompts (TD), visual cues (VC), and peer interaction (PI).

**Objectives:** The objectives of this study are to: 1) Determine the efficacy of the STELAR program for promoting paraprofessional use of EBPs with fidelity and 2) To explore the immediate effects of the increased efficacy on students accomplishment of short-term learning goals.

**Methods:** This study employed a single case, multiple probe design implemented in four special education classrooms and then replicated in a second set of four inclusive classrooms. In each classroom, one paraprofessional and one teacher participated in implementation of EBPs with autistic children in their class. The dependent variable was the percentage of correct features of the EBP implemented, as measured by an observational assessment of fidelity. During the initial baseline, R+ fidelity (of practice used with one child) was assessed. In the second phase, AFP for R+ was implemented while baseline for P was assess for a different learning task. The pattern of baseline and intervention data collection continued in subsequent phases. To explore effects on children, a mini-Goal Attainment Scale (GAS) was calculated to measure children's program toward their learning goal over a short period of time (0-4 rating, with 0 being baseline and 4 being accomplishing expected goal performance).

**Results:** The COVID 19 pandemic interrupted this planned study when schools closed in March, 2020 (Peer-EBP training never implemented). However, enough of the study was completed to establish experimental control (at least three replications) for R+, P, and TD in the special education classes and R+ and P in the inclusive classes.(Reviewer note: could only upload one figure-other comparable). For the inclusive classes, the first class did end its participation early because of staff issues. A statistical analysis that embedded a Bayesian approach within a multi-level model for EBPs (Swaminathan et al., 2012) was conducted for those EBPs for which we had experimental control. This analysis generated an effect size (ES) conceptually comparable to Cohen's *d*. The ESs for the special education and inclusive classes respectively were 6.89 and 5.79 for R+, 4.93 and 3.70 for P, and 4.74 for TD—all indicating extraordinarily strong effects. For students, the mean GAS rating, averaged across EBP sessions, was 3.23 (out of 4), indicating substantial progress.

**Conclusions:** The pattern of findings indicated strongly that AFP generated increases in the fidelity with which paraprofessional used EBPs with elementary-aged autistic children. Also, the GAS ratings suggested that children made progress on their learn goals during instructional sessions. Together this provides positive evidence supporting AFP as an efficacious professional development program

##### **323.002** (Oral) General Education Teachers Use of Evidence-Based Practices: The Role of Training, Knowledge and Barriers to EBP Use.

**L. Barry<sup>1</sup>, J. Holloway<sup>2</sup>, S. Gallagher<sup>3</sup> and J. McMAHON<sup>1</sup>,** (1)University of Limerick, Limerick, Ireland, (2)Psychology, National University of Ireland Galway, Galway, Ireland, (3)Department of Psychology, University of Limerick, Limerick, Ireland

**Background:**

While evidence-based practices (EBPs) are widely recommended for use with children with autism in educational settings, teachers continue to implement practices with little scientific support and experience a number of barriers in adopting EBPs. As children with autism are more frequently being educated in general education settings, exploring General Education (GE)

teachers use of EBPs and barriers they may experience is important in ensuring high-quality inclusive education for students with autism. To date, few studies have examined GE teachers use of EBPs and factors that may impact them, with the majority of research in this area being conducted in special education or clinical settings.

**Objectives:**

This study aims to examine factors that impact on GE teachers use of EBPs.

**Methods:**

112 GE teachers in the Republic of Ireland completed an online survey. The survey measured teachers training, their knowledge and use of EBPs (*Early Intervention Practices Scale; Paynter & Keen, 2014*), their attitudes towards EBPs (*Evidence Based Practice Attitudes Scale; Aarons, 2005*) and the barriers teachers experienced when implementing EBPs (*Barriers to Behavioural Interventions Scale; McGoey et al., 2014*).

The associations between EBP use and training, knowledge, attitudes and barriers were examined using correlations. Further analysis was conducted using hierarchical multiple regressions.

**Results:**

The data revealed that over a third of teachers received no autism and EBP training prior to teaching a student with autism. Results suggested that teachers used EBPs infrequently, and their knowledge of EBPs was low. Teachers had largely positive attitudes towards EBPs. Teachers experienced a number of serious barriers to implementing interventions including class size, lack of training and lack of time.

Training, teachers satisfaction with training, knowledge of EBPs, openness to EBP use and appeal of EBPs were all associated with EBP use. No barriers were associated with EBP use. A hierarchical multiple regression examining the association between barriers and EBP use while controlling for training, knowledge and attitudes revealed that no barriers were predictive of EBP use, however, knowledge and openness to EBPs were strong predictors of EBP use.

**Conclusions:**

Teachers scored many barriers as serious, however, none of these were associated with EBP use. Despite much research dedicated to examining barriers to EBP use, this data demonstrated that knowledge of EBPs and openness to EBPs may be key factors impacting the use of EBPs in GE settings. This may be particularly so in this context, as Irish teachers generally had low levels of knowledge and use of EBPs. More hours of training was associated with higher levels of knowledge and use of EBPs, indicating the need for intensive training to upskill GE teachers. As GE teachers are more frequently tasked with the education of children with autism in Ireland, this research highlights the need for high-quality training to improve teacher knowledge of EBPs.

**323.003** (Oral) Moving Beyond Individual Factors: Environmental Support and Barriers to the Social Participation of Autistic Adolescents in Inclusive Education

*Y. L. Chen and K. P. Koenig, Occupational Therapy, New York University, New York, NY*

---

**Background:**

Autistic adolescents experience challenges in social participation in inclusive education, yet positive peer experience is critical to adolescents' mental health and quality of life. Extant research on peer social participation of autistic students primarily focuses on individual social characteristics, while few studies examine the environmental factors supporting and hindering social participation.

**Objectives:**

To explore the environmental factors associated with autistic students' high and low social participation in inclusive education.

**Methods:**

This sequential explanatory mixed-methods study included two phases. (1) The quantitative phase investigated social interaction rates among seven autistic and 10 non-autistic students at an inclusive school club in 21 45-minute club sessions over a school year, using video-based social behavior coding. (2) Based on the observed social interaction rates, we first calculated the percentages of sessions with high and low social participation in autistic and non-autistic students, as indicated by the 25<sup>th</sup> and 75<sup>th</sup>tile of the social interactions rates in the school club over time. We then identified the club sessions where each student had their highest and lowest social participation (interaction rates below the 25<sup>th</sup>tile and above the 75<sup>th</sup>tile of the student's observations, respectively). In comparison between sessions with high and low participation, we conducted video observations and thematic analysis of conversation transcripts, focusing on the environments and contexts of peer interactions, including peer behaviors and reactions, teacher interventions, as well as classroom activities and setup.

### **Results:**

All students presented varying levels of social participation across sessions. Autistic students showed high social participation in 25% and low social participation in 19% of the club sessions (as compared with 27% and 27% in non-autistic students). Table 1 shows the average cut-off of social interaction rates for high and low social participation in autistic and non-autistic students.

Thematic analysis revealed environmental three themes associated with students' social participation including (1) interpersonal similarity and openness to differences, (2) teacher intervention and classroom climate, (3) and activity and physical environments. For autistic students, similarity with peers in terms of shared interests and social styles play major roles in engaging and reciprocal social interactions. Peers' openness with social acts different from the norms allowed social connections to grow, while in other instances peers' negative reaction or rejection precluded further interactions. Teacher interventions that celebrate both autistic and non-autistic students' strengths and accomplishments fostered relationship building and a climate of peer-learning. However, exclusive interventions with autistic students may create negative framing of autistic students' challenges and, in some instances, omitted non-autistic students' needs of support. Activities and physical environments that provided opportunities for exploration and self-expression facilitated peer interactions of sharing thoughts and discoveries. For autistic students, activities that encouraged the integration of their interests provided strong support of peer connections and exchanges upon shared passion.

### **Conclusions:**

Environmental factors such as interpersonal similarity, peer openness, teacher interventions, classroom climate, and activities play meaningful roles in the social participation of autistic students. Moving beyond individual social characteristics in autistic individuals can help improve the inclusiveness of social environments.

**323.004** (Oral) Characteristics Associated with Receipt of Reproductive Health Education Among Students with Autism  
*E. K. Schmidt and G. I. Orsmond, Department of Occupational Therapy, Boston University, Boston, MA*

---

### **Background:**

Youth who receive reproductive health education (RHE) are more likely to delay initiation of sex and use condoms or contraception and are less likely to experience unwanted pregnancy and sexually transmitted infections.<sup>1</sup> Receiving RHE may also decrease the risk of sexual abuse for youth with disabilities.<sup>2</sup> Research indicates that youth with autism are least likely to receive RHE compared to peers with other disabilities,<sup>3</sup> but no information is available specifically on characteristics associated with receipt of RHE for youth with autism.

### **Objectives:**

The purpose of this analysis was to examine the patterns of receipt of RHE for youth with autism using data from the National Longitudinal Transition Study-2 (NLTS-2).<sup>4</sup>

### **Methods:**

The NLTS2 dataset includes a nationally representative sample of youth with disabilities and provides information about secondary education services and supports, as well as postsecondary outcomes;<sup>4</sup> we analyzed the Wave 1 Program, Multiple Instructors, and Parent data sets. Among 617 students who received special education services for the disability category of autism, 82.3% ( $n=513$ ) were male, 17.7% ( $n=110$ ) were female, 61.3% ( $n=383$ ) were white, 38.7% ( $n=242$ ) were students of color, and 26.5% ( $n=166$ ) had co-occurring intellectual disability. All analyses were performed in SPSS and the school-program weight was applied to adjust for underestimation. We examined associations between receipt of RHE and youth gender, race, age,

family income, intellectual disability status, receipt of physical education,<sup>5</sup> and the youth's language skills and ability to understand.<sup>5</sup> We also examined the association between these variables and teacher's perceptions of the benefits of RHE for those who had not received it.<sup>4</sup> We performed Chi Square analyses for each independent variable with both dependent variables. An adjusted alpha level ( $p < .001$ ) was utilized to correct for Type I error due to multiple analyses with the same dependent variables.

### Results:

Youth with autism were less likely to receive RHE if they were female, younger than 17-18 years, a student of color, living in lower income households, and if they had co-occurring intellectual disability or had trouble speaking or understanding (see Table 1). Teachers perceived students were more likely to benefit from RHE if they were female, 16 years old, Black or Hispanic, lived in households making less than \$25,000 annually, and had no trouble speaking (see Table 2). Teachers did not perceive status of co-occurring intellectual disability as being associated with benefit from RHE. Further, they believed students who had trouble understanding would benefit most from RHE.

### Conclusions:

The findings of this study suggest the need for policies to ensure all students are receiving RHE, especially students of color, low income students, and those with intellectual disability or who have trouble speaking or understanding. Further, since teachers believed students who had little or no trouble speaking were most likely to benefit from RHE, additional education and training regarding accessibility and universal design is necessary to guarantee students receive equitable education. Future research could examine the effectiveness of techniques to improve accessibility and current RHE programs designed for students with autism.

## POSTER SESSION — EDUCATION

### Poster 417 - Education Posters

**417.001** (Poster) A National Portrait of Autism-Specific College Support Programs in the United States

*C. Kepple<sup>1</sup>, B. E. Cox<sup>2</sup> and C. B. Francis<sup>1</sup>, (1)Florida State University, Tallahassee, FL, (2)Educational Leadership and Policy Studies, Florida State University, Tallahassee, FL*

Background: 85 postsecondary institutions across the United States have begun programs specifically designed to provide support and services to college students with autism. These autism-specific programs (ASP's) go beyond the legally mandated accommodations provided to students with disabilities. However, there has yet to be any systematic examination of how they operate or the services they provide.

Objectives: This session reports on findings from a survey of a nationally-representative sample of autism-specific college support programs. Results from the study are broken down by institutional level (2-year/4-year), control (private/public), and geographic region. The presentation will 1) highlight the most comprehensive approaches currently used to support autistic students, and 2) offer scholars suggestions for future research to assess the efficacy of these programs.

#### Methods:

In the summer of 2020, directors of each of the 85 autism-specific support programs (ASPs) identified by McDermott and Nachman (2020) were asked about their programs' size, costs, and administrative structures. These directors also identified which (if any) of 10 literature-guided support services they provided to participating students. Responses were received by a nationally representative sample of programs from 60 institutions (42 public, 18 private; 53 4-year institutions, 7 community colleges). The session will provide a descriptive summary of national findings, including a breakdown by institutional level, control, and location.

#### Results:

Most of these initiatives are relatively young, with more than half of the programs having started in just the last 6 years; the oldest responding ASP began in 2002. These programs have an average of 38 students currently enrolled while they have served 112 students since their program's inception.

Although 20 of the programs are available at no additional cost to participating students, two-thirds of the programs charge fees above and beyond institutions' tuition and fees. Annual fees average between \$2,927 and \$4,144, with 21 programs reporting student costs of \$5,000 or more per student annually.

These ASPs provide an average of seven distinctive services to their students. Nearly all offer life-skills support (93%), social skills training (88%), and peer mentors (85%). Fewer than half offer formal mental health support (47%) or tutoring services (48%).

Conclusions: Results from this study indicate that autism specific college support programs across the country are providing students critical services that go well beyond legally mandated disability accommodations. While these programs have emphasized initiatives tailored to the unique characteristics and needs of autistic college students (e.g., daily life skills, social skills) comparatively few provide direct mental health support to their students. Now, however, such mental health support may be particularly important for these students as the ongoing pandemic forces students to make rapid transitions and dramatic shifts to routines and environments. We suggest this study serve as the foundation upon which future research should examine the efficacy of the services provided by these autism specific college support programs.

**417.002** (*Poster*) A Three-Year Evaluation of Purpose-Built Centres to Promote Inclusion of Autistic Pupils in Mainstream Schools

*I. Dale<sup>1</sup>, H. Judge<sup>2</sup>, D. May<sup>3</sup> and A. Jones Bartoli<sup>4</sup>, (1)The National Autistic Society, Sheffield, United Kingdom, (2)National Autistic Society, London, United Kingdom, (3)National Autistic Society, London, United Kingdom of Great Britain and Northern Ireland, (4)Goldsmiths, University of London, London, United Kingdom of Great Britain and Northern Ireland*

---

Background:

Over 130,000 pupils in state funded schools in England have autism as their primary Special Educational Need (SEN). Seventy percent of these pupils are educated in mainstream settings (Department for Education, 2018). Half of their parents say that their child's school place does not meet their needs. Fewer than half of children and young people on the autism spectrum say they are happy at school (National Autistic Society, 2017).

