Our work did not indicate an overall mixture effect of prenatal intake of food groups on child SRS scores. However, prenatal intake of red meat demonstrated a positive association and intake of dark leafy greens demonstrated a negative association with child SRS scores. Given the support for a role of prenatal inflammation in neurodevelopment, it is possible that pro- and anti-inflammatory effects of these foods, respectively, could serve as an explanation for these findings, which should be investigated further.

**410.061** (Poster) Additive or Interactive Associations of Eczema with Genotypes of GST Genes (GSTM1, GSTP1 and GSTT1) in Relation to ASD and ASD Severity in Jamaican Children

**S. Saroukhani<sup>1,2</sup>, M. E. Samms-Vaughan<sup>3</sup>, J. Bressler<sup>1,4</sup>, M. Lee<sup>5,6</sup>, C. E. Byrd-Williams<sup>7</sup>, M. Hessabi<sup>2</sup>, M. L. Grove<sup>1,4</sup>, S. Shakespeare-Pellington<sup>3</sup>, K. A. Loveland<sup>8</sup> and M. H. Rahbar<sup>1,2,9</sup>,**

Simmons Comprehensive Cancer Center, University of Texas Southwestern Medical Center, Dallas, TX, (7)Health Promotion & Behavioral Sciences, School of Public Health, The University of Texas Health Science Center at Houston, Austin, TX, (8)Louis A. Faillace, MD, Department of Psychiatry and Behavioral Sciences, McGovern Medical

**Background:** Autism Spectrum Disorder (ASD) is a neurodevelopmental disorder characterized by impaired social and communication skills, and repetitive, stereotyped behavior. There is evidence of increasing comorbidity of eczema with ASD. Polymorphisms in glutathione S-transferase (GST) genes can influence susceptibility to increased oxidative stress, which is a possible underlying mechanism for both eczema and ASD.

**Objectives:** To investigate additive or interactive associations of eczema, with three GST genes in relation to ASD and ASD severity in Jamaican children.

**Methods:** Using data from 344 pairs of age ( $\pm 6$  months) and sex-matched ASD cases and typically developing (TD) controls ( $n=688$ ), we assessed additive and interactive associations of eczema with polymorphisms in three GST genes (*GSTM1*, *GSTP1* and *GSTT1*) in relation to ASD, based on conditional logistic regression models. Using data from ( $n= 344$ ) ASD cases, we used General Linear Models to assess the association of eczema, and its possible interaction with the GST genes in relation to ASD severity as measured by Autism Diagnostic Observation Schedule-Second Edition (ADOS-2) standardized total, as well as the Social Affect (SA) and Restricted and Repetitive Behaviors (RRB) domains specific comparison scores (CSs).

**Results:** Most ASD cases (71.8%) and TD controls (74.4%) were 48 months or older and 83% of both groups were male. After adjusting for child's age and history of breastfeeding in an additive model, eczema was not significantly associated with either ASD [Matched Odds ratio (MOR) and 95% Confidence Intervals (CI): 1.0 (0.7, 1.4),  $P=0.96$ ] or ASD severity (all  $P > 0.27$ ). However, in a recessive genetic model for *GSTP1*, we found a significant interaction between eczema and *GSTP1* in relation to ASD ( $P = 0.03$ ). Among children with Val/Val genotype the odds of eczema in ASD cases was 1.94 that of TD controls [adjusted MOR (95% CI) = 1.94 (0.97, 3.89),  $P = 0.06$ ], while there was no significant association between eczema and ASD among children with Ile/Ile or Ile/Val genotypes [adjusted MOR (95% CI) = 0.85 (0.60, 1.20),  $P = 0.35$ ]. We also identified a marginally significant interaction between eczema and *GSTM1* in relation to ASD severity after adjusting for aforementioned covariates ( $P = 0.09$ ). Specifically, among ASD cases with *GSTM1* DD genotype, those with eczema had a marginally significant higher mean of ADOS-2 SA domain CS than those without eczema (7.3 vs. 6.8,  $P = 0.08$ ), whereas, there was no significant association between eczema and ADOS-2 SA domain CS among ASD cases with I/I or I/D genotype (adjusted mean in ASD cases with and without eczema = 7.2 vs. 7.3,  $P = 0.67$ ).

**Conclusions:** Our findings suggest no additive associations between eczema and ASD or ASD severity. However, we found an interactive association of eczema with *GSTP1* in relation to ASD, as well as a marginally significant interactive association of eczema with *GSTM1* in relation to ASD severity as measured by ADOS-2 SA domain CS. These findings are consistent with the role for GST genes in oxidative stress, ASD, and eczema, though their replication in other populations is warranted.

**410.062 (Poster)** An Exploratory Investigation of Organic Chemicals in Baby Teeth: Differences between Children with and without Autism. **R. Palmer<sup>1</sup>**, L. Heilbrun<sup>2</sup>, K. Favela<sup>3</sup> and R. Blase<sup>1</sup>, (1)The University of Texas at San Antonio, San Antonio, TX, (2)University of Texas Health Science Center at Houston, San Antonio, TX, (3)South West Research Institute, San Antonio, TX

---

**Background:** Shed baby teeth have been established to hold a record of exposure to heavy metals *in utero* and early childhood 1,2. Semi-volatile organic chemicals have been studied in shed baby teeth as a potential epidemiological tool to identify environmental triggers of developmental disorders such as autism.

**Objectives:** Here we have applied our comprehensive high-throughput non-targeted screening method to extensively catalog and categorize semi-volatile organic chemicals in shed baby teeth. Chemical exposures and concentrations in teeth were then compared between children and without autism.

**Methods:** Parents of children with and without autism donated their child's baby teeth as part of the UTHSCSA *Autism Tooth Fairy Project* to investigate toxicant exposures occurring during development. After removing the root and tissue material, each tooth was wiped with Isopropyl alcohol and ground to a powder using a mortar and pestle. Approximately 0.1 g of each ground tooth sample was spiked with a surrogate solution and extracted three times with 1.0 mL each of 90:10 Dichloromethane:Ether. The three 1.0-mL aliquots were combined and concentrated to a final volume of 50  $\mu$ L. A method blank consisting of 0.1 g of cleaned and heat-treated hydroxyapatite was extracted the same way. Comprehensive two dimensional Gas Chromatography Time-of-Flight Mass Spectrometry (GCxGC/TOFMS) analysis was performed using an Agilent 7890 gas chromatograph coupled to a LECO PEGASUS 4D. The assay was both targeted (using 134 authentic standards) and non-targeted.

**Results:** A total of 11,971 chemicals from 38 shed baby teeth were cataloged, including unknowns without a suitable library match. The average was 315 compounds per tooth. Of 42 teeth, 22 were from children with autism spectrum diagnoses and 20 were from typical developing children. In general these are xenobiotic compounds with a high confidence score, many of potential interest as toxic agents. A total of 161 compounds of interest were identified. Topical analgesics, ingredients of personal care products, flavors, fragrances, solvents, insecticides and repellants were well represented in the data-set, suggesting the oral or dermal absorption routes of deposition as an active mechanism.

**Conclusions:** Hair, urine, or saliva samples provide limited measures of exposures because they only reflect relatively recent exposures. As teeth begin to form in the 2nd trimester, layers of dentin are deposited (similar to rings on a tree). These layers sequester chemicals the child has been exposed to during gestation and early childhood. Information stemming from the "tooth exposome" is important for informing future epidemiologic research about the types of compounds that are present during critical periods of development. This research has implications for chemical avoidance and prevention of neurodevelopmental disabilities such as autism.

**410.063 (Poster)** An Exploratory Study in Pain Assessment Bias: Effects of Autism and Intellectual Disability on Pain Assessment By Medical Professionals.

**M. D. Failla<sup>1</sup>, E. Eyoh<sup>2</sup>, L. Oatney<sup>3</sup>, C. Convery<sup>4</sup> and C. J. Cascio<sup>5</sup>,** (1)College of Nursing, The Ohio State University, Columbus, OH, (2)Institute of Child Development, University of Minnesota, Minneapolis, MN, (3)College of Nursing, Columbus, OH, (4)Vanderbilt University Medical Center, Nashville, TN, (5)Department of Psychiatry and Behavioral Science, Vanderbilt University Medical Center, Nashville, TN

---

**Background:** Pain is a subjective experience, thus, self-report is considered the clinical “gold standard” for pain assessment. Reliance on traditional self-report measures could be problematic for autistic individuals due to differences in social communication or pain expression. Observation-based tools that aim to capture verbal, nonverbal (e.g., facial expressions, posturing), and other physiological or behavioral changes associated with pain have become the clinical “silver standard”. However, these tools may be influenced by medical provider bias in pain assessment. Challenges in assessing pain and lack of provider education are likely two of the biggest obstacles to appropriate pain management in autism.

**Objectives:** To investigate medical providers’ bias in pain assessment for autistic individuals.

**Methods:** We recruited medical providers with at least 1 year of professional experience (n=168) to participate in an online experiment regarding pain assessment. We paired 10 short vignettes with a 6-second video of an adult experiencing pain in a medical setting. Each vignette described a patient who was either neurotypical (n=5), autistic (n=3), or had intellectual disability (n=2). Vignettes described the patient history and the current healthcare encounter (e.g., broken ankle assessment in the emergency department). After reading the vignette and watching the video, participants rated how much pain they estimated the person in the video was experiencing on a visual analog scale (0-100). The 10 videos were distributed across gender (women=5 and men=5) and race (Black=3, White=7). Video and vignette pairings were presented in 2 versions (mixing videos across vignette conditions for experimental balance), interleaved across participants.

**Results:** While participants were alternatively assigned to experimental version, between the two versions, the participant groups were significantly different in age, gender, race, and medical profession. The groups also differed on overall estimated pain ratings (average pain rating in version 1:  $37.14 \pm 20.82$ , n=83; version 2:  $44.51 \pm 22.91$ , n=85;  $p < 0.0001$ ). Given the significant differences in group demographics, we explored the effects of autism diagnosis, and intellectual disability, while correcting for potential bias associated with experimental version, as well as gender and race of the person in the video. In version 1, autism diagnosis was associated with higher pain ratings ( $\beta = 7.130$ ,  $t = 3.542$ ,  $p < 0.0001$ ) and intellectual disability was associated with lower pain ratings ( $\beta = -9.197$ ,  $t = -4.451$ ,  $p < 0.0001$ ) compared to the neurotypical group. In version 2, autism diagnosis was associated with lower pain ratings ( $\beta = -5.734$ ,  $t = -2.924$ ,  $p = 0.004$ ) and intellectual disability was associated with higher pain ratings ( $\beta = 12.103$ ,  $t = 5.334$ ,  $p < 0.0001$ ) compared to the neurotypical group.

**Conclusions:** This exploratory study provides the first experimental evidence of possible provider bias in pain assessment for autistic adults or adults with intellectual disability, but suggests there may be many different factors important in pain assessment. Addressing assumptions or false beliefs about biological differences in pain tolerance for autistic individuals could begin to mitigate pain mismanagement in this population.

**410.064 (Poster)** Tracking Health in Kids (THinK)

**C. Lord<sup>1</sup>, K. Byrne<sup>2</sup>, S. Zheng<sup>3</sup>, S. S. Ghodsi<sup>4</sup>, J. Boucher<sup>5</sup> and S. Bishop<sup>6</sup>,** (1)UCLA Semel Institute for Neuroscience and Human Behavior, Los Angeles, CA, (2)University of California, Los Angeles, Los Angeles, CA, (3)Psychiatry, University of California, San Francisco (UCSF), San Francisco, CA, (4)University of California San Francisco, San Francisco, CA, (5)Pennsylvania State University, State College, PA

---

**Background:** Links between fevers and autism have been proposed in the clinical literature for several years. Anecdotal reports suggest the possibility of improvements in behavior for children with autism when these individuals experience a fever. Despite a substantial number of anecdotal reports, there is surprisingly little published data examining these effects. Data from the Simons Simplex Collection revealed that, of a sample of over 2000 children, 17% of families reported, retrospectively, that their children’s behavior improved when they had a fever. One other prospective study found that 83% of children demonstrated a significant improvement in behavior during fever in at least one domain of the Aberrant Behavior Checklist (ABC).

**Objectives:** The current study aimed to investigate, prospectively, whether we could replicate the findings of associations between autism and improvements in behavior during fever in a way that remedies the methodological limitations of previous studies. We set out to understand the degree to which children with ASD have specific and unique responses to fever, and whether these behavioral responses to fever differ from behavioral responses to other medical events not involving a fever.

**Methods:** This study consisted of 244 children between the ages of 2-7; 141 were diagnosed with ASD, the remaining 103 were not. Families collected data through a phone application three times per week to report whether anything out of the child’s day-to-day routine occurred (e.g., travel, missed appointments, sickness, etc.). Parents were asked to explain the event that transpired, record the child’s temperature, and respond to questions that pertained to the child’s behavior during the event. Additionally, parents recorded “baseline” temperatures and behavioral ratings at times in which no significant event had occurred.

**Results:** Multilevel modeling revealed a significant main fixed effect of fever conditions, suggesting that children’s social behavioral ratings (including items such as communication, play, happiness), level of eating and sleeping, and emotional and behavioral problems (including anxiety, behavior management, and irritability) worsened when they had a fever. Moreover, a significant interaction effect was observed for fever condition and diagnosis on the social behavioral ratings, where children with ASD were reported to show increasingly worsening social behavioral ratings during fever than those without ASD. No interaction effect was found for fever condition and diagnosis on eating and sleeping or emotional and behavioral problems. Data is still being analyzed to determine whether the behavioral differences during fever differ from behavioral differences during other non-fever medical events.

Conclusions: Behavioral changes during fevers were observed across the whole sample as compared to baseline recordings. Interaction effects (in which children with ASD exhibited different behavioral responses than children without ASD) were only present for ratings of social behaviors (such as happiness, play, and communicating ideas). We do think that behavioral improvements during fever is a phenomenon that occurs in a subset of individuals (based on consistent anecdotal reports). However, using a nuanced design like this and a relatively short period of time of study inclusion creates smaller sample sizes than may be necessary to identify this subgroup.

---

**Background:**

The heterogeneous nature of autism spectrum disorder (ASD) complicates the search for risk factors and effective treatment options. Previous studies on early ASD phenotypes reported between two and four subgroups that diverge on measures of developmental functioning (e.g., language abilities) and dysregulation (e.g., sleep problems) and converge on measures of sensory dysfunction. However, the number of subgroups is variable across analyses. Lack of replication makes it difficult to generalize and interpret individual study results. Another approach is to quantify the most distinguishing and common features of young children with varying levels of ASD symptoms. This approach could highlight symptoms that can be documented and treated versus those that additionally can be the focus of etiologic research.

**Objectives:**

Our objectives were to identify behavioral and developmental features that best define the heterogeneity and homogeneity in 2-5-year-old children with ASD and those with subthreshold ASD characteristics.

**Methods:**

Children were enrolled in a multisite case-control study of ASD. Behavioral and developmental data were collected from mothers and child evaluations. All children were asked to complete an early learning assessment. Participants with a positive ASD screen score or prior ASD diagnosis were additionally asked to complete gold-standard ASD measures. Children in the ASD group met study criteria based on these measures; children who did not meet study criteria were categorized as having subthreshold ASD characteristics. Multiple correspondence analysis (MCA) was employed to address the research objectives. MCA is a statistical technique that summarizes response profiles among categorical variables to reveal patterns in complex datasets. Each data point is plotted in multi-dimensional space to determine its proximity to an origin defined by distance measures. Datapoints farthest from the origin suggest considerable variation from the most common profile. Datapoints closest to the origin suggest little variation from the most common profile.

**Results:**

There were 1,480 children with ASD (81.6% boys) and 594 children with subthreshold ASD characteristics (70.2% boys) in the total sample, which was split into two samples based on SEED phase completed (i.e., Phase 1 or 2). Aggression, anxiety/depression, and sleep problems constituted one dimension that explained between 49% and 65% of the variance in ASD symptoms in both samples and in both groups of children. Expressive and receptive language skills constituted a second dimension that explained an additional 15% to 30% of the variance in both samples and in both groups of children. Atypical sensory response contributed to homogeneity in children with ASD but not those with subthreshold characteristics in both samples.

**Conclusions:**

Our findings suggest that dysregulation and developmental abilities are features of the broad spectrum of ASD symptoms that can impact functioning whereas sensory dysfunction may be a core feature of the disorder. Documentation of factors that contribute to diversity of early childhood phenotypes – especially aggression, anxiety/depression, and sleep problems – may support clinical monitoring and tailor individualized treatments. Since sensory dysfunction defines the most common ASD profile, evaluation and treatment of sensory concerns may lessen the impact of sensory deficits and guide future research on sensory dysfunction.

---

#### Background:

The Centers for Disease Control and Prevention estimate that about 53% of pre-school-aged children with autism spectrum disorder (ASD) have co-occurring intellectual disability (ID) (<https://www.cdc.gov/mmwr/volumes/69/ss/ss6903a1.htm>). In the U.S., ID is disproportionately identified in non-Hispanic Black (NHB) and Hispanic (HISP) children compared to non-Hispanic White (NHW) children in the population overall and among children with ASD. Social disadvantage is a leading risk factor for ID, and NHB and HISP families are more likely to experience social disadvantage than NHW families. Yet no identified study has explored whether social disadvantage is more strongly associated with ID in NHB and HISP children than NHW children with ASD.

#### Objectives:

Our objectives were to assess in a large community-based sample of children with ASD whether (1) NHB and HISP children were more likely to be classified as having ID than NHW children; (2) NHB and HISP families were more likely to experience social disadvantage than NHW families; and (3) social disadvantage was more strongly associated with ID among NHB and HISP than NHW children, independent of other established risk factors (e.g., premature birth).

#### Methods:

Children aged 2-5 years were enrolled in a multisite case-control study of ASD. Children classified as having ASD met cut-off criteria on gold-standard diagnostic measures. ID was defined as a Mullen Scales of Early Learning visual reception t-score of  $\leq 30$  points (i.e., proxy for nonverbal intelligence). Pre- and post-natal histories were obtained from a detailed maternal interview to identify factors associated with ID, which served as covariates in adjusted logistic regression analyses. Potential indicators of social disadvantage were obtained from the same interview and served as independent variables. Maternal race/ethnicity was also obtained from the same interview and was used to stratify regression models.

#### Results:

There were 1,284 children with ASD (81.4% boys) in the sample, of which 740 (50.7%) were NHW, 337 (23.1%) were NHB, and 207 (14.2%) were HISP. NHB and HISP children were significantly more likely to have ID than NHW children, and significantly more likely to experience social disadvantage (Table 1). Income relative to the federal poverty level (aOR 2.06; 95% CI = 1.34, 3.18), language spoken in the home (aOR 1.53; 95% CI = 1.03, 2.29), and maternal education (aOR 1.73; 95% CI = 1.27, 2.36), were associated with ID in the entire sample. However, none of these socioeconomic factors were associated with ID *within* racial/ethnic groups.

#### Conclusions:

NHB and HISP children with ASD were disproportionately identified with ID and social disadvantage when compared to NHW children in our sample. Consistent with previous studies, we found that social disadvantage was associated with ID for all children with ASD. However, in analyses stratified by race/ethnicity, no individual indicators of social disadvantage were associated with ID. These results suggest that there may be factors not measured in this study associated with the disproportionate burden of ID in NHB and HISP children with ASD, or that stratified sample sizes were not adequate to detect statistical differences. We next plan to explore county-level indicators of structural inequality such as racial segregation and income inequality to determine their influence on ID in different racial/ethnic groups (<https://www.countyhealthrankings.org/reports>).

#### **410.067 (Poster)** Autism Spectrum Disorder and Possible Related Factors in Pregnancy

**D. Eyuboglu<sup>1</sup> and M. Eyuboglu<sup>2</sup>,** (1)Child and adolescent psychiatry, Eskisehir Osmangazi University Medical School, Eskisehir, Turkey, (2)Child and Adolescent Psychiatry, Eskisehir Osmangazi University Medical School, Eskisehir, Turkey

---

#### Background:

Autism spectrum disorder (ASD) is a neurodevelopmental disorder that occurs in the early developmental period of life and characterized by deficits in social communication and interaction, along with limited, repetitive behavior or interests. Early diagnosis of ASD facilitates early access to intervention and promotes better developmental outcomes in young children. Therefore, studies focus on early markers while investigating risk factors.

**Objectives:** This study aimed to investigate environmental factors in the pre- and perinatal period and the other possible related factors of ASD, and to compare these variables with those of typically developing peers

## Methods:

A total of 55 children with ASD between the ages 20 and 66 months, who were diagnosed for the first time and 60 typically developing (TD) were included in this cross-sectional study. Children with ASD were selected from pediatric psychiatry outpatient clinic and diagnosed by an experienced child and adolescent psychiatrist, based on DSM 5 diagnostic criteria. The typically developing children who had no history of physical or developmental disabilities were selected for control group. Childhood Autism Rating Scale (CARS) and Autism Behavior Checklist (ABC) were administered by the clinician, to evaluate autism-related symptom severity of ASD children.

## Results:

The mean age of ASD and TD children were found to be  $35.2 \pm 9.6$  months and  $36.1 \pm 8.6$  months, respectively. Groups did not differ by age ( $p > 0.05$ ). The mean scores of CARS and ABC of children with ASD were  $40.6 \pm 3.8$ ,  $87.2 \pm 25.3$ , respectively. There were no significant differences, the method of conception (normal/using assisted reproductive techniques), drug use, smoking, alcohol/substance use, infection, gestational diabetes, gestational hypertension, preeclampsia, increased risk of abortus, hemorrhage, use of vitamins, delivery time (full-term/preterm/postterm) and method of delivery, between two groups ( $p > 0.05$ ). In ASD group, mothers were significantly more exposed to passive smoking ( $p < 0.05$ ). In addition, when the use of vitamin D during pregnancy and natal complications (hypoxia, etc.) were investigated, a significant difference was found between the two groups ( $p < 0.05$ ).

## Conclusions:

Based on our current knowledge of the disorder, it is clear that autism does not have a single cause. Investigation of environmental factors associated with ASD is critical, especially in terms of preventive mental health interventions. Our study has supported the importance of protection from passive smoking and vitamin D supplementation during pregnancy. As a result, regular pregnancy follow-up will enable the detection of risky pregnancies and early diagnosis, as well as preventive interventions.

**410.068 (Poster)** Exploration of Stressful Life Events during Pregnancy As a Risk Factor for Child Neurodevelopmental Outcome in Marbles: A High Familial Risk Cohort

**D. H. Hoang<sup>1</sup>**, S. Ozonoff<sup>2</sup> and R. J. Schmidt<sup>3</sup>, (1)University of California, Davis MIND Institute, Davis, CA, (2)Psychiatry and Behavioral Sciences, University of California at Davis, MIND Institute, Sacramento, CA, (3)Public Health Sciences, University of California Davis, Davis, CA

---

## Background:

Prenatal stress has been associated with elevated risk of autism spectrum disorder (ASD) in the child. While several types of prenatal stressful life events (SLEs) were not associated with ASD risk, one study<sup>1</sup> of prenatal stress through family discord found an increased risk of child ASD. Maternal stress might be more of a concern for a child at high familial risk due to having an older sibling diagnosed with ASD.

## Objectives:

Be the first to examine in a high familial risk cohort prenatal SLEs in association with ASD or other non-typical development (Non-TD) in the child.

## Methods:

The prospective MARBLES cohort includes 314 women with at least one child with ASD and then became pregnant with another child.

Mothers were asked at the end of their pregnancy if they had experienced any of the following SLEs: 1. Changing or losing jobs, 2. Death of a close family member or close friend, 3. Legal problems, including immigration, 4. Financial problems, including foreclosure, 5. Moving, being separated from family or close friends, or having a family member move into the household, 6. Serious problems or disagreements with relatives, neighbors, or in-laws, or 7. Any other major events, not already specified.

Child neurodevelopment was assessed longitudinally from birth through three years of age by trained psychologists who administered the Autism Diagnostic Observation Schedule (ADOS) and the Mullen Scales of Early Learning (MSEL). An algorithm based on ADOS and MSEL scores previously published by the Baby Siblings Research Consortium<sup>2</sup> was used to classify children with ASD, Non-TD, or typically developing (TD) outcomes.

Multinomial logistic regressions were fitted for the case status outcome, controlling for maternal race/ethnicity, age, and socioeconomic status for each of the seven SLEs separately and for a composite binary independent variable indicating whether 1+ SLE was experienced.

## Results:

Experiencing a death of a close family member or friend was significantly associated with a decreased risk of ASD (OR 0.45, 95% CI: (0.22, 0.90)). Experiencing financial problems (OR 2.23, 95% CI (1.03, 4.81)) and legal problems (OR 5.24 (95% CI: (1.81, 15.20))) were associated with an increased risk of non-TD in the child. All other associations were non-significant. Generally, SLEs during pregnancy were not associated with elevated risk of Non-TD or ASD in the child.

## Conclusions:

Findings agree with previous literature suggesting prenatal SLEs may not be risk factors for ASD and most were not strongly associated with Non-TD risk either. The increased risk of financial and legal problems on Non-TD merits further exploration, though precision was low. The association between experiencing death during pregnancy and ASD in the protective direction was unexpected; this might be explained by the resilience theory where the fetus was exposed to a traumatic event and becomes resilient so the child does not develop ASD later on. Future studies measuring stress using biomarkers or perceived stress are warranted to further understand the true association of prenatal stress and risk of ASD. Experiencing multiple SLEs in one pregnancy should also be explored as a risk factor.

**410.069** (Poster) Exploring the Barriers and Facilitators to Physical Activity Involvement in Autistic Youth with Mild Intellectual Disability  
*C. L. McIntyre, T. Q. Boucher, M. L. Mylett and G. Iarocci, Psychology, Simon Fraser University, Burnaby, BC, Canada*

---

**Background:** Autistic youth participate in physical activity (PA) at higher rates than youth diagnosed with intellectual disability (Borland et al., 2020). However, caregivers of children diagnosed with both autism and intellectual disability report that their child experiences significant difficulties obtaining support for physical and leisure activities compared to autistic children (Nichols et al., 2019) and children diagnosed with intellectual disability only (Tint et al., 2017). These youth may not experience the benefits of engaging in PA, such as improved mental health, academic achievement (Boddy et al., 2015), and increased self-efficacy (Menear & Neumeier, 2015). Thus, understanding the unique barriers and facilitators to PA for these youth is critical.

**Objectives:** While previous research has identified some barriers and facilitators to PA involvement for youth with ASD and/or intellectual disability, few studies have gathered this information from youth directly. This study examines barriers and facilitators to PA involvement in autistic youth with mild intellectual disability using semi-structured interviews and caregiver reports.

**Methods:** Fourteen caregivers and their child ranging in age from 8 to 16 years ( $M_{age}=12.23$ ,  $SD=2.51$ , 13 males) diagnosed with autism and mild intellectual disability participated. The Wechsler Abbreviated Scales of Intelligence, Second Edition (WASI-II; Wechsler, 2011) was used to assess youth's cognitive ability ( $M=65.64$ ,  $SD=10.73$ , range 51 to 75). The Health & Wellness and Risk Engagement & Protection Survey (HWREPS; McFee, 2018) was used for caregiver reports of their child's PA preferences. Caregivers also reported on the barriers and facilitators to their child's PA involvement. Youth participated in semi-structured interviews and reported on their PA preferences, the types of activities they dislike, and the things that prevent them from participating in PA. Transcribed interviews were coded using NVivo software.

**Results:** Four core themes were inductively identified by the first and second authors: (1) Intrapersonal Barriers (factors that are intrinsic to the person that impede PA involvement, such as their own cognitions, attitudes, and behaviours; e.g., disliking PA, having a preference for sedentary activities, expressing challenging behaviours that inhibit PA engagement), (2) Interpersonal Barriers (factors that are extrinsic to the person that impede PA involvement; e.g., lack of community support to foster PA engagement), (3) Intrapersonal Facilitators (factors that are intrinsic to the person that enhance PA involvement; e.g., enjoying PA, finding PA intrinsically rewarding, being motivated to improve one's abilities), and (4) Interpersonal Facilitators (factors that are extrinsic to the person that enhance PA involvement; e.g., receiving support and rewards from caregivers).

**Conclusions:** The findings reveal the unique barriers and facilitators to PA involvement in autistic youth with mild intellectual disability. By gathering this information from youth directly in addition to caregiver reports, these findings provide new perspectives on the factors that impede and enhance PA among these youth. The findings can be used to inform interventions designed to reduce barriers and increase facilitators to PA within schools and other organizations. A limitation is our predominantly male sample; future work should include more gender-balanced samples to examine the potentially unique barriers/facilitators to PA for autistic girls with mild intellectual disability.

**410.070** (Poster) Association of Early-Life Exposures to Diet Soda and Aspartame with Autism in Males: A Case-Control Study  
*S. P. Fowler<sup>1</sup>, D. Gimeno Ruiz de Porras<sup>2,3</sup>, M. D. Swartz<sup>4</sup>, P. Stigler Granados<sup>5</sup>, L. Heilbrun<sup>6</sup> and R. ---

## Background:

For more than a decade, prospective cohort studies have reported increased cardiometabolic, neurologic, and other risks among adults consuming diet sodas (DS) daily. Since its introduction into the U.S. diet in the early 1980's, case reports have linked the non-nutritive sweetener aspartame – used in most diet sodas (DS) and many other diet beverages and products – with neurological and other health problems in adults. Recently, maternal intake of diet beverages during pregnancy has been associated with increased risk of prematurity and overweight/obesity among exposed offspring, and a case-control study found increased gestational exposure, through maternal diet, to methanol, an aspartame metabolite, among children with autism compared with neurotypically developing children. Methanol may contribute to these outcomes by reducing antioxidant and detoxification capacity, and adversely impacting the maternal gut microbiota and intrauterine environment.

## Objectives:

In this study we tested the hypothesis that early-life exposures to DS and to aspartame, specifically, during gestation and breastfeeding, are associated with offspring autism status.

#### Methods:

We analyzed data from the case-control Autism Tooth Fairy Study, in which biological mothers of offspring with autism spectrum disorders (ASD; cases: n=235) and neurotypically developing offspring (controls: n=121) retrospectively reported their intakes of DS, other diet beverages, and tabletop sweeteners during pregnancy/breastfeeding. Mothers were asked to specify the brand name of each diet product used; aspartame contents of these products were derived from previous publications. We calculated total daily intakes during pregnancy/breastfeeding of DS itself, and of aspartame from these three dietary components. Adjusted exposure odds ratios (ORs) were then calculated for two early-life exposures:  $\geq 1$  DS/day, and  $\geq 177$  mg/day of aspartame (the minimum dosage in 1 aspartame-sweetened diet cola). We calculated ORs separately by sex, and for both sexes combined, for the following: all cases with ASD, all cases with autism, and cases with early-onset autism. ORs were derived using multilevel mixed-effects generalized linear model analyses, adjusted for mother's id, recruitment source, child's ethnicity (non-Hispanic white vs. other), year of birth, mother's education ( $\geq 4$  years of college vs. less), and household income ( $\geq \$100,000$ /year vs. less).

#### Results:

Among males, odds of early-life exposure to  $\geq 1$  DS/day were tripled among autism cases (OR=3.14; 95% confidence interval (CI): 1.02, 9.65) and even greater among early-onset autism cases (OR=3.49; 95% CI: 1.10, 11.08). Higher still among males were odds of early-life exposure to  $\geq 177$  mg/day of aspartame: OR=3.42 (95% CI: 1.12, 10.41) among autism cases, and OR=3.73 (95% CI: 1.18, 11.78) among early-onset autism cases. No statistically significant associations were found for autism in girls, or for total ASD in either sex.

#### Conclusions:

Our findings contribute to the growing literature raising concerns about the safety of consuming diet beverages and products during pregnancy. Because our study utilized retrospective dietary recalls in the context of a case-control study design, future research using prospectively gathered data from large cohorts would be important in confirming these associations. Meanwhile, women should exercise caution, and weigh carefully the potential harm to their offspring, when considering using these products during pregnancy and breastfeeding.

#### **410.071 (Poster) Gestational Diabetes and Risk of Autism Spectrum Disorder**

Persson<sup>1</sup>,** (1)AJ Drexel Autism Institute, Drexel University, Philadelphia, PA, (2)Aarhus University, Aarhus, Denmark, (3)Seaver Autism Center, Department of Psychiatry, Icahn School of Medicine at Mount Sinai, New York, NY, (4)Karolinska Institute, Stockholm, Sweden, (5)Mt Sinai School of Medicine, New York, NY, (6)Department of Psychiatry, University of Pittsburgh School of Medicine, Pittsburgh, PA, (7)Carnegie Mellon University, Pittsburgh, PA, (8)Seaver Autism Center for Research and Treatment, Department of Psychiatry, Icahn School of Medicine at Mount Sinai Hospital, New York, NY, (9)Psychiatry, Icahn School of Medicine at Mount Sinai, New York, NY

#### Background:

Maternal diabetes has been associated with risk of autism spectrum disorder (ASD) in offspring, but careful delineation of risk arising from Type 1, Type 2 or gestational diabetes has not been done. As the three manifestations of diabetes differ in pathogenesis it is important to consider them separately in order to investigate specific mechanisms of effect underlying the diabetes association with ASD.