Objectives:

A national autism charity and an education authority developed and built centres in three mainstream schools for pupils aged 11 to 16. The centres were intended to provide specialist support from trained staff, such as learning in small groups, therapies, and a calm setting to retreat to. An evaluation conducted over the first three years of the centres studied (1) the impact of this model for pupils, families and the wider school (2) lessons in how to implement this approach (3) whether this approach (or elements of it) can be considered good practice for adoption more widely.

Methods:

A mixed methods approach was taken. Data was collected via questionnaires and interviews with pupils, parents, specialist staff working at the centres, staff of the charity, and mainstream peers (matched by age and gender) as well as classroom observation. Parent packs asked questions about sensory processing, language, and input into their child's schoolwork and contact with school. Teacher packs asked about pupil-teacher relationships. A range of validated measures was used in the evaluation including the Child and Adolescent Social Support Scale (Malecki and Demaray, 2002), Self-Report Coping Scale (Causey and Dubrow, 1992) and Subjective Happiness Scale (Lyubomirsky and Lepper, 1999).

Results:

Autistic pupils often experience lower education related wellbeing. However there was no evidence of such a gap for the centres' pupils. There was early evidence that the presence of the centres and their pupils is improving attitudes in mainstream pupils. Pupils were well-supported in their social development. Centre pupils were starting to act as support for each other across year groups. The centres' approach to exclusions resulted in levels of fixed term exclusions no higher than elsewhere and the complete absence of permanent exclusions. Parental satisfaction was generally high. Parents said their children were unlikely to have managed in mainstream without the centres.

Conclusions:

Avoiding inappropriate placements is key to the achieving the maximum from the centres' limited resources. Appropriate staffing is a key strength of this kind of provision. Some elements of this approach can be considered best practice for adoption more widely: the permanent availability of a familiar, quiet and calm space; the ability and willingness of centre staff to provide highly tailored support; use of space in a very flexible way for activities and transitions; allowing specialist skills and interests to develop appears to be helping pupils thrive more than they did in primary school; and having older pupils available as a source of support. Key challenges facing any autism-specific education provision remain – for example understanding and support for co-occurring conditions such as mental health problems.

**417.003** (Poster) Autism and Evidence-Based Practices: Surveying Educators' Knowledge, Training and Use  
*P. LaCava, Rhode Island College, Providence, RI*

---

Background: The search for effective practices in autism spectrum disorders (ASD) has been an ongoing initiative (National Research Council, 2001; Simpson, 2005). Groups such as the National Professional Development Center ([NPDC]; Wong et al., 2014) have published critical reports on EBP, including EBP identification and practice guidelines. Despite these advances there still exists a research to practice gap (Parson et al., 2013). The overall goal of this research was to explore educators' knowledge, training, and use of EBP when working with students with ASD.

Objectives:

1. identify educator knowledge, training, and use about EBP
2. identify barriers to using EBP
3. identify professional development needs

Methods: A SurveyGizmo online questionnaire surveyed educators (teachers, related service providers, administrators) regarding their knowledge, training and use of EBP. Participants were recruited through autism related email list serves in southern New England. Survey content was validated by the review of 12 professionals and autistic people. A pilot study was conducted with 15 educators to verify technology, feasibility, and readability. Descriptive statistics were used to describe participants' demographics and survey item responses, while qualitative answers were organized into themes.

Results: 179 educators (84% female and Caucasian) completed the questionnaire. When asked, "What is evidence-based practice?" and able to choose more than one answer, over 90% agreed that EBP was a practice that has been vetted by rigorous research and review standards and shown to be effective, but only 24% agreed that EBP was a process of integrating the best evidence from research, professional judgement and student factors. Educators identified many factors that should be considered when choosing EBP including experience, student input, teacher capacity, family collaboration, etc.

Participants were asked to rate their level of awareness and use of the NPDC's 27 EBP (Wong et al., 2014). EBP used the most include: reinforcement, prompting, modeling and visual supports. EBP used the least include: parent implemented intervention, pivotal response training and discrete trial teaching. 16 of the EBP were reported being used by more than 50% of the sample. Despite these high reported levels of use, participants reported having limited EBP training. For example, while over 73% of the sample reported using reinforcement, only 25% of this group reported having been trained in this particular EBP. Other identified barriers to EBP use include time, resources, paperwork, and case load burden.

Conclusions: As this is a self-report survey, data should be interpreted with caution. Overall findings suggest that educators are aware of and use the most common EBP for students with ASD. Despite high reported use, educators shared several roadblocks to implementing EBP with limited training being the number one identified barrier. This finding was confirmed as participants also revealed that they use many EBP without having had training. How this impacts efficacy is unknown, but future research should include confirmation of EBP use along with fidelity checks and deeper investigation of how educators make decisions and evaluate EBP. Surveying autistic people and their families for their experiences and perspectives on EBP is also vital.

**417.004** (Poster) Autistic Traits and Risk Factors for Academic Performance: The Trails Study  
*A. K. Smitt<sup>1</sup>, P. J. Hoekstra<sup>2</sup>, A. de Bildt<sup>1</sup> and C. A. Hartman<sup>3</sup>, (1)Accare Child and Adolescent Psychiatry or University of Groningen, Groningen, Netherlands, (2)Department of Child and Adolescent Psychiatry, University Medical Center Groningen, University of Groningen, Groningen, Netherlands, (3)Department of Psychiatry, Interdisciplinary Center Psychopathology and Emotion Regulation (ICPE), University Medical Center Groningen, Groningen, Netherlands*

---

Background: Youth with autism spectrum disorder (ASD) have been granted the right to be educated in inclusive schools and receive enough specific support to achieve their academic potential. However, previous studies have demonstrated that youth with ASD score below expectations. In order to improve academic performance in adolescents with ASD, a starting point would

be to investigate how protective factors for academic performance found in the general population apply to adolescents with autistic traits and whether autistic traits are predictive in themselves and interact with these protective factors.

**Objectives:** We investigated the association of autistic traits with concurrent academic performance and change in academic performance across adolescence, controlling for sex and school type, and exploring the role of potential protective factors (IQ, social skills, and student-teacher relationship quality). We also examined whether externalizing problems are a risk factor for academic performance.

**Methods:** Adolescents ( $M_{age} = 11.11$ , 48% female, at T1) from the prospective cohort study *Tracking Adolescents' Individual Lives Survey* were studied, including typically developing ( $n = 2229$ ) and clinically referred adolescents ( $n = 543$ ). We assessed whether autistic traits combined with sex, school type, social skills, IQ, student-teacher relationship quality and externalizing problems related to: (a) initial teacher-rated academic performance, and (b) change in academic performance up to age 16, using longitudinal linear mixed models.

**Results:** Academic performance decreased across adolescence, but significant variance existed in the intercept and slope, thus the initial level and course of academic performance differed between adolescents. Male adolescents had a significantly steeper decline in academic performance over time. Initial level of academic performance was significantly higher for adolescents with higher IQ-scores, more social skills, and higher student-teacher relationship quality. The positive effects of IQ and social skills decreased significantly over time, whereas the positive effect of student-teacher relationship quality increased. Externalizing behavior affected neither the intercept nor the slope of academic performance. None of the risk or protective factors interacted with autistic traits.

**Conclusions:**

Social skills in the classroom, IQ-scores, student-teacher relationship quality and female gender positively affected academic performance, more so than autistic traits and independently from whether adolescents had few or many autistic traits. The relatively low intraclass correlation coefficient combined with the absence of an interaction of autistic traits with IQ, social skills, student-teacher relationship quality or externalizing problems in our study emphasizes the importance of assessing and tailoring interventions to individual strengths and weaknesses of all adolescents.

**417.005 (Poster)** Board Certified Behavior Analysts' Experiences Teaching Sex Education  
*S. L. Curtiss and M. Stoffers, University of Delaware, Newark, DE*

---

**Background:** The relationship between information and behavior is intricately woven in discussions of sex education (Kramer, 2019). Thus, it is unsurprising that Board Certified Behavior Analysts (BCBAs) are often called upon to provide sex education for individuals with developmental disabilities under the domain of supporting expressions of sexual behavior (Davis et al., 2016). It remains unclear how BCBAs navigate the social, moral, ethical, and practical concerns involved with providing sex education (Falligant & Pence, 2020).

**Objectives:** This project seeks to answer two research questions: (1) What is the nature of BCBAs sex education practice? And (2) What challenges do BCBAs face when providing instruction?

**Methods:** This study is a thematic analysis (Clarke et al., 2015) of one-hour-long interviews with nine BCBAs (see Table 1 for sample demographics). These participants were a sub-sample from a larger study on providing sex education to those with intellectual disabilities, which was developed with our research advisory board consisting of autistic adults.

**Results:** We identified three preliminary themes from interviews with BCBAs (see Table 2 for a description of themes and example quotes). In answer to our first research question, BCBAs reported an eclectic training background to prepare for the delivery of sex education services. While some BCBAs had extensive sexual education training, others described their training as “a Frankenstein's monster of experience that you accrue over the years.” Many BCBAs noted that sex education services were requested in the context of perceived problematic sexual behavior. For instance, some BCBAs were presented with caregivers who were concerned about the masturbatory activities of the individual. Other BCBAs supported individuals who were identified as sexual offenders or at risk of sexual offending. In answer to our second research question, BCBAs reported tension between compliance and autonomy, suggesting that insistence on compliance can lead to a greater risk of sexual abuse and may inhibit individuals from receiving access to sex education that aligns with their personal needs and desires.

**Conclusions:** This project provides a clearer understanding of the nature of sex education provided by BCBAs and the challenges they face. The findings suggest greater attention is needed in the area of specialized training on sex education and autism with

special attention to the role that sex education plays in reducing problematic sexual behavior. BCBA's were aware of the tension between the compliance-oriented nature of their therapy and the value of autonomy inherent in their sex education practice. In some cases, this led them to question the degree to which the behavior they were asked to address was truly problematic.

**417.006 (Poster)** Compass for Optimizing Educational Outcomes and Supporting Parent-Teacher Alliance

*L. A. Ruble<sup>1</sup> and J. H. McGrew<sup>2</sup>, (1)Special Education, Ball State University, Muncie, IN, (2)Psychology, Indiana University - Purdue University Indianapolis, Indianapolis, IN*

---

Background:

Unlike most ASD school-based interventions that focus primarily on classroom teachers, parents are a critical ingredient of the COMPASS intervention. As a parent-teacher consultation intervention, COMPASS brings together parents and teachers for an ecological assessment of the child's risk and protective factors across areas of development. Validated in three randomized controlled trials, COMPASS doubles IEP outcomes in the crucial areas of social, communication, and learning skills. Parent-teacher alliance is particularly promising because of its association with IEP progress and student outcomes (Ruble, et al., 2019).

Objectives:

The purpose of this study was to determine (a) if parent-teacher alliance after receiving COMPASS was significantly different from the comparison group, after controlling for initial alliance scores and (b) whether alliance was associated with child outcomes, after controlling for group assignment.

Methods:

Data come from a secondary analysis of RCTs. The first two RCTs were conducted with young children ( $n = 76$ ; 6 years; Ruble et al., 2010; 2013); the third was with high school students ( $n = 20$ ; 18 years; Ruble, et al., 2019). The studies' designs and measures were identical. Student cognitive mean score was 56.4 ( $SD = 25.8$ ) and adaptive behavior score was 63.62 ( $SD = 14.6$ ).

Measures included the Parent-Teacher Alliance Questionnaire (PTAQ), a 20-item measure of parent perceptions of their relationship with their child's teacher (Krakovich, et al., 2016). The internal consistency was .95.

For outcome assessment, two approaches were applied, one from parent and teacher ratings a second from a researcher. The first one asked parents and teachers to assess IEP goal progress with a Likert-type scale questionnaire on how much progress had been made to date using a five-point scale (1 'none at all' to 5 'a great deal') for each of the three monitored IEP goals. The internal consistency for the parent measure ( $\alpha$ ) was .81 and the teacher was .69. The second was based on Psychometric Equivalence Tested Goal Attainment Scaling (PET-GAS) to evaluate IEP progress by an independent evaluator unaware of experimental condition. Each goal is scaled using a five-point rating: -2 = present levels of performance to +2 = much more than expected. PET-GAS ratings were based on video demonstrations, work samples, and/or data collected by the teacher. Two coders independently coded 65% of the goals at baseline and three coders independently rated 35% at final evaluation. Interrater agreement .86 at final evaluation.

Results:

Analysis of the ANOVA indicated a trend toward significance between groups ( $p = .06$ ) for alliance scores, in favor of COMPASS, after controlling for preintervention scores,  $F(1, 84) = 3.57$ ,  $p = .06$ , partial eta squared = .041. Analysis of the partial correlations indicated a significant correlation between alliance and parent report of IEP progress.

Conclusions:

While parent perceptions of progress made on the IEP correlated with alliance, and teacher report of progress correlated with parent report, objective assessment of goal attainment outcomes did not. The results indicate further research is needed for leveraging consultation to enhance parent-teacher alliance, and thus child progress.

**417.007 (Poster) Conducting Standardized Assessments over a Technology Platform for Children with ASD**

---

**Background:**

The COVID-19 pandemic has forced practitioners to adapt assessments that are designed for in-person implementation to be appropriate for delivery over technology in the form of a tele-assessment (Krach et al., 2020). Krach et al., (2020) refer to adapted tele-assessment as administration using telecommunication technology for an assessment that has been adapted for technology platform but was standardized for face-to-face administration. Little guidance exists for adapting assessments to be appropriately delivered as teleassessments that takes into consideration the higher risk for error when using technology to deliver a test that was standardized for face-to-face administration.

As part of a larger study examining the efficacy of the electronic delivery of a reading comprehension intervention for students with autism spectrum disorder (ASD), our research team conducted standardized language assessments over Zoom. This presentation will discuss the process of collecting pre-test standardized language assessment data over Zoom.

**Objectives:**

The purpose of this presentation is to discuss the successes and challenges of conducting reliable and valid tele-assessments and participant performance. Information will be provided about redesigning these assessments for Zoom administration format (based on guidance from professional organizations and practical considerations), the process of conducting these assessments (the spaces and people involved), and the assessment scores.

**Methods:**

Our team worked with 19 children (ages 7-9) with ASD from different geographical regions across the United States. Assessments included subtests from the WJ-IV, WISC-IV, CELF-5, EVT-3, and CTOPP-2. Trained research team members administered all assessments and double scored all test records.