#### Objectives:

Investigate association between gestational diabetes, specifically, and ASD risk overall, by sex and in ASD subgroups defined by co-occurrence of intellectual disability (ID) or attention deficit hyperactivity disorder (ADHD).

#### Methods:

We applied a population-based cohort design comprised of all live births in Denmark of Nordic-born parents from 1998- 2008. Exposure to gestational diabetes was defined by an ICD-10 code O24.4 recorded in the National Patient Register by specialists for the mother during the index pregnancy. ASD, ADHD or ID in the child was based on reported ICD10 diagnoses (F84.0/.1/.5/.8/.9) by specialists to the Psychiatric Central Research or National Patient Register. We applied Cox proportional hazard regression to estimate the risk of ASD associated with maternal gestational diabetes. Children were followed from 18 months of age until ASD diagnosis, emigration, death or end of follow-up on December 31, 2016, which ever came first. In all models, gestational diabetes was the primary predictor. Covariates included for adjustment were: Model 1 – sex, birth year; Model 2 - model 1+ paternal age, income and education, maternal age, income and education, polycystic ovary syndrome in the mother, parity; Model 3 - model 2 + paternal psychiatric history, maternal psychiatric history. We repeated the analyses by sex and by ASD subgroups (ASD with/without ID; ASD with/without ADHD); co-occurrence was based on diagnostic status of the second condition at the end of follow-up and using multinomial logistic regression to estimate odds ratios (OR). The multinomial logistic regression also adjusted for time at risk in all three models.

#### Results:

The cohort comprised 558,713 births of whom 6,288 (1.1%) were exposed to gestational diabetes and 13,200 (2.4%) were diagnosed with ASD. In fully adjusted models (Model 3), gestational diabetes was associated with about a 50% increased risk for ASD overall, adjusted Hazard Ratio (aHR) 1.56 (95% CI 1.43-1.87); lower risk in females (aHR 1.22 (95% CI 0.90-1.67)) than males (aHR 1.66 (95% CI 1.43-1.93)); p-value for interaction by sex  $p=0.03$ , Figure) and no difference by ID co-occurrence (ASD/-ID: adjusted OR 1.57 (95% CI 1.36-1.82), ASD/+ID: adjusted OR 1.59 (95% CI 1.07-2.34) but somewhat higher risk in ASD with ADHD (adjusted OR 1.74 (95% CI 1.39-2.19) than ASD without ADHD (adjusted OR 1.49 (95% CI 1.26-1.77)).

#### Conclusions:

The estimates of risk for ASD following exposure to gestational diabetes were persistent, robust and fairly stable in magnitude across different multivariate models and ASD phenotypic subgroups, although with higher risks in males than females. The potential impact of unmeasured familial confounding and the potential for shared genetic factors between gestational diabetes and ASD may be contributing to the observed association.

#### **410.072 (Poster)** Maternal Cortisol in 3rd Trimester Predicted Traits of Autism in Offspring at 3 Years of Age. Odense Child Cohort

**N. Bilenberg<sup>1</sup>, B. B. Tobiasen<sup>2</sup>, J. J. Andreasen<sup>2</sup>, R. C. Jensen<sup>3</sup>, H. Boye<sup>4</sup>, T. K. Jensen<sup>5</sup>, D. Glinborg<sup>6</sup> and M. S. Andersen<sup>7</sup>,** (1)University of Southern Denmark, Odense C, Denmark, (2)University of Southern Denmark, Odense, Denmark, (3)Department of Endocrinology and Metabolism, Odense University Hospital, Denmark, University of Southern Denmark, Odense, Denmark, (4)Hans Christian Andersen Hospital for Children and Adolescents, Odense University Hospital, Denmark, Odense, Denmark, (5)Department of Environmental Medicine, Odense University Hospital, Odense C, Denmark, University of Southern Denmark, Odense, Denmark, (6)Department of Endocrinology and Metabolism, Odense University Hospital, Denmark, Odense University Hospital, Denmark, Odense, Denmark, (7)Department of Endocrinology and Metabolism, Odense University Hospital, Denmark, Odense, Denmark

**Background:** Prenatal cortisol exposure is essential for neurodevelopment. Based on animal and human studies cortisol levels during 3rd trimester of pregnancy could be associated with offspring risk of Autism Spectrum Disorder (ASD).

**Objectives:** To investigate associations between maternal cortisol during 3<sup>rd</sup> trimester pregnancy and traits of ASD in offspring.

**Methods:** The study included 1,131 mother-child pairs from the prospective Odense Child Cohort. Fasting morning serum cortisol and diurnal urine cortisol/cortisone were collected at gestational week 27-28 and were measured by mass spectrometry.

Offspring ASD traits were assessed at 3 years ( $n=1,131$ ) and at 5 years ( $n=717$ ) using the 13 item DSM-oriented Pervasive Developmental Problems (PDP) subscale from Child Behavior Checklist for ages 1½ to 5 years (CBCL/1½-5). Scale-scores (range 0-26) were dichotomized, and logistic regression models were used to investigate associations between maternal cortisol (continuous and tertile models) and offspring ASD traits (scores above the 90<sup>th</sup> percentile in the Danish national norm material). All regression models were adjusted for maternal age, pre-pregnancy Body Mass Index (BMI), parity, maternal smoking status, maternal educational level and parental psychiatric diagnoses.

**Results:** At birth of the index child, mothers had a mean age of 30 years ( $SD \pm 4.4$  years), median of pre-pregnancy BMI was 23.5 kg/m<sup>2</sup> [21.3; 26.6], 56% were primiparous and 52% gave birth to a boy. At three years of age ASD traits was seen in 20% (116/586) of boys and in 13 % (73/545) of girls. In univariate analysis, the presence of ASD traits were significantly associated with low maternal age, lower pre-pregnancy BMI, primiparity, GA <37 weeks, low maternal educational level and maternal smoking.

Maternal serum cortisol was associated with offspring ASD traits (3<sup>rd</sup> tertile unadjusted odds ratio (OR) [95% confidence interval] 2.02 [1.36; 3.00],  $p < 0.001$ , adjusted OR 1.64 [1.07; 2.52],  $p=0.023$ ). When stratified by offspring gender, this association was only seen in boys (3<sup>rd</sup> tertile: unadjusted OR 2.33 [1.42; 3.84],  $p=0.001$ , adjusted OR 1.82 [1.06; 3.12],  $p=0.029$ ). The association was lost at age 5 (all  $p$ -values > 0.21).

**Conclusions:** Higher maternal serum cortisol in 3<sup>rd</sup> trimester was associated with offspring ASD traits in boys at 3 years of age.

#### **410.073 (Poster)** Maternal Obesity, Diabetes, Preeclampsia, and Asthma during Pregnancy and Risk of Autism Spectrum Disorders and Gastrointestinal Comorbidities in Children

**S. Carter,** Department of Research & Evaluation, Kaiser Permanente Southern California, Pasadena, CA

**Background:** Studies have reported associations between exposure to maternal obesity, diabetes, preeclampsia, and asthma during pregnancy and autism spectrum disorders (ASD) in offspring. There has been little study of associations with ASD comorbid phenotypes, of which gastrointestinal (GI) conditions are the most common. Given emerging evidence of the influence of gut microbiota in ASD diagnosis and presentation, this study examines whether *in utero* exposure to these maternal conditions is associated with ASD with and without comorbid GI disorders.

**Objectives:** To identify risk of gastrointestinal ASD phenotypes associated with *in utero* exposure to maternal obesity, diabetes, preeclampsia, and asthma in a large, representative birth cohort.

**Methods:** This population-based retrospective cohort study included 308,536 mother-child pairs of singletons born between 2001-2014 in Southern California. Mothers and children were followed through electronic medical records. Children were followed until age 5. Data on maternal pre-pregnancy obesity (BMI  $\geq 30$ kg/m<sup>2</sup>), diabetes, preeclampsia, and asthma during pregnancy and child's ASD or GI diagnosis were extracted from EMR. Children were categorized into four groups: 1) no ASD no GI disorders, 2) no ASD with GI disorders, 3) ASD no GI disorders, and 4) ASD

with GI disorders. Multinomial logistic regression models estimated odds ratios (OR) and 95% CI of ASD/GI phenotypes in children associated with the exposure to each of four maternal conditions adjusting for birth year, maternal age, parity, maternal race/ethnicity, maternal educational qualifications, smoking in pregnancy, history of comorbidity, maternal mental health issue, census-tract parent income at age one, and child's sex.

Results: Over follow up, 5,131 (1.7%) children were diagnosed with ASD and 77,846 (25%) had GI disorders. Of the total sample, 1,814 (0.6%) had ASD with accompanying GI disorders, 3,317 (1.1%) had ASD without GI disorders, and 76,032 (25%) had GI disorders without ASD. GI disorders were present in 35.4% of children with ASD and in 25.1% of children without ASD. Table 1 presents the covariate adjusted ORs comparing odds of ASD and/or GI disorder diagnosis associated with maternal health conditions, relative to children without ASD or GI disorders. Compared to children without ASD or GI disorders, the four maternal conditions were generally associated with odds of having ASD both with and without GI disorders. However, for each maternal exposure, ORs were greatest in children with both ASD and GI disorders [obesity: 1.29 (1.15, 1.46); diabetes: 1.39 (1.19, 1.64); preeclampsia: 1.55 (1.29, 1.86); and asthma: 1.38 (1.15, 1.65)]. Exposure was also associated with GI conditions in children without ASD.

Conclusions: Exposure to maternal obesity, diabetes, preeclampsia, and asthma *in utero* may increase risk of ASD diagnosis in children with and without GI disorders, with the greatest effect sizes in children with both ASD and GI disorders. These maternal conditions may also increase risk of GI disorders in children without ASD. Further investigation of the role of the gut in effects of these *in utero* exposures on ASD is warranted.

#### **410.074 (Poster) Multiple Birth As a Risk Factor for Autism Spectrum Disorder: Findings from a Large Population**

**S. Gomez<sup>1</sup>, J. Shenouda<sup>2</sup>, K. Sidwell<sup>3</sup>, L. Kam<sup>4</sup> and W. Zahorodny<sup>5</sup>,** (1)Rutgers New Jersey Medical School, Newark, NJ, (2)Department of Pediatrics, Rutgers University, Newark, NJ, (3)Department of Pediatrics, Rutgers New Jersey Medical School, Newark, NJ, (4)Rutgers University, Newark, NJ, (5)Department of Pediatrics, Rutgers--New Jersey Medical School, Newark, NJ

Background: The prevalence of ASD has been steadily increasing over the past two decades. According to Autism and Developmental Disability Monitoring (ADDM) Network surveillance, ASD prevalence estimates have increased 175% between 2000 and 2016. In the most recent ADDM reporting cycle in 2016, New Jersey had the highest prevalence at 31.2 per 1,000. The higher prevalence is likely due to more comprehensive access to records leading to better ascertainment and/or to a higher concentration of risk factors such as parental age, increased use of c-section, and higher rates of multiple births (MB). The 2016 New Jersey multiplicity rate was 3.9% while the US rate was 3.4%. MBs are closely associated with these risk factors as well as fertility treatments. In a meta-analysis of perinatal and neonatal factors, multiple births were associated with increased autism risk among other factors such as c-section delivery and low birth weight. The findings regarding multiple births have been inconsistent and further studies from population-based studies are needed.

Objectives: The objective of this study was to estimate the incidence of ASD among singletons and multiple births and stratify the findings by birth weight using population-based samples across several cycles of active ASD surveillance between 2010 and 2016.

Methods: The data used in this study was from the New Jersey ADDM site. Ascertainment of ASD cases followed a two-phase process, using health and educational records followed by expert scoring and analysis. The years analyzed for this study included 2010, 2012, 2014, and 2016, totaling 4,051 ASD confirmed cases. Linkage to birth certificates was achieved for New Jersey-born children, thereby confirming their gestational status. Multivariate regression analysis (Poisson Regression) was used, adjusting for birth weight and maternal age.

Results: We compared risk of ASD among singleton and multiple gestational births and found across all surveillance cycles between 2010 and 2016, elevated ASD prevalence among multiple gestational births compared to singleton gestational births (3.7% vs. 1.9%). Adjusting for factors related to multiple births such as maternal age and birth weight, the risk of ASD was 2-times higher among multiple birth compared to singleton births (Crude PR = 1.9; 95% CI: 1.2-3.2; Adjusted PR = 2.0; 95% CI: 1.7-2.4). The prevalence ratio comparing multiple births to singleton births across the surveillance cycles ranged from 1.6 (95% CI: 1.2-2.1) in 2014 to 2.3 (95% CI: 1.7-3.0) in 2012.

Conclusions: Our data show multiple gestation as a risk factor for ASD. Across all surveillance years, ASD was more common in multiple gestation offspring than singleton offspring. When adjusted for common confounding variables such as low birth weight and advanced maternal age, there was still an elevated prevalence in multiple birth gestations compared to singleton births in all surveillance years. Greater multiple births in NJ may contribute to higher prevalence estimates in NJ compared to other states. Future studies should adjust for fertility treatments as well as c-section delivery.

#### **410.075 (Poster) Prenatal Fine Particulate Matter Nitrate Exposure and Childhood Autism Spectrum Disorders**

**M. M. Rahman<sup>1</sup>, Y. H. Shu<sup>2</sup>, T. Chow<sup>3</sup>, S. Carter<sup>4</sup>, X. Yu<sup>5</sup>, M. P. Martinez<sup>6</sup>, M. J. Kleeman<sup>7</sup>, P. Levitt<sup>8</sup>, J. Schwartz<sup>9</sup>, Z. Chen<sup>1</sup>, J. C. Chen<sup>1</sup>, S. P. Eckel<sup>1</sup>, F. W. Lurmann<sup>7</sup>, R. McConnell<sup>1</sup> and A. H. Xiang<sup>2</sup>,** (1)Department of Preventive Medicine, Keck School of Medicine, University of Southern California, Los Angeles, CA, (2)Department of Research & Evaluation, Kaiser Permanente Southern California, Pasadena, CA, (3)Spatial Science Institute, University of Southern California, Los Angeles, CA, USA, Los Angeles, CA, (4)Department of Civil and Environmental Engineering, University of California, Davis, Davis, California, USA, Davis, CA, (5)Children's Hospital Los Angeles, Los Angeles, CA, (6)Department of Environmental Health, Harvard T.H. Chan School of Public Health, Boston, MA, (7)Sonoma Technology, Inc., Petaluma, CA

Background: Emerging evidence suggests that prenatal exposure to particulate matter with aerodynamic diameter < 2.5  $\mu\text{m}$  (PM<sub>2.5</sub>) increases the risk of autism spectrum disorder (ASD). Ambient nitrate (NO<sub>3</sub>) is a significant component of PM<sub>2.5</sub>; it originates from the atmospheric oxidation of nitrogen oxides and nitrous oxide gas emissions generated mainly from combustion sources (e.g., motor vehicle traffic and power plants). The neurodevelopmental toxicity of ambient NO<sub>3</sub> is unknown.

**Objectives:** To examine the association of ASD with prenatal exposure to ambient PM<sub>2.5</sub>-NO<sub>3</sub> in a large representative cohort.

**Methods:** This population-based retrospective cohort study included 316,117 mother-child pairs with singleton deliveries in a large integrated health care system in southern California from 2001-2014. Children were followed using electronic medical records from birth up to December 31, 2019. Monthly estimates of PM<sub>2.5</sub>-NO<sub>3</sub> with a 1 km spatial resolution were obtained from a hybrid model developed by the Dalhousie University Atmospheric Composition Analysis Group. Prenatal exposure to PM<sub>2.5</sub>-NO<sub>3</sub> was assigned to each maternal address during the entire pregnancy, first, second, and third trimester, and were tested for associations with ASD diagnosis using Cox regression models adjusting for covariates. To evaluate the independence of the associations, we adjusted NO<sub>3</sub> model for the PM<sub>2.5</sub>. We also included “remainder PM<sub>2.5</sub> (e.g., total PM<sub>2.5</sub> minus NO<sub>3</sub>)” in the model to adjust for potential residual confounding due to other components.

**Results:** Over an average follow-up of 9 years, 6,267 children (5114 boys, 1177 girls) had an ASD diagnosis. NO<sub>3</sub> concentration during pregnancy and at each of the trimesters showed significant associations with increased ASD risk, after adjusting for child sex, maternal race/ethnicity, maternal age at delivery, parity, education, maternal commodity, medical centers, household income, maternal pre-pregnancy diabetes mellitus and obesity, birth year, and season. The adjusted hazard ratio (and 95% CI) of ASD risk associated with per interquartile (IQR=1.15 µg/m<sup>3</sup>) increase in NO<sub>3</sub> concentration in first gestational trimester was 1.07 (1.03, 1.12), second trimester was 1.07 (1.03, 1.12), third trimester was 1.07 (1.02, 1.11), and entire pregnancy was 1.11 (1.06, 1.16). These associations were robust to adjustments for total PM<sub>2.5</sub> and “remainder PM<sub>2.5</sub>”.

**Conclusions:** Our findings suggest that higher level NO<sub>3</sub> exposure during pregnancy was associated with increased ASD risk in children. Better understanding of effects of specific PM<sub>2.5</sub> components could lead to more targeted approaches to regulation.

#### **410.076 (Poster) Prenatal and Postnatal Factors Associated with Autism Severity**

N. T. Swaidan<sup>1</sup>, R. Taha<sup>1</sup>, S. Salloum-Asfar<sup>2</sup> and S. A. Abdulla<sup>2</sup>, (1)Neurological Disorders Research Center, Qatar Biomedical Research Institute (QBRI), Hamad Bin Khalifa University (HBKU), Education City, Qatar Foundation (QF), Doha, Qatar, (2)Qatar Biomedical Research Institute (QBRI), HBKU, Qatar Foundation, Doha, Qatar

---

**Background:** Autism spectrum disorder (ASD) is a complex neurodevelopmental condition that involves the interplay of genetic and non-genetic risk factors, causing a wide range of symptoms, which can be described as impairments in cognitive features and social communication, and a presentation of behavioral challenges including repetitive behaviors and highly restricted interests.

**Objectives:** We sought to identify potential prenatal, perinatal, and neonatal risk factors that may affect ASD severity in a population of children who were diagnosed clinically and through the use of ADOS-2 and exhibited a range of symptom severities.

**Methods:** The prospective cohort study included 84 children diagnosed with either mild or severe symptoms of ASD and ranged between 5-16 years old. Individuals that had incomplete clinical and demographic data, classified to exhibit moderate symptom severities, or conditions/cases solely specific to them were excluded from the original 94 cohort subjects. Potential risk factors were compared between 50 children diagnosed with severe ASD and 34 children diagnosed with mild ASD using multiple statistical tests including Mann-Whitney U test, chi-square test and simple and multiple logistic regression tests.

**Results:** Out of the 14 factors analyzed, three factors related to postnatal complications and comorbidities were significantly associated with ASD severe cases. These three were hypoxia ( $p = 0.038$ ); diseases during infancy that required hospital admission ( $p = 0.019$ ); and developmental changes that lead to ADHD as a comorbidity ( $p = 0.002$ ). Additionally, the development of language fluency in children with ASD were identified to be significantly related to severity levels as delayed/nonverbal communication were more common in severe cases ( $p < 0.001$ ), while verbal communication was more common in mild cases ( $p < 0.001$ ).

**Conclusions:** This study has found associations between specific risk factors during infancy and a subsequent diagnosis of individuals exhibiting severe symptoms of ASD. Awareness of the potential non-genetic etiological factors that may influence the severity of ASD is substantial to improve upon the current intervention strategies available as well as develop early and essential diagnostic methodologies that may alter the developmental trajectory ASD and its outcome.

#### **410.077 (Poster) Prevalence of Autism Spectrum Disorder in a Population of New Jersey Adolescents**

W. Zahorodny<sup>1</sup>, J. Shenouda<sup>2</sup>, M. Verile<sup>3</sup>, K. Sidwell<sup>4</sup>, R. Baltus<sup>5</sup>, M. Waale<sup>5</sup>, A. Fusco<sup>5</sup>, C. Cruz<sup>5</sup>, I. Gallo<sup>4</sup>, T. Gleeson<sup>5</sup>, G. Burack<sup>5</sup> and A. Mars<sup>5</sup>, (1)Department of Pediatrics, Rutgers-New Jersey Medical School, Newark, NJ, (2)Department of Pediatrics, Rutgers University, Newark, NJ, (3)Rutgers University- New Jersey Medical School, Newark, NJ, (4)Department of Pediatrics, Rutgers New Jersey Medical School, Newark, NJ, (5)Rutgers University, Newark, NJ

---

**Background:** ASD is a developmental disability defined by deficits in social communication and interaction and the presence of restricted, repetitive patterns of behavior, interest, or activity that usually persist over a lifetime (1). Indicators and epidemiologic surveys of ASD over the past twenty years indicate a substantial increase in prevalence. Almost all epidemiologic surveys have focused on school age children. ASD prevalence monitoring, at age 8 years, has been conducted in New Jersey and multiple US sites by the CDC Autism & Developmental Disabilities Monitoring (ADDM) Network. The prevalence and characteristics of ASD have not been described in a large US population of adolescents, by an active, comprehensive, epidemiologic study.

**Objectives:** The objective of the study was to estimate ASD prevalence among 16-year-olds born in 1998 residing in a well specified New Jersey area in 2014 and to describe the distribution of ASD in this population by sex, race/ethnicity and socioeconomic status.

**Methods:** The active, multiple source, ADDM ascertainment method was conducted as a 2-phase process involving comprehensive, retrospective review, scoring and analysis of information contained in professional evaluations. The method does not depend on family or practitioner reporting to determine case status and has the advantage of identifying individuals who show the ASD pattern, but did not have documented indication of ASD diagnosis. Prevalence estimates were based on surveillance determined ASD cases identified in a four-county region and population estimates were obtained from National Center for Health Statistics vintage 2019 postcensal estimates.

**Results:** In a population of 31,581 16-year-olds, born in 1998, 557 individuals were identified with ASD, consistent with a point prevalence of 17.6 per 1,000 (95% CI: 16.2-19.2). Males had higher prevalence (28.7 per 1,000; 95% CI: 26.2-31.4), compared to females (6.2 per 1,000; 95% CI: 5.1-7.6), representing a 4.6:1, male to female sex ratio. ASD prevalence was highest among whites (20.1 per 1,000; 95% CI: 17.8-22.6). Black adolescents had an ASD rate of 15.4 per 1,000 (95% CI: 12.9-18.4), while Hispanics had the lowest levels of identified ASD (12.2 per 1,000; 95% CI: 10.1-14.7). White adolescents were 1.3 times (95% CI: 1.1-1.6) and 1.7 times (95% CI: 1.3-2.1) more likely to be identified with ASD than Non-Hispanic Black and Hispanic peers, respectively. Prevalence varied by SES. ASD prevalence was two times greater among adolescents from High SES tracts (25.2 per 1,000 (95% CI: 21.8-29.2) ), compared to peers from Low SES tracts (12.5 per 1,000 (95% CI: 10.9-14.4) ).

**Conclusions:** For adolescents born in 1998 and residing in New Jersey in 2014, we identified overall ASD prevalence of approximately 2%.

**410.078 (Poster)** Prevalence of and Factors Associated with Reports of Child Maltreatment Among Children Identified By the Missouri Autism and Developmental Disabilities Monitoring Network

A. E. Duncan<sup>1</sup>, R. Fitzgerald<sup>2</sup>, M. Jonson-Reid<sup>1</sup>, B. Drake<sup>1</sup> and J. N. Constantino<sup>2</sup>, (1)Brown School, Washington University in St. Louis, Saint Louis, MO, (2)Washington University School of Medicine, St. Louis, MO

**Background:** Children and adolescents with developmental disabilities, in general, have been shown to be at higher risk of reported and substantiated maltreatment, although findings regarding whether this increased risk is shared by youth with autism spectrum disorder (ASD), in particular, are equivocal. Whether or not youth with autism are at greater risk of maltreatment than those without autism, knowledge of factors associated with reports of maltreatment is valuable for the purpose of designing interventions specific to this vulnerable population.

**Objectives:** The objectives of this study were to estimate the percentage of youth with a state-retained record of report of maltreatment and with substantiated child maltreatment; to characterize reports of maltreatment; and to identify demographic and behavioral factors associated with report of maltreatment, among children identified by the Missouri Autism and Developmental Disabilities Monitoring Network (MOADDM) as having suspected (possible or probable) or confirmed ASD.

**Methods:** State records of reports of child maltreatment were matched with records of children and adolescents aged 9-19 years who had been identified through MOADDM 2004-2014 . After calculating descriptive statistics, chi-squared tests and logistic regression were employed to identify demographic factors and autism behavioral correlates (e.g., temper tantrums, sleep problems) associated with having a report of child maltreatment, after adjusting for other factors significantly associated with autism.

**Results:** There were no significant differences between possible, probable and confirmed ASD cases for maltreatment variables, therefore results are presented for the full sample. Twenty-six percent (n=581) of the youth had at least one retained record of a report of child maltreatment, with over half (56.28%; n=327) having multiple reports. Among youth with reports, neglect was the most commonly reported form of maltreatment (70.40%), and 22.2% had a substantiated report. In unadjusted analyses, maltreatment report was associated with African American race, intellectual disability, and almost all autism-associated features assessed. After adjusting for covariates using logistic regression only African American and missing race (OR = 1.47, 95% CI = 1.08-2.01 and OR = 0.40, 95% CI = 0.19-0.83, respectively; comparison group: white), aggression (OR = 1.78, 95% CI: 1.30-2.42) and self-injurious behavior (OR = 1.54, 95% CI = 1.14-2.08) remained significantly associated with child maltreatment report.

**Conclusions:** These data build upon knowledge of the rates of child maltreatment from population-ascertained cohorts of children with ASD symptomatology. More than a quarter of the youth in the sample had reports of maltreatment. This is likely an underestimate given that the state regularly expunges some records of maltreatment. ASD behavioral correlates that increase the likelihood of a maltreatment report among youth with ASD symptomatology may be valuable in identifying children at increased risk and informing preventive interventions.

**410.079 (Poster)** Use of ATLAS.Ti to Improve Efficiency Active Surveillance of Autism Spectrum Disorder

L. Gu<sup>1</sup>, K. Sidwell<sup>2</sup>, J. Shenouda<sup>3</sup> and W. Zahorodny<sup>4</sup>, (1)Rutgers New Jersey Medical School, Newark, NJ, (2)Department of Pediatrics, Rutgers New Jersey Medical School, Newark, NJ, (3)Department of Pediatrics, Rutgers University, Newark, NJ, (4)Department of Pediatrics, Rutgers--New Jersey Medical School, Newark, NJ

**Background:** Currently, the largest ASD tracking method, the Autism and Developmental Disabilities Monitoring (ADDM) process, is an active case finding surveillance system involving the expert review of existing health and educational records of 4- and 8-year-old children. The methodology consists of 2 phases. In phase 1, research abstractors read through evaluations searching for specific words or phrases (triggers) that would indicate the need for abstraction. In phase 2, expert clinician reviewers analyze core features of ASD in the records to determine if a case meets the surveillance ASD case definition. However, the ADDM process takes two years to complete one cycle of data due to the need to manually review, abstract, and analyze data for thousands of children across multiple sites. Use of innovative technology such as ATLAS.ti, a text analytic program which allows the creation of auto-coding schemes to automatically find and flag user-specified phrases, can aid in streamlining and partially automating the surveillance process.

**Objectives:** The goal of the study is to develop an alternative automated strategy using ATLAS.ti to expedite both phases of the ADDM surveillance system.

**Methods:** The records of 8-year-olds evaluated through the ADDM method in 2016 were utilized. For abstraction determination, ATLAS.ti was automated to search for specific triggers that would indicate the need for abstraction. The results from a sample (n=66) were reviewed for quality assurance and compared to the results from the ADDM process. To determine the ASD case status, ATLAS.ti automatically identified and coded phrases that were indicative of DSM-5 ASD diagnosis criteria. The coded phrases were then analyzed to determine the case status according to DSM-5 guidelines. A sample (n=234) was used to assess performance and the results were compared to the case statuses determined through the ADDM process.

**Results:** For abstraction determination, a 100% accuracy rate was achieved with ATLAS.ti. There were no cases with an incorrect abstraction decision and no cases found to have abstraction triggers not identified in ATLAS.ti. When determining ASD case status, ATLAS.ti achieved a sensitivity of 85.5% and specificity of 89.5%. Sensitivity and specificity for each individual DSM-5 criteria code were identified (Table 1). The A1 code had the worst performance with a sensitivity of 48.2% but other codes performed with sensitivity and specificity ranging from 70-90%. The ATLAS.ti method was able to shorten the required time to review a single case to about 29 minutes while the ADDM procedure required 56 minutes (48.2% decrease) (Figure 1). The times required for phase 1 and 2 were reduced by 33% and 57.1% respectively.

**Conclusions:** For abstraction determination, the ATLAS.ti method is equally reliable as the ADDM method and more time efficient. It also performed reasonably accurately for ASD case determination and can be used to assist and prompt clinical experts during review. Overall, the ATLAS.ti program can reduce the time necessary to review cases by around half, therefore allowing accurate ASD surveillance to be determined in a timelier program-assisted manner. The ATLAS.ti program can also be further expanded to identify children with ASD through EMRs.

**410.080 (Poster) Role of Metabolic Genes (GSTT1, GSTP1, GSTM1) in Blood Lead Concentrations of Jamaican Children with and without Autism Spectrum Disorder**

**M. H. Rahbar**<sup>1,2,3</sup>, **M. E. Samms-Vaughan**<sup>4</sup>, **S. Kim**<sup>2,5</sup>, **S. Saroukhani**<sup>2,3</sup>, **J. Bressler**<sup>3,6</sup>, **M. Hessabi**<sup>2</sup>, **M. L. Grove**<sup>2,6</sup>, **S. Shakespeare-Pellington**<sup>4</sup> and **K. A. Loveland**<sup>7</sup>, (1)Division of Clinical and Translational Sciences, Department of Internal Medicine, McGovern Medical School, The University of Texas Health Science Center at Houston, Houston, TX, (2)Biostatistics/Epidemiology/Research Design (BERD) core, Center for Clinical and Translational Sciences (CCTS), The University of Texas Health Science Center at Houston, Houston, TX, (3)Department of Epidemiology, Human Genetics, and Environmental Sciences, School of Public Health, The University of Texas Health Science Center at Houston, Houston, TX, (4)Department of Child & Adolescent Health, The University of the West Indies, Mona Campus, Kingston, Jamaica, (5)Department of Biostatistics & Data Science, School of Public Health, The University of Texas Health Science Center at Houston, Houston, TX, (6)Human Genetics Center, School of Public Health, The University of Texas Health Science Center at Houston, Houston, TX, (7)Louis A Faillace, MD, Department of Psychiatry and Behavioral Sciences, McGovern Medical School, The University of Texas Health Science Center at Houston, Houston, TX

**Background:** Lead (Pb) is a toxic metal and lead poisoning during childhood is associated with neurodevelopmental impairment. Possible association between environmental exposure to Pb and Autism Spectrum Disorder (ASD) has been reported, though the findings are conflicting. Reports also suggest that polymorphisms of glutathione S-transferases (GST) genes play a key role in the detoxification of numerous exogenous chemicals including Pb.

**Objectives:** We investigated interactive associations of three metabolic GST genes (*GSTP1*, *GSTM1*, and *GSTT1*) with ASD status, and possible pairwise gene-gene interactions of these genes in relation to blood Pb concentrations in Jamaican children with and without ASD.

**Methods:** We used data from 344 ASD cases and their 1:1 age- ( $\pm 6$  months) and sex-matched typically developing (TD) controls (2-8 years old). We applied conditional logistic regression (CLR) models to compare various characteristics between ASD cases and TD children. We also used multivariable General Linear Models (GLMs) with the log-transformed blood Pb concentrations as the dependent variable to investigate the interaction between each of the three GST genes and ASD status in relation to blood Pb concentrations, while controlling for a known interaction between *GSTP1* and *GSTT1*, parish at child's birth, SES, consumption of lettuce, fried plantains, and canned fish.

**Results:** At enrollment, 71.8% of ASD cases and 74.7% of the TD controls were 48 months or older. About 83.1% of ASD cases and TD controls were male, and >94% were Afro-Caribbean. We found significantly lower geometric mean blood Pb concentrations in ASD cases than TD controls [1.74 vs. 2.27  $\mu\text{g/dL}$ ,  $P < 0.01$ ]. Also, in a co-dominant genetic model, among children with Ile/Val and Val/Val genotypes for *GSTP1*, ASD cases had significantly or marginally significantly lower adjusted geometric mean blood Pb concentrations than TD controls, after controlling for the aforementioned covariates [Ile/Val: ASD 1.78 vs. TD 2.13,  $P = 0.03$ ; Val/Val: ASD 1.50 vs. TD 1.94,  $P = 0.06$ ]. Similarly, among children with I/I or I/D ( $I^*$ ) genotype for *GSTT1* and *GSTM1*, ASD cases had a significantly lower adjusted geometric mean blood Pb concentration than their TD controls, after controlling for the aforementioned covariates [*GSTT1*  $I^*$ : ASD 1.61 vs. TD 1.91,  $P = 0.01$ ; *GSTM1*  $I^*$ : ASD 1.71 vs. TD 2.04,  $P = 0.01$ ].

**Conclusions:** To our knowledge, this is the first study that investigated interactive associations between GST genes and ASD status in relation to blood Pb concentrations in Jamaican children. Although the overall interactions were not statistically significant, we observed that children with ASD had lower blood Pb concentrations than TD controls, both in additive and interactive models. Also, we observed significantly lower blood Pb concentrations in ASD cases than TD controls among certain GST genotypes, before and after adjusting for several important covariates. Our findings show that having at least one Val allele for the *GSTP1* Ile105Val polymorphism and deletion polymorphism (DD) in *GSTT1* or *GSTM1* are associated with significantly lower blood Pb concentrations in children with ASD than TD controls, suggesting a possible role of these polymorphisms in detoxification of Pb.

**410.081 (Poster)** Sociodemographic Correlates of Health-Related Quality of Life in Children with ASD

**M. Mahjoob<sup>1</sup>**, E. Anagnostou<sup>2</sup>, B. Andrade<sup>3</sup>, J. A. Brian<sup>4</sup>, E. Kelley<sup>5</sup>, M. Ayub<sup>6</sup>, R. Cardy<sup>4</sup>, A. Iaboni<sup>7</sup>, J. ---

\*This abstract uses identity-first language which may be more representative of the autistic community's preferences.

**Background:** Health-related Quality of life (HrQoL) is an assessment of subjective wellbeing including physical and emotional health, self-esteem, family, friends, and everyday functioning. Currently, the correlates of HrQoL in autistic children focus on symptoms and functional abilities. The effect of sociodemographic correlates on HrQoL remain widely unknown due to lack of reporting or small sample sizes. Among neurotypical children, the literature suggests older age, female gender, low socioeconomic status, and identifying as Black or Latinx are typically associated with a lower HrQoL because of health inequities.

Understanding the effect of these sociodemographic correlates of HrQoL in autistic children is essential to evaluating disparities that may worsen health outcomes and to inform health policymakers accordingly.

**Objectives:** The goal of this study was to investigate the association between sociodemographic correlates of HrQoL in autistic children. Specifically, we explored whether (1) gender, age, household income, ethnicity and parental education were associated with differences in children's HrQoL, and (2) whether the impact of sociodemographic correlates on HrQoL were the same across other neurodevelopmental conditions or typical development.

**Methods:** A sample of children, from the Province of Ontario Neurodevelopmental Network (POND), with a diagnosis of autism spectrum disorder (ASD;  $n=298$ ,  $M_{age}=10.14$ ,  $SD_{age}=1.93$ ) and/or attention-deficit / hyperactivity disorder (ADHD;  $n=461$ ;  $M_{age}=9.71$ ,  $SD_{age}=1.90$ ), and neurotypical controls were recruited ( $n=154$ ;  $M_{age}=10.03$ ;  $SD_{age}=2.03$ ). Parent-reports of ethnicity, education level and household income information were collected. HrQoL was characterized by the Kid-KINDL, a self-report questionnaire for children from 7 to 13 years old.

**Results:** A diagnosis of ADHD ( $\beta=-10.05$ ;  $p<0.0001$ ) or ASD ( $\beta=-8.62$ ;  $p<0.0001$ ) were associated with reporting lower KINDL scores. Age, gender, household income, parental education level, ethnicity, and interactions between any of these variables were non-significant.

**Conclusions:** The results of this study suggest that a diagnosis of ASD or ADHD may be associated with reporting a lower quality of life. The non-significance of sociodemographic variables may be because of sample size or geography, as most of the participants are centralized in urban cities in Ontario where healthcare may be more accessible. Future research is required in larger samples from various geographical regions to better understand the relationship between sociodemographic variables and quality of life.

While the KINDL was used as a measure for HrQoL, it is important to acknowledge that quality of life is a subjective construct and may not be fully captured by an instrument such as the KINDL. To better understand the HrQoL of autistic children, qualitative and subjective HrQoL research is required. This work will be done with the hope to better equip clinicians, health policymakers and support services to empower every child in reaching their full life and health potential.

**410.082 (Poster)** Anxiety Symptoms Among Children with Autism Spectrum Disorders in Vietnam through Pediatric Anxiety Rating Scale

**C. V. Tran<sup>1</sup>** and D. Ngo<sup>2</sup>, (1)Department of Educational Sciences, Vietnam National University, Hanoi, Viet Nam, (2)National Center Special Education, Ha Noi, Viet Nam

---

**Background:** Previous findings in the field showed the high risk of co-occurring disorders in children with autism spectrum disorder (ASD) (Ghaziuddin, 2005). These comorbid disorders add to the impairment and dysfunction in ASD. Studies show that anxiety disorders, particular phobias, and separation anxiety were quite common in children with autism, accounting for about 40–60% (Farrugia et al., 2006; Leyfer et al., 2006). Anxiety disorders were believed to be the leading cause of exacerbation of autism symptoms. Thus, diagnosis and treatment of comorbid conditions could contribute to improved quality of life and general function.

**Objectives:** The present study aimed to identify the prevalence of anxiety symptoms in children with ASD and examine the relationship between parents' awareness of anxiety and anxiety state in children with ASD.

**Methods:** Using a questionnaire was a primary method in this study. A questionnaire was sent to 106 parents who had a child with ASD aged 6-12 years old. Besides general information, the questionnaire includes two parts: (1) The questions about knowledge of parents toward the anxiety in children (17 items) and (2) the Pediatric Anxiety Rating Scale for specific anxiety symptoms in children with ASD. 79.8% of participants were mothers, 18.3% were fathers, 18% had obtained a graduate degree, 56% had received a bachelor's degree. The surveyed parents' age ranged from 23 to 61 years old.

**Results:**

Regarding parents' knowledge about anxiety, none of the parents correctly answered 17 questions. The maximum score that parents can achieve was 14 points, with four parents achieving this score, accounting for 3.8% of the total. Most parents answered correctly from 8 to 12 questions, accounting for 66%. Besides, 15 parents responded only 1 to 5 questions correctly, accounting for 14% of the total number of subjects. The results from PARS indicated that there were 64.2% of children had symptoms of anxiety. In which, the most common signs were: bursting into tears when in a pressure– irritability situation, difficulty concentrating or mind becoming blank, tantrums, sleep disturbance, irritability, etc. The correlation analysis showed no statistically significant correlation between children's anxiety and parents' education level, family's economic status, children's age, and autism level ( $p>0.05$ ). There was a low positive correlation between children's anxiety and parents' knowledge of anxiety ( $p=0.016$ ;  $r=0.23$ ), indicating that the more parents know about anxiety, the more likely their children would have anxiety symptoms.

**Conclusions:** These findings may suggest more attention of parents when taking care of their children because of the high comorbid prevalence of anxiety. Besides, learning about the conditions that may be common in children with ASD is necessary to detect and intervene early. From the results, practice recommendations for families and children with ASD were provided.

**410.083 (Poster) Risk Factors for Emotional and Behavioral Problems in Children with Autism Spectrum Disorders in Vietnam**

*P. H. Nguyen<sup>1</sup> and C. V. Tran<sup>2</sup>, (1)VNU University of Education, Hanoi, Viet Nam, (2)Department of Educational Sciences, Vietnam National University, Hanoi, Viet Nam*

---

**Background:** The predicting factors of emotional and behavioral problems in children with typical development were indicated in previous studies, for instance, parents' mental health disorders or children's physical health problems, etc. (Nelson et al. 2007, Marcoux et al. 2012, Keyser et al. 2017). These findings established a broad foundation for programs to enhance well-being and treatment for mood and behavior disorders. Like children of the same age, children with ASD also have mental health problems. Determining the risk factors will provide information for building early intervention programs and models to decrease severe symptoms in their later developmental stages.

**Objectives:** Examining whether characteristics of family members, issues in the period of pregnancy, children's development, and education/intervention activities are predicting factors of emotional and behavioral problems in children with ASD.

**Methods:** Questionnaire and interview methods were used to collect information of (1) emotional and behavioral problems and (2) characteristics of family members, issues in the period of pregnancy, development, and education/intervention activities on 76 parents who have a child age 4-11 years old with ASD. Behavior Assessment System for Children, Second Edition (the BASC-2), was used to measure emotional and behavioral problems. In-depth interview methods were used to collect the data. Participants: 86.8% were mothers, 13.2% were fathers. 89.5% of children were male; 55.3% were the first child in the family, 35.5% were second, 7.9% were third. 68.4% studied at inclusive schools, 9.2% studied under the semi-inclusive model, and 22.4% studied full-time in special intervention agencies.

**Results:** Linear regression analysis was used to determine the familial factors impacting on emotional and behavioral issues of children with ASD. The results indicated that the independent variables in the *characteristic of family members* (e.g., personality of parents) influenced 17% the variation of somatization, and 12% the change of depression in children. *The issues in the period of pregnancy* (e.g., age of the parents when the child was born, period of pregnancy, children's birth weight, etc.) influenced 18% and 13% the variation of aggression and depression in children, respectively; these variables influenced 16% the variation of anxiety (difficulties in the period of pregnancy has significant contribution) and affected 11% the variation of withdrawn (numbers of the birth week has significant contribution). The variables in *children's development (cognition, language's ability, eating and sleeping's problems of children)* impacted 30% the variation of aggression, 19% the variation of anxiety, and influenced 13% the variation of depression (eating problem has significant contribution). *The education/intervention activities* (e.g., the form of education and interventional time, total intervention time, etc.) influenced 43% of externalizing problems; these variables also affected 29% the variation of anxiety (education methods at home have a significant contribution).

**Conclusions:** The factors in both parents' and children's abilities can significantly contribute to emotional and behavioral problems in children with ASD. These findings may open and need more research about the influence of pregnancy on these problems.

**410.084 (Poster) Victimization Among Students with Development Disorders Under Teachers' Viewpoint**

*C. V. Tran<sup>1</sup> and C. Le<sup>2</sup>, (1)Department of Educational Sciences, Vietnam National University, Hanoi, Viet Nam, (2)University of Education, Vietnam National University, Hanoi, Ha Noi, Viet Nam*

---

**Background:** Students with developmental disorders (DDs) usually face multiple challenges related to peer relationships when attending inclusive schools in the national education system. These challenges can lead to the experience of victimization in various forms. Adolescents with learning disabilities, intellectual disabilities, ADHD, and autism spectrum disorder who were bullied showed low levels of happy feeling (Lung, F. W et al., 2018). Determining the prevalence, causes, and ways of coping with victimization in children with developmental disorders plays an essential role in children's development and learning in an inclusive environment.

**Objectives:** This study investigates students' victimization experiences with developmental disorders participating in learning at inclusive schools based on teachers' reports to identify the current situation and related factors to raise community awareness about this urgent issue.

**Methods:** This study used a questionnaire to investigate the frequencies of various forms of victimization (i.e., relational, physical, property trespassing, and direct victimization) and causes and solutions for this phenomenon in children with DDs. The questionnaires were distributed to 55 teachers of inclusive classes having at least a child with developmental disorders. 7.3% of participants were male, 92.7% were female; the age was 23 to 54 years old with a mean age of 35.85 years; 89.1% had a bachelor's degree, 5.5% had a master's degree. For most participants, the number of

years teaching children with developmental disorders was less than five years. In 55 reported children with developmental disorders, 30% had autism spectrum disorder, 50.9% had an intellectual disability, etc.; 74.5% were male, and 25.5% were female; the age range from 7-13 years old and mean age was 8.8 years.

**Results:** All children were reported to be victimized by at least one of the forms. Regarding relational victimization, 10.9% were often refused to play together, 7.3% were slandered, and 5.5% were spread out untrue rumors by classmates. Regarding direct victimization, 9.1% was often teased, 5.5% was assigned with a bad nickname, 3.6% was threatened. In addition, there were 16.4% sometimes forced to do errands, 12.7% were kicked, hit by peers, more than 15% were property trespassed, such as taking money, school supplies without children's permission. According to teachers, the causes of victimization were: children with developmental disorders did not like playing with other children, had different behaviors, did not know how to play with peers; the classmates did not understand peers with DDs, and teachers had little time to take care of them. Teachers' most popular solutions involved teaching the difference, respecting and accepting the difference for other students (90.9%), and closely combining teachers and parents to support children (87.3%).

**Conclusions:** The above results showed alert prevalence of children with developmental disorders' victimization experience. These findings suggest future research that examines strategies for coping and reducing victimization among this population. Hence, there is a need for more study on this topic in Vietnam.

## VIRTUAL POSTER SESSION — EPIDEMIOLOGY

### 510 - Epidemiology --- (V)

**510.042 (Virtual Poster)** Are There Sex Differences While Assessing Interactive Associations of Environmental Exposure to Three Heavy Metals Lead (Pb), Mercury (Hg) and Manganese (Mn) with GST (GSTP1, GSTM1 and GSTT1) Genes in Relation to ASD in Jamaican Children **H. Zwiya<sup>1</sup>, M. E. Samms-Vaughan<sup>2</sup>, J. Bressler<sup>3,4</sup>, M. Lee<sup>5,6</sup>, C. E. Byrd-Williams<sup>7</sup>, M. Hessabi<sup>8</sup>, M. L. Grove<sup>3,4</sup>, S. Pellington<sup>2</sup>, K. A. Loveland<sup>9</sup> and M. H. Rahbar<sup>4,8,10</sup>**, (1)UTHealth School of Public Health, Houston, TX, (2)Department of Child & Adolescent Health, The University of the West Indies, Mona Campus, Kingston, Jamaica, (3)Human Genetics Center, School of Public Health, The University of Texas Health Science Center at Houston, Houston, TX, (4)Department of Epidemiology, Human Genetics, and Environmental Sciences, School of Public Health, The University of Texas Health Science Center at Houston, Houston, TX, (5)Department of Biostatistics & Data Science, School of Public Health, University of Texas Southwestern Medical Center, Dallas, TX, (6)Harold C. Simmons Comprehensive Cancer Center, University of Texas Southwestern Medical Center, Dallas, TX, (7)Health Promotion & Behavioral Sciences, School of Public Health, The University of Texas Health Science Center at Houston, Austin, TX, (8)Biostatistics/Epidemiology/Research Design (BERD) core, Center for Clinical and Translational Sciences (CCTS), The University of Texas Health Science Center at Houston, Houston, TX, (9)Louis A Faillace, MD, Department of Psychiatry and Behavioral Sciences, McGovern Medical School, The University of Texas Health Science Center at Houston, Houston, TX, (10)Division of Clinical and Translational Sciences, Department of Internal Medicine, McGovern Medical School, The University of Texas Health Science Center at Houston, Houston, TX

**Background:** Male preponderance is well established among ASD cases, however, the differences between males and females have not been thoroughly assessed in relation to metal exposure including Pb, Hg and Mn. Furthermore, glutathione S-transferase (GST) genes play a crucial role in suppressing oxidative stress caused by metal exposure due to the enzymatic function of the proteins encoded. We investigated possible gene-environment interactions between sex, GST genes, and environmental exposure to three heavy metals in relation to ASD and ASD severity in Jamaican children.

**Objectives:** To determine whether the association between heavy metals and ASD differs in males and females and by the genotypes of three GST genes (*GSTP1*, *GSTT1*, and *GSTM1*).

**Methods:** Using 344 pairs from a 1:1 sex- and age- matched case control study, we applied conditional logistic regression (CLR) models and Generalized Linear Models (GLM) with ASD status and ASD calibrated severity score (CSS) as outcome variables, respectively. Sex was assessed as an effect modifier for the association between each metal and ASD in both unadjusted and adjusted multivariable models. If a significant 2-way interaction was detected between sex and a GST gene, a metal exposure was added subsequently to explore a possible 3-way interaction.

**Results:** There were significant and marginally significant interactions between sex \* *GSTP1* and sex \* *GSTM1*, respectively, upon exposure to Pb ( $P = 0.04$ ,  $P = 0.09$ ) using recessive genetic models and CLR. For *GSTP1*, after adjusting for parental age, child's parish, consumption of salt fish and the interaction between *GSTT1* and *GSTP1*, we found a lower odds of Val/Val genotype for ASD cases than TD controls among females ( $MOR_{females} = 0.23$  95% CI: 0.05-1.11,  $P = 0.06$ ), and higher odds among males ( $MOR_{males} = 1.18$  95% CI: 0.66-2.16,  $P = 0.57$ ). Similar results were detected for the sex \* *GSTM1* recessive model. In GLMs using co-dominant and recessive genetic models, a marginally significant and significant interaction were detected between sex \* *GSTP1* in relation to ASD CSS upon exposure to Hg ( $P = 0.084$ ,  $P = 0.036$ , respectively). For the *GSTP1* recessive model, the mean difference in ASD CSS in those with Val/Val genotype compared to Ile/Ile or Ile/Val genotype was 0.30 for males and -1.34 for females adjusting for parental age, parental education, consumption of shellfish and interaction between *GSTT1* and *GSTP1*.

**Conclusions:** Hg or Pb exposure was significantly associated with ASD in both males and females. When we further evaluated associations with GST genes, significant and marginally significant 2-way interactions with sex were detected, with no significant overall 3-way interactions between sex, gene, and metal exposures. The association of Pb exposure with ASD significantly differed by sex under the *GSTP1* and *GSTM1* recessive genetic models. Similar sex differences in the association between Hg exposure and ASD CSS were detected under *GSTP1* co-dominant and recessive genetic models. While these findings may reflect potential sex-differences in metal detoxification mechanisms and bioaccumulation upon exposure to Pb and Hg, replication is warranted due to limitations in sample size for female participants in this study.

**510.043** (Virtual Poster) Background of Sleep Problems in Preschoolers; Analysis of Factors Including Neurodevelopmental Disorders

A. Kuki<sup>1</sup>, M. Saito<sup>2</sup>, Y. Sakamoto<sup>2</sup>, A. Terui<sup>2</sup>, A. Osato<sup>3</sup>, T. Mikami<sup>3</sup> and K. Nakamura<sup>3</sup>, (1)Hiroaki University, Hiroaki, Japan, (2)Department of Neuropsychiatry, Graduate School of Medicine, Hiroaki University, Hiroaki, Japan, (3)Research Center for Child Mental Development, Graduate School of Medicine, Hiroaki University, Hiroaki, Japan

---

**Background:**

Sleeping is important for children's growth. Therefore, medically, there are concerns that many children have sleep problems in recent years. Previous studies have reported that the percentage of children with sleeping disorder is different depending on countries or presence or absence of developing disorder.

**Objectives:**

The purpose of this study is to research what kind of factors are associated to children's sleep problems and whether sleep problems are different depend on factors.

**Methods:**

We used 2341 children's data (Hiroaki Five-year-old children Developmental Health Check-up Study: HFC Study). We analyzed the following items: JSQP (Japanese Sleep Questionnaire for Preschoolers) score, parent-survey(Income, family composition, and so on) mother and child hand book records, non scoring questions of JSQP and DSM-5 diagnosis JSQP score is the data about sleeping, and the other data is about children's environments, behaviors or characters. We defined sleeping disorder as JSQP-total-score $\geq$ 86 (Simizu, et al.2013), and chi-squared tests were performed to find significant differences of percentages of sleeping disorder due to children's environments, behaviors or characters. Furthermore, Kruskal-Wallis test was performed to find what type of problems appear due to the environment, behavior, or character.

**Results:**

The percentage of sleeping disorder was significantly high in these groups; ASD, ADHD (diagnosis), less than two million yen (annual income), no siblings (the number of siblings), 22:00 or later (bed time), 7:30 or later (wake up time), shorter than 9 hours (sleeping time) and shorter than one hour and one hour or longer (The time it takes to fell asleep). These facts showed different type of problem from each other.

Meanwhile, the percentage of SD was significantly low in these groups; TD, four to seven million yen, two or more siblings, earlier than 21:00 and 21:00 to 21:59, earlier than 6:30, shorter than 10 minutes and shorter than 20 minutes.

There were no significant differences in birth month and child care places during day time.

**Conclusions:**

Developing disorder and some factors in family background or behavior are associated to sleep problems in children. And also, depending on the difference of the factors, the type of sleep problems is different.

**510.044** (Virtual Poster) Disparities in the Proportion of Children with Autism Spectrum Disorder Classified As "Low Functioning" or with Co-Occurring Intellectual Disability: Evaluation of the Impact of Adaptive Behavior Scores

S. M. Furnier<sup>1,2</sup>, M. S. Durkin<sup>2,3</sup>, S. Ellis-Weismer<sup>4</sup>, C. Nadler<sup>5</sup>, K. Pazol<sup>6</sup>, N. Reyes<sup>7</sup>, S. Rosenberg<sup>8</sup>, E. Rubenstein<sup>9</sup> and L. Wiggins<sup>10</sup>, (1)Population Health Sciences, University of Wisconsin-Madison, Madison, WI, (2)Waisman Center, University of Wisconsin-Madison, Madison, WI, (3)Population Health Sciences, University of Wisconsin School of Medicine and Public Health, Madison, WI, (4)University of Wisconsin-Madison, Madison, WI, (5)Children's Mercy Kansas City, Kansas City, MO, (6)Division of Human Development and Disability, Centers for Disease Control and Prevention, National Center on Birth Defects and Developmental Disabilities, Atlanta, GA, (7)JFK Partners, University of Colorado Anschutz Medical Campus, Aurora, CO, (8)University of Colorado Anschutz Medical Campus, Aurora, CO, (9)Epidemiology, Boston University School of Public Health, Boston, MA, (10)Centers for Disease Control and Prevention, Atlanta, GA

---

**Background:** Epidemiologic and clinical studies of autism spectrum disorder (ASD) often rely on intelligence quotient (IQ) scores as the sole criterion for defining co-occurring intellectual disability (ID). However, definitions from ID organizations and diagnostic manuals specify limitations in adaptive behaviors as an additional criterion for ID. U.S. studies have found disparities among children with ASD, with significantly increased frequency of co-occurring ID among non-Hispanic Black (NHB) and Hispanic children relative to non-Hispanic White (NHW) children. Disparities in ID classification among children with ASD could be due to bias resulting from overreliance on IQ testing and insufficient attention to adaptive functioning and contributing social and structural factors.

**Objectives:** We hypothesized that defining co-occurring ID based on having both Mullen Scales of Early Learning (MSEL) and Vineland Adaptive Behavior Scales, 2<sup>nd</sup> Edition (VABS-II), scores  $\geq$  2 standard deviations below the mean would result in a lower proportion of children with ASD classified as having ID than when ID is defined using only MSEL scores. We then examined racial/ethnic disparities in the co-occurrence of ID

among children with ASD using both approaches and hypothesized that incorporating VABS-II scores to classify ID would reduce disparities in the frequency of low intellectual functioning among children with ASD.

**Methods:** The Study to Explore Early Development is a large multisite case-control study of children aged 2-5 years with ASD, developmental delays without ASD, or typical development. This analysis included 1,480 children with an Autism Diagnostic Interview-Revised- and Autism Diagnostic Observation Schedule-confirmed ASD classification. Alternative criteria were used to calculate percentages of children classified as having co-occurring ID based on (i) MSEL Visual Reception (VR) T-score  $\leq 30$ , used as a proxy for nonverbal IQ; (ii) MSEL Early Learning Composite (ELC)  $\leq 70$ ; and (iii) VR T-score  $\leq 30$  and VABS-II Adaptive Behavior Composite (ABC) standard score  $\leq 70$ . Prevalence ratios with 95% confidence intervals were calculated to evaluate racial/ethnic disparities in the frequency of co-occurring ID and whether addition of the VABS-II criterion reduced these disparities.

**Results:** Overall, 49.5% of children met ID criteria based on MSEL VR T-scores alone; addition of the VABS-II criterion reduced the proportion to 34.1%. The percentages of children with VR T-scores  $\leq 30$  were 40.0% for NHW, 64.6% for NHB, and 52.6% for Hispanic children; addition of the VABS-II criterion lowered these proportions significantly to 27.1% (NHW), 44.9% (NHB), and 35.5% (Hispanic). NHB and Hispanic children were approximately 1.6 and 1.3 times, respectively, more likely to meet ID criteria than NHW children. Prevalence ratios were significantly  $>1$  and unaffected by inclusion of the VABS-II ABC  $\leq 70$  criterion. Results using MSEL ELC scores were similar.

**Conclusions:** Using IQ as the sole criterion for ID may overestimate the prevalence of co-occurring ID in preschool children with ASD according to diagnostic criteria, suggesting the need for reexamination of how functioning is classified in ASD research. Our finding that disparities in co-occurring ID persisted after addition of the VABS-II criterion suggests that social and structural factors contributing to these disparities need to be better understood and addressed through additional studies.

**510.045 (Virtual Poster)** Estimating the Prevalence of Autism Spectrum Disorders in 3-Year-Old Children in Community-Based Survey  
**M. Saito<sup>1</sup>, T. Mikami<sup>2</sup>, A. Terui<sup>1</sup>, Y. Sakamoto<sup>1</sup>, A. Osato<sup>3</sup>, M. Takahashi<sup>3</sup>, M. Adachi<sup>3</sup>, T. Hirota<sup>4</sup> and K. Nakamura<sup>2</sup>,** (1)Department of Neuropsychiatry, Graduate School of Medicine, Hirosaki University, Hirosaki, Japan, (2)Research Center for Child Mental Development, Graduate School of Medicine, Hirosaki University, Hirosaki, Japan, (3)Department of Clinical Psychological Science, Hirosaki University, Hirosaki, Japan, (4)University of California, San Francisco (UCSF), San Francisco, CA

**Background:** In recent years, the prevalence report of autism spectrum disorder (ASD) has been increasing. From the viewpoint of epigenetics, genetic factors and environmental factors influence the expression of the phenotype of neurodevelopmental disorders. Epidemiological surveys are important in these studies, and it is necessary to steadily investigate the annual transition. The US CDC reports a prevalence of ASD aged 8 years at 1.85% (2020), and South Korea (YS Kim) reports a prevalence of ASD aged 7-12 years at 2.64% (95% CI = 1.91-3.37). (2010). Last year, Hirosaki University reported that the prevalence of autism spectrum disorder (ASD) at age 5 was 3.22% (95%CI : 2.66–3.76%) and that there was no change in the 4-year cumulative incidence (Saito M. 2020).

**Objectives:** In this study, we used the SRS-2 Interpersonal Response Scale (SRS-2) and a shortened version of PARS-TR to calculate the estimated prevalence of ASD in community 3-year-olds.

**Methods:** 1090 participants in the 2018 regional 3-year-old development health checkup (participation rate 99.8%: 1093 all subjects) and 1174 participants in the 2019 3-year-old child developmental health checkup (participation rate 97.5%: 1203 all subjects). Survey scale: (1) SRS-2 infant version (sensitivity 0.82 at 52 points of cutoff, specificity 0.80, Stickley, 2017), (2) PARS-TR shortened version ( $\alpha$  is 0.78 in PDD group, non-PDD group at 5 points of rating cutoff as of early childhood) The estimated prevalence of ASD was calculated using 0.67, Adachi, 2008). In parallel, SDQ and sensory profile shortened version were performed. The PARS-TR shortened version was implemented at the site's discretion even if the SRS-2 infant version had a score of 43 points or higher (community risk child standard) or a score of 42 points or lower. Exclude only non-participants. Statistical analysis used t-test and  $\chi^2$  test. This research was supported by the Hirosaki City Commissioned Research Fund, and was explained in writing with the approval of the Hirosaki University Graduate School of Medicine Ethics Committee, and the consent of parents was obtained.

**Results:** In the 2018 survey, 49 boys (8.6%) and 22 girls (4.2%) were SRS-2 infants with 52 points or more, for a total of 71 (6.5%). Of these, 31 responded to the PARS-TR shortened version with 5 points or more. Estimating the prevalence from these, the population ratio was 2.84% (95% CI: 1.997-4.022). Similarly, in the 2019 survey, SRS-2 infant version 52 points or more was 46 boys (7.5%) and 33 girls (5.9%), a total of 79 (6.7%). Of these, 33 responded to the PARS-TR shortened version with 5 points or more. Similarly, when estimating the prevalence of ASD, the population ratio was 2.81% (95% CI: 1.996-3.934), which was almost the same as the previous year's estimate.

**Conclusions:** Using the possibility of ASD diagnosis by SRS-2 and PARS-TR, the estimated prevalence of ASD in 3-year-old children was estimated to be 2.8%. There is no difference compared to the adjusted prevalence of 5-year-olds in the region, and the eyes of ASD that should be detected early in 3-year-old children.

**510.046 (Virtual Poster)** Identifying Classes of Neurodevelopmental Perinatal Risk Factors Among Mothers of Children at High Familial Risk for Autism Spectrum Disorder  
**A. Budavari<sup>1</sup>, R. Musci<sup>2</sup>, L. A. Croen<sup>3</sup>, M. D. Fallin<sup>4</sup>, I. Hertz-Picciotto<sup>5</sup>, K. Lyall<sup>6</sup>, C. J. Newschaffer<sup>7</sup>, R. J. Schmidt<sup>8</sup> and H. E. Volk<sup>1</sup>,** (1)Department of Mental Health, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (2)Mental Health, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (3)Division of Research, Kaiser Permanente Division of Research, Oakland, CA, (4)Wendy Klag Center for Autism and Developmental Disabilities, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (5)University of California at Davis, Davis, CA,

**Background:** Perinatal complications have been implicated in the etiology of ASD and related neurodevelopmental impairments. Previous approaches to studying these risk factors, such as single factor, sum scores, or weighted sum scores, have been limited in their ability to consider multiple, co-occurring factors and their underlying mechanisms. A novel, person-centered approach can address these shortcomings by allowing for the simultaneous examination of multiple perinatal risk factors through the clustering of mothers.

**Objectives:** The current study utilized data from the Early Autism Risk Longitudinal Investigation (EARLI) to identify classes of mothers based on their reported neurodevelopmental perinatal risk (NPR) factors.

**Methods:** EARLI enrolled pregnant mothers, who had a previous child with ASD, and followed a subsequent child through 36 months of age. NPR factors are pregnancy-related risk factors (e.g., reproductive history, supplement use, perinatal complications) that have been previously associated with poor neurodevelopmental outcomes. NPR factors were collected prospectively through weekly pregnancy diaries, self-report questionnaires, and clinician administered interviews. We conducted a Latent Class Analysis (LCA) using 10 NPR factors reported during the mother's pregnancy with the younger sibling. The best latent class solution was identified using fit statistics and clinical judgement.

**Results:** The sample included 247 mothers (61% white, mean age at sibling's birth = 33.8 +/- 4.74). Our LCA indicated a 4-class solution best fit the data. Class 1 (n = 146, 59%), "Low Complications", was characterized by overall low levels of NPR factors. Class 2 (n = 49, 20%), "High Infection and Mental Health Symptoms", was characterized by mothers most frequently endorsing any infection during pregnancy in combination with diagnoses of depression and anxiety during the pregnancy with the younger sibling. Class 3 (n = 34, 14%), "Vaginal Bleeding and Low Supplement Use", was characterized by increased frequency of reported vaginal bleeding, high pre-pregnancy weight, and poor supplement intake during pregnancy. Class 4 (n = 18, 7%), "Mixed Supplement Use, High Infection, and Moderate Mental Health", was identified based on endorsement of the lowest rates of prenatal vitamin use, along with the highest rates of multivitamin, folic acid, and vitamin D supplement use, as well as high frequency of infection and moderate frequency of depression and anxiety diagnoses.

**Conclusions:** Mothers of children with ASD could be classified into four distinct patterns of NPR factors during their subsequent pregnancy. The high rates of specific NPR factors, such as vaginal bleeding and infection, may serve as targets for intervention, while the unique combination of NPR factors in each class demonstrates how multiple exposures and mechanisms may combine to increase risk for poor outcomes. These findings suggest shortcomings of previous approaches, given that multiple NPR factors, arising from different underlying mechanisms, occur in tandem. Future work will examine the association between the classes identified here with numerous covariates (e.g., ASD polygenic risk score, biomarkers of maternal immune activation) and child neurodevelopment outcomes.

#### **510.047** (Virtual Poster) Inclusion of Low-Income Children in Estimates of the Population Prevalence of Autism Spectrum Disorder: A Data Linkage Study

**O. M. Pokoski<sup>1</sup>, M. S. Durkin<sup>2</sup>, S. M. Furnier<sup>1</sup> and A. Salinas<sup>3</sup>,** (1)Population Health Sciences, University of Wisconsin-Madison, Madison, WI, (2)Population Health Sciences, University of Wisconsin School of Medicine and Public Health, Madison, WI, (3)Waisman Center, University of Wisconsin-Madison, Madison, WI

---

**Background:** Epidemiologic studies have found socioeconomic, racial, and ethnic disparities in diagnosing autism spectrum disorder (ASD) in the United States, with resulting prevalence estimates being positively correlated with socioeconomic status (SES) and elevated in non-Hispanic White (NHW) relative to other populations. Previous studies may be biased due to limited population coverage and under-representation of low-income children. Administrative data sources have potential to estimate statewide prevalence of ASD more efficiently and could aid in including lower income populations.