**Results:**

Some assessments were redesigned to be administered via Microsoft PowerPoint and adaptations made to allow for participant mouse control when pointing was required. However, this process did not work for everything, and some exceptions included the PPVT-5, Passage Comprehension on the WJ-IV, and Block Design on the WISC-IV. Some assessments were not possible to complete over Zoom (i.e., Repeated Sentences on the CELF-5); if the test administrator was unable to repeat themselves, this typically posed a problem for the participants as there were sometimes delays or noisy backgrounds, making it difficult to hear. Another design issue we observed was associated with any assessments that were presented without visual stimuli; participants struggled to attend to material that was presented only verbally (i.e. Understanding Spoken Paragraphs on the CELF-F). The presence of parents or other specialists (i.e., behavior technicians) was sometimes positive as they could help keep their child focused on the task at hand; however, this was often a distraction to participants (e.g., participant looking to parents for answers) or an influence to the participants' answers (e.g., parents occasionally providing, hinting at, or correcting answers). All assessments are currently in the process of being scored and will be completed by INSAR 2021 to be more fully discussed.

**Conclusions:**

The redesign and adaptation of these assessments for the Zoom environment for this population of children with ASD proved to be quite challenging when relying on professional organization recommendations during the COVID-19 pandemic. Best practices, lessons learned, and guidance for future telehealth assessment will be discussed.

**417.008** (Poster) Cultural Influence on Parents-Teachers Collaboration Towards Educating Children with ASD in Nigeria and South Africa during Crises

**O. A. Kehinde<sup>1</sup>, O. J. Lindly<sup>2</sup>, B. Ntombela<sup>3</sup> and C. Hermann<sup>4</sup>,** (1)English, University of Zululand, KwaDlangezwa, South Africa, (2)Health Sciences, Northern Arizona University, Flagstaff, AZ, (3)Department of English, University of Zululand, KwaDlangezwa, 3886, South Africa, (4)Psychology, University of Zululand, KwaDlangezwa, 3886, South Africa

---

**Background:** People's culture has potential to shape their thinking and trigger different action, though this phenomenon is not peculiar to one region or society. Notably, parents and teachers remain primary caregivers of children with autism spectrum disorder (ASD), and they are also expected to work collaboratively to offer necessary training and care at home and school. Despite this necessity during crises such as recent COVID-19 pandemic, the nature and extent of their collaboration might have been influenced by culture of some parents, such as those who are in remote areas in Nigeria and South Africa where research and awareness are limited and thus making ASD, various available interventions, and methods of educating children with autism to be poorly understood and ineffective.

**Objectives:** This study aimed to examine what influence culture has on the collaboration of parents and schools/ teachers who are main caregivers towards educating children with ASD in Akinyele Local Government Area, Nigeria, and Zululand District, KwaZulu-Natal, South Africa.

**Methods:** The study adopted a qualitative approach, and data was collected using semi-structured interviews with the help of an interview guide. Using purposive sampling, 5 parents were recruited from 3 different areas in Akinyele Local government while 10 parents were recruited from 5 different areas in Zululand District and they were interviewed for the study. The data was analysed using thematic content analysis, and the study strictly adhered to ethical considerations.

**Results:** The findings of the study revealed that only a few parents of children of children diagnosed with ASD reached out to schools/ teachers regarding how to keep learning going at their respective homes during national lockdown due to COVID-19 pandemic. It was also found that there was notable cultural influence on the way some parents (especially male parents in Zululand) related with their schools or teachers as they acted out cultural practice of 'men don't cry' also in this situation. Some female parents also reported that such practice has affected their relationship with schools/ teachers of their children with ASD, thus they seldom asked for help about what can be done at home to continue educating their children with autism during COVID-19 pandemic. Also, the cultural belief of many parents in Nigeria restricted them to visit schools/ teachers that were even ready to help with teaching materials or some teaching guides as some participants termed COVID-19 as a deadly and contagious disease believed to be caused by extreme heat sent by a god, thus validating limited knowledge on ASD in many remote areas.

**Conclusions:** Schools and parents need to discuss and design terms of achieving more effective and productive collaboration that focuses on continuous teaching of children with ASD, especially the collaboration mostly needed by parents during pandemic, natural disaster, and curfew. Parents should review their cultural beliefs and stick to those that can help establish and maintain close relationship with schools/ teachers in order to benefit from their guide and innovation that can help parents educate their children with ASD during different crises.

**417.010** (Poster) Educational and Diagnostic Classification of Autism Spectrum Disorder and Associated Characteristics  
**N. Buranova<sup>1</sup>, J. Stichter<sup>2</sup>, M. Stormont<sup>3</sup>, M. Herzog<sup>2</sup> and R. M. O'Donnell<sup>4</sup>,** (1)Special Education, University of Missouri, Columbia, MO, (2)University of Missouri, Columbia, MO, (3)University of Missouri, Columbia, Columbia, MO, (4)Health Psychology, Thompson Center for Autism & Neurodevelopmental Disorders, Columbia, MO

---

**Background:**

**Research continues to highlight discrepancies between clinical diagnoses of Autism Spectrum Disorder (ASD) and the determination of special education eligibility for services within school settings.** That inconsistency may result in the absence or lack of services provided to students with ASD (Christiansen, 2016). There is limited research conducted on the impact of those discrepancies on the identification of appropriate services for students with ASD within schools. The current study examined the characteristics of students with ASD and how they relate to educational eligibility and clinical diagnoses.

**Objectives:**

The purpose of this study is to investigate if educational eligibility and clinical diagnosis of autism are associated with specific language, social-emotional, and other key characteristics. More specifically, among students with autism, what characteristics are differentially associated with their diagnosis and can therefore be targeted for evidence-based treatments? If treatments for autism

are effective in increasing peer relationships and social competence but schools do not differentiate students with autism from those with other types of disabilities, then students may not be matched with appropriate interventions to meet students' needs.

#### Methods:

The study accessed data from a four-year cluster-randomized trial of 283 students with and without reported ASD diagnosis. The following measures/indicators were used and compared in the study: special education eligibility, Autism Diagnostic Observation Schedule (ADOS-2; Lord et al., 2012), Children's Communication Checklist-2 (CCC-2; Bishop, 2006), School Social Behavior Scales (SSBS; Merrell, 1993). The results of the assessments were analyzed to determine the differences and overlap of the assessment tools used for determining the educational eligibility of Autism and medical diagnosis of ASD.

#### Results:

Five MANOVAs tests were run, two were significant, one was approaching significance and two were not significant. The MANOVA with dependent variables related to social competence and social relations yielded significant differences among groups with and without ADOS diagnoses  $F = 3.47, p = .001$ . Groups did not differ based on an IEP diagnosis of autism  $F = .56, p = .69$   $F = .48, p = .87$ . Tukey follow-up comparisons documented significant mean differences between the group of students with autism and the group without autism for all subscales with the group with autism having more impaired social functioning.

Conclusions: A central finding of this study includes that an educational eligibility classification was not associated with characteristics of autism but ADOS-2 classification of autism (autism, autism spectrum disorder, no autism) was associated with key ASD characteristics. More specifically, we found that the educational diagnosis of Autism did not distinguish between students with and without autism on key characteristics of language, peer and social relations and competence, or academics and other interests. It isn't clear how students with autism were determined eligible for an IEP if they did not differ from peers with other disabilities on key social and language outcomes. This can be a result of the absence of consistent standards for identifying students under the Autism category. ADOS-2 classification was found to be a more solid diagnostic measure for important and differential characteristics associated with autism.

#### **417.011 (Poster) Estimating the Prevalence of Autism Among Postsecondary Students in the United States**

**B. E. Cox<sup>1</sup>, C. B. Francis<sup>2</sup> and C. Kepple<sup>2</sup>, (1)Educational Leadership and Policy Studies, Florida State University, Tallahassee, FL, (2)Florida State University, Tallahassee, FL**

---

#### Background:

How many postsecondary students have autism? Although this question is seemingly simple and straightforward, the current literature does not provide a solid answer. The few studies that have attempted to do so yield dramatically different estimates, in part because they all have critical limitations that prevent them from yielding an authoritative figure. Without good data about the prevalence of autism in higher education, postsecondary policy makers and institutional administrators are unlikely to recognize the importance of this population or be persuaded to expand efforts to support these students.

#### Objectives:

In this paper we identify, analyze, and synthesize data drawn from multiple sources to estimate the prevalence of autism within postsecondary institutions in the United States.

#### Methods:

Drawing from a review of 400 publications, 16 prominent national surveys used by postsecondary institutions, and 7 federal datasets, this project 1) assesses the generalizability of estimates based on previously published literature, 2) extrapolates estimates from Eagan et al.'s (2016) study of 137,456 college freshmen attending over 184 postsecondary institutions, and 3) conducts original analyses of 3 nationally-representative datasets from the Institute of Education Sciences.

Of the 16 widely used multi-institutional surveys of postsecondary students we reviewed, only one (Eagan et al., 2016) asked explicitly about autism. Likewise, only two of the seven nationally representative data sets we examined from the Institute of Education Sciences (IES) include data necessary to estimate the preponderance of college students with autism: the Baccalaureate & Beyond (B&B, 2016-2017), the National Postsecondary Student Aid Study (NPSAS, 2016). Data from these studies were weighted to provide nationally representative estimates of the prevalence of autism in higher education.

## Results:

Without accounting for students' reluctance to self-disclose autism once in college, nationally representative data relying on student self-reports suggests there may be as few as 50,281 undergraduate college students who report having autism in the United States. Calculations from other multi-institution data sources yield higher estimates, between 83,801 and 103,748. However, when we account for the fact that some individuals with autism do not receive a diagnosis until after college (Author, 2017) and 38% of students with formal autism diagnoses do not disclose that information once in college (Newman et al., 2011), we think it more likely that there are between 81,098 (50,281 / 0.62) and 167,335 (103,748 / 0.62) total undergraduate students with autism in the US today.

## Conclusions:

These estimates may be critical to ensuring that the growing population of college students with autism receives appropriate attention, support, and resources from their postsecondary institutions. Educational administrators can use the estimates to show that college students with autism are a sizable population that warrants increased attention from postsecondary institutions. Moreover, our examination of these wide ranging data sources also revealed the paucity of empirical evidence from which researchers can currently generate plausible estimates of autism's prevalence in postsecondary education. Future research on the topic will require the development and analysis of additional large-scale, multi-institutional, representative data sets.

### **417.012 (Poster)** Examining Ethnicity As a Moderator of the Relation between Pre-Parent Factors and Actual/Perceived Knowledge of ASD

*S. C. Boland<sup>1</sup>, R. A. Lindsey<sup>1</sup> and T. D. Barry<sup>2</sup>, (1)Washington State University, Pullman, WA, (2)Psychology, Washington State University, Pullman, WA*

---

## Background:

There is little known about parenting knowledge in pre-parents, as most studies focus on those that are already a parent. Additionally, evidence suggests there may be ethnic disparities in age of diagnosis for children with autism spectrum disorder (ASD) due to caregivers' lack of awareness of early signs of neurodevelopmental delay (Mandell et al., 2009).

**Objectives:** The present study aimed to evaluate how prior experience with children, undergraduate education, and family SES may relate to pre-parents' actual and perceived ASD knowledge and how ethnicity may moderate those relations.

## Methods:

Participants were 221 undergraduate students who identified as pre-parents (i.e., have no children but plan to have children in the future). They completed questionnaires via Qualtrics including *A Survey of Knowledge of Autism Spectrum Disorder* (ASK-ASD), assessing perceived (ranging from 1 to 3) and actual (ranging from 0 to 1) ASD knowledge, and a demographic questionnaire, which included ethnicity (coded 0 = White, 1 = Non-White), experience with children in five roles (e.g., babysitter; coded 0 = no, 1 = yes), and previous enrollment in specific Psychology undergraduate classes (coded 0 = no, 1 = yes). An experience composite (ranging from 0 to 5) and a classes composite (ranging from 0 to 16) were created by summing the items for the respective constructs.

## Results:

Zero-order correlations indicated that ethnicity related to actual and perceived knowledge of ASD and family SES, with White participants having significantly more perceived and actual knowledge and higher family SES. Both experience and family SES were significantly positively correlated with ASD knowledge.

Six moderated multiple regressions examined whether ethnicity interacted with experience, classes, or family SES (considered separately) in predicting both actual and perceived ASD knowledge. At Step 1, the significant main effects found in the zero-order correlations held, with no additional main effects emerging (Table 1). That is, ethnicity, experience, and family SES were significant unique predictors in each of their respective analyses [although ethnicity and family SES only predicted a marginal amount ( $p = .05$ ) of unique variance in perceived ASD knowledge]. At Step 2 (interaction effect), only the interaction between ethnicity and experience predicted unique variance in actual knowledge,  $b = -0.03$ ,  $SE = 0.02$ , [95% CI (-0.06, -0.003)], and perceived knowledge,  $b = -0.09$ ,  $SE = 0.04$ , [95% CI (-0.17, -0.001)]. Post-hoc plots (Figure 1) showed that the positive relation between child experience and perceived/actual ASD knowledge only emerged for White participants. Levels of experience did not predict levels of actual/perceived knowledge for Non-White participants.

## Conclusions:

Ethnicity, family SES, and child experience contributed to participants' ASD knowledge. The lack of finding of a contribution from classes suggests that Psychology curriculum may need to place a heavier emphasis on neurodevelopmental differences, and future research should evaluate if specific courses contribute to variability in ASD knowledge. The interaction between ethnicity and child experience indicated that Non-White participants may rely on other factors when acquiring ASD knowledge of ASD. The findings may provide clinical implications to how pre-parent knowledge of neurodevelopmental disabilities could enhance early diagnoses.

### 417.013 (Poster) Examining Restricted Repetitive Behaviours and Interests As Predictors of Math Ability Among Students with Autism

L. Trafford<sup>1</sup>, K. Howard<sup>1</sup>, E. Gaudet<sup>2</sup>, R. Del Colle<sup>3</sup>, C. Labonté<sup>1</sup> and H. M. Brown<sup>1</sup>, (1)Educational Psychology, University of Alberta, Edmonton, AB, Canada, (2)Educational Psychology, University of Alberta, Edmonton, AB, CANADA, (3)University of Alberta, Edmonton, AB, Canada

**Background:** A widely held, stereotyped belief is that students with autism tend to be mathematically gifted. This stereotype has some support in the annals of autism research, but more recently, researchers have revealed that the rates of both math giftedness and math weakness and/or disability among students with autism are higher than we would expect in a typical population (Chiang & Lin, 2007; Mayes & Calhoun, 2006; Oswald et al., 2015). Although IQ and language ability are known predictors of both neurotypical (e.g. Byrnes & Miller, 2007) and neurodiverse (e.g. Oswald et al., 2015) students' math abilities, more research is needed to determine how students who share a common diagnosis can have such disparate outcomes in the same area of academic performance. It is possible that students' consistent, systematic, and uniquely autistic engagement with restricted, repetitive behaviours and interests (RRBIs), such as special interest engagement, represents an area of strength that may lead to improved math abilities.

**Objectives:** To examine the role that RRBIs have in predicting the math abilities of students with autism.

**Methods:** Forty-nine students with autism (92% male) completed standardized assessments of IQ (*Leiter-3 & Raven's Progressive Matrices*) and language ability (*Clinical Evaluation of Language Fundamentals, Fifth Edition* Formulated Sentences subtest). Scores from the *Social Responsiveness Scale, Second Edition* Restricted Interests and Repetitive Behaviours subscale were used as a measure of students' RRBI symptom severity. A standardized measure of foundational math ability (*KeyMath-3 Diagnostic Assessment, Canadian Basic Concepts composite*) was administered as the outcome measure. A hierarchical regression analysis was used to determine the unique amount of variance in math scores explained by RRBI symptom severity, above and beyond known predictors of IQ and language ability. Assumptions of multiple regression (i.e. homoscedasticity, linearity) were met according to statistical testing in IBM SPSS (v. 24).

**Results:** IQ and language ability were significant predictors of participants' math ability in the first regression model (IQ  $\beta = .647$ , language ability  $\beta = .323$ ), whereas RRBI symptom severity did not account for a significant amount of variance in participants' math ability scores when added to the second regression model ( $\Delta R^2 = .002$ ). Students with higher IQs and better language abilities had overall better math abilities, whereas the severity of students' RRBIs had no substantial influence on participants' math abilities.

**Conclusions:** Despite the lack of support for the original hypothesis that RRBIs, like special interest engagement, would strengthen students' math abilities, this study makes two critical contributions to the literature:

- (1) The results replicate previous research on the utility of IQ and language ability as predictors of math ability for students with autism; and
- (2) A deeper look at available RRBI measures reveals a need for more strength-based measures of RRBIs, given that existing measures like the *Social Responsiveness Scale, Second Edition* are both deficit-based and nonspecific—a single symptom severity score cannot adequately distinguish strength-based constructs of special interest engagement from deficit-based constructs of insistence on sameness and stereotyped movements.

**417.014** (Poster) Factors Predictive of High School Diploma Assigned to High School Students with Autism Spectrum Disorder  
**D. Kan<sup>1</sup>, L. F. Rentschler<sup>2</sup> and K. Hume<sup>3</sup>,** (1)School of Education, University of North Carolina at Chapel Hill, Chapel Hill, NC, (2)School of Education, University of North Carolina - Chapel Hill, Chapel Hill, NC, (3)Frank Porter Graham Child Development Institute, University of North Carolina at Chapel Hill, Chapel Hill, NC

---

**Background:** For students with ASD, attainment of a standard high school diploma paves the way for the successful pursuit of employment and/or higher education. Admittance to degree-bearing college programs requires the standard diploma and employment opportunities available to individuals without a standard diploma are far more limited (Whittenburg et al., 2019). However, eligibility policies for standard diplomas vary widely across the country (Guy et al., 2000). These varying local policies serve as the de facto gatekeepers to students' postsecondary education, career options, and earning potential. Students with disabilities who spend more time in general education courses are more likely to be eligible for a standard high school diploma (Thurlow et al., 1997). Yet, student and community characteristics that factor into the decision-making process for standard diploma eligibility still remain largely unknown.

**Objectives:** Since earning a high school diploma can serve as an important element in closing the autism employment gap, an examination of the factors that drive diploma earning is warranted. Research questions are: 1) To what extent is the percentage of time spent in general education predictive of diploma status for students with ASD?; 2) To what extent is state of residence predictive of diploma status for students with ASD?; and 3) When controlling for the influence of percentage of time spent in general education and state of residence, to what extent do student characteristics, family profile, and/or school and community factors predict diploma status for students with ASD?

**Methods:** Data is derived from a randomized control trial study conducted by Center on Secondary Education for Students with Autism Spectrum Disorder, and only pretest phase (prior to intervention) was included for analysis. 60 high schools were recruited from 3 states, NC, WI and CA, and 547 students enrolled in the study.

Relationship between diploma type and percent time spent in general education and state of residence respectively were identified using chi-square tests and simple logistic regression. Next, block-wise hierarchical modeling procedure was employed with percent time in general education and state of residence held constant, with each block regressed on diploma type. Three blocks of predictors, in order of entrance, were: 1) student ability characteristics; 2) environmental characteristics; and 3) student and family demographic characteristics.

**Results:** Alone, percent time spent in general education, state of residence, IQ, and adaptive behavior significantly predicted whether a student with ASD receives a standard high school diploma. Together, percent time spent in general education and state of residence improved model fit by 48%, suggesting these are the 2 strongest predictors of diploma type. Students who spend a greater amount of time in a classroom that provides instruction on general education curriculum and students from WI were more likely to graduate with a standard diploma.

**Conclusions:** Students in WI, a state that promotes a more inclusive model, are more likely to achieve the standard diploma. This suggests that an inclusive model of education can help students achieve the standard diploma, which may then improve their chances for better postsecondary outcomes in employment and education.

**417.015** (Poster) From a "Disorder" to "a Way of Being": The Effects of an Online Training on Pre-Service Teachers' Stigma and Their Understanding of Emotional and Empathic Capacities of Autistic Students  
**J. MacCormack,** University of Lethbridge, Lethbridge, AB, Canada

---

**Background:** In light of the difficulties autistic students have in schools (Fleury et al., 2014; Hughes et al., 2011), six in 10 autistic students believe that the main thing they need is a teacher who understands autism (All-Party Parliamentary Group on Autism, 2017). Teachers' knowledge of autism has been improving over the decades (Busby et al., 2012), but teachers still tend to hold on to inaccurate ideas about the lived experiences of autistic students (Lalvani, 2015; Vincent & Ralston, 2019). The gap between knowledge and understanding suggests that factual knowledge about the diagnostic criteria should also emphasize diversity over conceptions of pathology. Online training has been associated with reduced stigma and increased understanding among undergraduates (Gillespie-Lynch et al., 2015), and this study replicates a prior training study (Saade et al., under review) because the how online training can enrich the understanding of pre-service teachers remains unknown.

**Objectives:** To examine if autism training is associated with improved knowledge and stigma for pre-service teachers at one university in western Canada.

Methods: Pre-service teachers ( $N=105$ , 26.7% male) participated in an online pre-test, followed by an autism training, and a post-test. The pre/post-test included open-ended questions (e.g., “what is autism?”) and questions about demographics, a ten-question measure of stigma (social distance scale), and a participatory autism knowledge measure (PAK-M). Of the PAK-M questions, the current study focused on questions relating to emotional and empathic capacities of autistic people ( $\alpha=.77$ ).

Results: Completing the online training did not significantly improve pre-service teachers’ knowledge of common myths (e.g., “Most autistic people have low intelligence”). However, the training did improve the pre-service teachers’ understanding of issues related to emotional and empathic capacities of autistic people. A paired-samples t-test was conducted to compare knowledge about emotional and social capacities of people on the spectrum before and after training. Accuracy of these answers improved from pre-test ( $M=1.84$ ,  $SD=.55$ ) to post-test ( $M=1.4$ ,  $SD .48$ );  $t(104)=9.16$ ,  $p<.001$  (effect size was large,  $d =.85$ ).

A paired-samples t-test was conducted to compare stigma towards people on the spectrum before and after the training. Stigma was reduced from pre-test ( $M=1.69$ ,  $SD=.58$ ) to post-test ( $M=1.51$ ,  $SD .56$ ) conditions;  $t(104)=5.64$ ,  $p<.001$  (effect size was small,  $d = .31$ ).

Analyses of open-ended answers (“what is autism?”) demonstrated while answers given *before* the training were generally accurate (“spectrum of disorders”), the after-training answers reflected a nuanced understanding of autism (e.g., “A way of being”). The biggest change was that after the training, pre-service teachers were more likely to say that people with autism have the capacity to feel empathy (e.g., “are empathetic towards other people”) and to contribute to their social networks (e.g., “Autistic people are valuable members of our communities”).

Conclusions: While the effect of the training on pre-service teachers was small for distinguishing non-social characteristics of autism, the effect of the training was large when it came to autistic students’ emotional and empathic capacities. These findings suggest that an online training can reduce stigma and improve understanding of the emotional and empathic capacities of autistic students.

**417.016** (Poster) How Did the Transition to Online Instruction Impact Neurodivergent Youth? It’s Developmental, My Dear Watson

A. Riccio<sup>1</sup>, J. Herrell<sup>2</sup>, E. Grossman<sup>3</sup>, A. Hurst<sup>4</sup>, B. Rosenberg<sup>5</sup>, C. Ulerio<sup>2</sup> and K. Gillespie-Lynch<sup>6</sup>, (1)Department of Psychology, The Graduate Center, City University of New York (CUNY), New York, NY, (2)Tech Kids Unlimited, Brooklyn, NY, (3)Psychology, The Graduate Center, CUNY, New York, NY, (4)New York University, New York, NY, (5)Technology, Culture, Society, New York University Tandon School of Engineering, Brooklyn, NY, (6)Department of Psychology, College of Staten Island; CUNY Graduate Center, Brooklyn, NY

---

Background: The developmental impacts of the shift to online instruction due to COVID-19 remain largely unknown. Increased self-discipline is required online, which may impact younger learners disproportionately due to the continuing development of executive functioning (EF) abilities (Diamond & Lee, 2011). Autistic people often experience EF difficulties (Hill, 2004), which could hamper online learning. However, some autistic people prefer computer-mediated to in-person communication (Gillespie-Lynch et al., 2014). Indeed, some autistic students describe being happy with the transition online (Reicher, 2020).

Objectives: To examine changes in student-reported and parent-reported learning and social engagement in a summer program for neurodivergent youth from 2019 (in-person) to 2020 (remote instruction).

Methods: Neurodivergent youth (2019  $n=53$ ,  $M_{age}=10.1$ ; 2020  $n=39$ ,  $M_{age}=10.6$ ) and teens (2019  $n=49$ ,  $M_{age}=16.0$ ; 2020  $n=53$ ,  $M_{age}=16.4$ ) were surveyed on the last day of a five-day technology-themed informal educational workshop. Classrooms were split into youth (~7-13 yo) and teens/young adults (~14-21 yo). Parents completed surveys at the end of each summer. Among the 112 youth whose parents disclosed their diagnoses, 76 were autistic and 54 had ADHD (29 also had ASD). Twenty-five students attended in both 2019 and 2020.

Results: Given that some students became teenagers between 2019 and 2020, we included age as a continuous covariate in longitudinal analyses of students who attended both years. Students reported no losses in computer and social learning ( $ps>.21$ ) and increased job skill learning online ( $p=.04$ ). An interaction between age and job skill learning revealed that age was positively correlated with heightened job skill learning online ( $p = .03$ ).

Cross-sectional analyses revealed that autistic students reported greater computer learning relative to peers with other diagnoses ( $p = .04$ ), as well as interactions between ASD and year ( $p = .02$ ), ASD and ADHD ( $p = .04$ ) and ASD, year and age grouping ( $p = .008$ ). The autistic advantage in computer learning was only apparent in-person ( $p < .011$ ) and not online ( $p = .79$ ).

Parent reports of autistic students' engagement with computer activities were correlated with student-reported computer learning ( $p=.02$ ). A mixed analysis of parent-reported computer engagement at the program and school indicated that computer engagement was higher at the program than at school ( $p<.001$ ). An interaction between age and year was observed ( $p=.001$ ). Parent-reported computer engagement at the program was higher for children in-person ( $M=4.6$ ) than online ( $M=3.9$ ;  $p=.002$ ). Parent-reports of teen computer engagement did not differ by year ( $p=.43$ ). An analysis of parent-reported social engagement at the program revealed another interaction between year and age ( $p = .02$ ). Parents reported *heightened* social engagement online relative to in-person for teens ( $p = .03$ ) and no change for children ( $p = .25$ ).

Conclusions: The transition online did not decrease participants' learning and engagement in most domains. Mirroring reports that some neurodivergent people prefer online learning, neurodivergent teenagers may often be more engaged online. Findings contradict the misconception that autistic people are asocial computing machines (Draissma, 2009) by suggesting that an autistic advantage in computer skill learning grows from in-person scaffolding.

**417.017 (Poster)** Jasper in the Classroom: Supporting Peer Engagement for Preschool Students with Autism Spectrum Disorder  
**J. Panganiban'** and C. Kasari<sup>2</sup>, (1)Semel Institute, University of California Los Angeles, Los Angeles, CA, (2)University of California, Los Angeles, Los Angeles, CA

---

Background: As rates of autism spectrum disorder (ASD) continue to rise, school based services may be the most efficient way to provide early intervention. However, many teachers lack the experience or training to address the unique needs of students with ASD. Training teachers to assess and target core challenges of ASD may be a way to help address the specific needs of students with ASD. JASPER is an evidence-based intervention for children with ASD that has shown consistent improvements in engagement and social communication in the school setting for students with ASD (Lawton & Kasari, 2012; Chang, Shire, Shih, Gelfand, & Kasari, 2016; Shire, Chang, Shih, Bracaglia, Kodjoe, & Kasari, 2017). While previous research has focused on implementing JASPER within classroom routines, training teachers to effectively modify existing curriculum with JASPER strategies may be another avenue to provide support for students with ASD.

Objectives: The present study aims to train preschool classroom teachers to modify small group curriculum with JASPER strategies to address two core challenges of students with ASD, engagement and social communication.

Methods: Forty-nine preschool aged students with ASD (mean = 49 months) enrolled in mixed disability classrooms across 12 schools (19 teachers) were recruited for the study. The students, 95% male, represented diverse backgrounds (81% Hispanic or Latinx, 5% African American, 3% Asian, and 11% other/mixed). Schools were randomized to receive training to incorporate JASPER strategies into their existing curriculum or to a control group providing the standard preschool curriculum. Standardized measures of social communication (Early Social Communication Scales; Mundy et al., 1986; Seibert et al., 1982) and cognition (Mullen Scales of Early Learning; Mullen, 1995) were administered at entry and exit. Ten minute small group rotations with the classroom teacher were filmed at entry and exit and coded for student engagement based on the engagement states described by Adamson, Bakeman, and Decker (2004).