**Objectives:** The aims of this study were to: (1) describe the statewide prevalence of ASD in the state of Wisconsin among children and adolescents between the ages of 5 and 18 years in 2018 using administrative data from the Department of Public Instruction (DPI) and claims for Medicaid covered healthcare for low-income families; and (2) describe the impact of including Medicaid data on observed racial and ethnic disparities in ASD prevalence.

**Methods:** Students with an ASD primary disability code were ascertained through DPI data for those enrolled in public schools in Wisconsin in 2018. Medicaid claims data from 2018 were reviewed for ASD diagnostic information for children and adolescents born between 2000 and 2013. The overall prevalence of ASD was then calculated for each source by dividing the count of individuals with ASD by the total population enrolled in public schools and Medicaid, respectively. To get an unduplicated count of ASD combining the sources, individuals in the Medicaid data were matched to the DPI records based on first name, last name, date of birth, sex, and race. Odds ratios with 95% confidence intervals (CI) were calculated to evaluate the racial and ethnic disparities in the frequency of ASD and evaluate whether disparities based on school data were affected by the inclusion of Medicaid claims.

**Results:** Based on public education data alone, ASD prevalence was estimated to be 14.9 (95% CI: 14.6, 15.2) per 1,000 students. Combining Medicaid and DPI data sources, the unduplicated prevalence of ASD in Wisconsin increased to 19.2 (95% CI: 18.9, 19.5) per 1,000 children and adolescents between the ages of 5 and 18 in 2018. Among low-income children enrolled in Medicaid, ASD prevalence was estimated to be 37.4 (95% CI: 36.7, 38.1) per 1,000. When prevalence was estimated from education data alone, it was significantly lower for Hispanic and non-Hispanic Black (NHB) students relative to NHW students. However, after the inclusion of Medicaid data, Hispanic and NHB children were 1.94 and 1.47 times more likely than NHW children to have ASD, respectively.

Conclusions: Using Medicaid claims data is necessary to obtain a complete prevalence estimate of ASD for the state of Wisconsin. Racial and ethnic differences in ASD prevalence are reversed with the inclusion of these data, as opposed to solely examining those identified as having ASD in public schools in Wisconsin. Further research is needed to determine why children with ASD served by Medicaid are not captured as having ASD based on educational data alone.

**510.048 (Virtual Poster)** Maternal Vitamin D Level and Air Pollution Exposure during Pregnancy: Findings from the Early Markers for Autism (EMA) Study

**X. Qu<sup>1</sup>, H. E. Volk<sup>2</sup>, J. L. Ames<sup>3</sup>, G. C. Windham<sup>4</sup>, K. Berger<sup>4</sup> and L. A. Croen<sup>5</sup>,** (1)*Mental Health, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD*, (2)*Division of Research, Kaiser Permanente Northern California, Oakland, CA*, (3)*Environmental Health Investigations Branch, California Department of Public Health, Richmond, CA*, (4)*Sequoia Foundation, La Jolla, CA*, (5)*Division of Research, Kaiser Permanente Division of Research, Oakland, CA*

---

Background: Literature has reported that both higher air pollution exposure and lower Vitamin D (VD) concentrations during pregnancy may increase the risk of autism spectrum disorder (ASD). The overall null findings for VD and air pollution in some studies might be explained by potential correlation and confounding effects, as VD from sunlight will decrease as air pollution levels increase.

Objectives: This study aims to explore the existence of an association between maternal VD level and air pollution during pregnancy, and how this relationship affects the association of maternal VD level with ASD and intellectual disability (ID) in the offspring.

Methods: We examined maternal VD levels and air pollution exposure during pregnancy in the Early Markers for Autism (EMA) study, which is a population-based case-control study in Southern California. Children with ASD without intellectual disability (ASD without ID; n=190), ASD with ID (ASD with ID; n=175), ID without ASD (ID only; n=159) were identified through the Department of Developmental Services record and compared to general population controls (n=430) from birth certificate. 25-Hydroxyvitamin D (25(OH)D) was measured in maternal serum samples collected during weeks 15-19 of gestation. 25(OH)D was examined continuously and also dichotomized as deficient/insufficient (<75 nmol/L), and sufficient (≥ 75 nmol/L). Air pollution exposure to NO<sub>2</sub>, Ozone, PM<sub>10</sub> and PM<sub>2.5</sub> for the month prior to the date of the mid-pregnancy serum collection was assigned using measurements from the Environmental Protection Agency's Air Quality System based on the maternal residential address during pregnancy. We first assessed the association of maternal VD level and air pollution exposure using linear and logistic regression models among general population controls. Then we compared the logistic regression models of VD and child outcomes with and without adjustment for four air pollutant exposures. Sociodemographic and maternal characteristics were adjusted in the models, including child sex, birth year, birth reason, maternal age, maternal race/ethnicity, insurance type, county, maternal education, parity.

Results: Maternal VD level decreased with increasing exposure to NO<sub>2</sub>, PM<sub>10</sub> and PM<sub>2.5</sub> and increased with increasing exposure to Ozone. The association of VD level with PM<sub>10</sub> (b=-5.53 (-9.65, -1.41)), NO<sub>2</sub> (OR=1.62 (1.08, 2.46)) and PM<sub>2.5</sub> (OR=1.91(1.18, 3.13)) remained significant after adjustment for covariates. There was no significant association of maternal VD level with ASD with ID, ASD without ID or ID without ASD. When adjusting for each of the air pollutant exposures, the above relationships did not change, except that the point estimate of the association between ASD with ID and maternal VD level increased slightly after adjusting PM<sub>2.5</sub> exposure level.

Conclusions: Our results indicated there was an association between air pollution exposure and maternal VD level in mid-pregnancy in general population, but little evidence supporting that the association confounds the impact of maternal VD level on ASD or ID statistically. Future research in large samples is needed to assess both independent and interactive effects of maternal air pollution exposure and VD level on ASD risk, with attention to different developmental time windows.

**510.049 (Virtual Poster)** Parental Occupational Exposures Are Associated with Autism Behaviors.

**E. C. McCanlies<sup>1</sup>, J. K. Gu<sup>2</sup>, W. T. Sanderson<sup>3</sup> and I. Hertz-Picciotto<sup>4</sup>,** (1)*CDC/NIOSH, Morgantown, WV*, (2)*HELD/BB, NIOSH, Morgantown, WV*, (3)*College of Public Health, University of Kentucky, Lexington, KY*, (4)*University of California at Davis, Davis, CA*

---

Background: Individuals with autism spectrum disorder (ASD) frequently display skill deficits or challenging behaviors such as stereotypy, hyperactivity, or aggressive behaviors. Little research has been conducted showing the role of environmental factors with ASD behaviors and to our knowledge, no studies have been done evaluating parental occupational exposures and cognitive, adaptive, and behavioral scores in children with ASD.

Objectives: The aim of the current study was to investigate the relationship between parental occupational exposures and cognitive, adaptive, and behavioral scores in children with ASD.

Methods: Demographic, diagnostic, and prenatal parental occupational exposure data for 534 children with ASD and their parents were collected in the case-control Childhood Autism Risks from Genetics and Environment (CHARGE) study. Children were assessed using the Mullen Scales of Early Learning (MSEL), Vineland Adaptive Behavior Scales (VABS), and Aberrant Behavior Checklist (ABC). The MSEL is an early learning assessment of child expressive language, receptive language, visual reception, and fine motor skills. The VABS is a parent interview of child adaptive behaviors in communication, daily living, social, and motor skills. The ABC is a parent questionnaire that assesses irritability, social withdrawal, stereotypic behavior, hyperactivity, noncompliance, and unusual speech. Higher MSEL and VABS scores indicate greater skill acquisition whereas higher ABC scores indicate more problem behaviors. Occupational exposures to 16 agents were estimated semi-quantitatively by experienced industrial hygienists (IH) based on parents' job histories. For each agent, mean composite and subscale scores on cognitive, adaptive and behavioral domains were estimated across no, low, and high levels of exposure using ANCOVA models.

Results: As fathers' exposures to auto/mechanic fluids, cutting/machining fluids, pharmaceuticals, ethylene oxide, and plastics/polymers increased, MSEL and VABS scores decreased, and ABC scores increased among children with ASD. Similarly, mothers' occupational exposures to metals, ethylene oxide and anesthetic gases were associated with lower MSEL and VABS scores and higher ABC scores. Specific subscales affected by multiple exposures were expressive language (MSEL), socialization and communication (VABS), and irritability and hyperactivity (ABC).

Conclusions: Several classes of parental occupational exposures showed associations with poorer language and social skills and greater irritability and hyperactivity among children with ASD. This study is among the first to suggest that neurodevelopmental toxicity from parental workplace exposures may play a role in functional impairments for children with ASD.

**510.050** (Virtual Poster) Responses to COVID-19 Pandemic and Their Associations with Neurodevelopmental Traits in a General Population Sample of 5 Years Old Children in Japan

**Y. Sakamoto<sup>1</sup>, M. Saito<sup>1</sup>, T. Hirota<sup>2</sup>, A. Osato<sup>3</sup>, A. Terui<sup>1</sup>, T. Mikami<sup>2</sup> and K. Nakamura<sup>1</sup>,** (1)Department of Neuropsychiatry, Graduate School of Medicine, Hirosaki University, Hirosaki, Japan, (2)University of California, San Francisco (UCSF), San Francisco, CA, (3)Research Center for Child Mental Development, Graduate School of Medicine, Hirosaki University, Hirosaki, Japan

---

**Background:** Some studies have reported that COVID-19 pandemic has significant impact on children's mental health. Particularly, UNICEF has advocated that we should have it in mind that children with autism may also have some specific needs for support due to the difficulties.

**Objectives:** This study aimed to investigate responses to COVID-19 pandemic and their associations with neurodevelopmental traits in a general population sample of 5 years old children in Japan.

**Methods:** The subjects were recruited from participants in the 5-year-old developmental checkup in Hirosaki city, Japan. Between July 2021 to August 2021, the 652 children were eligible for the checkup. Caregivers of 463 children (85.7% participation rate) completed and returned the CRISIS AFAR, a questionnaire about COVID-19, and consented to this study (boys:girls =252:211, mean age=63 months). The following measures were used: CRISIS AFAR, the Autism Spectrum Screening Questionnaire(ASQ), the Strength and Difficulties Questionnaire(SDQ), and the Developmental Coordination Disorder Questionnaire(DCDQ) Japanese version. The CRISIS AFAR includes questions about children's daily behaviors and emotions/worries, and it was translated into Japanese by research collaborators. One of the SDQ subscales is "Prosocial behavior" (SDQ-PB). The DCDQ subscales are "control during movement"(gross motor), "fine motor", and "general coordination". Statistical analysis was performed using Pearson correlation coefficient( $p<0.05$ ).

**Results:** 64% of children worried that they might also get infected, and their friend and their family could get infected. 66% of children worried that they might get sick somewhere due to the infection. 40% of children worried that the infection could make him/her sick. 93% of children talk about infections. 92% of children were disappointed with the cancellation of events. Pearson correlation coefficient showed that positive correlation between ASQ and "Worries about their sick" ( $r=0.092$ ,  $p<0.05$ ); negative correlation between ASQ and "Talk about infections"( $r=-0.129$ ,  $p<0.05$ ); positive correlation between SDQ-PB and "Worries about infecting family"( $r=0.150$ ,  $p<0.05$ ); positive correlation between SDQ-PB and "Worries that child might get sick somewhere ( $r=0.091$ ,  $p<0.05$ )"; positive correlation between SDQ-PB and "Talk about infections"( $r=0.114$ ,  $p<0.05$ ); positive correlation between SDQ-PB and "Disappointing with the cancellation of events" ( $r=0.094$ ,  $p<0.05$ ); positive correlation between DCDQ-control during movement and "Talk about infections" ( $r=0.110$ ,  $p<0.05$ ); positive correlation between DCDQ-fine motor and "Talk about infections"( $r=0.186$ ,  $p<0.05$ ); negative correlation between DCDQ-general coordination and "Worries about their sick"( $r=-0.098$ ,  $p<0.05$ ). From the above, 1) The children with autism tend to worry about their own sick and not talk about it. 2) The children with less prosocial behavior tend not to talk about infection, not to worry about infecting them and/or their family, and not to disappoint about cancellation of an event. 3)The children who have difficulty with gross motor and fine motor tend not to talk about infection. 4) The children who have difficulty with general coordination tend to worry about their own sick.

**Conclusions:** This study showed the association between responses to COVID-19 pandemic and neurodevelopmental traits in 5 years old children. We should take neurodevelopmental traits into account when we assess the impact of COVID-19 pandemic on children's mental health.

**510.051** (Virtual Poster) Significant Adverse Experiences and Neurodevelopmental Difficulties in Childhood and Adolescence: A Scoping Review  
**J. Baud, K. Williams and A. Ure, Monash University, Clayton, VIC, Australia**

---

**Background:**

Adverse childhood experiences (ACEs), including abuse, neglect, and household dysfunction, may impact neurodevelopment in children and adolescents. However, the relationship is complicated by social disparity and the vulnerability of individuals with neurodevelopmental difficulties to experience maltreatment.

**Objectives:**

This study aims to synthesise extant literature associated with ACEs and its association with specific neurodevelopmental difficulties (NDs), including autism spectrum disorder (autism), attention deficit/hyperactivity disorder, language difficulties, learning difficulties, global developmental delay and intellectual disability in children and adolescents.

## Methods:

The Joanna Briggs Institute (JBI) scoping review guidelines were followed to complete the current scoping review. Peer reviewed studies were identified using a comprehensive search strategy across four electronic databases. From a total of 3269 papers screened, 180 were included for full text review. From these, 26 primary studies and 3 case studies were included for data synthesis.

## Results:

There is overwhelming evidence to suggest a positive association exists between ACEs and NDs, with most evidence for an association between the experience of neglect, and language and/or 'autism-like' difficulties. A first group of studies (42%) reported on prevalence of NDs (ranging in 3.85% – 85%) amongst samples of children with a history of ACE. A second group of studies (58%) assessed the association between ACEs and NDs (ORs ranging from 1.24 – 17.5) by comparing NDs in groups of children with and without a history of ACE. Only one included study utilized a longitudinal approach, demonstrating children exposed to family violence in infancy were more likely to exhibit communication and language problems at age ten. Seven included studies explored temporal associations between variables, age and duration of neglect during institutionalisation and subsequent identification of NDs. No studies reported the age of onset of NDs.

## Conclusions:

Whilst an association between ACEs and NDs is clear, the nature of the relationship remains poorly understood. Prospective research is needed to better understand the potential interplay of factors, including timing of exposure to ACEs and its potential impact on the developing brain, as well as trial assessments that differentiate subgroups of trauma as a cause, co-contributor, and consequence of neurodevelopmental difficulties. Also needed are trials to assess the effectiveness of interventions once ACEs are identified. Understanding the role of ACEs and the experience of trauma is important to ensure trauma-informed care, appropriate interventions, and support for neurodevelopmental difficulties. To achieve this, clinicians should routinely ask about ACEs.

**510.052** (Virtual Poster) A Systematic Review and Meta-Analysis of the Prevalence of Suicidality in Autistic and Possibly Autistic People without Co-Occurring Intellectual Disability.

V. E. Newell<sup>1</sup>, S. A. Cassidy<sup>1</sup> and C. Richards<sup>2</sup>, (1)School of Psychology, University of Nottingham, Nottingham, United Kingdom, (2)School of Psychology, University of Birmingham, Birmingham, United Kingdom

---

## Background:

Suicidality is extremely common in autistic people, yet exact prevalence rates vary widely across research (Cassidy, Robertson, Townsend, O'Conner & Rodgers, 2020). It is estimated that 11% to 66% of autistic individuals experience suicidal ideation, and anywhere between 1% to 35% report attempting suicide (Hedley & Uljarevic, 2018). Autistic people without a co-occurring intellectual disability are particularly at risk, being nine times more likely to die by suicide compared to non-autistic people (Hirvokski et al., 2016; Kirby et al., 2019). Moreover, possible undiagnosed autism is also associated with an increased risk of suicidality, along with a higher level of autistic traits seen in adults who have attempted suicide (Cassidy, Bradley, Cogger-Ward & Rodgers, 2021; Richards et al., 2019).

## Objectives:

1) To synthesise the literature and calculate pooled prevalence estimates for suicidality in autistic people and possibly autistic people without co-occurring intellectual disability; 2) To evaluate the influence of person/study characteristics associated with suicidality; 3) To determine the quality of evidence available.

## Methods:

The review was conducted in line with the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) and was prospectively registered with PROSPERO (registration no. CRD42021266451). The electronic databases of PubMed, OVID PsycINFO, OVID Embase and OVID MEDLINE and Web of Science were systematically examined from 1992 until July 2021. Eligibility criteria required studies to be published, written or available in the English Language, have an observational design, and employ quantitative methods providing a measure of prevalence.

## Results:

Forty-nine studies were identified for inclusion. Forty-seven of these examined samples or groups of autistic people, seven studies examined possibly autistic people, and four included both autistic and possibly autistic people. The narrative synthesis demonstrated that prevalence in autistic people ranged from 8% to 72% for overall suicidality or suicide risk, 1.6% to 87.7% for suicidal ideation, 12% to 40.9% for suicide plans, along with 1% to 74.6% for suicide attempts or behaviours. Conversely, in possibly autistic people, prevalence ranged from 42.6% to 62% for overall suicidality or suicide risk, 11.5% to 35.4% for suicidal ideation, 10.3% to 46% for suicide plans and 2.85% to 64.9% for suicide attempts and behaviours. The wide ranges in prevalence may be partly explained by differences in sample characteristics and study methodology. A quality assessment of included studies and meta-analysis are forthcoming.

## Conclusions:

High prevalence rates of suicidality are found in both autistic and possibly autistic people. In order to better understand and prevent suicide in these populations, future research should aim to adapt measures of suicidality, identify unique risk factors, and extend existing theories of suicide.

**510.053** (*Virtual Poster*) Biochemical Assessments of Thyroid Profile and Its Association with Cognitive Level Among Children with Autism in a Tertiary Care Center of Bangladesh

**J. Shefa**, Bangabandhu Sheikh Mujib Medical University, Institute of Paediatric Neurodisorder and Autism (IPNA), Dhaka, Bangladesh

---

**Background:** The causation of autism is still unknown. Thyroid hormones are important for brain development of a child, which also have immunomodulatory actions. It has a vital role on cognitive function also. So dysregulation of Thyroid hormones may have a potential role in children with Autism Spectrum Disorder (ASD).

**Objectives:** The objectives of this study will assess the thyroid profile and cognitive level among children with Autism and to find out the correlations between them.

**Methods:** This will be a Cross-Sectional case- control study, 100 children will be taken in each group and age range were 2 to 12 years. Random sampling method will be used. ASD children will be selected from out-patient department of Institute of Paediatric Neurodisorder and Autism (IPNA) Bangabandhu Sheikh Mujib Medical University (BSMMU), where the patients will be regularly visited for diagnosis, assessment and management. Autism Spectrum Disorder will be diagnosed by DSM-5 criterias. On the other hand same number of controlled children will be selected with same age group from randomly selected regular schools in Dhaka city. After selecting cases and controls, sample of blood will be collected and examine for Biochemical assays of thyroid function in the form of free triiodothyronine (FT3), free tetraiodothyronine (FT4), thyroid-stimulating hormone (TSH) will be done by using commercially available enzyme-linked immunosorbent assay (ELISA) kits. Cognitive level of ASD children will be measured by trained psychologist with The *Bayley Scales of Infant and Toddler Developme* (BSID-III), The Wechsler *Intelligence Scale for Children* – Revised 4<sup>th</sup> Edition (WISC-R IV) and The Wechsler Preschool and Primary Scale of *Intelligence* Fourth Edition(WPPSI-IV).

**Results:**

For measurement of cognition BSAID III was used among 98.4 % children. 41.3% children had mildly delayed cognition level. It was found that FT3, FT4 levels were almost normal with slightly increased and incase of TSH slightly decreased. No association was present between Thyroid hormone level and cognition level of ASD children.

**Conclusions:** From the result of this study, it may be concluded that there were presence of Thyroid hormone level abnormalities among autism spectrum disorders children with mild impairment of Cognition level. But there was no significant association detected. Therefore, routine thyroid test of pregnant mother and new born may be useful for early detection of thyroid hormone abnormality and also detect the level of impairment of cognition.

**Keywords:** Autism Spectrum Disorder(ASD), Thyroid hormones, , Cognitive level

**510.054** (*Virtual Poster*) Child and Family Factors Predicting Study Inclusion and Participation in a Genetic Study of Autism

**T. Ho<sup>1</sup>**, **S. Riffle<sup>2</sup>**, **E. Neuhaus<sup>3</sup>**, **B. Rodriguez<sup>2</sup>** and **J. Gerds<sup>4</sup>**, (1)seattle children's Autism Center, Seattle, WA, (2)Seattle Children's, Seattle, WA, (3)Seattle Children's Research Institute, Seattle, WA, (4)University of Washington LEND, Seattle, WA

---

**Background:**

Genetic studies of autism spectrum disorder (ASD) hold tremendous promise for understanding underpinnings and mechanisms of ASD and associated features. However, genetic research has historically failed to adequately enroll and support minority participants towards study completion. Because generalizability of results relies upon equitable representation of individuals and families across the spectrum, the extent to which genetic findings can be generalized to minority groups in the population is unknown. Understanding of factors facilitating or impeding families' inclusion in genetic research can aide in providing support and increasing representation of study findings.

**Objectives:**

We sought to evaluate factors associated with families' participation in one of the 31 clinical study sites within the SPARK (Simons Foundation Powering Autism Research) network, in order to identify barriers to study completion among participating families overall, and among Hispanic or Latinx families.

**Methods:**

Participating families (N=1333, 22% female probands) had at least one member with ASD ("proband"), and were invited to provide genetic and phenotypic information. Linear and logistic regression models were generated to consider child factors (biological sex, age at diagnosis, ASD severity via the Social Communication Questionnaire) and family factors (household income, marital status of biological parents, simplex vs multiplex status) on age at study enrollment, likelihood of genetic sample completion by the proband and two biological parents, and length of time

to proband sample completion. Models were examined for the full site sample, and then again for the subset of families endorsing Hispanic or Latinx descent.

## Results:

Proband age at study enrollment was associated with a number of factors ( $R^2=.26$ ,  $F(6, 940)=56.49$ ,  $p<.001$ ), such that younger age at enrollment was associated with earlier diagnosis ( $t=17.33$ ,  $p<.001$ ), lower ASD severity ( $t=7.47$ ,  $p<.001$ ), household income below the group median ( $t=3.55$ ,  $p<.001$ ), and married biological parents ( $t=-2.67$ ,  $p=.008$ ). Successful return of samples was predicted by earlier ASD diagnosis and married parents ( $\chi^2(6)=26.86$ ,  $p<.001$ ), and proband samples were returned more quickly when probands were diagnosed relatively later ( $t=-2.80$ ,  $p=.005$ ), had household incomes below the sample median ( $t=2.03$ ,  $p=.04$ ), and came from simplex families ( $t=4.02$ ,  $p<.001$ ;  $R^2=.02$ ,  $F(6,902)=4.31$ ,  $p=.005$ ).

In families endorsing Hispanic or Latinx descent, ASD severity and household income also emerged as predictors of successful sample return ( $\chi^2(6)=26.01$ ,  $p<.001$ ), with more likely return when probands had fewer ASD symptoms ( $p=.009$ ) and families' income was below the median ( $p=.001$ ). Thus, although rates of trio sample completion were comparable among families with (62.5%) and without (61.9%) Hispanic or Latinx descent ( $\chi^2(1)=.02$ ,  $p=.89$ ;  $N=1126$ ), we identified unique factors predicting completion for this group of families.

## Conclusions:

Although some factors predicting study completion were shared across subgroups of our participating families, the relative importance of these factors may be unique within subgroups, as family income and ASD severity predicted sample completion specifically for our Hispanic or Latinx families. Understanding factors such as these enables timely identification of strategies to address barriers to participation among Hispanic or Latinx study families. Future work should continue to explore barriers to research participation in order to increase diversity and representation in genetic research.

### 510.055 (Virtual Poster) Examining Associations between Prenatal Biomarkers of Oxidative Stress and ASD-Related Traits Using Quantile Regression

**M. E. Carey<sup>1</sup>**, **S. Melnyk<sup>2</sup>**, **S. J. James<sup>3</sup>**, **N. Snyder<sup>4</sup>**, **C. Salafia<sup>4</sup>**, **C. J. Newschaffer<sup>5</sup>**, **I. Hertz-Picciotto<sup>6</sup>**, **L. A. Croen<sup>7</sup>**, **M. D. Fallin<sup>8</sup>**, **H. E. Volk<sup>9</sup>**, **R. J. Schmidt<sup>9</sup>**, **K. Lyall<sup>1</sup>** and **J. Rando<sup>10</sup>**, (1)A.J. Drexel Autism Institute, Drexel University, Philadelphia, PA, (2)Arkansas Children's Research Institute, Little Rock, AR, (3)University of Arkansas for Medical Sciences, Little Rock, AR, (4)Institute for Basic Research, Staten Island, NY, (5)College of Health and Human Development, Pennsylvania State University, University Park, PA, (6)University of California at Davis, Davis, CA, (7)Division of Research, Kaiser Permanente Division of Research, Oakland, CA, (8)Wendy Klag Center for Autism and Developmental Disabilities, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (9)Public Health Sciences, University of California Davis, Davis, CA, (10)AJ Drexel Autism Institute, Philadelphia, PA

**Background:** Oxidative stress (OS) has been hypothesized as a mechanism involved in autism spectrum disorder (ASD) etiology, given the potential susceptibility of the fetus to reactive oxidative species and the importance of OS pathways in neurodevelopment. However, prospective research assessing prenatal OS and ASD-related outcomes in the child is lacking.

**Objectives:** To examine the association between prenatal OS and child ASD-related outcomes.

**Methods:** Participants (n=153) were drawn from the Early Autism Risk Longitudinal Investigation (EARLI), a multisite enriched risk cohort following pregnancies among women who already had an autistic child. Biomarkers of OS, including glutathione (GSH) and glutathione thiol/disulfide (GSSG) were measured in third trimester maternal plasma samples, and 8-oxo-deoxyguanine (8-OHdG) in maternal DNA samples. ASD-related outcomes were assessed via (1) Social Responsiveness Scale (SRS) raw total scores and (2) according to best estimate clinical diagnosis following clinical evaluation, Autism Diagnostic Observation Schedule score, and the Mullen Scales of Early Learning-Early Learning Composite score; groups included typically developing (TD, n=74), atypical development but not meeting criteria for ASD (non-TD, n=49); and ASD (n=30). Associations between the ratio of GSH:GSSG, as a measure of oxidative balance, and 8-OHdG, as a measure of oxidative damage to DNA, and SRS scores were examined using quantile regression, which allows for an exposure-outcome relationship to differ across percentiles of continuous outcomes. Increases in the level of GSH:GSSG are indicative of decreases in OS. Conversely, as levels of 8-OHdG increase so does OS. Secondly, we conducted linear regression analyses for comparison. Associations between OS biomarkers and categorical diagnoses were examined via logistic regression modeling the probability of ASD or non-TD compared to TD. All adjusted analyses included the covariates child's sex, maternal age, maternal race/ethnicity, and pre-pregnancy body mass index.

**Results:** In quantile regression analyses, there was some suggestion of minor increases in SRS scores with increasing GSH:GSSG ratio for mid-level quantiles of SRS only, but overall, strong associations were not observed with either measure of OS (Figure 1). Results were broadly consistent for SRS raw total scores using adjusted linear regression models (GSH:GSSG  $\beta$ : 2.00, 95% CI: -0.02, 4.01; 8OHdG  $\beta$ : 0.02 95% CI: -0.68, 0.71). Analyses examining associations with categorical outcomes suggested a marginal, but non-significant protective association for antioxidant balance and ASD according to the GSH:GSSG ratio (Table 1 - adjOR: 0.82, 95% CI: 0.66, 1.04), as well as with non-TD (adjOR: 0.90, 95% CI: 0.75, 1.08).

**Conclusions:** Overall, results from this high familial risk cohort do not support a strong relationship between markers of OS in the third trimester and ASD-related outcomes, though we did observe a marginal protective association between greater antioxidant balance (more GSH:GSSG) and categorical ASD-related outcomes. Our modest and null findings could relate to the timing of our measurement, given that OS changes over the course of pregnancy, or may relate to our study's high familial risk nature. Future work should consider these and other markers of OS, at other time points, and in additional, non-high-risk populations.

**510.056 (Virtual Poster)** Factors Predicting Timing of Referral, Diagnosis, and Intervention Use for Toddlers after a Positive Autism Screen in Primary Care

**Y. (. Zhu<sup>1</sup>, C. Sullivan<sup>2</sup>, L. A. Kirby<sup>3</sup>, S. Compton<sup>4</sup> and G. Dawson<sup>4</sup>, (1)School of Medicine, Duke University, Durham, NC, (2)Duke University, Durham, NC, (3)Yale Child Study Center, New Haven, CT, (4)Department of Psychiatry and Behavioral Sciences, Duke Center for Autism and Brain Development, Durham, NC**

---

**Background:** Despite clear evidence that autism spectrum disorder (ASD) can be reliably diagnosed at 18 months of age and early intervention leads to better outcomes, the median age of ASD diagnosis remains at 51 months. Universal screening with the Modified Checklist for Autism in Toddlers, Revised with Follow-up (M-CHAT-R/F) leads to earlier age of diagnosis. However, cultural and language barriers play important roles in creating disparities in receiving timely referrals for diagnostic evaluations and treatments among underserved groups, diminishing the clinical benefit of early screening.

**Objectives:** The aim of this study was to better understand whether demographic factors and/or presence of a priori providers' or caregivers' ASD and developmental concerns are correlated with different lengths of time between receiving a positive M-CHAT-R/F screening during a well-child visit and being referred for an evaluation, completing a diagnostic evaluation and initiating relevant intervention services. We sought to identify the key barriers that families face when seeking referrals, evaluations and treatments. Given that the COVID-19 pandemic occurred during the data collection period, its impact on the probability and timing of evaluations and interventions was also evaluated.

**Methods:** Retrospective analysis of Duke University Health System (DUHS) electronic health record (EHR) data was conducted by a medical student and two clinical psychologists on 213 children who had screened positive on the MCHAT-R/F during a well-child visit and/or had a documented EHR ASD diagnosis, regardless of M-CHAT-R/F score. Interrater reliability was tested and found to be adequate prior to analyses.

**Results:** Hispanic families experienced longer delays in receiving a referral for an ASD evaluation ( $p < 0.05$ ), completing a diagnostic evaluation ( $p < 0.05$ ) and initiating speech ( $p < 0.05$ ) and occupational services ( $p < 0.05$ ) compared to non-Hispanic families. White families were more likely to receive occupational therapy ( $p < 0.05$ ) and received the therapy earlier ( $p < 0.05$ ) than Black families. ASD and/or developmental concerns observed by caregivers and/or providers during the 18-24 months age period, documented in the EHR, were associated with an increased chance of being referred for an ASD evaluation, completing an evaluation, receiving an ASD diagnosis and initiating intervention services. The COVID-19 pandemic decreased the chance of receiving a referral and completing an ASD evaluation while increasing the time it took to receive an ASD diagnosis.

**Conclusions:** These results indicate that racial and ethnic background, as well as the presence of a provider or caregiver concern, play a role in the timeliness with which families receive referrals, evaluations and initiate interventions. These results suggest that attentive listening to caregivers' concerns and a better understanding of cultural barriers that influence referral timing and service initiation may help Hispanic and Black children receive more optimal care. Efforts to improve communication means between patients and providers through increased availability of patient portals in non-English languages and tailored educational resources could improve access to services, allowing children from diverse backgrounds to benefit fully from universal screenings and leading to better outcomes.

**510.057 (Virtual Poster)** Is There an Association between Maternal Nativity with Trajectories of Autism Symptoms and Adaptive Functioning?

---

**Background:**

Although autism is highly heritable, evidence suggests its aetiology is multifactorial, including genetic and environmental factors that interact in complex ways over development. Maternal nativity or immigration status has previously been proposed as a risk factor as it may relate to adversity in country of origin, socioeconomic disadvantage, and barriers to healthcare, which in turn are robust predictors of poorer health outcomes in mothers and their children. Existing literature has focused on whether immigration status is related to an increased prevalence of autism. In this study we build on previous work by examining whether maternal nativity is associated with overall level and with change over time in autism symptoms and adaptive functioning in childhood.

**Objectives:**

To examine whether maternal nativity is associated with autism symptoms and adaptive behaviour, assessing both level and developmental course measured from preschool to late childhood.

**Methods:**

Participants were 380 children from the Pathways in ASD sample, an inception longitudinal cohort of autistic children based in Canada. Maternal nativity (“Canada-born” or “Born outside Canada”) was self-reported at time of recruitment (within 4 months of preschool diagnosis) or 6 months afterwards. To assess trajectories of autism symptoms and adaptive behaviour, the present analyses used Autism Diagnostic Observation Schedule (ADOS) and Vineland Adaptive Behaviour Scale (VABS) measures collected at four time points when participants were between 2 and 11 years of age.

Growth curve models were used to assess association of predictors with outcomes as follows: Model 1) nativity as predictor, study site as covariate; Model 2) nativity as predictor, and study site, maternal ethnicity, income, child sex, a measure of IQ, and age at diagnosis, as covariates; Model 3) model 2 plus an interaction term between nativity and income.

### Results:

There was no association between maternal nativity and autism symptom severity level. However, nativity (being born outside of Canada) was associated with increasing growth in symptom severity over time after accounting for covariates. For adaptive behaviour, being born outside Canada was significantly associated with lower level of adaptive behaviour, but this association was removed by the inclusion of IQ and low income in the model, which were both significantly associated with lower adaptive behaviour level. Nativity was not associated with growth in adaptive behaviour.

### Conclusions:

The severity of autism symptoms seen in children of non-native mothers worsened over time compared to those in children of native mothers, suggesting these individuals may be disproportionately impacted by reduced access to support services due to factors such as socioeconomic, language, and cultural barriers. Our findings therefore highlight these populations must be high priority for targeted support and intervention to reduce the risk of health inequalities in autistic children of non-native families

**510.058 (Virtual Poster)** Prevalence of Sleeping Disorders and Patterns of Medication Use in Individuals with Neurodevelopmental Disorders Using Health Insurance Claims Data from the United States

**M. Johnson<sup>1</sup>**, A. Yakubu<sup>2</sup>, T. Wiese<sup>3</sup> and M. del Valle Rubido<sup>3</sup>, (1)Roche Products Ltd, Welwyn Garden City, United Kingdom, (2)Genesis Research, Real World Evidence Solutions, Hoboken, NJ, (3)Roche Pharma Research and Early Development, Roche Innovation Center, Basel, Switzerland

---

### Background:

Up to 80% of children with neurodevelopmental disorders (NDDs) are reported to have disrupted sleep, with detrimental effects on cognition, mood and behavior. While sleep hygiene training and behavioral interventions are recommended as first-line therapies for sleeping disorders, evidence relating to effectiveness is mixed. Available pharmacological therapies, including atypical antipsychotics, are commonly prescribed for ‘off-label’ use. The characteristics and medication use of those with NDDs and sleeping disorders has not been studied in a large cohort with a broad age range.

### Objectives:

To evaluate prevalence, characteristics and medication use of individuals with sleeping disorders and NDDs (including autism, Fragile X, Rett, Williams, Prader-Willi, Angelman and Smith-Magenis/Miller-Dieker syndromes) in the USA.

### Methods:

A cross-sectional analysis of individuals with sleeping disorders was conducted using health insurance claims data, IBM® MarketScan® Research Databases, from the USA. Individuals were included if they had observable data on the cross-sectional date of December 31<sup>st</sup>, 2018 for Multi-State Medicaid Database and December 31<sup>st</sup>, 2019 for Commercial and Medicare Databases (owing to data availability). Individuals with sleeping disorders had ≥1 ICD-10-CM codes for sleeping disorders or prescription(s) for sleep medication between 2016 and the cross-sectional date. Among those with sleeping disorders, individuals with NDDs (≥1 ICD-9/10-CM codes for NDDs on or before the cross-sectional date) were identified. No age restrictions were applied. Demographics, comorbidities and sleep medications were assessed with descriptive analyses.

### Results:

Sleeping disorders were reported in 9.3% of the total cohort (>31 million people). Of 2,970,823 individuals identified with sleeping disorders, 64,342 (2.2%; 65.6% of which were covered by Medicaid) also had a NDD, most commonly autism (61,056; 94.9%). Most of those with a sleeping disorder and NDD were aged <18 years (58.3%). Of those with a sleeping disorder and NDD, 71.7% were male versus 40.0% in the total sleeping disorder population (reflecting the expected male predominance among some NDDs). Sleep medications were more commonly prescribed to individuals with a sleeping disorder and NDD (80.9%) than to the total sleeping disorder population (71.9%). Among those with a sleeping disorder, the top five most commonly used sleep medications were: trazodone (28.9%), zolpidem (19.3%), gabapentin (17.7%), hydroxyzine (14.1%) and lorazepam (8.9%). In contrast, the top five among those with a sleeping disorder and NDD were: trazodone (32.9%), clonidine (32.4%), guanfacine (24.8%), cetirizine (19.8%) and hydroxyzine (19.4%). While most likely given over the counter to more individuals, melatonin was occasionally prescribed (2.3% of those with sleeping disorders).

### Conclusions:

In this large cohort of individuals from the USA, sleeping disorders were highly prevalent. Over 64,000 individuals with a sleeping disorder also had a NDD, most commonly autism. The pattern of sleep medication use differed in those with a sleeping disorder with and without a NDD. Among individuals with NDDs, antihistamines and adrenergic agonists were prescribed more frequently, presumably for sedating side-effects, rather than the more common sleep medications (zolpidem or benzodiazepines). These data provide insights into the characteristics of those with a NDD and sleeping disorder and into the therapeutic management of these conditions.

**510.059 (Virtual Poster) Profile of Children with ASD and Food Selectivity**

**G. M. Kuravackel<sup>1</sup>, A. Schaefer<sup>2</sup>, L. Sears<sup>3</sup> and R. Lele<sup>4</sup>,** (1)University of Louisville School of Medicine, Louisville, KY, (2)Clinical Psychology, Spalding University, Louisville, KY, (3)University of Louisville, Louisville, KY, (4)Bioinformatics and Biostatistics, University of Louisville, Louisville, KY

---

**Background:**

Autism Spectrum disorder (ASD) is characterized by difficulties with social interactions, communication, restricted interests and preference for sameness in behavior (APA, 2021). Food selectivity, often referred to as “picky eating”, is a common problem in children with ASD and is of particular concern because of its negative impact on nutrient adequacy and family mealtimes (Bandini, et al., 2017). One recent review estimated that children with ASD have a five-fold risk of feeding problems compared to children without ASD (Sharp et al. 2013). Children with ASD are overly selective in their eating patterns; consume less varied diets with very few fruits and vegetables and is associated with inadequate nutrient intake, mealtime behavior problems and parent stress ((Ranjan & Nasser 2015; Curtin et al. 2015).

**Objectives:**

The goal of this study was to examine the association of behavior and assessment profiles of children with food selectivity in newly diagnosed children with ASD between the ages of 3 to 12 years.

**Methods:**

A chart review was conducted on 125 diagnostic evaluations conducted on children between the ages of 3 to 12 years between the years of 2015-2017 that ended with a conclusive diagnosis of ASD based on clinical data received from parent/teacher report, intake report and assessment findings. The chart review was conducted at a University based Medical center. A rating scale for Behavior Rigidity was determined from the clinical intake based on the “restricted, repetitive patterns of behavior” listed in the diagnostic criteria for ASD in the DSM-V. The authors rated behavior rigidity as No Rigidity=0; moderate rigidity= 1 (if meets 1 to 2 criteria) high rigidity=2 (if meets 3-4 criteria) and severe rigidity=3 (over 4 criteria). In a similar manner food selectivity was rated as 0=no food selectivity reported; 1= moderate selectivity reported (limited food repertoire) and 2= high selectivity reported (not more than 2 food groups). Demographic factors such as ethnicity, sex, age, urban vs rural, ratings on the Autism Diagnostic Observation Schedule-2 (ADOS-2) and adaptive scores were used in the final analysis. Frequencies, and correlations were run to explore trends and associations between food selectivity, demographic and assessment findings.

**Results:**

Frequency statistics demonstrated a trend of high reported levels of behavioral rigidity and food selectivity in children diagnosed with ASD (Rigidity: 94% reported ratings of 1 and higher; Food Selectivity: 63% reported ratings of 1 and higher). Logistic regression analyses indicated that females are more likely to have “high” food selectivity when compared with “low” and “medium” food selectivity groups combined together. Also, “high” food selectivity was observed as preference for carbohydrates and as ADOS-2 total scores increased ( $p = 0.067$ ).

**Conclusions:**

In ASD, factors contributing to the combination of high food selectivity include gender, strong preference for carbohydrates and overall higher ratings of autism including social communication behaviors on the ADOS-2. Understanding these contributing factors can assist in developing treatment plans for food selectivity. Larger samples from different locations are required for better generalization of results. This study received IRB approval prior to chart review.

**510.060 (Virtual Poster) Suicide Versus Non-Suicide Death in Autistic Individuals: A 25-Year Population-Based Matched Cohort Study in Ontario, Canada**

**M. C. Lai<sup>1,2,3,4</sup>, N. R. Saunders<sup>4</sup>, A. Huang<sup>5</sup>, A. Artani<sup>5</sup>, D. Wilton<sup>5</sup>, J. Zaheer<sup>6</sup>, S. Ameis<sup>7</sup>, H. K. Brown<sup>8</sup> and Y. Lunskey<sup>2</sup>,** (1)The Margaret and Wallace McCain Centre for Child, Youth and Family Mental Health, Centre for Addiction and Mental Health, Toronto, ON, Canada, (2)Azrieli Adult Neurodevelopmental Centre, Centre for Addiction and Mental Health, Toronto, ON, Canada, (3)Department of Psychiatry, University of Toronto, Toronto, ON, Canada, (4)The Hospital for Sick Children, Toronto, ON, Canada, (5)ICES, Toronto, ON, Canada, (6)Centre for Addiction and Mental Health, Toronto, ON, Canada, (7)The Margaret and Wallace McCain Centre for Child, Youth, & Family Mental Health, Campbell Family Mental Health Research Institute, Centre for Addiction and Mental Health, Toronto, ON, Canada, (8)Department of Health & Society, University of Toronto Scarborough, Toronto, ON, Canada

---

**Background:**

Autistic people may experience increased suicide risk compared to non-autistic people, with various sizes of risk reported by 6 population-based studies in Sweden, Taiwan, United States, and Denmark. The reported risk is particularly high in females and individuals without intellectual disability (ID). Reasons for this heightened risk and the differing pattern by autism sub-populations remain unclear but may involve available health and social support (that varies by jurisdictions) and co-occurring psychiatric conditions. Identifying modifiable factors associated with suicide in autistic people offers new directions for preventative efforts.

#### Objectives:

- (1) To compare the risk of suicide death in autistic versus non-autistic people (with other causes of death treated as competing risk), stratified by sex-assigned-at-birth.
- (2) To examine if socio-demographic factors, psychiatric diagnoses, and ID explains the risks of suicide and non-suicide death.

#### Methods:

Using health administrative data housed at ICES, Ontario, Canada that included all individuals in Ontario with a physician-recorded autism diagnosis in hospital or ambulatory care health records during 1988-2018, we conducted a 1:4 autistic:non-autistic matched-cohort study (age-matched within sex). We applied cause-specific competing risk models on death by suicide versus other causes, in 334,690 individuals (17,982 autistic versus 71,928 non-autistic females; 48,956 autistic versus 195,824 non-autistic males), followed for death outcomes during 1993-2018. Hazard ratios were stratified by sex-assigned-at-birth. We ran unadjusted and adjusted models (for neighborhood income and rurality, psychiatric and ID diagnoses) to observe whether risks were attenuated after adjustment.

#### Results:

Over the 25 study-years, among autistic people the incidence of death (every 100,000 individuals) was 95 (female) and 116 (male) for suicide, and 9799 (female) and 3413 (male) for non-suicide. Among matched non-autistic people, the incidence was 46 (female) and 83 (male) for suicide, and 8114 (female) and 2591 (male) for non-suicide. The hazards were higher in autistic versus non-autistic females for suicide death (cause-specific hazard ratio, HR 1.98, 95%CI [1.11-3.56]) and non-suicide death (1.08 [1.03-1.14], as competing risk that did not alter suicide risk findings); in autistic versus non-autistic males, the hazards for suicide death were not different (1.34 [0.99-1.82]) but significantly higher for non-suicide death (1.15 [1.09-1.22]). Adjustments for neighborhood income and rurality did not alter these patterns. Adjustments for each lifetime psychiatric diagnosis including schizophrenia spectrum, anxiety or mood, substance-use, and personality disorders attenuated most HRs for suicide death to non-significant levels, with small influences on non-suicide death (except schizophrenia), for both sexes. Adjustments for the effect of ID substantially increased the HR in females for suicide death (2.35 [1.28-4.32]) but attenuated that for non-suicide death (1.02 [0.96-1.08]); the same change was observed for males for suicide death (1.62 [1.18-2.23]) and non-suicide death (1.00 [0.94-1.06]).

#### Conclusions:

In Ontario, autistic female individuals and those without ID had higher risks of death by suicide. This pattern is similar to that reported in other jurisdictions, though with smaller effect sizes. Psychiatric diagnoses accounted for increased risk of suicide death, whereas ID and schizophrenia spectrum accounted for increased non-suicide death, across sexes. Support for autistic people must consider the risk stemming from co-occurring psychiatric conditions.

#### **510.061** (Virtual Poster) Psychometric Epidemiology: Population Based Reasoning to Identify ASD Screening Tools That Are Weaker Than Publicized

**B. Barger<sup>1</sup>** and **J. R. Olmstead<sup>2</sup>**; (1)Georgia State University, Atlanta, GA, (2)Epidemiology (Contagious Disease), Georgia Department of Public Health, Atlanta, GA

#### Background:

Increasing research shows that the diagnostic accuracy of many autism screening tools are substantially lower than expected. This is primarily driven by studies following up on false negatives (FN) allowing for greater clarity of missed cases. Many years typically pass from originally publicized diagnostic accuracy studies without follow up to more expensive follow up studies. Thus, policy groups risk promoting screening tools that do not live up to their promise. Methods are needed allowing the field to identify weaker than expected screening tool diagnostic accuracy metrics.

#### Objectives:

This study builds out a simple method suggested by Barbaro & Dissinayake (2010) using published epidemiological population estimates to identify “likely missed cases” allowing for a recalculation of ASD screener sensitivity.

#### Methods:

We applied a “pop adjusted” approach to data from recent meta-analyses of diagnostic accuracy of ASD screening tools (Olmstead, 2020, K = 24; Sanchez-Garcia et al., 2019, K = 18, to show how estimating likely missed cases impacts reported sensitivity. First, we identified ASD prevalence

rates based on the national ASD prevalence closest to the year of publication. Pop-adjusted accuracy metrics were developed for each identified study by determining the expected ASD cases within a sample dependent on the nation's prevalence, resulting in pop-adjusted TN and pop-adjusted FP metrics. Pop-adjusted sensitivity was then developed from adjusted TN and FP. For example, Chlebowski et al. (2013) reported data on 18,446 children 18 to 24 months on the M-CHAT/R. Using CDC national prevalence data estimating that 1/68 U.S. children had an ASD, we then calculated estimates of how many children with ASD might be reasonably expected in the sample:

CDC (2012):  $1/68 = x/18,446$ ;  $x \sim 271$

Compared to the 98 identified ASD cases in Chelbowski's sample (6 FN and 92 TP), pop-adjusted samples indicated ~173 likely missed cases, leading to a pop-adjusted FN of ~179 (6 originally identified) and TN ~18,096 (original 18269-173). Pop-adjusted sensitivity then drops from a reported 94% to 34%. Studies identifying more cases than indicated by pop-adjustments kept originally reported FN and TN. When studies did not report data points for FN or TP these were calculated from available data provided standard formulas. Details of the PRISMA based systematic review methodology and meta-analyses may be found in Sanchez-Garcia et al. (2019) and Olmstead (2020).

#### Results:

Initial estimates indicate that 7/18 (38.9%) of studies reported from Sanchez Garcia et al. (2019) and 6/15 (40%) of Olmstead (2020) studies had decreases in their FN rates impacting reported sensitivities. These adjustments lead to substantial drops in meta-analyzed pooled sensitivity estimates (Olmstead decreasing from ~75% to ~53%; Sanchez-Garcia et al. decreasing from ~75% to ~54%). US based studies were more likely to be impacted than non-US.

#### Conclusions:

Epidemiological population estimates may be psychometrically useful in estimating potentially missed FN ASD cases in screening studies. Formulas for hand and R-calculations will be provided. Field insights are needed to determine optimal populations estimates.

### **510.062** (Virtual Poster) The Conjoint Impact of Preterm Birth, Low Birth Weight, and Literature Implicated Covariates on Identified Autism Spectrum Disorder

S. Sanchez-Alvarez, **B. Barger** and E. Graybill, Georgia State University, Atlanta, GA

---

#### Background:

Premature birth and low birth weight (LBW) are implicated in the etiology of autism spectrum disorder (ASD); however, these postnatal factors are rarely considered conjointly. Both are also implicated in the etiology of intellectual disability (ID) and developmental delays (DD) (co-morbid with ASD), which are rarely controlled for in analyses.

#### Objectives:

This study considers the relationship between premature birth and LBW, singly and conjointly, on identified ASD. Literature-derived covariates (e.g., ID and DD) are also considered.

#### Methods:

Weighted/stratified logistic regression analyses of the National Survey of Children's Health (NSCH) for the years 2016-2018 were conducted to determine the relationship between preterm birth and LBW on identified ASD. Child level covariates included: sex (female [Reference]), age (<4 [Reference], 4-8, 9-12, and  $\geq 13$  years), developmental delay (no [Reference]), ID (no [Reference]), birth order (third or greater older child [Reference], only, oldest, and second oldest child), and race/ethnicity (non-Hispanic Other [Reference], non-Hispanic White, non-Hispanic Black, and Hispanic. Family included: age of mother at birth (18-24 [Reference], 25-29, 30-34, and  $\geq 35$  years), family structure (2 parents married [Reference], 2 parents not married, single mother, and other), usual source of care (no usual source [Reference]), caretaker education level (>high school [Reference], and high school or less), primary language (non-English [Reference], and English), insurance type (private only [Reference], public only, public and private, and uninsured), personal doctor/nurse (yes, one person [Reference], yes, more than one person, and no), and family poverty ratio [FPL] (400+ poverty [Reference], <100% poverty, 100-199% poverty, and 200-399% poverty).

#### Results:

Of 102,341 available cases 2.4% had an ASD. Typical birthweight children had fewer (2.3%) ASD cases compared to low birth weight (LBW, 2.7%) and very low birth weight (VLBW, 4.7%) children; more preterm children had an ASD (4.1%) compared to non-preterm (2.1%). Bivariate analyses showed that compared to non-LBW children, greater odds of ASD were seen for LBW (OR=1.39[1.09-1.77]) and VLBW children (OR=2.13[1.28-3.54]). Odds of ASD was much higher for children with ID (OR=34.55[25.17-47.43]) or DD OR=41.87[32.55-53.84]. Smaller increased odds of ASD were also seen for Black and Hispanic children, older children, birth order, family structure, caretaker education, usual source of care, having a personal doctor or nurse, poverty level, and health insurance. Considered conjointly, preterm birth remains associated with increased odds of ASD (OR=1.96[1.38-2.78]), but LBW is not. Conjoint consideration with covariates resulted in no statistical relationship between preterm birth and lower odds for LBW (OR=0.63[0.40-0.98]) and a trend for VLBW (OR=0.50[0.22-1.11]); child gender, age, and birth order maintained associations

with small increased odds of ASD; presence of DD maintained a strong association with increased ASD odds (OR=32.49[26.10-40.43]), but ID's relationship lowered (OR=2.65[1.88-3.74]).

Conclusions:

Researchers should take care when conducting studies on the relationship between prematurity and birthweight on identified ASD. This analysis indicates that prematurity accounts for the variance of birthweight when considered conjointly. Furthermore, DD and ID should be further investigated as potential moderator/mediators impacted by prematurity and birthweight.

## Family Issues and Stakeholder Experiences

### PANEL — FAMILY ISSUES AND STAKEHOLDER EXPERIENCES

#### 213 - Challenges and Resilience: Effects of the COVID-19 Pandemic on Autistic Individuals and Their Families across the Lifespan

**Panel Chair:** Matthew Lerner, *Psychology, Stony Brook University, Stony Brook, NY*

**Discussant:** Emily Simonoff, *King's College London, Institute of Psychiatry, Psychology and Neuroscience, London, United Kingdom*

**213.001 (Panel)** COVID-19: The Important Roles of Stress, Anxiety, and Coping in Adolescents with and without Autism and Their Parents  
**B. A. Corbett<sup>1</sup>**, R. A. Muscatello<sup>1</sup>, M. E. Klemencic<sup>1</sup> and J. M. Schwartzman<sup>2</sup>, (1)*Psychiatry and Behavioral Sciences, Vanderbilt University Medical Center, Nashville, TN*, (2)*Vanderbilt University Medical Center, Palo Alto, CA*

**Background:** In the wake of COVID-19, the world has become a more uncertain, unpredictable environment – a breeding ground for stress and anxiety, especially for individuals with autism spectrum disorder (ASD) who often respond poorly to change.

**Objectives:** The objective of the study was to examine stress, coping and anxiety in a data-driven, real-time assessment of adolescents with and without ASD and their parents at the height of the COVID-19 shutdown and three months later. A robust, theoretical model in which stress response and coping are considered on three dimensions (voluntary vs. involuntary; engagement vs. disengagement; primary vs. secondary control) (Compas, 2001). Also, state (current) and trait (persistent) anxiety were measured.

**Methods:** Participants included 122 fully-characterized adolescents (ASD=61, TD=61), and their parents (96.3% mothers). Five standardized measures were administered via REDCap to ascertain stress and coping explicitly related to the COVID-19 pandemic (RSQ COVID-19-Child, Adult, Parent (about Child)) and anxiety (STAI-C, STAI-A). Four aims examined: Aim 1, Child: stress, coping and anxiety via self-reports of youth with and without ASD. Aim 2, Parent: examined stress, coping and anxiety on parents regarding their own self-reported stress and anxiety. Aim 3, Predictive: the influence of adults' self-reported stress and coping style on the perception of their child's stress and coping skills. Aim 4, Longitudinal: impact of COVID-19 longitudinally by comparing stress and coping over two time-points. For youth, Trait anxiety was compared over three time points: T0 (Pre-COVID-19), T1 (lockdown) and T2 (re-opening). Aim 5, Coping and Anxiety: the influence of coping style at T1 on trait anxiety at T2 for Child and Adult. Multivariate, univariate analyses of variance and hierarchical regression were used.

**Results:** Significant differences emerged with ASD youth endorsing more trait anxiety ( $p<.05$ ) and response to specific stressors (e.g., virus, access to healthcare) ( $F(14,91)=2.82$ ,  $p=.002$ ;  $\Lambda=0.698$ ,  $\eta^2=.302$ ). Parents of children with ASD showed higher self-reported anxiety ( $p<.05$ ), yet scores were elevated for both parent groups. ASD parents reported more stress ( $F(1,106)=22.38$ ,  $p<.001$ ,  $\eta^2=.174$ ), especially related to the virus, access to healthcare, work, and concern for the future. TD youth and their parents used more Primary and Secondary Control Coping whereas ASD youth and their parents used more Disengagement Coping. Coping Style for Child (Primary, Secondary) and Adult (Secondary) predicted trait anxiety at T2.

**Conclusions:** Results reveal striking differences in youth with ASD and their parents regarding anxiety, stress, and coping. The important role of coping style was a significant predictor of later anxiety for youth and their parents above and beyond diagnosis. Findings highlight the need for essential support, access to services, and strategies to enhance psychological and emotional well-being.

**213.002 (Panel)** Trajectories of Self-Reported Internalizing Symptoms Among Autistic and Nonautistic Youth during the COVID-19 Pandemic  
**T. C. Day<sup>1</sup>**, M. L. McNair<sup>1</sup>, D. Reicher<sup>2</sup>, A. H. Gerber<sup>1</sup> and M. D. Lerner<sup>1</sup>, (1)*Psychology, Stony Brook University, Stony Brook, NY*, (2)*Psychiatry, Stony Brook University, Stony Brook, NY*

**Background:** Autistic people experience anxiety and depression at higher rates (Hudson et al., 2019; Wijnhoven et al., 2018) and these internalizing symptoms (IS) remain elevated throughout adolescence (Gotham et al., 2015). In nonautistic children and adolescents, large increases in IS at the beginning of the COVID-19 pandemic (Racine et al., 2021) were followed by subsequent decreases in the summer and fall of 2020 (e.g., Hawes et al., 2021; Andreas & Brunborg, 2021). However, little is known about IS during the pandemic in autistic youth despite their elevated risk for depression and anxiety and the disruptions to home, school, and service access (Baweja et al., 2021).

**Objectives:** Assess the trajectories of IS in autistic and nonautistic youth during the COVID-19 pandemic. We hypothesized that (1) baseline IS will be higher in autistic youth and (2) relative to autistic youth, IS in nonautistic youth will decrease.

**Methods:** Participants included 75 autistic and nonautistic (determined via ADOS-2; Lord et al., 2012) youth (all FSIQ  $\geq 70$ ). The Revised Child Anxiety and Depression Scale (RCADS; Chorpita et al., 2000) was administered once every two weeks from June 2020 to December 2020 during the COVID-19 pandemic. Multilevel models were used to assess changes in IS.

**Results:** Fifty autistic youth ( $N_{female}=10$ ,  $M_{age}=12.9$ ,  $SD_{age}=2.59$ ,  $range=8.50-17.4$  years) and 25 nonautistic youth ( $N_{female}=14$ ,  $M_{age}=12.6$ ,  $SD_{age}=2.65$ ,  $range=8.54-16.5$  years) completed the RCADS. Baseline IS did not differ between groups ( $p=.27$ ). Average IS did not differ by group status, but an interaction between time and group emerged (Table 1; Model 3). IS did not change over time in the nonautistic group ( $B=.014$ ,  $SE=.015$ ,  $p=.35$ ) while in the autistic group, IS decreased over time ( $B=-.021$ ,  $SE=.0096$ ,  $p=.03$ ). Post-hoc analyses revealed a similar interaction between time and group for the Social Anxiety subscale ( $B=-.041$ ,  $SE=.020$ ,  $p=.04$ ) and Generalized Anxiety Disorder (GAD) subscale ( $B=-.031$ ,  $SE=.015$ ,  $p=.04$ ): in the autistic group only, GAD symptoms decreased over time ( $B=-.018$ ,  $SE=.0083$ ,  $p=.03$ ). Changes over time were not observed in the depression, OCD, panic, nor separation anxiety subscales within the autistic or nonautistic groups.

**Conclusions:** Baseline levels of IS did not differ between autistic and nonautistic youth, suggesting that all youth displayed average (non-clinical) IS by June 2020. Contrary to hypotheses, autistic youth demonstrated a *decrease* in IS, specifically in GAD and Social Anxiety, over time relative to nonautistic youth. These results reveal a potential unique source of resilience in autistic youth, which may be due to less anxiety about in-person schooling and socializing, as well as more choice in daily routines (Spain et al., 2021). More specifically, the impact of “hidden curricula” (e.g., social norms) endemic to schools may have been reduced by the pandemic (Reicher, 2020). Social distancing may normalize sitting alone during lunch, and mask wearing may reduce requirements to read facial expressions; furthermore, some autistic students prefer virtual instruction because of reductions in social obligations (Hurwitz et al., 2021). Future investigations examining for whom such adaptations (e.g., virtual instruction) are warranted as the school environment evolves in response to – and beyond – the COVID-19 pandemic.

**213.003 (Panel) A Mixed Methods Study of the Impact of COVID-19 on the Mental Health and Wellbeing, and Mental Health Service Access during COVID-19, of Autistic Adults in Australia**

**D. Hedley<sup>1</sup>, K. Denney<sup>2</sup>, M. Uljarevic<sup>3</sup>, S. M. Hayward<sup>4</sup> and M. A. Stokes<sup>5</sup>,** (1)Olga Tennison Autism Research Centre, La Trobe University OTARC, Melbourne, VIC, Australia, (2)Olga Tennison Autism Research Centre, La Trobe University, Melbourne, VIC, Australia, (3)School of Psychological Sciences, University of Melbourne, Stanford, CA, Australia, (4)Cooperative Research Centre for Living with Autism (Autism CRC), Brisbane, QLD, Australia, (5)Deakin University, Burwood, VIC, Australia

**Background:** Recent research has highlighted the mental health impacts of the COVID-19 pandemic on people with disability, i.e., autistic people. Among negative mental health impacts are increases in depression and anxiety symptoms, and concerns about safety, security, employment, medication and food access (Oomen et al., 2021). Studies suggest that vulnerable populations, including those with disabilities, may be at increased risk of self-harm and suicidal ideation and behavior. It is therefore important to examine potential relationships between the impacts of COVID-19, mental health and wellbeing, and suicide risk in an autistic population; as well as their access to mental health services during this time.

**Objectives:** This study explored a) potential relationships between the impact of COVID-19, mental health and wellbeing, including suicide risk, in autistic adults and b) any changes to mental health care and service access as a result of COVID-19.

**Methods:** A mixed methods interview design was adopted. Quantitative data were collected during the second wave of the COVID-19 pandemic. Qualitative data were collected during the third wave. Participants were 111 autistic adults (women = 58.6%, men = 32.4%, non-binary/not disclosed = 9.0%;  $M_{age} = 42.45$ ,  $SD = 13.03$  years). COVID-19 impact was assessed with the COVID-19 Impact Scale (CIS). Mental health and wellbeing were assessed with the Personal Wellbeing Index (PWI-A) and Patient Health Questionnaire (PHQ-8). Suicidal ideation and behavior was assessed with the Suicide Behaviour Questionnaire, Revised (SBQ-R). In an interview we asked a subset of participants “Has your access to mental health care changed during the COVID-19 pandemic?”

**Results:** COVID-19 impact showed small associations with poorer personal wellbeing,  $r = -.224$ ,  $p = .023$ ,  $[-.409, -.016]$ , and higher depressive symptoms,  $r = .268$ ,  $p = .006$ ,  $[.056, .445]$ . COVID-19 impact was not significantly associated with the SBQ-R suicide risk score,  $r = .081$ ,  $p = .418$ ,  $[-.118, .264]$ . Themes from qualitative data indicated: no change of access to mental health care; no meaningful change in mental health service provision despite the introduction of new programs by the government; telehealth services are welcomed; and delays to accessing typical services.

**Conclusions:** The impact of COVID-19 is reflected in worsening mental health and wellbeing, particularly in those with predisposing conditions or vulnerabilities, such as disability or co-occurring mental health conditions. The COVID-19 pandemic was significantly associated with poorer wellbeing and higher depression symptomatology. There was no significant association between COVID-19 impact and suicide risk. Participants reported that telehealth and the introduction of government programs improved their access to mental health care; however there were also longer wait times and delays in accessing assistance.

**213.004 (Panel) Longitudinal Changes in Depression and Other Mental Health Symptoms Among Autistic Adults during the COVID-19 Pandemic**  
**S. Zheng<sup>1</sup>, J. L. Taylor<sup>2</sup>, R. Adams<sup>3</sup> and S. Bishop<sup>4</sup>,** (1)Psychiatry, University of California, San Francisco (UCSF), San Francisco, CA, (2)Vanderbilt University Medical Center, Nashville, TN, (3)Cincinnati Children's Hospital Medical Center, Cincinnati, OH, (4)University of California San Francisco, San Francisco, CA

Autistic adults are at risk for experiencing numerous stressors related to the COVID-19 pandemic, such as uncertainties/disruptions in routines and employment. Some studies on the early impact of the pandemic showed elevated COVID-19 related distress and mental health problems among autistic adults, whereas others reported no significant increases in mental health symptoms or even positive effects related to reduced social demands. As the U.S. society starts to reopen, longitudinal studies are necessary to further elucidate the long-term impact of COVID-19 related disruptions on the mental health of autistic adults.

#### Objectives:

We aim to examine (1) changes in mental health symptoms across four timepoints over 16 months (March 2020 to July 2021) and (2) the impact of anxiety, stress, and loneliness on depression in autistic adults in the context of the COVID-19 pandemic.

#### Methods:

A cohort of 315 independent autistic adults (aged 18 to 35; 48% female) were recruited in early March 2020 (baseline) for a study on mental health services. A follow-up survey was sent to the same cohort of adults in May 2020, and two additional follow-ups were sent to a subsample of 210 consented adults in March 2021 and July 2021. For each data collection, autistic adults completed online surveys including the Beck Depression Inventory-II (BDI-II), Depression Anxiety Stress Scale (DASS-21), and Asher Loneliness Questionnaire. See Table 1 for descriptive statistics of mental health symptoms over time.

#### Results:

Repeated measures ANOVA showed that at the group level, autistic adults reported statistically significant (1) decreases in depressive symptoms measured on BDI-II over time since May 2020; (2) initial decreases in anxiety levels in May 2020 that then returned to baseline; (3) decreases in loneliness in May 2020 and July 2021 compared to baseline; and (4) increases in stress levels in March and July 2021 compared to baseline. To examine the effect of changes in stress, anxiety, and loneliness on later depression, we built a multi-level model with BDI-II depressive symptoms at follow-up timepoints as the outcome variable and controlled for baseline depressive symptoms. The model identified the significant random effect of time and the time-lagged (T-1) random effect of loneliness (see Table 2 for model specification and outputs), indicating that the changes in depressive symptoms and the positive effect of the feeling of loneliness on later depressive symptoms vary significantly across individuals. In fact, the intraclass correlation for depression over time is 0.76, indicating large between-individual variances.