Results: Both the treatment and control groups improved in standardized measures of joint attention ( $F(1,40) = 5.53, p = .02$ ), requesting ( $F(1,40) = 8.27, p = .006$ ), expressive language ( $F(1,37) = 20.757, p < 0.001$ ), and receptive language ( $F(1,37) = 21.282, p < 0.001$ ). Furthermore both groups increased overall time engaged during small group rotations ( $F(1,40) = 10.62, p = .002$ ). However, students in the treatment group were more likely to be engaged with peers during small group rotations at exit (Odds Ratio = 2.99, Confidence Interval = 0.161, 2.03). Teachers in the treatment group achieved high fidelity in implementing JASPER strategies when compared to the control group ( $F(1,26) = 18.662, p = .0002$ ), replicating previous work training teachers in JASPER.

Conclusions: Teachers can play an integral role in supporting engagement for students with ASD. Training teachers to incorporate JASPER strategies into their preschool curriculum can help facilitate peer engagement. Peer engagement can be difficult for students with ASD, but appropriate supports from teachers can provide students more opportunities for peer socialization throughout the school day.

**417.018** (Poster) Learning about Neurodiversity at School: Key Concepts for Communicating Neurodiversity to Primary School Children, from the Leans Project Co-Design Process

A. M. Alcorn<sup>1</sup>, S. McGeown<sup>2</sup>, D. Aitken<sup>3</sup>, W. Mandy<sup>4</sup>, F. Murray<sup>5</sup> and S. Fletcher-Watson<sup>1</sup>, (1)Salvesen Mindroom Research Centre, University of Edinburgh, Edinburgh, United Kingdom, (2)Institute for Education, Community and Society, University of Edinburgh, Edinburgh, United Kingdom, (3)Salvesen Mindroom Centre, Edinburgh, United Kingdom, (4)University College London, London, United Kingdom of Great Britain and Northern Ireland, (5)Autistic Mutual Aid Society Edinburgh (AMASE), Edinburgh, United Kingdom

---

**Background:** Around the world, a large proportion of autistic children attend mainstream schools (i.e. schools that are not specialised provision for disabilities). Teachers and peers may have a poor understanding of neurodevelopmental differences in their learning and thinking, which can negatively impact children’s school experiences. Educating broadly about the concepts of *neurodiversity and neurodivergence*, just as curricula may already cover biodiversity and cultural differences, is an opportunity to teach about brain-based differences beyond diagnostic labels. Teaching separately about autism, dyslexia, ADHD etc. misses cross-condition commonalities, and may lack relevance to typically developing children, or neurodivergent children without diagnoses or supports--whether due to resourcing, attitudes, or race- and gender-related diagnostic disparities. The LEANS project proposes whole-class teaching about neurodiversity as an “umbrella” concept, in order to increase pupil and teacher understanding of differences in learning, interaction, and sensory experiences, and to promote inclusive actions and attitudes. Unlike some existing education resources focused on neurodivergence, LEANS is not an intervention for a perceived classroom “problem”, but upskills all pupils and staff members, focusing on capacity for positive future changes.

**Objectives:** Through co-design with educators, identify strategies and concepts needed to teach about neurodiversity as an “umbrella concept” in a way that is accessible and engaging for mainstream primary pupils age 8-11, and their teachers. In this project, “teaching neurodiversity” includes addressing attitudes and actions in the school community, not increased factual knowledge alone.

**Methods:** Neurodiverse teams of researchers (n=7) and experienced educators (n=8) collaborated in seven 90-minute online design workshops to elicit content ideas. These were structured around five main discussion topics: introducing neurodiversity, the classroom, other school activities (e.g. sport, the arts), friendship and social interaction, and applying neurodiversity knowledge.

**Results:** Across workshops and domains, the same concepts consistently re-appeared as essential to explaining neurodiversity and neurodivergence in school, and conveying their relevance to individuals. These included: learning to distinguish ‘needs’ from ‘wants’; understanding and adopting equity-based concepts of fairness, especially where these relate to additional supports/resources at school; and recognising the equal validity of different types of communication, sense-making, and engagement with learning. The team further identified the need to make neurodiversity education distinct from other widespread educational messaging on differences (i.e. “everyone is unique”). Neurodivergence is a *different type of difference*, both in degree and in type, than those with which children may already be familiar.

**Conclusions:** Outputs from the neurodiverse design team emphasise that teaching neurodiversity in schools is not primarily about definitions or facts; it requires attention to a surrounding ‘family’ of concepts. Grasping needs, equity, and validity issues are the necessary groundwork to justify and motivate changes in people’s attitudes and actions. The design process also highlighted the challenge of making neurodiversity information distinct from other difference-focused educational messages.

Resource development is ongoing, plus review by additional educators and community members. LEANS will be evaluated for efficacy in UK primary schools in 2021, focusing on changes in pupil and teachers’ neurodiversity-related knowledge and attitudes. The final resource pack will be available for free in late 2021.

**417.019** (Poster) Loneliness in Relation to Age and Peer Engagement in Children and Adolescents with Autism Spectrum Disorder

M. Dean<sup>1</sup>, W. I. Shih<sup>2</sup>, C. Kasari<sup>2</sup> and F. Orlich<sup>3</sup>, (1)Education, California State University, Channel Islands, Camarillo, CA, (2)University of California, Los Angeles, Los Angeles, CA, (3)Seattle Children's Hospital, Seattle, WA

---

**Background:**

Children and adolescents with Autism Spectrum Disorder (ASD) tend to have fewer social connections and reciprocal friendships compared to typically developing students (Dean, Harwood, & Kasari, 2014; Locke, Ishijima, Kasari, & London, 2010). Within existing relationships, individuals with ASD also report poorer friendship quality (Chamberlain et al, 2007; Kasari et al, 2011; Kasari et al, 2015). These social challenges are associated with increased loneliness, which becomes more pronounced in

adolescence (Humphrey & Lewis, 2008; Locke et al., 2010; Pisula & Łukowska, 2012). Research is needed to examine the emergence of loneliness across a wide age span, and to explore the relationship between loneliness and social engagement at school.

#### Objectives:

The primary objective of this study was to examine the emergence of loneliness in children and adolescents with ASD. A secondary aim sought to examine the relationship between participants' self-report of loneliness and observed engagement states.

#### Methods:

This is a secondary analysis of data that were collected from two large multi-site randomized control trials, in which children and adolescents with ASD participated in social skills interventions across four sites. Data were derived from baseline assessments, which were collected prior to the start of intervention.

Children and adolescents with ASD (N = 199) from elementary, middle, and high school, (6 -19 years;  $M= 10.34$ ,  $SD= 3.52$ ) had a confirmed diagnosis of ASD (ADOS, Lord, Rutter, Dilavore & Risi, 2002), average or above average intelligence ( $IQ \geq 70$ ; Stanford-Binet, Fifth Edition), and were educated in a general education classroom for a minimum of 80% of the school day. Participants were observed two times during unstructured social periods at school (recess/break and lunch) using the Playground/Teen Observation of Peer Engagement (POPE/TOPI; Kasari et al., 2016, Oti et al., 2010). Participants also completed the Loneliness Rating Scale (self-report; Asher, Hymel, & Renshaw, 1984). Correlation and regression analyses were utilized to evaluate the relationship between self-reported loneliness and age, and observer-rated social engagement.

#### Results:

There was a significant positive correlation with age and loneliness such that older children reported higher levels of loneliness ( $r= 0.29$ ,  $p= .001$ ). Similarly, children who were in middle/high schools reported significantly greater loneliness compared to children in the elementary schools ( $\beta= 16.64$ ,  $p= <0.001$ ). There was no association between loneliness and observed joint engagement ( $r= -0.07$ ,  $p= 0.38$ ) or solitary ( $r= 0.06$ ,  $p= 0.46$ ).

#### Conclusions:

The study findings highlight the complexity of loneliness in children and adolescents with ASD. Adolescents with ASD reported significantly greater loneliness compared to children with ASD. Participants who spent a majority of time jointly engaged were just as likely to report feelings of loneliness as participants who spent a majority of time in solitary. These findings suggest that one does not need to be physically alone to feel lonely. Alternatively, some children with ASD appear content with spending a majority of time in solitary. More research is needed to examine possible discrepancies between desired and actual relationships.

#### **417.020** (Poster) Measurements of Spontaneous Communication Initiations in Children with Autism in Preschool to Third Grade Classrooms

**S. L. Birkeneder**<sup>1</sup> and **N. Sparapani**<sup>2</sup>; (1)School of Education, University of California, Davis, Davis, CA, (2)UC Davis MIND Institute, University of California, Davis, Sacramento, CA

---

#### Background:

We have made great strides in understanding and measuring communication in young children with autism in clinical settings. Yet, there is still much to learn about how and why elementary-age children with autism spontaneously communicate within classrooms and the developmental features that are associated with the frequency and function of their communication initiations.

#### Objectives:

We examine the frequency and function of spontaneous communication initiations ("communication initiations") within a sample of children with autism during early to middle childhood, as they engage with their teachers and peers during structured and unstructured classroom activities. We investigate the latent structure of communication initiations within the classroom and explore how children's characteristics (i.e., autism severity) influence their communication initiations.

#### Methods:

This study used archival classroom video observations (R324130350) from the beginning of the school year, in which communication initiations were coded as part of a larger project evaluating classroom active engagement (Sparapani et al., in preparation). The videos captured times when educators (teachers and paraprofessionals) and children worked together during 1 to 1, whole group, or small group contexts. Children (N=113; Mage=6.16) ranged from preschool to 3rd grade from 63 schools and 17 districts in CA (80% special education). Nine communicative functions were coded and analyzed using count and proportion metrics.

Results:

(Preliminary)

For a statistical summary of all initiating communication functions, see Table 1 below.

We observed high proportions of zeros for most of the communication functions, (43% –91%), and therefore dichotomized the variables for analysis to prevent model fitting errors. Guided by the literature, we specified and identified two models as well as a unidimensional construct to represent the most parsimonious structure of communication initiations. We evaluated the absolute and relative fit of the models using confirmatory factor analysis with the WLSMV estimator and Mplus software. We trimmed “protesting” from the model due to its very low occurrence. The unidimensional model evidenced good fit overall and the best fit to the data (RMSEA = 0.068 [0.018–0.107]; CFI = 0.950;  $\chi^2/df = 1.53$ ). All of the factor loadings were significantly different from zero ( $p < 0.05$ ).

We used structural equation modeling to examine the unique contribution of children’s age, cognitive and adaptive abilities, and severity of autism symptoms to the communication latent factor. Children’s adaptive behavior explained a significant amount of variance in children’s communication initiations ( $\beta = -0.31$ ;  $p < 0.05$ ) over and above its shared covariance with the other predictors. Age was approaching significance (0.08).

Conclusions:

This study provides a descriptive analysis of how and why school-aged children with autism initiate communication and the developmental characteristics that influence their communication. These data provide preliminary evidence for a quantitative measure of communication in the classroom. A unidimensional model of communication initiations may reflect a low occurrence rate of specific communicative functions, or it might suggest that children’s communication is more nuanced in older years.

**417.021** (Poster) Outcomes of High-Quality Training on Teacher Implementation of Ebps for ASD

*M. Melgarejo<sup>1</sup>, A. Nahmias<sup>2</sup>, T. Holt<sup>3</sup>, J. Suhrheinrich<sup>4</sup>, P. Schetter<sup>3</sup> and A. C. Stahmer<sup>1</sup>, (1)San Diego State University, San Diego, CA, (2)Stony Brook University School of Medicine, Stony Brook, NY, (3)UC Davis, Sacramento, CA, (4)UC Davis MIND Institute, University of California, Davis, Sacramento, CA*

---

Background:

Children with autism spectrum disorder (ASD) receive a majority of services in schools. Although evidence-based practices (EBPs) for ASD exist, the research on teacher implementation of EBPs in schools indicates low usage and poor fidelity. In response the California Autism Professional Training and Information Network (CAPTAIN) was created to scale-up the use of EBPs for ASD. CAPTAIN is a statewide cross-agency collaboration with over 400 members representing school and community agencies, including 97% of Special Education Local Plan Areas in the state. Using a train-the-trainer model, CAPTAIN provides training to members annually and supports regional plans for training and implementation. Members are required to provide high quality training on ASD and EBPs as well as provide implementation coaching to at least three providers or programs annually.

Objectives:

To examine the effects of receiving high quality training and coaching from a CAPTAIN member on provider EBP knowledge and implementation outcomes of EBP fidelity and classroom quality.

Methods:

A statewide survey was sent online to providers that asked about their EBP training experiences and EBP use for the 2018-2019 school year. Respondents included 1,582 special educators, paraeducators, general educators, and direct service providers from across California. Of these 1,582 respondents, 330 had received EBP training from a CAPTAIN member. An additional online survey assessing EBP knowledge, self-rated EBP fidelity, and classroom quality was sent to 253 teachers, both to those who had received training by a CAPTAIN member (n = 60) and those who had not (n=193).

### *Measures*

**EBP Knowledge and Fidelity.** For each EBP used, teachers completed a knowledge assessment and implementation checklist from the NPDC-ASD.

**Classroom Quality.** Teachers completed the self-report version of the Autism Program Environmental Rating Scale (APERS; Odom et al., 2018), which is designed to assess the overall quality of program environments for students with ASD.

**EBP Attitude.** Respondents completed the Evidence-Based Practice Attitude Scale (EBPAS; Aarons, 2004), which measures general attitudes toward adoption of EBPs.

### *Data Analysis*

Data analysis using ANOVA, GLM, GEE, and Chi square indicated positive outcomes for providers that received training by CAPTAIN members.

### *Results:*

CAPTAIN trained providers had significantly higher EBP knowledge, reported feeling more competent implementing EBPs, more knowledgeable explaining their primary EBP, and reported higher levels of EBP openness than providers not trained by CAPTAIN. Teachers were twice as likely to self-report above 80% fidelity on EBPs if trained on the EBP by CAPTAIN than providers not trained at a trend level. Trained providers also reported using all of the components of their primary EBP to a greater extent, used their primary EBP with “most or all students” with higher frequency and reported collecting fidelity of implementation data and student data. Finally, trained teachers reported significantly higher classroom quality compared to teachers who were not trained.