#### Conclusions:

Findings from our longitudinal study on mental health in autistic adults highlighted two implications: (1) Different aspects of mental health (i.e., depression, anxiety, stress, loneliness) show different patterns of changes over time in response to social-environmental events, and therefore need to be considered separately (and in relation to each other). (2) Mental health problems in autism vary greatly between individuals, reinforcing the need to consider individual differences in risk, resilience, and response to stressors. We plan to further examine how individual characteristics (e.g., employment, relationship, social experiences) might impact longitudinal changes in mental health symptoms in autistic adults.

## PANEL — FAMILY ISSUES AND STAKEHOLDER EXPERIENCES

### 221 - Understanding the Stigmatisation of Autistic People across Contexts and Settings

**Panel Chair:** Monique Botha, *Department of Psychology, University of Stirling, Stirling, United Kingdom*

**Discussant:** Morton Ann Gernsbacher, *Department of Psychology, University of Wisconsin-Madison, Madison, WI*

**221.001 (Panel)** “I Felt like I Deserved It Because I Was Autistic”: Understanding the Impact of Interpersonal Victimization in the Lives of Autistic People

**A. Pearson<sup>1</sup>, K. Rose<sup>1</sup>, J. Rees<sup>1</sup> and S. Forster<sup>2</sup>,** (1)*Psychology, University of Sunderland, Sunderland, United Kingdom*, (2)*Social Work, University of Sunderland, Sunderland, United Kingdom*

**Background:** Autistic adults are more likely to experience interpersonal victimisation compared to non-autistic peers. Research has suggested that this heightened prevalence predicts poorer mental health outcomes, including higher prevalence of post-traumatic stress disorders. However there has been little focus on the social factors that drive heightened prevalence (i.e. stigma), and how this interacts with outcomes, and access to support and recovery.

**Objectives:** The aim of the current study was to explore experiences of interpersonal victimisation in autistic adults through the lens of the social process model of stigma. We specifically focussed on the impact of interpersonal victimisation on identity, and barriers and facilitators of support and recovery.

**Methods:** We recruited 102 autistic adults (aged 19-73) to take part in a qualitative study on their experiences of victimisation. We offered the opportunity to take part asynchronously by responding to an online survey with structured interview questions, or synchronously via a live semi-

structured interview. One hundred people took part in the asynchronous version, and 2 gave spoken interviews. We analysed the data from these interviews using reflexive thematic analysis, with a blended inductive/deductive approach. We used Frosts process model of social stigma to form the deductive coding framework, and completed inductive coding in an open and organic manner.

**Results:** We identified 4 main themes in the dataset. Theme 1, 'The usual for autism' focussed on participants perceptions that the victimisation they had experienced was normal for autistic people, and that they deserved it. Theme 2, 'Personhood: revoked' focussed on feelings of otherness, and the relationship between victimisation, masking, and autistic burnout. Theme 3, 'Unpacking the baggage' focussed on the emotional impact of victimisation, and how the participants made sense of their experiences. Theme 4, 'If you want to make an apple pie from scratch, you have to invent the universe first' identified the role of power dynamics in support-seeking, the impact of good interpersonal relationships and knowledgeable therapists on recovery, and the importance of autistic community.

**Conclusions:** The findings from this study support the importance of acknowledging the role of stigma in the interpersonal victimisation of autistic adults. Experiences of victimisation were driven by perceptions of otherness and being labelled negatively, which led participants to blame themselves. Participants responded to victimisation by masking and suppressing their identity to avoid further trauma, which led to exhaustion and burnout. The experience of victimisation often took a long time to process emotionally, but being able to make meaning out of these experiences helped participants start to recover. Recovery was further facilitated by the presence of supportive relationships and access to good quality therapy, however structural inequalities made this inaccessible to many. Our findings suggest that intervention to reduce the heightened prevalence of interpersonal victimisation in autistic adults need to focus on stigma reduction, and removing structural inequalities that prevent access to support and recovery.

#### **221.002 (Panel) Perceptions of Autistic Adults across Personal and Professional Contexts**

**K. M. DeBrabander<sup>1</sup>, D. R. Jones<sup>1</sup>, R. A. Ackerman<sup>2</sup> and N. J. Sasson<sup>1</sup>,** (1)University of Texas at Dallas, Richardson, TX, (2)The University of Texas at Dallas, Richardson, TX

---

**Background:** Non-autistic (NA) adults form less favorable impressions of autistic adults and report greater reluctance to interact with them (e.g., Sasson et al., 2017) but these findings have been generated within limited and artificial scenarios (e.g., auditioning for a reality TV show) rather than reflecting the diversity of real-world contexts experienced by autistic adults.

**Objectives:** This study compares how autistic adults are perceived across broader personal (e.g., dating) and professional (e.g., job interview) contexts.

**Methods:** Twenty-one autistic and 21 NA adults, new to this study and matched on core demographic features, were filmed participating in six personal and professional contexts for 45s each: job interview, dating profile, making a friend, finding a partner for class project, discussing an interest, and auditioning for a reality TV show (i.e., the context from Sasson et al., 2017). Videos were shortened to thin-slices (10-15s) and shown to 979 NA undergraduates pseudo-randomly assigned to one context in which they rated all 42 stimulus participants. After each video, participants completed the First Impression Scale (Sasson et al., 2017), which consists of six trait items and four items assessing social interest in the stimulus participant.

**Results:** Consistent with prior research, autistic adults were rated less favorably than NA adults on all first impression items (except dominance) across contexts ( $p < .05$ ). However, significant interactions between diagnostic group and context emerged for all items ( $p < .05$ ) other than attractiveness. Post hoc analyses revealed that NA participants maintained a first impression advantage over autistic participants across contexts, but the size of this advantage varied, with autistic adults being rated more favorably in some contexts than others. They were rated as more likeable, trustworthy, and intelligent when talking about their interest than when in a job interview ( $p < .001$ ), a pattern that did not occur for NA participants. In contrast, impressions of NA but not autistic participants improved in the job interview on trust and awkwardness ( $p < .01$ ), with a trend on intelligence ( $p = .055$ ), compared to the original TV context. Autistic adults were also rated as less likely to be hired from their job interview than NA adults ( $p = .029$ ). For social interest items, autistic adults received lower ratings than NA adults across contexts, but the magnitude varied. Interest in having a conversation with NA participants varied across contexts but remained similarly low across contexts for autistic participants.

**Conclusions:** First impressions of autistic and NA adults are modulated by context. Only ratings of attractiveness did not produce an interaction between diagnosis and context, likely because higher attractiveness ratings for NA adults are not influenced by the changes elicited by context. Autistic adults were rated most favorably when discussing their interest and least favorably when interviewing for a job. In contrast, NA participants improved in the interview context on some items relative to baseline. In sum, biases against autistic social presentations appear magnified in job interview contexts and are associated with lower ratings of employability. These findings argue for more nuanced evidence concerning the environmental factors contributing to social disability and discrimination experienced by autistic adults.

#### **221.003 (Panel) Characteristics of Autistic People and Characteristics of Raters: An Investigation into Factors Contributing to Heightened Autism Stigma in South Koreans Vs Americans**

**S. Y. Kim<sup>1</sup> and K. Gillespie-Lynch<sup>2</sup>,** (1)Duksung Women's University, Seoul, Korea, Republic of (South), (2)Department of Psychology, College of Staten Island, City University of New York, Staten Island, NY

---

**Background:** Previous research suggests that autism stigma is heightened in South Korea relative to the United States (US) (Kim et al., 2021). In Korea, emphasis on social norms contributes to heightened autism stigma (Kim et al., 2021). Given that internalized stigma likely contributes to the poor mental health of autistic people (Botha & Frost, 2020), there has been increasing research interest in understanding and alleviating autism stigma. However, little remains known about how specific characteristics of autism may contribute to autism stigma internationally.

**Objectives:** We aimed to 1) examine if Korean and American non-autistic people show different levels of stigma toward unlabeled vignettes depicting autistic people depending on the domains of autistic characteristics portrayed (i.e., social, non-speaking, and repetitive interests and restricted behaviors [RIRB]) and 2) identify what variables predict stigma toward autistic behaviors in each domain.

**Methods:** Two-hundred fifty-nine Koreans and 240 Americans completed online surveys. Participants read three unlabeled vignettes depicting a character exhibiting primarily: 1) social difficulties, 2) RIRB, or 3) a non-speaking person. Participants were randomly assigned to read either low or high support vignettes within each domain and to indicate their desired social distance from the character in each vignette. See Table 1 for participant information and variables measured. Repeated-measure ANCOVA was performed to examine the effect of domains and country on stigma, controlling for age and gender. Multiple regressions examined stigma toward social, non-speaking, and RIRB vignettes with variables that were correlated with stigma in each domain as predictors.

**Results:** Main effects of domains ( $F = 11.37$ ;  $p < 0.0001$ ) and country ( $F = 152.31$ ;  $p < 0.0001$ ) were observed. Koreans reported more stigma than Americans. Stigma was higher toward RIRB ( $M = 2.90$ ) than social characteristics ( $M = 2.72$ ). Stigma towards non-speaking people ( $M = 2.80$ ) did not differ from those exhibiting primarily social or RIRB characteristics. Being Korean was correlated with heightened stigma across domains, but this association disappeared in Non-speaking and RRB domains once autism knowledge, neurodiversity endorsement, contact quantity, and support needs were accounted for (Table 2). Heightened autism knowledge and neurodiversity endorsement and low support needs predicted lower stigma across all domains. High contact quantity predicted low autism stigma in Non-speaking and RRB domains. Additionally, cultural tightness, correlated with stigma in RRB domain only among Koreans ( $p = .0007$ ), predicted autism stigma in RRB domain.

**Conclusions:** RIRBs and high support needs were more stigmatized across both countries. Findings suggest that both characteristics of autistic people and individual differences of raters, including their autism knowledge and neurodiversity endorsement, exert more impact on autism stigma than nationality. Even after accounting for individual differences, Koreans reported more stigma toward a character exhibiting primarily social difficulties, suggesting the emphasis on how to *appropriately* behave in social situations is contributing to high autism stigma in South Korea. Efforts to increase autism knowledge and help people appreciate the neurodiversity movement may reduce autism stigma in both South Korea and the US.

**221.004 (Panel) Understanding Cues for Stigmatisation in the Narratives of Autism Researchers**  
**M. Botha** and E. Cage, Department of Psychology, University of Stirling, Stirling, United Kingdom

**Background:** Research about autism is particularly prolific, with at least 18,490 papers published between 2005-2014 (Sweileh et al., 2016). In 2019 and 2020 alone there were over 7,000 publications each year (Kirby & McDonald, 2021). There is a lack consensus around the nature of autism, nor how autistic people should be described. Some researchers adopt a medical perspective, which centres autism into bodies of autistic people as disorder. Others adopt a neutral embodiment perspective which focuses on autism as natural and biological, which is a difference/disability without inherently being disorder. Lastly, some researchers adopt a social model which focuses on the role of society and environments in disabling autistic people. Autism research has been criticised for othering autistic people (Michael, 2021) and for research-based violence (Botha, 2021). Participatory methods are increasing and might challenge these othering notions. To our knowledge, there have not been investigations into the views held by autism researchers.

**Objectives:** First we analysed the different narratives being used by autism researchers and whether they contained stigmatising cues. Second, we analysed whether variables such narratives (medical or otherwise) or participatory methods predicted stigma cues while controlling for other connections to autistic people or length of experience in research.

**Methods:** In total, 172 autism researchers took part. Most were female (72.8%), in the UK (36.4%) or USA (33%), 19% were autistic autism researchers. Researchers came from a range of disciplines and career stages with on average 8.56 years' experience. They completed an online mixed methods survey, answering five qualitative questions, where they had to describe autism, autistic people, the cause of autism, the main goal of autism research, and the main aim of their own research. Quantitative questions recorded information on experience, language preferences, connections with autistic people (familial and non-familial), and experiences of participatory research. We used content analysis to analyse researchers' qualitative responses.

**Results:** We coded 55.8% ( $n = 96$ ) of the accounts as medical, 32.6% ( $n = 56$ ) as neutral embodied, and 11.6% ( $n = 20$ ) as social model narratives. In 59.9% of researchers answers there was at least one stigmatising cue. We used hierarchical binary logistic regression to identify whether narrative or participatory methods predicted stigmatising cues, while controlling for length of research career, familial and non-familial connections to autistic people. Narrative significantly predicted the odds of stigmatising cues with both the embodied ( $\text{Exp}(B) = .16$ ) and social ( $\text{Exp}(B) = .06$ ) perspectives predicting lower odds of stigmatising cues ( $ps < .001$ ). Greater participatory research methods predicted significantly lower odds of stigmatising cues ( $\text{Exp}(B) = .60$ ,  $p = .03$ ). Neither familial nor non-familial connections predicted cues for stigmatisation once degree of participation or perspective were included in the model.

**Conclusions:** Medical narratives are still predominant, but not exclusively how researchers characterise autism. Participatory methods predicted significantly lower odds of stigmatising cues in researchers accounts and may be particularly important in reducing the stigmatising or othering accounts of autistic people.

## ORAL SESSION - 4A — FAMILY ISSUES AND STAKEHOLDER EXPERIENCES

### 304 - Autistic Experiences

### 304.001 (Oral) Autistic and Non-Autistic Stakeholder Participation in Autism Research

S. L. Curtiss<sup>1</sup>, M. Subih<sup>1</sup>, F. Madison<sup>2</sup>, S. Tillman<sup>3</sup> and W. Ingram<sup>2</sup>, (1)University of Delaware, Newark, DE, (2)Independent Scholar, Newark, DE, (3)Independent Scholar, Newark, DE

---

**Background:** Participatory research is a framework for approaching inquiry such that those who would traditionally be research participants become partners in the research process (Cornwall & Jewkes, 1995). There have been increasing calls for participatory autism research, but little is known about the strategies researchers use and their perceptions of involvement.

**Objectives:** The objective of this study was to understand participatory autism research better. Specifically, we asked (1) what strategies do investigators use, (2) what barriers do they face, and (3) what do they see as the importance of involvement? We also asked if there were differences in involvement between autistic and non-autistic stakeholders (such as parents, educators, and clinicians).

**Methods:** This study is a fully mixed sequential equal status design (Leech & Onwuegbuzie, 2009) in which we first asked participants to complete a survey, and then a subsample was interviewed. Corresponding authors who had published in autism-focused journals from 2015–2019 were emailed an invitation to participate in a survey (n=2,722). Of these, 215 participated in the survey, and 21 of these participants also agreed to one-hour-long interviews. The authors, three of whom identify as autistic, developed the survey and interview protocol. We analyzed both qualitative and quantitative data descriptively. Paired samples t-tests were used to identify statistical differences between autistic and non-autistic stakeholder groups. The qualitative data was structurally coded (Saldaña, 2016) to expand and provide detail into the quantitative findings and guide additional analysis.

**Results:** The tables summarize the results of the analysis. In general, there was infrequent use of the participatory research approaches. Participants were more likely to have an advisory board and present research to non-autistic stakeholders. The quote in Table 1 highlights an approach we did not ask in the survey—how community building can foster participatory research. Participants moderately endorsed each of the barriers to research, with “not being sure how to engage stakeholders” and “questioning how stakeholders may enhance research” having the least agreement. A lack of incentives and confidence with engagement seemed to be more significant barriers for autistic stakeholder participation, whereas not being sure how their participation could enhance research was a greater barrier for non-autistic stakeholders. The quote in Table 2 highlights the connection between barriers to involvement (e.g. funding) and the importance of involvement (e.g. balancing power). In terms of the importance of involvement, there was moderate endorsement of each item. In general, the scores on importance were higher for autistic stakeholders. The quote in Table 3 provides a detailed example of how stakeholder involvement enhanced the research process.

**Conclusions:** This research indicates that stakeholder engagement in autism research does have support; however, attempts to engage stakeholders are lagging behind. There were many similarities between different stakeholder groups; however, a difference seems to be more support for how the participation of autistic stakeholders is important for research.

### 304.002 (Oral) The Experiences and Perceptions of Professional Autistic Actors in Film and on Television

M. Dean<sup>1</sup> and A. Nordahl-Hansen<sup>2</sup>, (1)Education, 2013, Camarillo, CA, (2)Faculty of Education, Østfold University College, Halden, Norway

---

Background:

Film and television portrayals of autism can simulate personal experiences for people who have otherwise not had direct substantive contact with autistic individuals—people form perceptions of autism based on the characters they observe on the screen (Nordahl-Hansen et al., 2018). Given the recent upsurge in autistic portrayals in film and on television, it is important to understand the involvement of autistic stakeholders in the development of autistic characters, and the extent to which these groups value autistic representations.

Objectives:

We sought to examine the experiences and perceptions of professional autistic actors who have played autistic characters in film and on television.

Methods:

This study uses Interpretative Phenomenological Analysis (IPA) (Smith et al., 1999), in which professional autistic actors participated in interviews and discussed their professional opportunities and work experiences as autistic actors in film and on television. Participants also described their perceptions of autistic characters. Ethical approval was granted by the University's Institutional Review Board prior to the start of recruitment.

Autistic community engagement was built into the study design; autism stakeholders, including community members, and parent- and self-advocates helped to develop the interview protocol and procedures, and assisted in recruitment efforts. Per community endorsement, actors were sent the interview questions prior to the scheduled appointment, and were given the choice to participate in the interview via Zoom, phone, chat, or email. All actors chose the Zoom format.

Nine autistic actors (6 male; 3 female) participated in the study. Participants played autistic characters in film or on television, and roles included guest stars, recurring guest stars, and voiceover actors on television, and leading and supporting roles in film. Actors were in or were eligible to join the Screen Actors Guild. Participant ages ranged from 16 to 34 years. Actors identified as Caucasian (n=5), mixed race (n=2), Asian (n=1), and Latinx (n=1).

The interviews followed an in-depth, semi-structured format, with open-ended questions related to employment/workplace experiences on film and television sets, autistic identity, and autistic representations. Interviews were recorded via zoom and transcribed verbatim. An inductive coding process was used to become familiar with the data, generate initial codes, and collate codes into themes (Braun & Clarke, 2006).

#### Results:

Four key themes emerged from the data analysis: Opportunities for autistic actors, employment accommodations, when and when not to disclose, and representations promote awareness but more nuance is needed.

#### Conclusions:

Production companies' targeted efforts to promote authentic casting have helped to increase employment opportunities for autistic actors. Affiliation with autism-specific acting studios, disability resource centers, and representation by agents and managers who specialize in representing actors with disabilities helps autistic actors access and take advantage of these opportunities. If necessary, for authentic casting, actors are willing to disclose autism, but worry that type-casting will limit opportunities to play non-autistic characters. Actors recognized that autism is a spectrum and they therefore could not relate to every autistic character. Actors had negative perceptions of "over-the-top" portrayals, and appreciated nuanced portrayals.

#### **304.003** (Oral) Understanding the Research Priorities and Perspectives of Autistic Female and Nonbinary People

**O. C. Putnam<sup>1</sup>, M. Swisher<sup>2</sup>, T. A. Niblack<sup>3</sup>, C. M. Perry<sup>4</sup> and C. Harrop<sup>1</sup>,** (1)Department of Allied Health Sciences, University of North Carolina - Chapel Hill, Chapel Hill, NC, (2)The University of North Carolina - Chapel Hill, Chapel Hill, NC, (3)University of North Carolina at Chapel Hill, Chapel Hill, NC, (4)Department of Allied Health Sciences, University of North Carolina at Chapel Hill, Chapel Hill, NC

---

**Background:** Currently there is a disconnect between the funding and research priorities of the autism community and the funding priorities and decisions made by government and other funding agencies (den Houting et al., 2020; Pellicano et al., 2014). Further, stakeholders commonly surveyed within the autism community, such as parents, may have conflicting priorities to autistic individuals themselves (Frazier et al., 2018). In the United States, little work has been done to evaluate the priorities of autistic adults. Further, the voices of female and non-binary autistic individuals have been under-represented in this work, despite reporting different life experiences to males (Bargiela et al., 2016; Cridland et al., 2014; Sedgewick et al., 2019). Considering these experiences and priorities when developing new research is critical.

**Objectives:** To understand the research priorities of a sample of autistic adults, with an overrepresentation of female and nonbinary participants.

**Methods:** 52 autistic adults (29 female, 12 nonbinary, 11 male; 46 formally diagnosed, 6 seeking diagnosis; Mean age =31 years (range 16-70); Mean age of diagnosis =23 years (range 3-67)) completed an online survey. Participants were asked to rank the seven research questions included in the Interagency Autism Coordinating Committee Strategic Plan (IACC; October 2017). Weighted ranks of the questions were calculated. Additionally, participants were asked to respond to the free-response question, "What topics do you think should be investigated by researchers?". Themes were pulled from the written responses using content analysis.

**Results:** IACC questions related to services, infrastructure, and adulthood were ranked the highest while questions related to recognizing autism, interventions, biology, and causes were ranked lowest (Table 1). High-ranked IACC priorities, such as services and supports, were reflected in the written priorities of participants. A content analysis of free-response answers (Figure 1) revealed that participants were most interested in seeing research related to "Inclusivity" (N = 32), "Autism Phenotype" (N = 29), "Services/Supports" (N = 27), "Co-Occurring Conditions" (N = 21), "Recognition/Diagnosis" (N = 14), "Training/Education" (N = 11), and "Treatments/Interventions" (N = 7). Values that emerged throughout the free-response questions included valuing neurodiversity in society, education, and research, and researching autism for the purpose of understanding and support rather than for seeking a "cure". Additionally, participants promoted the value of including autistic perspectives in the shaping of research and treatment practices and in creating infrastructure.

**Conclusions:** While written research priorities overlapped to some degree with the current strategic plan questions, participants placed more of an emphasis on autism acceptance, support and services, and lifespan issues. Our results align with those of previous studies surveying autistic adults (Benevides et al., 2020; Pellicano et al., 2014) and contribute to the scaffolding of future research questions that best reflect the values and priorities of the autistic community. Importantly, the oversampling of female and nonbinary adults in the current study provided insight into priorities that may not emerge from typical predominantly male sample, such as an earlier identification of females, eating disorders, and knowing how autism presents in female and nonbinary people.

#### **304.004** (Oral) Implicit Attitudes Towards Autism in the British Press

**T. Karaminis<sup>1</sup>, U. Maden-Weinberger<sup>2</sup>, G. Beattie<sup>2</sup> and C. Gabrielatos<sup>2</sup>,** (1)Department of Psychology, Edge Hill University, Ormskirk, United Kingdom, (2)Edge Hill University, Ormskirk, United Kingdom

---

**Background:** Feeling accepted is crucial for the successful integration of autistic people in education, work, and society and has a significant impact on their mental health. Autism acceptance also becomes increasingly important as our understanding of the condition shifts from clinical-based models towards neurodiversity-based models. But how accepting is society towards autism and autistic people? One way to address this question is through the lens of the press. The press reflects and constructs public views. The language used to portray autism in the press can reveal implicit attitudes, perceptions, and stereotypes and offer insight into the acceptance of autism and autistic people.

**Objectives:** This study aims to investigate how the British Press uses language to describe autism using a corpus-linguistics and critical-discourse-analysis methodological framework (corpus-based CDA). It also aims to examine changes in the representation of autism over time and differences between individual newspapers, for example, in the style of reporting (tabloids vs. broadsheet) or political orientation (left vs. right).

**Methods:** We created a corpus with newspaper articles relevant to autism by querying the ProQuest Newsletter Database for 2011 - 2020. The corpus included articles from paper and online editions of ten national newspapers. After preprocessing and duplicate removal, the final corpus consisted of around 24,000 autism-related articles (1 million sentences; 19 million words). We used the corpus-based CDA framework to construct emergent representations of the terms autism and autistic. Firstly, we performed measurements and statistical calculations to identify collocates of "autism" and "autistic" (words associated with these terms strongly and reliably and thus reflecting some of their meaning). Subsequently, we examined collocates within the grammatical constructions and the semantics contexts in which they occurred. Finally, we examined the attitudes that the lexicogrammatical patterns expressed in a given context.

**Results:** The number of articles referring to autism increased, on average, by 15% per year between 2011 and 2020 with considerable differences in this upward trend between individual newspapers. As a result, in 2020, 1 in 100 articles referred to autism in the Independent (left-leaning broadsheet), but only 1 in 1000 in Sun/Express/Mirror (tabloids). The emergent definitions of autism suggested that autism is portrayed more frequently as a disorder or disability than a difference. Autism is usually described with negative language, and is listed together with comorbid neurodevelopmental and physical and mental health conditions. Autistic individuals are spoken about and lack agency in the described actions. For example, children are portrayed as attributes of their mothers, who might take actions to improve their child's life or create a more inclusive world. Finally, there is a strong male bias in the representation of autism as most stories refer to males rather than other genders. This gender bias has declined slowly over the years.

**Conclusions:** Our results suggest a trend of increasing newsworthiness and coverage of autism in the British press. Autism, however, is often portrayed using negative language and with a strong male-gender bias in its coverage. These representations might hinder public awareness and acceptance of autism and neurodiversity.

## ORAL SESSION - 11B — FAMILY ISSUES AND STAKEHOLDER EXPERIENCES

### 323 - Family Systems

**323.001** (Oral) Financial Hardship in Families of Children with Autism Spectrum Disorders: A Report from the r-Kids Study  
**F. Lynch<sup>1</sup>, J. Dickerson<sup>1</sup>, J. Bulkley<sup>1</sup>, E. Fombonne<sup>2</sup>, L. A. Croen<sup>3</sup>, Y. Daida<sup>4</sup>, B. Hatch<sup>5</sup> and A. Varga<sup>1</sup>,** (1)Kaiser Permanente Center for Health Research, Portland, OR, (2)Department of Psychiatry, Oregon Health & Science University, Portland, OR, (3)Division of Research, Kaiser Permanente Division of Research, Oakland, CA, (4)Kaiser Permanente Center for Integrated Health Care Research, Honolulu, HI, (5)Oregon Health & Science University, Portland, OR

#### Background:

Many families of children with autism (ASD) experience financial distress or hardship related to their child's ASD. However, most prior studies examined limited aspects of financial distress or relied on parent-reported diagnoses of ASD. Studies also lacked control groups of children without ASD that would allow for comparisons of financial difficulty for families of children with other chronic health conditions, or those without a significant condition.

#### Objectives:

The objectives of this analysis are to extend previous work by examining a more comprehensive model of financial hardship in families of children with ASD, and to compare these patterns to two independent control groups: families of children with Asthma, and families of children without either of these health conditions (Control). In addition, we examined other correlates of financial hardship such as family structure (e.g., single parent households), and severity of ASD.

#### Methods:

Data come from the recently completed r-Kids study which recruited parents of children from three large integrated health systems and several safety net clinics in the US. Children were randomly selected from electronic health records to identify children between 3 and 16.5 years with diagnoses of ASD, Asthma, or Control. Children with Asthma and Control children were matched to the ASD group distribution on age and sex. Parents were then invited to participate, and a total of 1,461 parents joined the study, (564 ASD, 468 Asthma 429 Control) and completed on-line or telephone surveys. The survey was comprised of the Family Economic Impact Inventory (measuring financial hardship impacts of caring for a child's health), and instruments measuring demographics, insurance status, and symptom severity for children with ASD or asthma. All materials were provided in English and Spanish. Financial hardship outcomes, defined as material conditions (e.g., medical debt), psychological response (e.g., distress due to costs of care), and coping behaviors (e.g., delaying care due to cost), were calculated as annual measures and were compared between groups using a variety of multivariable regression methods. Models were fit separately for each outcome. We applied a two-sided  $\alpha=0.05$  for all inferential tests.

#### Results:

Children were between the ages of 3 and 16.5 years old, predominantly male (79%) because comparison groups were matched by age and sex to ASD children. The sample was ethnically diverse (43% non-Hispanic white; 21% Hispanic; 35% non-Hispanic Asian, Black, Native Hawaiian, or other race/ethnicity). Families of children with ASD were significantly more likely to experience at least one type of financial hardship compared to the control group (OR: 5.38,  $p < .001$ ) and asthma group (OR: 2.88,  $p < .001$ ). Families of children with ASD were also significantly more likely to have greater hardship in all three domains of financial hardship (material conditions psychological response, and coping behaviors).

#### Conclusions:

Families of children with ASD experience significant financial hardship related to their child's condition. Public and health insurance policies to help mitigate these impacts could aid families in managing care for children with ASD.

### **323.002** (Oral) Attitudes and Behaviors Related to COVID-19 Vaccines Among Parents of Children with ASD and Autistic Adults

*N. L. Matthews<sup>1</sup>, A. Klott<sup>1</sup>, J. Scholtes<sup>1</sup>, M. Mitchell<sup>1</sup>, B. B. Braden<sup>2</sup> and C. J. Smith<sup>1</sup>, (1)Southwest Autism Research & Resource Center, Phoenix, AZ, (2)College of Health Solutions, Arizona State University, Tempe, AZ*

---

**Background:** Previous research suggests heightened vaccine hesitancy among parents of children with autism spectrum disorder (ASD) relative to the general population (Chang & Kochel, 2020). Considering evidence that individuals with ASD are at increased risk to be hospitalized with COVID-19 (Karpur et al., 2021), it is important to understand specific attitudes and behaviors related to COVID-19 vaccines in the ASD community.

**Objectives:** To explore attitudes and behaviors related to COVID-19 vaccines among parents of children with ASD and autistic adults.

**Methods:** Participants were 135 members of the ASD community (99 parents of children with ASD and 36 autistic adults) who responded to the third and fourth time points of a larger longitudinal study on the experiences of individuals with ASD during the pandemic (Table 1). All participants lived in the state of Arizona. Participants responded to a series of questions measuring their attitudes and behaviors related to COVID-19 vaccines in the spring (April/May) and summer (August/September) of 2021.

**Results:** Table 2 reports participants' household vaccination status, plans for vaccinating children, and descriptive statistics for Likert scales measuring attitudes and beliefs about COVID-19 vaccines. Wilcoxon signed rank tests indicated that participants in both samples were significantly more likely to indicate that they believed the vaccine was safe for adults and children in the summer compared to the spring. Parents were significantly less likely to indicate that they were concerned about long-term effects of COVID-19 vaccines in the summer compared to the spring. Ratings related to perceived effectiveness and adverse effects for children did not change significantly over time.

Parents of older children were more likely than parents of younger children to indicate that they believed that COVID-19 vaccines are safe for adults (Spring:  $\rho = 0.21$ ,  $p = .04$ ; Summer:  $\rho = 0.18$ ,  $p = .08$ ) and children (Spring:  $\rho = 0.27$ ,  $p = .01$ ; Summer:  $\rho = 0.24$ ,  $p = .02$ ) and were less likely to indicate concerns about their children experiencing adverse effects from COVID-19 vaccines (Spring:  $\rho = -0.24$ ,  $p = .02$ ; Summer:  $\rho = -0.23$ ,  $p = .02$ ). Parent age was negatively associated with concerns about children experiencing adverse effects (Summer:  $\rho = -.20$ ,  $p = .05$ ).

**Conclusions:** Percentages of the parent and autistic adult samples reporting that all eligible members of their household were fully vaccinated was consistent with or higher than the general population of Arizona (AZDHS.gov). Attitudes and beliefs related to COVID-19 vaccines became more positive over time in both groups. Despite this, a sizable minority of participants reported that no one in their household plans to receive a COVID-19 vaccination and that they do not plan to vaccinate any of their children. Although promising that vaccine uptake appears consistent with the general population, this convenience sample may not generalize to the wider ASD community. Additional research and continued education and outreach efforts are necessary to better understand and reduce vaccine hesitancy in the ASD community.

### **323.003** (Oral) Examining Indicators of Psychosocial Risk and Resilience in Parents of Autistic Children

*A. D. Dimachkie-Nunnally<sup>1</sup>, R. S. Factor<sup>2</sup>, A. Sturm<sup>3</sup>, L. Abbeduto<sup>4</sup>, L. V. Soorya<sup>5</sup>, A. Wainer<sup>6</sup> and A. Gulsrud<sup>6</sup>, (1)UC Davis MIND Institute, University of California, Davis, Sacramento, CA, (2)Virginia Polytechnic Institute and State University, Blacksburg, VA, (3)UCLA, Los Angeles, CA, (4)M.I.N.D. Institute, UC Davis, Sacramento, CA, (5)Department of Psychiatry, Rush University Medical Center, Chicago, IL, (6)UCLA Semel Institute for Neuroscience & Human Behavior, Los Angeles, CA*

---

#### Background:

There is evidence that parents of autistic children experience increased levels of stress, even in comparison to parents of children with other neurodevelopmental disabilities (Estes et al., 2009), which has been previously attributed to behavioral challenges associated with autism spectrum disorder (ASD; Lyons et al., 2010). Less attention has been given to other possible contributors to stress in this population, such as the contribution of children's adaptive behavior. Additionally, little is known regarding potential protective factors that may ameliorate the experience of stress among parents of autistic children.

#### Objectives:

The present study aims to determine the relationship between autistic children's clinical characteristics and indicators of their parents' psychosocial risk and resilience.