### *Conclusions:*

These preliminary findings show promise for the efficacy of the CAPTAIN model to increase dissemination and effective implementation of EBP at the classroom level. Future research will involve objective assessment of teacher and student outcomes that result from CAPTAIN participation.

**417.022 (Poster)** Person-Centered IEP Transition Planning for Students with Autism Spectrum Disorders: What Are We Still Missing?

**C. E. Lee<sup>1</sup>** and **J. G. Kim<sup>2</sup>**; (1)Vanderbilt University Medical Center, Nashville, TN, (2)Georgia Institute of Technology, Atlanta, GA

---

**Background:** After exiting the school system, students with autism spectrum disorder (ASD) face challenges in post-school outcomes including low rates of employment, independent living, and post-secondary education. Engaging students and their families in transition planning early on has been identified as a way to improve post-school outcomes, which is underscored by Individuals with Disabilities Education Act (IDEA) mandates. Reauthorizations to the IDEA have also emphasized the person-centered approach, including the voices of students with ASD in transition planning. Despite such mandated policies and guidelines, person-centered transition practices are not uniformly implemented. The present study utilized a qualitative approach to investigate barriers and facilitators to the implementation of person-centered transition planning for students with ASD.

**Objectives:** The primary objective of the present study was to better understand barriers and facilitators of person-centered transition planning practices for students with ASD, from the perspective of multiple stakeholders.

**Methods:** We conducted qualitative, in-depth interviews with 22 stakeholders including four youth with ASD, ten parents of youth with ASD, and eight professionals (e.g., special education teacher, transition specialist). The average ages were 17.1 years

( $SD = 7.2$ ) for youth with ASD, 50 years ( $SD = 7.6$ ) for parents, and 51 years ( $SD = 14.5$ ) for professionals. Only three participants were male including one youth with ASD and two professionals. The semi-structured interviews ranged from 60-90 minutes. Using the interview transcripts, we coded data line by line using constant comparative analysis and emergent coding.

Results: Analysis of interview transcripts yielded 40 codes, and five separate themes. We used a combined Self-Determination Theory and Ecological Systems Theory to interpret the barriers and facilitators of person-centered transition planning practices (see Figure 1). First, the characteristics of youth with ASD influenced their involvement in person-centered transition planning such as self-determined motivation, balance between the dream and the reality, goal ownership, passive or active role of students, anxiety, and the severity of autism. Second, with respect to microsystem (e.g., parents and teachers), we found that person-centered transition planning was well-implemented when parents advocated for including students with ASD in the process and when teachers implemented appropriate data-driven assessment and progress monitoring. Third, with respect to mesosystem (e.g., interaction between microsystems), it was critical to have ongoing communication among stakeholders and connections with outside agencies. Lastly, we found that community resources were critical in limiting or promoting person-centered planning outcomes.

Conclusions: Person-centered transition planning practices for students with ASD show inconsistencies and areas needing improvement. Multiple stakeholders could support engaging students with ASD in person-centered transition planning at different levels. As efforts to improve transition services and outcomes continue, it will be important to consider and address the barriers and facilitators described by stakeholders.

**417.023** (Poster) Racial/Ethnic Disproportionality of Autism in Special Education in California  
*P. Luermo, Special Education, San Diego State University, San Diego, CA*

---

Background: Racial/ethnic disproportionality in special education for racial/ethnic minority children is a persistent issue in the field. Special education disproportionality is defined as the degree to which belonging to a given group (e.g., gender, race/ethnicity, or socioeconomic class), affects the probability of being found eligible for special education placement (Cruz & Rodl, 2018). Disproportionality can result in overrepresentation or underrepresentation of certain groups in special education eligibility and placement. While there are established issues of under-identification of Latinx families of children with autism, less is known about the interplay between over-identification and under identification by diverse racial/ethnic groups. In order to examine the over/under identification interplay, we conducted an exploratory analysis of significant disproportionality in special education of students with autism in California.

Objectives: RQ1: What are the characteristics of Local Educational Agencies (LEAs) identified as significant disproportionate in the special education category of autism in California? RQ2: What demographics factors (e.g., race/ethnicity, family income, English proficiency) impact disproportionality in autism?

Methods: To answer RQ1, we obtained data from the California Department of Education (school year 2018-2019) and identified LEAs ( $N=130$ ) with significant disproportionality in various disability categories. Risk ratios were used to calculate the probability of students in a given racial/ethnic group to be identified in a given disability category (i.e. autism) within the LEA. We used descriptive statistics (e.g., Mean, standard deviation) to analyze each LEA with overrepresentation of students in the special education category of autism (a risk ratio of 3.0 or more). Lastly, we conducted a comparative analysis of risk ratios for each of the racial/ethnic groups represented in the final sample of disproportionate districts in autism.

Results: From the initial 130 LEAs/districts, a total of 7 LEAs ( $N=7$ ) were identified as significant disproportionate for the over-identification of any given racial/ethnic group in with autism. Specifically, all the LEAs were identified as significant disproportionate for the over-identification of White students with autism. Hence, White students had a risk ratio of 3.00 or more in each of the 7 LEAs. This means that White students were 3 times more likely to be placed in the special education category of autism than the rest of the other racial/ethnic groups within the LEA. Preliminary analysis show that the 7 disproportionate districts are strikingly similar across 3 main demographic factors in each LEA (racial/ethnic distribution, percentage of economically disadvantaged students, and percentage of English Learners). Importantly, all the disproportionate districts also had an under-identification of Latinx students with autism.

Conclusions: The under-identification of Latinx students may result in the overrepresentation of White students with autism. This study sheds light into the interplay of over-identification of White students with autism and the under identification of Latinx students with autism. Additional data collection is under way to examine the experiences of parents of children with autism as they access an autism eligibility and services in the 7 disproportionate LEAs.

**417.025 (Poster)** Reviewing the Evidence for Using Video-Based Intervention to Teach Employable Skills to Transition-Age Students with ASD

**B. B. Chen** and **G. Yakubova**, *University of Maryland, College Park, MD*

---

**Background:** For youth with autism spectrum disorder (ASD), finding employment after high school, particularly employment that offers hours and wages comparable to that of their neurotypical peers, is often difficult. One aspect contributing to this employment gap is students' lack of applicable vocational skills. Video-based intervention (VBI), an evidence-based practice (EBP) for teaching skills to students with ASD, may be one method to bridge this skills gap. However, given that much of the VBI literature focuses on daily living skills, rather than marketable vocational skills (i.e., a skill that one could realistically receive pay for performing), the effectiveness of VBI to teach employable skills requires further evaluation.

**Objectives:** The purpose of this study was to empirically evaluate the effectiveness of VBI to teach marketable vocational skills to transition age (14-21) youth with ASD through a synthesis of the literature. Further, we aimed to analyze (1) the effectiveness of particular facets of the VBI used, (2) the types of skills taught, (3) the characteristics of students for whom VBI was effective, and (4) the degree to which VBI has been implemented in authentic contexts. To date, there has yet to be a systematic review on this topic that goes beyond descriptive measures of the literature base.

**Methods:** A systematic search of the literature yielded 23 studies that met the inclusion criteria. Studies were assessed and coded for content, participant demographics, What Works Clearinghouse (WWC) design standards, and quality indicators (Horner et al., 2005; Gersten et al., 2005). Studies that met design standards with or without reservations were analyzed using visual analysis, success estimates, and Tau-U effect sizes.

**Results:** Overall, VBI was found to be effective in teaching marketable vocational skills to students with ASD. Of the 19 studies that met standards with or without reservations, 16 studies had success estimates of 100%. In addition, 14 studies indicated strong effects (Tau-U  $\geq$  0.93), four had medium-to-high effects (Tau-U=0.66-0.92), and only one had weak effects (Tau-U<0.66). Although the use of video modeling and video prompting was relatively equal across the total sample, studies that demonstrated strong effects were more likely to use video prompting. The use of supplemental supports such as error correction, were used among 39% of studies and did not appear to be more or less effective than studies that did not use them. Skills taught with VBI ranged across eight major content areas, with the most common being clerical and food preparation. The synthesis included 59 participants with ASD, with a mean age of 17.1 years old, and were primarily male (94%) with co-occurring intellectual disability (ID; 61%). Other demographic characteristics were rarely reported. Only 35% of studies were implemented in authentic settings, and only 26% by an authentic agent.

**Conclusions:** The findings indicate that VBI is effective in teaching employable skills to transition-age youth with ASD and could feasibly be used to address the postsecondary employment gap. However, further diversification in terms of participant demographics, types of skills, and authentic implementation contexts is needed.

**417.026 (Poster)** Specialized Training in Autism Spectrum Disorder: Characteristics of Law Enforcement Officers Who Seek Training to De-Escalate Emergency Situations

**L. Gardner<sup>1</sup>** and **J. M. Campbell<sup>2</sup>**: (1)*Johns Hopkins All Children's Hospital, St. Petersburg, FL*, (2)*Psychology, Western Carolina University, Cullowhee, NC*

---

**Background:** As the incidence rates of Autism Spectrum Disorder (ASD) continue to increase in children and adults, so do interactions between Autistic persons and law enforcement. Lack of training and knowledge of autism may result in LEOs misinterpreting ASD specific behavior as noncompliant, threatening, disorderly, or suspicious. A number of highly publicized negative encounters between Autistic individuals and LEOs have resulted in several states requiring formalized training for LEOs in ASD. However, little is known regarding the content or impact of these training programs. There is currently no empirical literature examining personal characteristics of officers who self-select to participate in specialized in-person training in autism spectrum disorder.

**Objectives:** The primary author created a bi-monthly training program for LEOs that prepares officers to respond to calls involving individuals with ASD. The present study included 234 LEOs who completed a 4-8 hour autism-specific training due to personal interest, direction from their employer, or a combination thereof. The purpose of the present study was to determine differences in personal and professional characteristics of LEOs who elected to seek specialized training in autism.

**Methods:** Two-hundred and thirty-four LEOs attended nine separate training sessions. LEOs were 63.4% ( $n = 151$ ) male with a mean age of 40.95 years ( $SD = 10.5$ ) and 13.48 years of law enforcement experience ( $SD = 9.2$ ). A total of 145 (61.97%) LEOs indicated attending the training per employer requirements, and 38.03% ( $n = 89$ ) reported attending due to personal interest. To

evaluate LEOs' prior experiences, participants completed a questionnaire that included relationships with individuals with ASD and professional experience.

Results: Findings revealed that 50.6% ( $n = 45$ ) of LEOs who self-selected to participate in the training reported a personal relationship with someone with autism, which is greater than LEOs who were required to attend the training 23.6% ( $n = 35$ ),  $\chi^2(1, N = 234) = 18.00, p < .001$ . LEOs were equally likely to have completed autism-specific,  $\chi^2(1, N = 234) = 0.34, p = .56$ , and Crisis Intervention Training,  $\chi^2(1, N = 234) = 0.43, p = .84$ , regardless of whether they were required to complete training or not. Gender was not related to LEO self-selection,  $\chi^2(1, N = 234) = 0.07, p = .79$ .

Conclusions: The results of the present study compared differences in personal characteristics of officers who chose to attend specialized in-person training in autism spectrum disorder versus those who attended per requirements of their employer. Overall, LEO characteristics including gender, years of law enforcement experience, previous autism training, or previous training in crisis de-escalation did not differ between the two groups. However, having a personal relationship with someone with autism was reported at much higher rates among LEOs who self-selected to attend the training.

**417.027 (Poster)** Supporting Autistic Adults in Postsecondary Settings: A Systematic Review of Peer Mentorship Programs  
**R. M. Besney<sup>1</sup>, K. Duerksen<sup>2</sup>, M. Ames<sup>2</sup> and C. McMorris<sup>3</sup>,** (1)Werklund School of Education, University of Calgary, Calgary, AB, Canada, (2)Department of Psychology, University of Victoria, Victoria, BC, Canada, (3)Department of Paediatrics, University of Calgary, Calgary, AB, Canada

---

Background: There is an increasing number of autistic individuals attending college or university; however, graduation rates remain low, with 39% of autistic students matriculating within 8 years of study, versus 60% of the total student populace matriculating within 6 years. This is despite autistic students having strengths which lend themselves to success in academia, such as memory skills, detail orientation, and passionate interests. The failure of post-secondary institutions to support the individual needs of these students is thought to be one contributing factor. For example, it is often reported that adjustment to dormitory living, learning in larger settings, and personnel hierarchies (i.e., counselors, teaching assistants, professors) pose as challenges. As well, difficulties with social relationship formation have been cited. A promising approach is the emergence of peer mentorship programs designed to provide individualized, one-on-one support for autistic post-secondary students. However, there is no literature to date which has systematically examined such programs.

Objectives: A systematic review was conducted that described existing peer mentorship programs for autistic students in post-secondary education, as well as their effectiveness.

Methods: A search of five databases (PsycINFO, Medline, Embase, Scopus, and Web of Science) identified nine unique programs that were evaluated in 11 peer-reviewed articles.

Results: Programs existed in predominantly White, English speaking countries (United Kingdom, Canada, United States, and Australia). Most programs (78%) involved both individual peer mentor meetings and group meetings. Some of the latter were social in nature, whereas others were skills/strategy based. Programs reported various positive outcomes, some of which included social skills, academic performance, and a sense of belonging. A number of themes were identified in studies that conducted qualitative analyses, with overarching themes suggesting the importance of the peer-mentor relationship. Notably, the evidence for these programs was mostly qualitative, small in sample size, and there was considerable heterogeneity in the design, delivery, and goals of these programs, as well as the evaluation methodology used.

Conclusions: Peer mentorship programs are a promising means of addressing the needs gap of autistic students, with a variety of positive and diverse outcomes reported. This is significant considering the potential to improve post-secondary experience and increase the likelihood of graduation. Making statements about the overall effectiveness of peer mentorship programs is challenging due to heterogeneous program design and goals, however. Further research is needed to quantify program effectiveness and conduct program comparisons.

**417.028 (Poster)** Teacher Experiences of Implementing Ideas Maker Program, a Research-Based Inclusive STEM Curriculum in Public Middle Schools  
**K. Murthi<sup>1</sup>, Y. L. Chen<sup>1</sup>, K. P. Koenig<sup>1</sup>, W. Martin<sup>2</sup>, R. Vidiksis<sup>3</sup> and A. Riccio<sup>4</sup>,** (1)Occupational Therapy, New York University, New York, NY, (2)Education Development Center, New York, NY, (3)EDC, New York, NY, (4)Department of Psychology, The Graduate Center, City University of New York (CUNY), New York, NY

---

Background: Students on the spectrum have strengths well-suited for STEM careers (e.g., cognitive traits of systemizing thinking and attention to detail) and present high postsecondary enrollment rates in STEM-related majors. However, barriers to their

success in STEM workplaces persist, including their challenges in social communication and executive functioning, as well as a lack of autism-inclusive STEM education programs. To support autistic secondary students' STEM competency in inclusive public middle schools, we developed an inclusive engineering design program called Inventing, Designing, and Engineering for All Students (IDEAS). The IDEAS program has demonstrated positive effects on STEM competency and social interaction. Understanding the experiences of school teachers leading the program would provide valuable insights on program implementation and improvement.

**Objectives:** To present teachers' perceptions and experiences running Maker clubs, their perception of its advantages and disadvantages, and their suggestions and action plan to improve the club curriculum.

**Methods:** In this qualitative study, we interviewed 10 teachers leading the program at three public middle schools in a large, urban area over two school years. Two focus groups with teachers across schools were conducted at the midpoint of the program to identify teachers' challenges and barriers of program implementation. Six group interviews were conducted with teachers at each school at the end of each school year to facilitate conversations regarding school-specific program experiences and issues. We further collected teachers' program implementation logs (n=25) and field observation notes (n=149) at the three schools. Thematic analysis was conducted to explore teacher experiences.

**Results:** Thematic analysis revealed that teachers valued the flexibility of this program, which enabled them to adjust the clubs to their schedule and learning needs. They enjoyed co-learning and co-making with their students in their new role as facilitators and cheerleaders rather than adopting their conventional role as knowledge providers. This propelled students to take charge of their making and designing, thus enabling them to become "expert makers." Furthermore, teachers new to the program appreciated their support from co-leaders as they facilitated these clubs, which enabled them to organize themselves and club sessions better. These clubs' safe and nurturing space equipped them to understand their students' abilities and interests better, and teachers incorporated them effectively in the clubs and sometimes even in the classroom. Many teachers also appreciated how the club space enabled Autistic students to manage their frustration while working, regulate emotions, and socialize organically with peers by connecting over their interests. Teachers attributed the logistical and organizational challenges they faced to the need for more exposure and practice with technology and infrastructural shortcomings. Despite facing these challenges, teachers were eager to learn, open to adopting changes, and collaborating with the research and support teams to overcome the challenges.

**Conclusions:** Involving teachers in the planning and execution of clubs resulted in developing a sustainable environment where clubs were adapted to meet student needs. Since teachers modified the curriculum plans, they felt empowered and included in the process and hence voiced their concerns and ideas to enhance these clubs.

**417.029 (Poster) Teacher-Student Interactions within Mathematics Instructional Contexts in Classrooms Serving Students with Autism**

*N. Sparapani<sup>1</sup>, N. S. Tseng<sup>2</sup>, S. L. Birkeneder<sup>3</sup>, T. S. Wood<sup>4</sup>, A. D. Nunnally<sup>1</sup>, L. Towers<sup>3</sup>, J. Vega Garcia<sup>3</sup> and C. Alexander<sup>5</sup>, (1)UC Davis MIND Institute, University of California, Davis, Sacramento, CA, (2)Teacher Education, University of California, Davis, CA, (3)School of Education, University of California, Davis, Davis, CA, (4)School of Education, University of California, Irvine, Irvine, CA, (5)University of California, Davis, Davis, CA*

---

**Background:** An increasingly robust body of literature identifies teacher-student interactions as a linchpin for student development and learning and an important intervention target for students with typical development and at-risk populations (e.g., Downer et al., 2010). Empirical evidence has documented links between teacher language and student active engagement (Connor et al., 2020) as well as predictive associations between high quality interactions and students' academic and social outcomes (e.g., Burchinal et al., 2008). Few studies have evaluated interactions between students with autism and their teachers.

**Objectives:** To examine how teachers (with a range of knowledge, skills, and practices) teach mathematics lessons, the amount and type of talk they use with students with autism, and how teacher moves (practices and language) relate to student engagement and student-level characteristics (cognitive and adaptive abilities, problem behaviors, autism symptoms).

**Methods:** Participants included 84 preschool–3rd grade students with autism and 65 teachers from general and special education classrooms across 17 districts in CA. We utilized archival video observations (R324A140005) to examine the dynamic relations among teacher instructional “moves” (instructional practices and teacher language) and student active engagement in the context of mathematics instruction. We drew from existing literature for guidance to examine teachers' instructional moves and the *Classroom Measure of Active Engagement* (CMAE; Sparapani et al., 2016) to evaluate student engagement. Trained observers coded the observations using Noldus Observer® Video-Pro Software (XT 13; 2017), achieving and maintaining high interrater agreement using occurrence agreement (>80%).

Results: We report preliminary findings from 58 students (Mage = 6 years) and their teachers (n = 36) across 90 mathematics tasks. Overall, teachers primarily delivered mathematical tasks that required low/medium cognitive demand (recall and procedural tasks), rarely provided students access to learning materials, and predominantly used language to direct student behavior (e.g., sit down; M=19.48 instances, SD = 26.66). Some teachers used very little responsive language while others were very responsive (M=11.96, SD = 17.86). We observed moderate to strong positive associations between teachers' use of responsive language and students' emotion regulation ( $r = 0.71$ ;  $p < 0.01$ ), productivity ( $r = 0.64$ ;  $p < 0.01$ ), and teacher-rated adapted behavior (VABS;  $r = 0.36$ ;  $p = 0.05$ ). Teachers used less responsive language with students who exhibited more problematic behavior (PDDBI;  $r = -0.51$ ;  $p = 0.05$ ). Finally, students' cognitive abilities and presence of problematic behavior predicted the types of tasks teachers provided to them,  $F(29) = 2.29$ ;  $p < 0.05$ .

Conclusions: Findings suggest that the nature of the mathematical task facilitates different learning opportunities for students with autism and also provides insight into salient features of teachers' practices and talk that promote (or hinder) student engagement. These data document variability in teacher language, which is in part, is due to specific student characteristics that influence their talk. The results may provide a means for teachers to reflect on their instructional moves, observing nuances of instructional practices and talk that could improve the learning experiences of students with autism and potentially create change in student learning over time (Van es et al., 2017).

**417.030** (Poster) Teaching Online during a Pandemic: Special Educators' Experiences Working with Parents  
*R. K. Schuck and R. Lambert, Gevirtz Graduate School of Education, University of California, Santa Barbara, Santa Barbara, CA*

---

Background: Due to the COVID-19 pandemic, school buildings worldwide abruptly closed in Spring 2020, forcing a shift to online learning. This task was especially difficult for special educators working with children with autism, as this population often benefits from close relationships with teaching staff, direct/one-on-one instruction, and implementation of behavioral and motivational strategies to improve engagement and encourage routines. Teachers therefore had to work much more closely with parents than ever before, with many relying on parents to implement the curriculum, particularly those with younger students.

Objectives: The current study presents a qualitative investigation into elementary special educators' perspectives on and experiences with working with parents while teaching online due to COVID-19. The study aimed to answer the following questions: 1) How did teachers collaborate with parents during this time? 2) What shifts were there in teacher-parent relationships? 3) What are the implications regarding parent educational involvement going forward?

Methods: Six elementary special educators teaching in autism-only or majority-autism classrooms in districts throughout California participated. (Five additional participants are not reported herein, as their classrooms were not majority-autism.) Three teachers served students with mild-moderate disabilities; the others served students with moderate-severe disabilities. All teachers had self-contained special day classes except for one resource teacher who taught via push-in/pull-out. Four teachers taught at schools with over 60% minority students enrolled. All participants were interviewed via Zoom using a semi-structured interview guide. Interviews lasted 50 minutes on average. Interview transcripts were coded inductively and analyzed using thematic analysis.

Results: Four themes were generated: 1) Strengthening Parent-Teacher Relationships; 2) Importance of Non-Academic Support; 3) Parents as Instructional Partners; and 4) Challenges to the Teacher Role. Regarding relationships, teachers reported both they and parents appeared to have more insight into what the other was experiencing. Teachers often made reference to having a lot of empathy toward students' families and highlighted the importance of good rapport. Teachers also discussed wanting to provide socio-emotional support first and foremost, with many expressing a concern for families' safety and basic needs. Some teachers had issues with parent engagement, and though many parents tried implementing strategies at home, teachers recognized the difficulties of parents assuming the teacher role. Finally, teachers expressed dealing with challenges in terms of accountability (e.g. taking attendance) and providing feedback to parents (e.g. teaching parents to use strategies that foster independence).

Conclusions: While recognizing the challenges inherent in online teaching for students with autism, teachers in this study gained insight into their students' families and emphasized the importance of parent-teacher relationships. They also highlighted ways in which the experience teaching during the COVID-19 pandemic may positively influence their teaching in the future (e.g. by ensuring more consistent communication and emphasizing rapport-building). The findings are not only useful to special educators still navigating teaching during the pandemic but will also be of use to those teaching in-person in the future. Future research must follow-up on these findings to see if this experience changes teachers' perspectives on involving parents in their students' education long-term.

**417.031 (Poster)** Teaching Students on the Autism Spectrum: Joys and Trials

*C. M. Anderson, C. I. Wood, L. N. Franklin and A. O. Iampieri, Health Sciences, Towson University, Towson, MD*

---

**Background:** Children and teenagers with autism spectrum disorder (ASD) spend a great deal of time in school, and many of the interventions they receive are delivered there. How competent, compassionate, and well supported teachers are directly impacts students with ASD and their families. Unfortunately, little is known about these teachers' day-to-day achievements and struggles.

**Objectives:** To explore the experiences of educators serving students with ASD as well as the roles played by colleagues, administrators, students' families, and larger systems.

**Methods:** Qualitative interviews addressing experiences teaching students with ASD in public schools were conducted with 19 educators, including special and general education teachers. Interview transcripts were analyzed using the constant comparative method associated with a grounded theory approach.

**Results:** Four major themes emerged from educators' narratives. **(1) "Getting Autism."** Teachers described a bond with students with ASD and pride in their ability to read and respond to them. *It's knowing that those kids can understand everything I'm saying and to not talk about them like they can't. I've always tried to talk to them...as if they can understand me because they can. And tried really hard to communicate with them in a way that they can communicate.* **(2) Allies and Adversaries.** Teachers sometimes found their best support came from involved parents or fellow professionals – people who helped them problem solve and advocate for their students. At the same time, parental denial or colleagues' misunderstanding of ASD could impede progress. *They want to send him out of the room because he is spinning in the background. "Okay. Is he disturbing anything?" If he needs to spin for a little while to get that movement and he is still...absorbing what the teacher is saying, does he really need to leave? He might need to sit in the back of the classroom and bounce on a ball while he is listening... We have to be creative with how we offer that.* **(3) Tangled Systems.** Teachers worked within bureaucracies governed by federal and state laws, district policies, and institutional beliefs. Resources were scarce; restrictions were plentiful. *The school psychologist is only allowed to say the A-word as, "We are concerned that the student is showing signs of..." Families then must go and find somebody out in the world who can diagnose which takes forever.* **(4) Taking a Toll.** Teachers were spending their days with children on the spectrum who were sometimes aggressive or emotionally labile. This, plus frustrations with larger systems, had physical and psychological consequences. *I have been sent to the hospital. They will hurt you. It's not because they're vicious or horrible people. They just lose control of themselves.*

**Conclusions:** Educators with an understanding of autism contribute a great deal to their students' progress and sense of well-being and acceptance. However, they often struggle with a wider school community that has little understanding of autism, as well as bureaucratic burdens. A deeper understanding of the issues facing these professionals may help school districts and families more effectively support them and their students.

**417.032 (Poster)** The Academic Learning Experiences of Autistic University Students: Challenges with Alexithymia, Cognitive Flexibility, Social Satisfaction and Mental Health

*B. J. Scott, J. J. Millington and S. Anns, University of Sussex, Brighton, United Kingdom*

---

**Background:** The number of autistic university students has increased in recent years; however, the levels of completion and achievement are still lower for these students compared to their peers (Levy & Perry, 2011; Drake, 2014). Completion of a university degree consistently predicts positive adult outcomes and autistic graduates have more favourable long-term prospects in employability and income compared to non-autistic graduates (Hendrickson et al., 2013). As a consequence of the core traits of autism, many of the academic, social, and daily living challenges can be magnified for autistic students, making the transition to higher education challenging (e.g., Hillier et al., 2017; Jackson et al., 2018), particularly in areas such as information processing, flexible planning, and social difficulties (Anderson et al., 2017; Gurbuz et al., 2019; Anderson et al. 2019; Jansen et al. 2018).

**Objectives:** The aim of this study is to examine the academic and social learning experiences of autistic university students and to explore their relationship with cognitive flexibility, alexithymia and mental health diagnosis. Based on the current literature we expect that (i) autistic students will report relatively more challenges with academic learning experiences compared to their neurotypical peers, (ii) they will show relatively more difficulties with cognitive flexibility, alexithymia and mental health, and that (iii) these factors, with the addition of social satisfaction, will predict relatively more learning challenges.

**Methods:** The study was completed by 82 autistic and 107 non-autistic students enrolled in universities in the UK, Ireland, Australia, and New Zealand. Group membership was confirmed by the Social Responsiveness Scale-Second Edition Adult Version (SRS-2; Constantino & Gruber, 2012). An original questionnaire, the Academic Learning Experiences Questionnaire (ALE-Q) was devised, incorporating constructs such as anxiety in group learning, sensory issues in a lecture environment, group

vs. independent study, and memory and organization of learning materials. The Toronto Alexithymia Scale (TAS-20; Bagby, Parker & Taylor, 1994) and the Cognitive Flexibility Scale (CFS; Martin & Rubin, 1995) were added to the measures above in an online Qualtrics survey and a link to the Group Embedded Figures Test (GEFT; Witkin et al., 1971) was provided at the end of the survey.

Results: Preliminary results show significant differences between groups of autistic and non-autistic students' academic learning experiences, with autistic students reporting significantly more challenges on the ALE-Q. Additionally, significant group differences were found on the CFS, the TAS-20 as well as in student social satisfaction. Furthermore, an anxiety diagnosis, low social satisfaction, lower cognitive flexibility and alexithymia significantly predicted more negative academic learning experiences for autistic students. In comparison, only an anxiety diagnosis was a significant predictor of negative academic learning experiences for non-autistic students.