## Methods:

Participants included a sample of 263 autistic children (77.9% males, 68.6% white) aged between 1 and 16 years ( $Mage = 7.37$ ;  $SD = 3.92$ ), as well as their biological mothers ( $Mage = 40.64$ ;  $SD = 7.014$ ) and fathers ( $Mage = 42.88$ ;  $SD = 7.74$ ). Data were collected as part of a cross-sectional study that involved one wave of data collection from SPARK participants. Parents completed self-report measures of mental health (Patient Health Questionnaire-9 [PHQ-9; Spitzer et al., 1999], General Anxiety Disorder-7 [GAD-7; Spitzer et al., 2006]) as well as resilience and wellbeing (Caregiver Strain Questionnaire [CGSQ; Brannan et al., 1997]; Well Being Scale [WBS; <https://www.radc.rush.edu/docs/var/overview.htm?category=Well-being>], Barkley Deficits in Executive Functioning Scale Short Form [BDEFS; Barkley, 2011]). Additionally, data were collected on several child clinical factors, including the Repetitive Behaviors Scale – Revised (RBS-R; Bodfish et al., 2000) and the Vineland Adaptive Behavioral Scales (VABS; Sparrow et al., 1984).

## Results:

Parents in this sample endorse high levels of mental health concerns, with 61.2% of mothers and 55.1% of fathers at clinical risk for a depressive disorder. Children's repetitive behaviors (RBS-R) were found to correlate with risk for depressive disorders (PHQ-9) among mothers ( $r = .215$ ,  $p = <.001$ ), as well as risk for anxiety disorders (GAD-7) among both mothers ( $r = .207$ ,  $p = <.001$ ) and fathers ( $r = .132$ ,  $p = <.05$ ). An even stronger relationship was found between children's adaptive behavior (VABS) and parents' daily strain (CGSQ), with greater impairment in adaptive behavior associated with greater daily strain for both mothers ( $r = -.327$ ,  $p = <.001$ ) and fathers ( $r = -.332$ ,  $p = <.001$ ). Conversely, parents' executive functioning (EF) skills emerged as possible protective factors against mental health risks; specifically, stronger parent self-reported inhibition and emotion regulation skills were associated with greater parent wellbeing (see Table 1 and Table 2).

## Conclusions:

The current study leveraged a large sample of autistic children and their biological parents to examine the relationship between children's clinical characteristics and parent's mental wellbeing. Results indicate that, although parents of autistic children do experience high rates of internalizing mental health concerns that relate to child adaptive functioning and RRBs, parent EF may act as a protective factor against adverse mental health. These findings indicate a need to further examine resilience factors and ensure appropriate and targeted supports are available for parents of autistic children.

### **323.004 (Oral)** Influence of Siblings on Teacher-Reported Trajectories of Challenging Behaviors in Autism

**N. E. Rosen<sup>1</sup>, H. K. Schiltz<sup>2</sup> and C. Lord<sup>1</sup>**, (1)UCLA Semel Institute for Neuroscience and Human Behavior, Los Angeles, CA, (2)Psychology, Marquette University, Milwaukee, WI

**Background:** Individuals with autism spectrum disorder (ASD) frequently exhibit challenging behaviors throughout the lifespan, especially from childhood through early adulthood (Lecavalier, 2006). Untreated challenging behaviors can have pervasive effects, with notable impacts on social functioning, academic achievement, psychiatric outcomes, and quality of life (Kim, 2000). Challenging behaviors have been shown to change over time as a function of various individual-level factors (e.g., cognitive ability). Much of this research, however, has relied upon parent-report and no study to date has examined the influence of broader family-level factors, such as siblings, on these trajectories despite the important role that siblings play in the lives and development of individuals with ASD.

**Objectives:** This study aimed to examine trajectories of teacher-reported challenging behaviors (i.e., hyperactivity, irritability, social withdrawal), and predictors of patterns of behaviors including the presence of a sibling and the sibling diagnostic profile, from ages 9-22 among individuals with ASD or non-spectrum delays.

**Methods:** Participants included 165 individuals with ASD or non-spectrum developmental disorders from an ongoing longitudinal study from childhood through adulthood. Teachers completed the Aberrant Behavior Checklist (ABC; Aman, 1986) across 20 timepoints (ages 9-22) to assess participants' challenging behaviors. Change in ABC hyperactivity, irritability, and social withdrawal scores was examined using multilevel models. Presence of siblings and sibling diagnostic profiles were examined as predictors of initial level (i.e., intercept) and change (i.e., slope) in ABC scores, controlling for relevant demographic factors (i.e., autism severity, IQ, caregiver education).

**Results:** Multilevel models revealed that participants showed marginal improvement in hyperactivity symptoms ( $B = -0.32$ ,  $p = 0.09$ ), non-significant improvement in irritability ( $B = -0.17$ ,  $p = 0.32$ ), and negligible change in social withdrawal ( $B = -0.06$ ,  $p = 0.70$ ) from ages 9-22 per teacher-report. Compared to those without siblings, participants with siblings had significantly lower levels of hyperactivity at age 9 ( $B = -5.50$ ,  $p = 0.04$ ), though experienced less improvement in hyperactivity across time ( $B = 1.18$ ,  $p = 0.01$ ). Among participants with siblings, those with closest-age siblings with behavioral disorders showed significant increases in hyperactivity ( $B = 0.83$ ,  $p = 0.02$ ) and irritability ( $B = 0.66$ ,  $p = 0.04$ ) over time compared to a decline in participants with siblings without behavioral disorders; notably, both groups demonstrated similar levels of hyperactivity and irritability at age 9 ( $p > 0.05$ ).

**Conclusions:** Findings extend our understanding of challenging behavior trajectories by focusing on teacher perspectives and examining effects of siblings. Teachers provide unique insight into how these behaviors manifest in ASD across varied situations and contexts outside of those observed by parents (e.g., classroom, hallway, recess). In keeping with expectations for a general positive influence of siblings, individuals with ASD with siblings presented with fewer hyperactivity symptoms in childhood, though, potentially as a result, seem to have less room for improvement over time than individuals with ASD without siblings. Additionally, given that siblings often serve as behavioral models for individuals with ASD (Shivers, 2015), it is not surprising that individuals with ASD who have siblings with behavioral disorders experienced greater challenges across time

in hyperactivity and irritability. Findings highlight the importance of providing behavioral support to multiple children within the same family (with/without ASD) who struggle to regulate their behavior and emotions.

## POSTER SESSION — FAMILY ISSUES AND STAKEHOLDER EXPERIENCES

### 411 - Family Issues and Stakeholder Experiences I

**411.085** (Poster) A Systematic Review of Social Support for Siblings of Children with Neurodevelopmental Disorders

**S. Kirchhofer<sup>1</sup>, T. M. Vatne<sup>2</sup>, S. Orm<sup>3</sup>, Y. B. Haukeland<sup>4</sup>, T. Fredriksen<sup>5</sup>, C. Wakefield<sup>6</sup> and K. W. Fjermestad<sup>1</sup>,** (1)Psychology, University of Oslo, Oslo, Norway, (2)Frambu Resource Centre for Rare Disorders, Siggerud, Norway, (3)Department of Psychology, University of Oslo, Oslo, Norway, (4)University of Oslo, Oslo, Norway, (5)Innlandet Hospital Trust, Lillehammer, Norway, (6)University of New South Wales, Sydney, NSW, Australia

**Background:** Siblings of children with neurodevelopmental disorders are at risk of various negative emotional and behavioral outcomes, including increases in internalizing problems such as anxiety and depression symptoms. Differences in sibling outcomes have been found across studies, with siblings of children with autism spectrum disorder found to be more at risk for negative psychosocial functioning compared to siblings of children with Down syndrome and other developmental and intellectual disabilities. Social support is an important protective factor for siblings of children with neurodevelopmental disorders such as autism spectrum disorders. **Objectives:** This review investigates the level of social support received by siblings of children with neurodevelopmental disorders, explores associated variables, and examines measurement instruments used to study social support in this population. **Methods:** A pre-registered systematic review was conducted (CRD42020207686). We searched PsycINFO, MEDLINE, Web of Science, and Scopus for articles on social support and siblings of children with neurodevelopmental disorders. **Results:** Fifteen articles were included. Thirteen studies were descriptive. Two studies investigated sibling social support after an intervention. The mean level of social support across sibling diagnostic groups were found to be 76% of the maximum scores, indicating moderately high support. Multiple variables were found to be negatively related to social support (e.g., sibling depression, loneliness, and stress). Variables that were positively related to social support included prosocial behavior, total competence (academic, social and in activities), problem-focused coping and family quality of life. Potential moderators of the relationship between social support and psychosocial adjustment variables included type of sibling disorder (diagnostic group), the source of social support, and perceived importance and amounts of social support. Overall, support for siblings of children with autism tended to be lower than for siblings of children with other disorders. Seven different measures of social support were used across the 15 studies, measuring different types of support and from various sources. The reliability and validity of these measurement instruments varied considerably. **Conclusions:** Lower levels of social support have been linked to more negative psychosocial adjustment among siblings of children with autism spectrum disorders and other neurodevelopmental disorders. Future research is encouraged to further investigate ways to increase social support for siblings to improve outcomes.

**411.086** (Poster) Associations Among Parent Emotion Regulation, Parent Stress, and Child Behavior Problems

**A. Rovane<sup>1</sup> and R. Hock<sup>2</sup>,** (1)Psychology, University of South Carolina, Columbia, SC, (2)University of South Carolina, Columbia, SC

#### Background:

Literature to date suggests that parents of children with ASD are likely to experience heightened stress and rely more on maladaptive emotion regulation strategies to handle stress and negative emotion, compared with parents of other neurodevelopmental disabilities. Parent stress and child challenging behaviors in ASD have a strong association both concurrently and longitudinally. However, less is known about how parent emotion regulation is related to challenging behaviors in children diagnosed with ASD. Because people with poorer emotion regulation often handle stress in a negative manner, poor emotion regulation may heighten the association between parent stress and behavior problems in ASD.

#### Objectives:

The current study seeks to explore relationships between these parent stress, parent emotion regulation, and child behavior problems in families with ASD, and it seeks to answer the following questions:

1. Are there significant relationships between parent emotion regulation, parent stress, and child behavior challenges among parents of children with ASD?
2. Does parent emotion regulation predict child behavior problems in ASD; if so, does parent emotion regulation moderate the relationship between parent stress and child behavior problems?

#### Methods:

Participants were mothers ( $N = 49$ ) of school-aged children [ $M(SD)$  child age: 7.9 (1.68), 71.4% males] with ASD who were recruited for a study examining family patterns in ASD. Participants supplied demographic information and completed the Difficulties with Emotion Regulation—Short Form, The Parental Stress Scale, The Child Adjustment and Parent Efficacy Scale—Developmental Disabilities (behavior problems subscale), and the Social Communication Questionnaire. All variables were entered into a bivariate correlation matrix to address aim 1. For aim 2, a 2-step hierarchical regression model was constructed to predict whether control variables (child age, gender, and ASD symptoms), parent stress, and parent emotion regulation predicted child behavior problems. All variables were entered into step 1. In step 2, an interaction term between parent stress and parent emotion regulation was added.

## Results:

The mean age of mothers in the sample was 40.36 (SD=6.3) years. Of the participants, 67.3% were white, 34.7% were employed full time, and 74% were college educated. **Aim 1.** Parent emotion regulation was significantly related to parent stress ( $r = .65, p < .001$ ) and child behavior problems ( $r = .59, p < .001$ ), and behavior problems were significantly related to parent stress ( $r = .53, p < .001$ ). **Aim 2.** In step 1, parent emotion regulation significantly predicted behavior problems ( $b = .41, p = .02$ ), while parent stress approached significance ( $b = .31, p = .07$ ). The control variables and interaction term were nonsignificant, and the model explained a significant proportion of variance [ $F(4, 37) = 7.55, R^2 = 46\%, p < .001$ ].

## Conclusions:

The present study demonstrates that how a parent regulates themselves when faced with stress and negative emotion may be more influential on child behavior than their stress level alone. The moderating effect of emotion regulation was not observed in this cross-sectional study. Given its theoretical importance to parent-child relationships, future research examining the reciprocal relationship between parent emotion regulation and child challenging behaviors is warranted.

### **411.087 (Poster)** Associations between Caregiver Depression and Social Support Among Diverse Caregivers of Children with Autism

**A. Taiwo<sup>1</sup>, E. Glenn<sup>2</sup>, L. L. McIntyre<sup>1</sup> and C. L. Neece<sup>3</sup>, (1)Special Education and Clinical Sciences, University of Oregon, Eugene, OR, (2)Duke Center for Autism and Brain Development, Durham, NC, (3)Psychology, Loma Linda University, Loma Linda, CA**

---

**Background:** Research has suggested that mothers of children with autism spectrum disorder (ASD) are increasingly at risk for mental health problems like stress and depression. Risk factors that increase the likelihood of maternal depression include SES, access to social support, child disability status, and child challenging behaviors. There is moderate research showing that social support buffers the effects of stress on parents of children with ASD, but fewer have examined its effect on maternal depression, particularly the types of social support (formal, informal, family) that is more helpful to parents. In addition, most studies examining social support utilize White, English-speaking caregivers with high education and SES, the extent to which studies utilize Latinx/Hispanic caregivers with varied English-speaking abilities, SES, and education are relatively under-investigated.

**Objectives:** This study examines the types of social supports that are viewed as most helpful in an ethnically and linguistically diverse sample of caregivers of young children with developmental delay (DD) or ASD. We examine if perceived helpfulness varies by ethnicity (Latinx, non-Latinx) and if social support is associated with caregiver depression ratings.

**Methods:** This sample consists of 130 caregivers and their preschool children (3-5yrs) who have a diagnosis of ASD or DD who were participating in an ongoing longitudinal study examining the effects of stress-reduction and parenting interventions to improve child and parent outcomes. All measures for the present study were collected as part of the baseline assessment. Social support was measured using Family Support Scale (FSS) and depression was measured using the Center for Epidemiological Studies-Depression (CES-D). Demographics were self-reported. We used descriptive statistics and a one-way ANOVA to test our research questions.

**Results:** About two-thirds (62.3%) of the sample identified as Hispanic/Latinx (43% Spanish-speaking at home). Approximately half of the sample reported an annual family income of \$40,000 or lower, with more than half (53.9%) receiving a high school education or less. 40% of children had an ASD diagnosis. Families rated formal supports as most helpful ( $M = 2.36$ ), and informal supports as least helpful ( $M = 1.43$ ). Based on ethnicity, Latinx/Hispanic caregivers rated formal supports as more helpful ( $p < .05$ ) when compared to non-Latinx. In addition, higher family social support ratings were associated with lower depression scores.

**Conclusions:** Our results suggest that families overall are finding formal supports (i.e., physicians, other professional helpers) to be more helpful than informal (co-worker, parent groups) and family supports (parents, spouse), which is inconsistent with the larger literature on social support. In terms of caregiver depression, family supports in particular, were associated with lower depression scores. These results suggest that both family and formal supports are useful to caregivers of young children with ASD/DD, possibly through different processes. Perhaps given the age of the children in the current study, formal support is especially beneficial to families so that they can be connected to services and information for their newly diagnosed children. Future studies could inform how to improve caregivers' solicitation for supports, in addition to intervention studies that target malleable factors related to caregiver depression.

### **411.088 (Poster)** Autism Community Priorities in Diverse Low-Resource Settings: A Country-Wide Scoping Exercise in India

**S. Chakrabarty<sup>1</sup>, R. Nandi<sup>1</sup>, R. Shekhar<sup>1</sup>, I. Dey<sup>1</sup>, S. Nayar<sup>2</sup>, J. R. Ram<sup>3</sup>, S. Mukerji<sup>3</sup> and B. Chakrabarti<sup>1,4,5</sup>, (1)India Autism Center, Kolkata, India, (2)Auckland University of Technology, Auckland, New Zealand, (3)Mental Health Foundation, Kolkata, India, (4)Centre for Autism, School of Psychology & Clinical Language Sciences, University of Reading, Reading, United Kingdom, (5)Psychology, Ashoka University, Sonapat, India**

---

**Background:** While most research on autism and other neurodevelopmental conditions takes place in high-income countries, the majority of autistic individuals and their families live in low and middle-income countries. The priorities of and challenges faced by the autism community in these countries need to be systematically investigated in order to chart an informed course of action for research, services, and policy. While over 20 studies have been conducted in other countries to map the priorities of the autism community, there has been no such systematic assessment in the South Asian region.

**Objectives:** To map the landscape of priorities of the Indian autism community on skills, intervention, and research in a nationwide sample.

**Methods:** A mixed-methods approach was used for this study. The first phase used an online survey to rank individual priorities in each of three sections: skills, interventions, and research. In the second phase, follow-up interviews were conducted with a subset of the respondents, who were chosen through stratified random selection based on demographic variables and support needs. Both the questionnaire and the interview schedule were prepared in English, Hindi, and Bengali to allow for wider participation.

**Results:** In all, 280 participants (comprising autistic adults and parents of autistic children) completed the study. Within the list of skills, self-help skills were given the highest priority and believed to be crucial for the development of independence. Skills required to support the family and participate in family activities constituted the second-highest priority. Within interventions, Speech and Language Therapy was identified as the top priority. This result echoes similar findings reported by a nationwide survey of parents of autistic children in North America. The second priority was identified to be mental health counselling. Interestingly, follow-up interviews revealed that most parents cited mental health counselling as one of the top priorities for themselves, rather than for their autistic children. They reported that it can help them better understand and respond to their children's needs. Within research, there was consensus that the primary priority was to recognise the most effective ways to support people with autism, reflecting similar findings reported in a recent study on research priorities in Australian parents. Surprisingly, research on gender and ASD was accorded the lowest priority by the current sample. Overall, all respondents demonstrated a positive attitude towards research and considered it to be a vehicle for bettering the lives of autistic individuals.

**Conclusions:** The study highlights the key priority of the community in making autistic individuals independent. Consequently, interventions and skills linked to this priority were identified to be more important. The study also points to a need to equip caregivers through training and support. Service providers must keep these priorities in mind while designing learning and living programmes for autistic individuals. Furthermore, this study corroborates findings from similar exercises in other countries, which suggest that the goal of autism research should be to guide and lead the development of various services necessary for the well-being of autistic individuals.

**411.089 (Poster)** Autistic People Don't like Music – an International Survey on Community Opinions of Autistic Portrayals on Film and TV  
**A. Nordahl-Hansen<sup>1</sup>, M. Dean<sup>2</sup>, S. Fletcher-Watson<sup>3</sup> and S. Orm<sup>4</sup>,** (1)Faculty of Education, Østfold University College, Halden, Norway, (2)Education, 2013, Camarillo, CA, (3)Salvesen Mindroom Research Centre, University of Edinburgh, Edinburgh, United Kingdom, (4)Innlandet hospital, Lillehammer, Norway

---

**Background:** Autistic portrayals in TV-series and movies are important sources shaping the public perception of autism. Concerns have been raised that, although these portrayals contribute to increased awareness about autism, they may also be stereotypical and homogeneous in nature (Dean & Nordahl-Hansen, 2021).

**Objectives:** To investigate attitudes towards portrayals of autistic people in TV-series and movies in the autistic community compared with other groups.

**Methods:** This is, to our knowledge, the largest survey ever on this topic consisting of  $n=2119$  participants from 90 countries. Autistic adults ( $n=798$ ,  $M_{age}=30.3$ ,  $SD=10.2$ , 48% female), family and friends of autistic people ( $n=652$ ,  $M_{age}=35.5$ ,  $SD=11.0$ , 58% female), professionals and students within an autism-relevant field ( $n=486$ ,  $M_{age}=36.0$ ,  $SD=10.1$ , 79% female) and individuals who had not met any autistic people in person ( $n=183$ ,  $M_{age}=30.1$ ,  $SD=10.2$ , 42% female) responded to a survey about their opinions of seven portrayals (*Atypical*, *The Bridge*, *The Good Doctor*, *The Big Bang Theory*, *Community*, *Rain Man*, and *Music*) of autistic people in films and TV-series, and how to improve them. The questionnaire contained a 7-item scale ( $\alpha=.83$ ) capturing attitudes towards autistic portrayals in general and a 5-item scale ( $\alpha=.76$  to  $.86$ ) capturing attitudes towards specific TV and film characters. Data were analyzed using descriptives and analysis of variance (ANOVA) with Bonferroni post-hoc tests.

**Results:** The autistic portrayal in the movie *Music* was disliked by autistic people, whereas the autistic portrayal in the TV-series *Community* was the most favored and were viewed as positive. A significant difference was found between participant groups' attitude towards autistic portrayals in general ( $F(3, 2115) = 68.326$ ,  $p<.001$ ). Autistic people held more negative opinions of autistic portrayals than the other groups (all  $p$ -values  $<.001$ , Hedges  $g = -.56$  to  $-.72$ ). For the TV-series *Community*, there was also a significant difference between groups ( $F(3, 780) = 7.709$ ,  $p<.001$ ). Autistic people were more positive about the autistic portrayal in *Community* compared with family and friends ( $p=.016$ , Hedges  $g = .25$ ) and professionals and students ( $p<.001$ , Hedges  $g = .48$ ). There was also a significant difference for the film *Music* ( $F(3, 269) = 16.829$ ,  $p<.001$ ). Autistic people were more negative about *Music* compared to family and friends ( $p<.001$ , Hedges  $g = -.84$ ) and professionals and students ( $p<.001$ , Hedges  $g = -1.30$ ). Of the total sample, over 91% of the total sample recommended *Community*, compared to 91% not recommending *Music*. Participants strongly disagreed to statements about *Music* promoting positive awareness of autism (74.1%), promoting understanding of autism (74.1%). Over 65% strongly agreed *Music* was a stereotypical portrayal of autism.

**Conclusions:** The results show the autistic community has a clear negative stance on attitudes toward movies like *Music* that tend to portray autism in a stereotypical manner. Conversely, autistic persons rate *Community* as more favorable than other groups, possibly due to a more multifaceted, and less prototypical alignment to diagnostic symptom criteria (Nordahl-Hansen et al., 2017).

**411.090 (Poster)** Autistic Women Portrayed on Instagram #Fann #Actuallyautistic #Letsputafaceonthatasd  
**M. Stevens<sup>1</sup> and E. M. Blijd-Hoogewys<sup>2</sup>,** (1)Miranda Stevens Photography, Breda, Netherlands, (2)INTER-PSY, Groningen, Netherlands

---

## **Background:**

There is still a lot unknown about female autism. There are still many misunderstandings, among practitioners as well as among autistic women themselves and their network. The Female Autism Network of the Netherlands (FANN) tries to change times by sharing honest and open stories of

autistic girls and women in an easy-accessible way, via Instagram. This is done, among other things, with photos accompanied by interviews, often portraying a perspective of personal recovery.

Personal recovery has been defined as ‘a deeply personal, unique process of changing one’s attitudes, values, feelings, goals, skills and/or roles . . . a way of living a satisfying, hopeful and contributing life even with the limitations caused by illness’ (Anthony, 1993). A systematic review showed that there are five major recovery processes involved in personal recovery from mental health: connectedness, hope and optimism about the future, identity, meaning in life, and empowerment (known as CHIME; Leamy et al., 2011).

### Objectives:

To get an understanding of how autistic girls and women cope with their autism.

### Methods:

In a period of 8 months, 43 autistic females ( $n = 12$  girls;  $M_{\text{age}} = 12.24$ ,  $SD = 4.20$  years) ( $n = 31$  women;  $M_{\text{age}} = 36$ ,  $SD = 9.28$  years;  $M_{\text{age of ASD diagnosis}} = 30.95$ ,  $SD = 10.45$ ; 33% with a romantic relation; 21% with children) were portrayed on FANN Instagram, by a photograph and an interview (see Figure 1). The pictures were taken by a female autistic photographer. The interviews were based on four questions answered in writing by the autistic female at stake: (1) describe yourself briefly, (2) describe the impact of autism on your life, (3) what are you proud of in your life? and (4) what kind of tips do you have for autistic peers? We analyzed the interviews using Qualitative content analysis.

### Results:

Based on what autistic females portrayed spontaneously in their stories (no hearing back protocol was applied), their love for animals was mentioned often, most pronounced in children (42% in women, 83% in girls). Most common hobbies were being creative (37%), music (23%), writing (19%), nature (14%), and sports (14%). Most common negative impact of autism was the experienced sensory overload (58%) and being overtired (49%). For women with a later autism diagnosis, not knowing this diagnosis before has led to both physical and mental problems, and lost identity. However, having autism also led to more perseverance (35%). Most common mentioned tips for autistic peers were (1) stay true to yourself (65%), and (2) dare to ask for help (16%). Reactions of Instagram followers are overwhelmingly supportive.

### Conclusions:

The results paint a picture of female autism, where sensory problems and being overtired is mentioned regularly by autistic females. The posts give other autistic females a way to experience connectedness, hope and optimism about the future, and gives them examples of an autistic identity, different meanings in life, and empowerment (CHIME). They show a way to personal recovery, showcasing their troubles but also their perseverance and staying true to themselves.

### 411.091 (Poster) Social Inclusion and Autism in Mainstream Secondary Education. What Is Needed?

S. Kamp<sup>1</sup>, E. M. Blijd-Hoogewys<sup>1</sup>, B. LP, Y. T. Tsou<sup>2</sup>, K. Liu<sup>3</sup>, A. Koutamanis<sup>3</sup> and C. Rieffe<sup>2,4,5</sup>, (1)INTER-PSY, Groningen, Netherlands, (2)Institute of Psychology, Leiden University, Leiden, Netherlands, (3)Faculty of Architecture & the Built Environment, Delft University of Technology, Delft, Netherlands, (4)Faculty of Electrical Engineering, Mathematics and Computer Science, University of Twente, Enschede, Netherlands, (5)Institute of Education, University College London, London, United Kingdom

---

### Background:

Children do not solely attend school to learn math and grammar, but also to meet friends, play, and socialize, which are important interactions to reach optimal social development by adulthood. A so-called ‘sense of belonging’ is key for social wellbeing, but also crucial for children to stay motivated for school (Korpershoek et al., 2020). Conversely, thwarted social interactions often lead to school absenteeism (Gubbels et al., 2018).

Since the introduction of the Dutch Appropriate Education Act in 2014, attempts have been made to include pupils with special needs in mainstream secondary education, including autistic pupils. However, this has been only partially successful. Schools seem to have focused mainly on the educational needs of these pupils and less on their sense of belonging. To make meaningful changes, the perspective of autistic pupils is key.

### Objectives:

The aim was to get a deeper understanding to what extent young autistic people, within mainstream secondary schools, experience a sense of belonging and what, according to them, is needed for amelioration.

### Methods:

We conducted three focus groups ( $N = 12$ ) with autistic (former) mainstream education pupils (age = 13-19 years). All levels of education were represented. Two focus groups were online; the third was at a mental health care facility. Each lasted 50 to 60 minutes and was audiotaped. Verbatim transcripts were analyzed using Thematic analysis (Braun & Clarke, 2006).

## Results:

Autistic pupils reported to have little contact with their fellow students, to not belong, and to experience uncomfortable loneliness. Being alone made them stand out in a negative way. Most pupils had accepted to be without a friend at school and made no more effort. They retained from small talk. Breaks were considered extra difficult due to busy environments - with too many students in crowded hallways (bumping into each other, loudly chatting away), poor access to their school locker, too few seats in the canteen, too few quiet zones, and bad acoustics - all leading to sensory overload, fatigue, and stress. Many avoided breaks by retreating in classrooms or by skipping school all together.

## Conclusions:

Sense of belonging and social inclusion is a basic human right, also for autistic pupils in mainstream education, but this requires active policies from schools. Both schools and designers need to be educated as to the particular requirements and capacities of all users in order to be able to produce inclusive environments. Our study shows that the actual physical (built) school environment should indeed be examined and adapted. Creating more calm and less crowded spaces in schools are a precondition for autistic teens to enter, let alone participate. Only without chronic fatigue or stress at school, other interventions to improve their social inclusion can be successful. Further research within our project is aimed at obtaining deeper understanding of what a sense of belonging means for autistic pupils and those around them, and how to achieve this while addressing different aspects in the physical (built), social, and cultural environment.

**411.092 (Poster)** Black Families' Experiences of Autism Diagnosis: Preliminary Parent Feedback to Inform Culturally Competent Care  
A. Miceli<sup>1</sup>, A. Vehorn<sup>1</sup>, T. Pinnock<sup>2</sup>, Y. Dada<sup>3</sup>, J. Hine<sup>1</sup>, Z. Warren<sup>3</sup> and A. S. Weitlauf<sup>4</sup>, (1)Vanderbilt University Medical Center, Nashville, TN, (2)Meaharry Medical College, Nashville, TN, (3)Vanderbilt University Medical Center - Treatment and Research Institute for Autism Spectrum Disorder, Nashville, TN, (4)Vanderbilt Kennedy Center, Vanderbilt University Medical Center, Nashville, TN

---

**Background:** Black families face significant barriers in receiving a timely diagnosis of autism spectrum disorder (ASD). Lack of knowledge of ASD, distrust of health systems, and racial bias on the part of healthcare professionals all contribute to diagnostic delays (Constantino et al. 2020). Deliberate evaluation of structural racism within current ASD screening models must occur in order to address race-based diagnostic care disparities for Black families. To better understand Black families' ASD diagnostic journeys, we surveyed diagnostic experiences and the potential impact of race/ethnicity on the diagnostic process for 400 Black caregivers of children with ASD.

**Objectives:** We surveyed 400 caregivers of Black children with ASD about their experiences with the ASD diagnostic process and the potential impact of racial and ethnic identity on this process.

**Methods:** 400 families of children with ASD (mean age: 71 months, 323 male) were recruited from the Simons Foundation SPARK cohort Research Match program. Individuals were eligible if they were data consented for SPARK, were the parent or guardian of a child with ASD aged 8 years and under, and the parent and child self-identified as Black or African American (including multiracial families). The SPARK research team sent invitation emails in batches until our recruitment goal of 400 was reached. Respondents completed the survey with their eldest child with ASD in mind.

**Results:** Primary areas of interest were first concerns and perceptions of race/ethnicity on the diagnostic process. Caregivers' first concerns (Table 1) included speech (87.5%), social skills (61.3%), behavior (57.8%), and motor skills (34.8%). Most children were diagnosed after age 2 years, with 34.4% of children not diagnosed until age 3-5 years. Almost a third of families (28%) reported that race/ethnicity had an impact on their care. Although most caregivers (82.3%) did not feel that cultural differences between them and their providers impacted the diagnostic process, some (16.3%) indicated that cultural differences did play a role. (Table 2). When asked what would have made the diagnostic process easier, 51% of caregivers said receiving an evaluation sooner; 42% said professionals listening to their concerns sooner; and 36.8% said receiving more support from family (Table 2).

**Conclusions:** Survey responses provide insight into caregivers' primary pre-diagnosis concerns and ideas for improved care. Given that a substantial minority of respondents reported that race/ethnicity impacted the diagnostic experience, it remains critically important to consider diverse viewpoints and parenting experiences when developing new models of developmental screening. Caregivers provided detailed qualitative feedback that future research will examine to support creation of culturally competent screening tools.

**411.093 (Poster)** Building Capacity for Inclusive Informal STEM Learning Opportunities for People with ASD  
A. Johns<sup>1</sup>, J. Anbar<sup>1</sup>, S. Kiefer<sup>1</sup> and C. J. Smith<sup>1</sup>, (1)Southwest Autism Research & Resource Center, Phoenix, AZ, (2)Mel and Enid Zuckerman College of Public Health, University of Arizona, Tucson, AZ

---

## Background:

Individuals with Autism Spectrum Disorder (ASD) are more likely to be unemployed compared to their neurotypical peers. Of adults with ASD who participated in the National Longitudinal Transition Study-2, 42% reported they had never been employed (Roux et al., 2015). Those who had been employed primarily worked part-time/low-income jobs.

While approximately 60% of individuals with ASD do not have an intellectual disability (Baio et al., 2018), only 44% of autistic adults pursue post-secondary education (Newman et al., 2011). When pursuing higher education, individuals with ASD enroll in Science, Technology, Engineering,

Math (STEM) majors more commonly than their peers, regardless of disability status (Wei et al., 2013). There is an increasing demand for STEM professionals in the workforce (Olson & Riordan, 2012) and individuals with ASD are an untapped resource.

### **Objectives:**

We conducted a survey to learn about families' experiences visiting museums and informal STEM education environments (ISE) to determine how ISEs can better promote inclusive learning opportunities for individuals with ASD.

### **Methods:**

Survey data was collected from parents of children (ages 11-18) with ASD that visited an ISE between 2016-2019 (n=69). The survey focused on ISE inclusivity, the level of engagement at ISEs, the effect ISE experiences had on their child, and whether these experiences strengthened their child's interest in STEM. These questions used a 1 (strongly disagree) to 5 (strongly agree) Likert scale. Parents also reflected on memorable experiences while visiting ISEs and provided suggestions for improving visits for autistic individuals.

### **Results:**

When reflecting upon interactions with staff/patrons at ISEs, 33% of families said that their child had a negative experience. Further, only 16% of parents strongly agreed that an ISE staff member engaged with their child in a manner that encouraged discovery and learning. After visiting a museum, only 7% of parents strongly agreed that their child had developed a new interest in a STEM topic. 25% of respondents expressed that hands-on activities helped provide opportunities for inclusion and learning.