Conclusions: Preliminary findings indicate that autistic students face more challenges around cognitive flexibility, alexithymia, social satisfaction and mental health, and that these are related to their academic learning experience at university. Awareness of these challenges in this growing student subpopulation is vital if universities are to provide individualised, effective support and findings from this study should contribute to informing such support.

**417.033** (*Poster*) The Experiences, Practices, and Needs of General Education Teachers Including Autistic Students in High-Poverty Schools

*K. Oliver<sup>1</sup>, M. Mello<sup>1</sup> and A. C. Stahmer<sup>2</sup>, (1)Psychiatry and Behavioral Sciences, University of California at Davis MIND Institute, Sacramento, CA, (2)UC Davis MIND Institute, University of California, Davis, Sacramento, CA*

---

Background: Inclusion of autistic students in general education classrooms is becoming increasingly common, however, teachers consistently report a lack of adequate knowledge, training, and resources to effectively educate these students. These barriers are compounded in districts where large percentages of students live in poverty, as the quality of instruction tends to be lower, teachers tend to be less qualified, and inclusion of autistic students in general education is often more common. Examining general education teachers' perceptions and experiences with inclusion and their use of evidence-based practices (EBPs) for autistic students is important for providing targeted training and support that fits the context and needs of teachers working in high-poverty schools.

Objectives: Our primary objective is to examine the perceptions, experiences, and use of EBPs for autism by general education teachers including autistic students in high-poverty schools. Research questions include: 1) What are the barriers to inclusion? 2) What are the facilitators to inclusion? 3) What strategies for supporting autistic students do these general education teachers use that are consistent with EBPs for autism?

Methods: This study utilized qualitative focus groups with 27 general education teachers working in schools with high percentages of students receiving free or reduced lunch ( $M = 68.6\%$ ,  $SD = 14.1$ ). Participants taught kindergarten through eighth grade in public and charter schools in 16 counties across California, had an average of 12.8 years ( $SD = 8.9$ ) of teaching experience, and taught at least one autistic student as the lead teacher in a general education classroom. All schools had at least 50% of students receiving free or reduced lunch. Ten focus groups each consisting of 2-5 teachers and at least one facilitator were conducted over Zoom. Groups lasted approximately 45 minutes. Researchers sent teachers fictional student vignettes for discussion, asked questions, and encouraged teachers to share their personal experiences. Thematic analysis was used to analyze focus group data. Approximately 30% of transcripts were co-scored for interobserver reliability (95.9%).

Results: Teachers reported three main barriers to inclusion: 1) characteristics of autistic students (e.g., disruptive behavior, challenges with social communication), 2) simultaneously meeting the needs of peers, and 3) negative responses to autistic student from peers. The primary facilitators of inclusion were: 1) consultation and collaboration with professionals (e.g., special education teacher, school psychologist, etc.), 2) instructional aide for student/classroom support, and 3) diverse range of peer needs (e.g., many other students also had individualized learning needs/supports). The most common strategies teachers used that are consistent with EBPs for autism were: 1) visual supports, 2) reinforcement, and 3) peer-based intervention.

Conclusions: Results can guide how general education teachers working in high-poverty schools are trained and supported. Specifically, barriers need to be addressed, facilitators need to be leveraged, and teacher training could target specific EBPs for autism that other general education teachers are using and perceive positively. This could reduce teacher burden and increase buy-in and sustainment of EBPs. This is a significant addition to the literature on promoting inclusion for autistic students in high-poverty districts.

**417.034 (Poster)** The Need for Educational Screen Time Guidelines for Children with ASD: An Exploratory Study on Clinicians' Perceptions

*Y. Mayer<sup>a</sup>, T. Goldberger<sup>a</sup>, N. Dispirito<sup>a</sup>, M. Cohen Eilig<sup>a</sup>, A. Glodjo<sup>b</sup> and T. Jarus<sup>c</sup>, (1)UBC, Vancouver, BC, Canada, (2)Developmental Pediatrics, Sunny Hill Health Centre at BC Children's Hospital, Vancouver, BC, Canada, (3)Sunny Hill Health Centre at BC Children's Hospital, Vancouver, BC, Canada, (4)UBC, Vancouver, BC, Canada*

---

**Background:** Children with ASD have a higher affinity to screen time and can benefit from technology use, yet there is a lack of literature addressing the appropriate guidelines that outline the safe and effective use of such technology. The lack of understanding may result in misuse of technology and lead to significant impacts on functional, behavioral, and physical outcomes. Much of the research currently focuses on screen time overuse in children with ASD, providing no clear strategies for limiting risk factors while still benefiting from technology use.

**Objectives:** This exploratory study aimed to explore the perceptions of clinicians around screen use for children with ASD, the current barriers to screen management and guidelines, and factors to consider in developing educational guidelines for families and other stakeholders specific to children with ASD.

**Methods:** Participants in this exploratory qualitative study were fifteen clinicians working with children with ASD for at least five years; twelve of the clinicians had the experience of 10 years and up. The participants consisted of four occupational therapists (OT), six speech language pathologists (SLP), four behavioral analysts (BA), and one participant who was a behavioral interventionist (BI) and an education assistant (EA). The participants were invited to participate in semi-structured in-depth focus groups or individual interviews to gather information about their perspectives on their clients' screen-use and their roles in supporting families of children with ASD with screen-time management. A summative content analysis ( was implemented to summarize the data. This type of analysis allowed for interpretation of the content in a qualitative approach based on quantitative data (Hsieh & Shannon, 2005). The summative content analysis allowed for meaning interpretation, as well as an exploration of the frequency of content, which enabled a stronger understanding of which clinical concerns appeared to be the most imperative.

**Results:** Four main themes emerged from the data: (A) There are existing barriers to managing screen time, including lack of knowledge and awareness of parents and stakeholders; lack of advocacy for more evidence-based interventions for screen time use among children with ASD; and Challenges observed in implementing screen-management strategies. (B) Factors impacting screen use and addiction including individual characteristics and profile; environmental factors; behavioral Factors and the nature of Screen Use (C) Clinical considerations and recommendations for screen time management including human-based activities for healthy development; strategies for managing screen time; meeting the needs of the family; the need to base decisions on reliable sources of information. (D) The nature of the ASD screen time guidelines and recommendations for their future development.

**Conclusions:** These findings inform the understanding of current challenges that clinicians face when supporting families with managing screen time of children with ASD and clinicians' recommendations for developing guidelines. The findings also point out the current barriers and opportunities to create a clear, comprehensive set of educational guidelines.

**417.036 (Poster)** Understanding the Impact of the Covid-19 Pandemic on the Education of Autistic School Age Children and Their Families

*D. May<sup>a</sup>, I. Dale<sup>b</sup> and H. Judge<sup>c</sup>, (1)National Autistic Society, London, United Kingdom of Great Britain and Northern Ireland, (2)The National Autistic Society, Sheffield, United Kingdom, (3)National Autistic Society, London, United Kingdom*

---

**Background:**

Research on the experiences of U.K parents and carers of autistic children and young people during lockdown due to the Covid-19 pandemic, has shown that 'many families felt let down by the government and had to face lockdown tackling new struggles, often with significantly reduced support' (G Pavlopoulou, R Wood, C Papadopoulos – 2020)

A national autism charity conducted a survey to understand the impact of the pandemic on autistic people and their families, including the effect on the education of autistic school age children during this challenging time.

**Objectives:**

The aim of the survey was to understand the impact of the pandemic on its audiences of autistic people and families so better information, advice and support could be developed by this charity in partnership with a national mental health charity.

## Methods:

An online survey was conducted across the U.K and co-designed with autistic people and families. It was promoted across a number of channels between June and July 2020. The survey focused on the impact of the COVID-19 pandemic and was completed by 4232 respondents including 1623 parents of school aged autistic children.

**Results:** The autistic children whose parents responded to the survey were educated in a range of settings, although as would be expected, the majority were in mainstream schools. While there were some differences by type of setting, the stark reality is that overall, seven in ten parents said that during lockdown, their child had difficulty understanding or completing school work and around half said their child's academic progress suffered.

Many parents also said that having to support their children during home schooling increased their stress levels, particularly among those who were also working. While for a minority of autistic children, it was a relief to stay at home as it reduced social anxiety, for some parents the lack of contact or support with school staff, particularly in mainstream schools, further added to daily struggle of home schooling.

## Conclusions:

The lockdown due to the Covid-19 pandemic and resulting school closures in spring and summer 2020 had a significant impact on the educational experiences of school children. Autistic children who often receive extra support while at school were particularly affected due to this support not being available to help them to complete their work at home during lockdown. Consequently, some children may have now fallen behind in their education. The necessary restrictions also negatively impacted the mental health of many adults and children, among the general population, while a higher than average proportion of the autistic population already have co-existing mental health difficulties. A survey of families of disabled children during lockdown also found that the majority (70-80%) reported worsening emotional and mental health for both their children and themselves (Disabled Children's Partnership: 2020).

**417.037 (Poster)** Using Parent-Created and Parent-Implemented Video Prompting to Promote the Acquisition of Daily Living Skills for an Adolescent with ASD

*G. Yakubova and B. B. Chen, University of Maryland, College Park, MD*

---

**Background:** Developing the skills to live independently in adulthood is a major goal for any young adult transitioning out of high school, but may be a particular point of focus for those with autism spectrum disorder (ASD), who often struggle to complete daily living tasks independently. Given that parents are often the most knowledgeable about their child's performance and goals related to daily living tasks, it is worthwhile to train parents to create and implement their own customizable, evidence-based intervention, such as video prompting (VP), to teach their child these tasks.

**Objectives:** The purpose of this study was to evaluate the effects of a parent-created and parent-implemented VP intervention with error correction on their child's independent completion of three daily living tasks.

**Methods:** A multiple-probe across tasks design of single-case research design (SCRD) consisting of baseline, intervention, and maintenance phases, was used to evaluate the effects of a parent-created and implemented VP intervention on the independent completion of three daily living tasks selected by the parent (confirming an appointment, flossing, and frying an egg). The parent of a 14-year-old with ASD attended a one-time training, where she learned how to select three relevant and complex daily living tasks, task analyze, record her modeling of the task, create, edit, and narrate VP clips, and implement study procedures, including error correction using a system of least prompt (SLP). Following the training, the parent created the VP clips and implemented the multiple-baseline design with her child at home, recording the sessions to send to the research team for data collection and ongoing feedback. Task completion was scored by the percent of task analysis steps completed correctly and independently per session. Social validity and fidelity of the parent's implementation were also collected.

**Results:** The child improved in his ability to complete all tasks independently with greater accuracy compared to baseline, e.g., confirming an appointment task (31% during baseline to 92-100% range during intervention), flossing (13-20% during baseline to 67-100% during intervention), and frying an egg (6-13% during baseline to 87-100% during intervention). The child maintained the acquired skills at a one-week follow-up. The parent implemented study procedures with high fidelity across phases and tasks (mean scores ranging 88-100%). The weighted average Tau-U demonstrated a strong effect between baseline and intervention and baseline and follow-up, Tau-U= 1.0, 90% CI [0.631, 1].

**Conclusions:** VP, which is an evidence-based practice that can be easily created and accessed using everyday technology, can help a person with ASD complete daily living tasks in a home setting and increase independent functioning in daily life. The findings of the current study offer implications for future research and practice on training parents on the use of evidence-based practices (video prompting and system of least prompts) to support their child's acquisition of daily living skills.

**417.038 (Poster) Varying Perspectives: Teachers & Parents on the Planning for School Transitions**

*F. A. Castellon<sup>1</sup>, N. Libster<sup>1</sup>, M. Tafolla Magana<sup>1</sup>, J. Yang<sup>2</sup> and S. Seese<sup>1</sup>, (1)University of California, Los Angeles, Los Angeles, CA, (2)Department of Psychiatry and Biobehavioral Sciences, UCLA, Los Angeles, CA*

---

**Background:** Students with autism spectrum disorders (ASD) often have difficulty with transitions, including school-level transitions. Major school-level transitions may increase the risk of reduction in school-based services and regression of both academic and social/emotional development progress (Nuske et al., 2019). Therefore, it is important for teachers and parents to communicate and prepare for their students' school-level transitions. Multi-informant approaches to assessment are increasingly important in capturing behaviors across contexts (e.g., home and school; De Los Reyes, 2004). For students with ASD, informant discrepancies between parent and teachers are frequently cited (Lopata et al., 2016). This could be identified as a risk factor for unsuccessful school transitions especially for students from Title 1 schools, where communication and resources are often limited for parents and teachers.

**Objectives:** Compare parent and teacher reports of satisfaction with planning transitions for students with ASD from Title 1 schools, and examine differences in satisfaction between parents and teachers of kindergarten students versus elementary school students.

**Methods:** This study utilized baseline data from a larger randomized control trial (in preparation) which examined the effects of a parent-based intervention designed to improve school-level transitions for children with ASD. A total of 45 children with ASD had both parents and teachers complete the Transition Evaluation Questionnaire (TEQ). The TEQ measures parent and teacher satisfaction with planning for the child's transition between the current and future school. Seven items were rated on a 5-point Likert scale and summed to create a total score (higher scores indicated greater satisfaction). A correlation test was implemented to measure the correlation between the parent-report and teacher-report total scores. In addition, independent samples t-tests were conducted to investigate differences in parent and teacher TEQ scores between kindergarten students transitioning to elementary school (n=23) and elementary students transitioning to middle school (n=19).

**Results:** Parent-report total scores (M = 17.52, SD = 6.43) and teacher-report total scores (M = 17.67, SD = 6.55) on the Pre-TEQ were not significantly correlated,  $r(43) = -0.01$ ,  $p = 0.92$ . In addition, both parents and teachers of kindergarten students were more satisfied with transition planning than parents and teachers of elementary students. The mean parent-report total score for kindergarten students (M = 19.43, SD = 7.09) was significantly higher than that of elementary students (M = 16.47, SD = 4.15),  $t(45) = -18.42$ ,  $p < .001$ . The mean teacher-report total score for kindergarten students (M = 17.91, SD = 6.19) was also significantly higher than that of elementary students (M = 17.47, SD = 7.55),  $t(45) = -16.54$ ,  $p < .001$ .

**Conclusions:** Parent and teacher report discrepancies remain an issue for school-based research amongst children with ASD. Results suggest that parent and teacher reports regarding satisfaction with school transition planning also differ. Moreover, parent and teacher satisfaction with planning transitions was significantly lower for elementary students compared to kindergarten students. Overall, these findings have implications for future interventions that target communication between parents and teachers to help school transitions for students. Additionally, more support may be necessary for higher school-level transitions.