Helpful accommodations (e.g. sensory packs, noise-canceling headphones, re-entry into the museums) were reported by 9% of respondents. Some parents suggested additional accommodations; 25% of families requested quiet areas/calm-down rooms for children to decompress and 12% requested alternative entry options (such as purchasing tickets online to avoid their child having a meltdown while waiting to gain entry).

### **Conclusions:**

This research shows how ISEs can improve visits for individuals with ASD. Adding accommodations might increase the number of autistic patrons, but accommodations will not ensure that the individual feels included and engaged. Our goal is for neurodiverse individuals to feel valued, accepted, and included when visiting ISEs to strengthen their interest in STEM and, ultimately, gain employment within the field.

This research helped develop ASD-informed training that fosters inclusive STEM learning environments for neurodiverse individuals. Currently, four museums are receiving this training, and it has been developed in a way that can be replicated across the country.

### **411.094 (Poster) COVID-19 Vaccine Hesitancy in the Autism Community**

**S. D. Barns<sup>1</sup>, J. R. Wright<sup>1</sup>, A. Goler<sup>1</sup>, C. W. Lehman<sup>1</sup>, J. K. Law<sup>1,2</sup>, A. Daniels<sup>1</sup>, L. Green Snyder<sup>1</sup>, S. Consortium<sup>1</sup>, P. Feliciano<sup>1</sup> and W. K. Chung<sup>1,3</sup>,**  
(1)Simons Foundation, New York, NY, (2)Maryland Center for Developmental Disabilities, Maryland Center for Development Disabilities, Kennedy Krieger Institute, Baltimore, MD, (3)Department of Pediatrics, Columbia University, New York, NY

Background: SPARK (Simons Foundation Powering Autism Research for Knowledge) is the largest research cohort of individuals with autism and their family members, with more than 100,000 individuals with autism enrolled. SPARK surveyed participants at six time-points over the course of the COVID-19 pandemic to investigate the impact of the pandemic and to better understand COVID-19 vaccine acceptance and hesitancy in the autism community.

Objectives: To describe the attitudes toward COVID-19 vaccines, and to report the factors that correlate with COVID-19 vaccine hesitancy.

Methods: 9,249 caregivers and guardians of individuals with autism responded to an initial survey sent by email in March, 2020. Subsequently, all individuals who initially responded were sent follow-up surveys at 5 different time-points from April, 2020 to July, 2021. In November, 2020 and March, 2021, participants were asked whether or not they intended to receive the COVID-19 vaccine when it became available, and if they intended for others in their household to receive it. They were also asked whether or not anyone in their household had received the vaccine in March, 2021 and July, 2021. Analyses were conducted to determine variables associated with vaccine hesitancy and refusal. Variables included sex, autism diagnosis, geography, income, previous beliefs towards vaccines, COVID-19 positivity, practicing COVID-19 safety measures, and genetic diagnoses related to autism. All analyses were performed using R Statistical Software.

Results: We found the highest levels of vaccine hesitancy in November, 2020 prior to the COVID-19 vaccine being approved by the FDA, with 60% of participants indicating that they were unsure or would not receive the vaccine. Over time, hesitancy dropped to 26% by March, 2021. In the most recent survey performed in July, 2021, only 15% of respondents reported that no members of their household had received the COVID-19 vaccine, compared to the national average of 25% of adults living in fully unvaccinated households (Hamel et al 2021). We found that having a lower income, living in more rural settings, and having a previous COVID-positive case within a household were significantly associated with vaccine hesitancy. The factors that correlated most strongly with vaccine refusal were not practicing COVID-19 safety measures (p<.001) and previous endorsement (asked at registration in SPARK) of the belief that vaccines caused their child's autism (p<.001). Variables that did not show a significant association with vaccine hesitancy included: sex, autism diagnosis, and having a genetic diagnosis related to autism.

Conclusions: We found that vaccine hesitancy was highest prior to COVID-19 vaccines being approved by the FDA and before they were widely available in the United States. Over the spring of 2021, vaccine hesitancy dropped to 15% among our survey respondents. We found that previous beliefs on the role of vaccines in a family member's autism were strongly correlated with current COVID vaccine refusal. Data collected from the national SPARK cohort can help inform strategies to address vaccine hesitancy.

**411.095 (Poster)** Caregiver Depression during the COVID-19 Pandemic: A Study on Latino Families of Children with Autism and Developmental Disabilities

*W. Zeng and S. Magana, Steve Hicks School of Social Work, University of Texas at Austin, Austin, TX*

---

Background: The COVID-19 pandemic has dramatically changed the world and everybody's life. Minoritized families of children with autism and developmental disabilities (DD) were impacted to a greater extent because of multiple disadvantages pre-pandemic and additional caregiving responsibilities. As part of a larger research that investigates health and health behaviors among Latino families, we examined how the COVID-19 pandemic affected maternal caregivers' mental health. The results will inform policy and practices to better support families of children with autism and DD amid these times with heightened uncertainties.

Objectives: We aimed to learn 1) the prevalence of depression among Latina caregivers of children with autism and DD, 2) what were the individual, family, and socioeconomic factors associated with maternal depression, and 3) practical strategies to support these families.

Methods: Data collection was performed across two study sites in two urban cities in Texas and Illinois, respectively. Participants were 68 maternal caregivers of 75 children (some families have more than one child with autism and DD). From July 2020 to September 2021, trained research assistants interviewed families via three separate phone or video calls over a period of 4–6 weeks, with each interview lasting 60–75 mins. Demographic, quantitative, and qualitative data were collected via a set of standardized measures and open-ended questions that assessed caregiver-child dyads' health and health behaviors. The main outcome examined in this abstract was maternal depression, as assessed by the Center for Epidemiological Studies Depression Scale (CES-D). Bivariate regressions were run to determine what factors were associated with maternal depression (CES-D) scores.

Results: On average, maternal caregivers were 43.9 years old. They were mostly married/living with partner (82%), foreign-born (82%), and had an annual household income of <\$35,000 (59%). The children were on average 11.3 years old, mostly boys (72%), born in the US (92%), and had a primary diagnosis of autism/Asperger syndrome (75%). Sixty percent of the families experienced at least one negative economic change during the pandemic, while only 40% received any kinds of COVID-19 financial assistance from the government. Bivariate analyses indicated that, 1) Thirty-seven percent of the maternal caregivers were at risk of having depression (CES-D scores  $\geq 16$ ); 2) Annual household income ( $F=3.71, p<.001$ ), whether the family received any COVID-19 financial assistance ( $F=3.28, P=.001$ ), food security ( $F=2.56, p=.01$ ), and perceived support from a significant other ( $F=2.18, P=.04$ ) were associated with maternal depression (CES-D) scores.

Conclusions: The findings of this study indicated that, 1) low-resourced Latino families of children with autism and DD were hit hard especially economically during the pandemic, and 2) financial difficulties were a major contributor to elevated depression among maternal caregivers. Policy and practices should provide tangible measures of support for these families which may include access to food bank/pantry, direct financial assistance, assistance with finding employment, and so on.

**411.096 (Poster)** Caregiver Perspectives on Barriers and Facilitators to Primary Healthcare Encounters for Autistic Adults

*L. I. Duker (Stein)<sup>1</sup> and E. R. Goodman<sup>2</sup>, (1)Chan Division of Occupational Science and Occupational Therapy, University of Southern California, Los Angeles, CA, (2)Chan Division of Occupational Science and Occupational Therapy, USC Chan Division of Occupational Science and Occupational Therapy, Los Angeles, CA*

---

Background: Primary care is associated with greater access to healthcare services, improved health outcomes, cost savings, and mitigation of the negative impact of socioeconomic factors on health. Autistic adults experience barriers to utilization and high-quality primary care, reporting heightened stress, decreased satisfaction, and increased unmet physical and mental healthcare needs. The need to minimize existing barriers and identify strategies to facilitate successful healthcare encounters for consumers and primary care providers (PCPs) is increasingly important as autistic adults represent a growing segment of society. Currently, little research exists examining primary healthcare interventions for this population.

Objectives: The purpose of this study was to elucidate the barriers and facilitators to primary care health encounters for autistic adults, in order to inform the development of new or improve existing interventions.

Methods: We conducted interviews with caregivers of autistic adults living in Los Angeles (n=21) and Philadelphia (n=11). This data represents a subset of a larger study which conducted interviews/focus groups with autistic adults (n=34), caregivers of autistic adults (n=32), and PCPs treating autistic adults (n=14) in Los Angeles and Philadelphia. Caregiver interviews lasted an average of 34 minutes and were transcribed verbatim. Thematic analysis using a grounded theory approach was employed to describe barriers and facilitators to primary care health encounters. This project included a meaningful percentage of underserved and diverse populations, specifically Latino and African American participants.

Results: Sixteen themes or subthemes emerged from the interviews and clustered broadly into two categories — barriers and facilitators to care. Reported **barriers to primary care encounters** for autistic adults included: (1) *communication difficulties* that resulted in misunderstandings between patients and PCPs; (2) *PCP's lack of autism-specific knowledge* which impeded the receipt of patient-centered care; (3) *sensory overstimulation* from the physical environment that led to anxiety and emotional dysregulation; and (4) the *caregiver burden* which described the amplified stress and anxiety due to experiences with navigating the medical system, care coordination, and managing challenging behaviors exhibited by their adult child with autism. **Facilitators to improve care** included tailored accommodations for autistic adults; these differing strategies were

implemented by: (1) *PCPs* who aimed to improve experience by employing time modifications (e.g., reduction of time in waiting room, increase in one-on-one time with the patient), using alternative equipment, and affording greater autonomy to the autistic adult during medical encounters; (2) *caregivers* who utilized pre-visit discussions to describe the impending healthcare encounter to the adult with autism, and strategically scheduled appointments to minimize discomfort and anxiety while waiting; and (3) *autistic adults* who used distraction techniques such as technology (e.g., iPad, phone, television) and targeted strategies to remove noxious sensory stimuli during healthcare encounters (e.g., removal of examination table paper, dimming lights, use of headphones).

**Conclusions:** This study describes perceived barriers to successful care as well as strategies to facilitate positive primary care health encounters for autistic adults, as reported by their caregivers. Findings have the potential to provide a blueprint for the development of client-centered interventions to improve the quality of primary healthcare services for this population.

**411.097 (Poster) Caregiver Perspectives on Reading Instruction for Elementary School-Aged Children with Autism Due to the COVID-19 Educational Disruption**

*N. S. McIntyre<sup>1</sup> and M. C. Zajic<sup>2</sup>, (1)School of Communication Sciences and Disorders, University of Central Florida, Orlando, FL, (2)Health & Behavior Studies, Teachers College, Columbia University, New York, NY*

---

**Background:**

Children with autism commonly demonstrate atypical reading development (McIntyre et al., 2017) and receive services in general and special education settings. The COVID-19 pandemic caused massive disruption to the US education system, and emerging data highlights the stress placed on families when schools shut down that may be linked to the increased time spent providing services that an educator typically would provide (Manning et al., 2020). Learning from the primary caregivers who have been closely involved in their elementary-aged student's education during COVID-19 will help researchers and educators understand more about literacy learning at 3 timepoints (TPs): before, during, and after the COVID-19 educational disruption.

**Objectives:**

To examine whether the following changed over 3 TPs: 1) quantity, frequency, effectiveness of caregiver home reading instruction; 2) caregiver satisfaction with access to special education (SPED) resources; 3) caregiver belief that their child made progress in reading achievement; 4) caregiver belief that their child's reading instruction needs were being met.

**Methods:**

Primary caregivers in the US of an elementary-aged autistic child were eligible to participate in this online survey study. Participants completed questions on demographics, Individualized Educational Plan (IEP) reading goals, and caregiver reading support and perceptions. There are three reporting time periods: TP1, 5/2019-3/2020; TP2, 3/2020-8/2020, TP3, 8/2020-5/2021.

**Results:**

Current analyses discuss 40 initial participants (with 400 participants expected by late 2021). Initial participants reflect a diverse sample of mostly male children (77%) in grades K-5<sup>th</sup>. 60% of households are non-White or mixed-race; 48% qualify for free or reduced-price lunch; a language other than English is spoken in 30% of the homes. Approximately 70% of the sample had IEP goals for reading at all 3 TPs.

Wilcoxon signed-rank tests were used for all analyses:

OBJ1: The number of caregivers providing reading instruction at home did not change significantly from TP1 to TP2 ( $Z=-1.89, p=.06$ ) or TP2 to TP3 ( $Z=-.38, p=.70$ ). Also, the frequency of the reading instruction did not change significantly from TP1 to TP2 ( $Z=-1.22, p=.22$ ) or TP2 to TP3 ( $Z=-.30, p=.76$ ). However, while caregiver perception of their effectiveness did not change significantly from TP1 to TP2 ( $Z=-1.63, p=.10$ ), it did increase significantly from TP2 to TP3 ( $Z=-1.93, p=.05$ ).

OBJ2: Caregiver satisfaction with access to SPED services decreased significantly from TP1 to TP2 ( $Z=-2.85, p=.004$ ), then increased significantly from TP2 to TP3 ( $Z=-2.85, p=.004$ ).

OBJ3: Caregiver belief that their child was making general progress in their reading achievement decreased significantly from TP1 to TP2 ( $Z=-3.07, p=.002$ ), then increased significantly from TP2 to TP3 ( $Z=-3.51, p<.001$ ).

OBJ4: Caregiver belief that their child's reading instruction needs were being met decreased significantly from TP1 to TP2 ( $Z=-3.11, p=.002$ ), then increased significantly from TP2 to TP3 ( $Z=-3.71, p<.001$ ).

**Conclusions:**

About half of the caregivers provided frequent reading instruction at home, which did not change significantly across time, but their sense of effectiveness grew significantly by TP3. The COVID-19 educational disruption significantly negatively impacted perceptions of access to SPED

services, meeting student reading instructional needs, and student progress in reading achievement. Analyses of the complete dataset will reveal more lessons learned about caregivers' role in supporting reading.

**411.098 (Poster)** Characterizing Family Social Support from Adolescence through Young Adulthood in Autism

**H. K. Schiltz**, and **C. Lord**, (1)*Psychology, Marquette University, Milwaukee, WI*, (2)*UCLA Semel Institute for Neuroscience and Human Behavior, Los Angeles, CA*

---

**Background:** A strong social support system can bolster family functioning and promote a host of positive parent and child outcomes. For families of autistic youth, social support is a particularly important resource, as it can ameliorate the high level of stress placed on these families and support parent well-being (Boyd, 2002; Marsack & Samuel, 2017; Smith et al., 2011). A dearth of studies, however, have considered the multidimensional nature of social support (e.g., Bromley et al., 2004) to understand which sources of social support are most helpful and frequently utilized. Additionally, there are few longitudinal studies of family functioning in autism; no study to date has explored changes in family support from adolescence into young adulthood.

**Objectives:** In families of autistic adolescents, this study aims to 1) characterize helpfulness and utilization of multiple sources of social support, 2) explore trajectories of social support from adolescence into young adulthood, and 3) examine autism severity and cognitive ability as predictors of social support trajectories.

**Methods:** A sample of 128 autistic adolescents (Age  $M=16.17$ ;  $SD=1.25$ ) were drawn from an ongoing longitudinal study. Social support was measured at six time points (TPs) from adolescence through young adulthood using a modified version of the Family Support Scale (FSS; Bromley et al., 2004; Dunst et al., 1988). FSS subscales include Family, Friends, Community, and Professional support; reporters rate the helpfulness and frequency of utilization. Development appropriate standardized IQ measures indexed cognitive ability and the ADOS Calibrated Severity Score captured autism severity.

**Results:** At TP1, Professional support was rated as the most helpful but second most utilized, Friends and Family were the second most helpful but the most utilized, and the least helpful and utilized was Community support. Level of helpfulness and utilization were positively correlated within each type of support (Table 1). Multilevel modeling in *Mplus* revealed that, controlling for parent education, helpfulness of Family ( $B=-0.02$ ,  $p=0.10$ ) and Friend ( $B=-0.02$ ,  $p=0.12$ ) support did not change across adolescence to young adulthood, while Community ( $B=-0.05$ ,  $p<0.01$ ), Professional ( $B=-0.07$ ,  $p<0.001$ ), and Overall ( $B=-0.04$ ,  $p<0.001$ ) support demonstrated significant declines. Utilization of all social support sources significantly declined across time. Cognitive ability and autism symptoms were not related to the level or trajectory of helpfulness of social support, and only cognitive ability was negatively related to the intercept of utilization of Professional support ( $B=-0.01$ ,  $p<0.01$ ).

**Conclusions:** These findings provide the first longitudinal characterization of family social support across adolescence to young adulthood among families of autistic youth. Declines were identified in the helpfulness of Professional and Community support, as well as the frequency of utilization of all types of social support during this time period, independent of adolescent cognitive ability and autism severity. Given the importance of social support for well-being, these declines highlight the need to bolster accessibility of social support during the transition from adolescence into young adulthood for families of autistic youth. Future research should explore how social support changes into later adulthood and the consequences of declining social support for aging autistic adults and their families.

**411.099 (Poster)** Comparison of Psychological Functioning and Parental Burnout in Heterosexual and Same-Sex Parents of Children with ASD

**R. L. Harmon**<sup>1</sup>, **C. A. Paisley**<sup>2</sup>, **A. B. McClain**<sup>1</sup>, **A. M. Birnschein**<sup>1</sup> and **T. S. Tomenyi**<sup>1</sup>, (1)*Psychology, The University of Alabama, Tuscaloosa, AL*, (2)*School of Medicine, University of Colorado, Aurora, CO*

---

**Background:** Previous research has shown that parents of children with autism spectrum disorder (ASD) often report high levels of psychological distress (Hastings et al., 2005; Hayes & Watson, 2012; Lai et al., 2015). Additionally, stress levels are known to be high among LGBTQ+ parents (Goldberg, 2010). Although one study found no differences in levels of stress between heterosexual and same-sex parents of typically developing (TD) children (Farr et al., 2010), no study to date has examined potential differences in psychological functioning in parents of children with ASD. The current study aims to expand on previous findings through examining psychological distress and parental burnout amongst heterosexual and same-sex parents of children diagnosed with ASD.

**Objectives:** The current study aimed to understand differences in parental stress, depression, anxiety, and burnout during the COVID-19 pandemic between parents of children with ASD in heterosexual relationships and parents of children with ASD in same-sex relationships.

**Methods:** A total of 81 parents of children diagnosed with ASD (ages 4 to 16) were included in analyses. Fifty-one parents were in heterosexual marriages/relationships (33 females and 18 males). Thirty parents were in same-sex marriages/relationships (19 male, 11 female). Parents provided sociodemographic information and completed the *Depression, Anxiety, and Stress Scale – 21* (Lovibond & Lovibond, 1995) and *Parental Burnout Assessment* (Roskam et al., 2018). These measures were collected in the context of a larger study exploring differences in psychological functioning between parents of TD children and parents of children with ASD.

**Results:** Independent-samples *t*-tests revealed significant differences in parental depression, parental anxiety, and parental burnout between parents in heterosexual relationships and parents in same-sex relationships,  $p$ 's  $< .05$ . Parents in same-sex relationships ( $M = 14.90$ ,  $SD = 1.88$ ) reported significantly more depression compared to parents in heterosexual relationships ( $M = 11.92$ ,  $SD = 5.59$ ),  $t(79) = -2.33$ ,  $p = .023$ ,  $d = -.535$ . Parents in same-sex relationships ( $M = 14.17$ ,  $SD = 5.35$ ) also reported significantly more anxiety compared to parents in heterosexual relationships ( $M = 11.47$ ,  $SD = 5.71$ ),  $t(79) = -2.10$ ,  $p = .039$ ,  $d = -.0483$ . Similarly, parents in same-sex relationships ( $M = 74.80$ ,  $SD = 37.96$ ) reported significantly more

burnout compared to parents in heterosexual relationships ( $M = 55.69$ ,  $SD = 38.58$ ),  $t(79) = -2.14$ ,  $p = .035$ ,  $d = -.491$ . Furthermore, parents in same-sex relationships reported significantly higher burnout on three of the four subscales: Contrast in Parental Self, Feelings of Being Fed Up, and Emotional Distancing,  $p$ 's  $< .05$ ; however, there were no significant differences in Exhaustion in Parenting Role  $p = .109$ . Additionally, no significant differences were found in parental stress,  $p = .109$ .

**Conclusions:** Our findings suggest a greater need for future investigation in the psychological functioning and burnout in LGBTQ+-identifying parents of children with ASD, and more generally, developmental disabilities, as this would allow clinicians to assess what interventions may be beneficial in treating mental health symptoms and increasing caregiver quality of life.

**411.100 (Poster)** Computer-Assisted Heart Rate Variability Biofeedback As a Method of Stress Reduction for Parents of Children with Autism: A Pilot Study

**D. Hoerberg**, *Gevirtz Graduate School of Education, University of California, Santa Barbara, santa barbara, CA*

---

**Background:** Despite their success, treatment adherence and satisfaction with currently existing methods of relaxation training or mindfulness-based stress management techniques for reducing stress and anxiety in parents and caregivers of children with autism (ASD) remain low. These methods are often time consuming to learn and practice, require a trained or licensed professional for instruction, and typically rely on less objective measurements. Recent technological advancements have led to the development and miniaturization of a user-friendly and inexpensive biofeedback training device that relies on a cardiovascular biomarker, heart rate variability (HRV-HRVBF), to quickly identify and control the physiological mechanisms commonly associated with feelings of stress and anxiety.

**Objectives:** To 1) assess the practicality and usefulness of HRVBF for a parent of a child with ASD 2) determine the effect of HRVBF on parental self-reported symptoms of state anxiety 3) to compare observed behaviors associated with maternal affect, interest, stress, and communication, and 4) child affect and compliance during a structured interaction before and after use of HRVBF.

**Methods:** A single parent-child with autism dyad was recruited and selected for this study. The dyad was observed during a "stressful or challenging" interaction chosen by the mother for approximately 17 sessions: alternating between baseline and intervention conditions every 3-5 sessions. The mother was instructed to use the HRVBF device immediately before interacting with her child for 5-minutes prior to each of the intervention sessions and to refrain from using it during baseline sessions. Self-reported and observational measures of stress and changes in maternal and child behavior with and without HRVBF, as well as the social validity and feasibility of using the device were collected and assessed using a variety of measures.

**Results:** Self-reported symptoms of anxiety and stress were lower when using the device ( $M=49.6$ ;  $M=53.5$ ) than without ( $M=35.6$ ;  $M=36$ ). Likewise, behaviors associated with maternal affect and maternal states of relaxation were observed more during sessions with the device than without. Changes in maternal communication style, child affect, and child compliance remained inconclusive or more indicative of change across time. Results from the social validity questionnaire strongly supported the use of- and experience with HRVBF by the participating mother.

**Conclusions:** The current study expands on our understanding of the use of HRVBF as a stress management tool, by incorporating a relatively new, underrepresented member from the population of parents of children with ASD who are more prone to experiencing relatively high feelings of parental stress and anxiety. This study is unique in that it demonstrates potential of a more practical and feasible proxy or supplement to- relaxation training and a more objective measurement of physiological symptoms associated with these outcomes. Although the sample size is limited, the methods and results of this study extensively demonstrate some of the positive behavior changes, as well as the self-reported feelings of decreased stress and anxiety, and overall satisfaction, in the selected mother when using HRVBF during an otherwise stressful and challenging interaction.

**411.101 (Poster)** Coping and Well-Being Associations Among Parents of Autistic Adolescents and Young Adults with and without Intellectual Disability

**H. Singer<sup>a</sup>**, **E. B. Clarke<sup>a</sup>**, **H. K. Schiltz<sup>a</sup>** and **C. Lord<sup>b</sup>**, (1)*University of California, Los Angeles, Los Angeles, CA*, (2)*Psychology, Marquette University, Milwaukee, WI*, (3)*UCLA Semel Institute for Neuroscience and Human Behavior, Los Angeles, CA*

---

## **Background:**

Parent well-being, despite its link to many family outcomes (such as child well-being), is an understudied component of the family system. Most existing literature examines the higher rates of negative outcomes (e.g., poor mental health and high stress) among parents of children with autism spectrum disorder (ASD), and reports on parenting during early childhood; few studies have explored broader positive aspects of parent well-being (e.g., purpose in life or self-acceptance), or outcomes of parents of autistic adolescents and adults. Furthermore, although approximately 40 percent of people with ASD have co-occurring intellectual disability (ID), few studies have examined whether ID plays a role in connections among parent well-being and factors that may foster well-being (i.e., coping strategies).

## **Objectives:**

To 1) examine links between parent well-being and parent coping style in parents of adolescents/young adults with ASD and 2) examine the effect of child intellectual disability status on parent well-being and coping.

## **Methods:**

101 parents were drawn from an ongoing longitudinal study of ASD. Parent measures were collected when their adolescent was roughly age 18 ( $M = 17.85$  years;  $SD = 1.31$  years). Parent well-being and coping were measured via self-report on the Scales of Psychological Well-being (SPWB) and the Brief Coping Orientation to Problems Experienced Inventory (Brief COPE), respectively. The SPWB yields scores for total well-being, purpose in life, self-acceptance, and personal growth. The current analyses include three Brief COPE subscales: active-, emotion-, and avoidance-focused coping. Adolescent nonverbal IQ, assessed at age 9 with standardized developmentally appropriate tests, was used to classify the samples as with ID (child IQ < 70) or without ID (child IQ  $\geq$  70). Pearson correlations were used to examine the association between parents' SPWB scores and COPE scores across all parents and within each ID group (i.e., with or without ID).

## Results:

Across all parents, higher levels of problem-focused coping were significantly associated with greater purpose in life, self-acceptance, personal growth, and total well-being scores (Table 1). For emotion-focused coping, significant positive associations emerged with purpose in life and personal growth, but not self-acceptance. Avoidant coping was not significantly related to well-being. Examining these associations within each ID group revealed similar links between well-being and problem-focused coping (Table 1). Emotion-focused coping, however, appeared to be more strongly linked with well-being for parents of autistic adolescents with ID than those without (Table 1).

## Conclusions:

These findings provide preliminary evidence that greater use of certain parent coping strategies (i.e., problem- and emotion-focused) have important implications for promoting positive well-being in parents of adolescents/young adults with ASD. Results also suggest that coping-well-being associations may vary based on child intellectual disability status, such that emotion-coping may be a more powerful strategy for supporting parent well-being among parents of children with ID.

Parent well-being is tightly intertwined with other family system subunits, including child well-being. These results highlight the critical need to bolster parents' capacity to use adaptive coping strategies to foster healthy and happy families of autistic adolescents/young adults. Follow-up analyses will include longitudinal exploration of parent coping-well-being relations.

### 411.102 (Poster) Differences in Parent Perceptions of and Family Experiences with Autism Among Vaccine Hesitant and Non-Hesitant Parents of Children with ASD in the SPARK Cohort

**M. L. Ayala-Brittain<sup>1</sup>, S. Gardner<sup>2</sup>, S. S. Mire<sup>3</sup>, E. Fombonne<sup>4</sup> and R. P. Goin-Kochel<sup>5</sup>,** (1)Psychological, Health and Learning Sciences, University of Houston, Houston, TX, (2)University of Houston, Houston, TX, (3)Psychological, Health, and Learning Sciences, University of Houston, Houston, TX, (4)Department of Psychiatry, Oregon Health & Science University, Portland, OR, (5)Baylor College of Medicine, Houston, TX

**Background:** Despite the public-health benefits of vaccines, a growing number of families are vaccine-hesitant (i.e., have concerns about vaccines that may lead to vaccination delay/refusal). Parents of children with autism spectrum disorder (ASD) are particularly at risk, as up to 40% of parents of children diagnosed with ASD believe that vaccines played a role in their child's condition (Sahni et al., 2020). Several factors have been associated with both vaccine hesitancy (e.g., beliefs about ASD etiology, demographics) and parents' beliefs in vaccines as a cause of ASD (e.g., child's history of skill loss, child's language level). However, less is known about how parents' attributions regarding their child's ASD and their personal or family adjustment to the ASD diagnosis may influence vaccine hesitancy.

**Objectives:** To examine associations between parents' attributions about ASD, parents' personal and family adjustment to the ASD diagnosis, and vaccine hesitancy within the SPARK (Simons Foundation Powering Autism Research for Knowledge) national cohort.

**Methods:** A total of 39,461 SPARK families were invited via email (4/10/19—6/8/19) to participate in a study about families' ASD-related attributions, personal or family support and stress, and perceptions about vaccination. 8,118 (20.6%) participants submitted complete data on the *Parent Attitudes about Childhood Vaccines* (PACV; measure of vaccine hesitancy), the *Revised Illness Perception Questionnaire-ASD* (IPQ-R-ASD; parental attributions about ASD), and the *Family Adjustment Measure* (FAM; personal and family adjustment for parents of children with ASD). The average age of participants (92% mothers) was 42.6 years ( $SD=8.6$ ) and that of their children was 11.9 years ( $SD=6.3$ ).

**Results:** 1,766/8,118 (21.8%) participants in this sample were vaccine hesitant (PACV score  $\geq 50$ ). Compared to non-hesitant parents, vaccine hesitant parents (VHPs) had significantly higher scores on the IPQ-R-ASD's Identity, Consequences, Timeline-Cyclical, and Emotional Representations subscales, and significantly lower scores on the Timeline Acute/Chronic, Treatment Control, and Illness Coherence subscales (all  $p < 0.001$ ; Cohen's  $d$  ranged from 0.10—0.45). Likewise, VHPs had significantly higher scores on the FAM's Parental Distress subscale and significantly lower scores on the Family Based Support, Social Support, and Positive Coping Skills subscales compared to non-hesitant parents (all  $p < 0.001$ ; Cohen's  $d$  ranged from 0.16—0.38). Data are being merged with the most recent SPARK-dataset release for subsequent analyses to identify parents' internal experiences and/or perceptions as potential predictors of vaccine hesitancy in parents of children with ASD.

**Conclusions:** Perceptions about ASD and experiences of personal and family support and stress differ significantly between VHPs and non-hesitant parents. Compared with non-hesitant parents, VHPs associate more behaviors with ASD, perceive more negative consequences of ASD, report less understanding of the diagnosis, and report higher stress and less support. Taken together, these findings suggest that vaccine hesitancy could indicate a subgroup of parents who may require more clinical attention and support (i.e., parent- or family-focused intervention) than parents who are not vaccine hesitant.

### 411.103 (Poster) Do Cultural Adaptations Matter? Comparison of Socially Valid Measurements during Caregiver Training of Children with Autism

**Background:** For families of children with autism spectrum disorder (ASD), caregiver training has the power to positively impact the child's development and the family's quality of life. With training, caregivers can learn how to implement strategies to successfully increase adaptive skills in their child with ASD. Nevertheless, culturally and linguistically diverse (CLD) families face unique challenges when attempting to access services that match their culture and language. Furthermore, the scarcity of appropriate practices when serving CLD families and the shortage of bilingual therapists in the United States add to the limitations of providing culturally adapted services. To reduce this disparity, it is essential to better understand the impact of current practices, when there is a mismatch between the family and training language, and when training has been linguistically adapted.

**Objectives:** The purpose of this pilot study was to evaluate the effects of implementing caregiver training with and without linguistic adaptations to Latino caregivers of children with ASD. Specifically, we wanted to capture the social validity measures of caregivers' behaviors (*personalismo*, involvement, indices of happiness, and acceptability) when Latino caregivers with limited English proficiency receive training in English versus Spanish.

**Methods:** Four low-income Latino mothers from the United States and Honduras participated in this pilot study. An alternating treatments design embedded with a concurrent delayed multiple probe design was conducted to investigate the relative effects of language on instruction, using English versus Spanish and teaching caregivers, via Telehealth, two different skills: (a) matching to sample and (b) motor imitation during play.

**Results:** Results indicated that CLD families can benefit from training regardless of the language mismatch and that, with training, caregivers can positively impact their child's skill acquisition. However, training that has been culturally adapted to match the family language was easier to learn and more comfortable for caregivers. Also, mothers were more involved during training sessions that were culturally adapted. For instance, caregivers shared more personal information — "*personalismo*"—asked more questions, and showed more indices of happiness (e.g., laughing). Treatment gains were maintained during two-week and one-month follow-ups.

**Conclusions:** Caregiver training for CLD families can increase the caregiver's ability to teach their child with ASD new skills. Nevertheless, culturally adapted training showed a higher level of caregiver involvement and happiness, demonstrating that caregiver training that adapts to the families' native language may increase the families' well-being in a timely, efficient manner.

#### **411.104 (Poster)** Elucidating the Perspectives of Autistic Youth about Their Healthcare Experiences

**B. O'Hagan<sup>1</sup>, E. Crable<sup>2</sup>, A. Ursitti<sup>3</sup>, S. Foster<sup>3</sup>, A. Friedman<sup>1</sup>, L. Bartolotti<sup>1</sup> and S. Krauss<sup>3</sup>,** (1)Developmental and Behavioral Pediatrics, Boston Medical Center, Boston, MA, (2)University of California San Diego, San Diego, CA, (3)Boston Medical Center, Boston, MA

---

**Background:** Co-occurring medical and psychiatric conditions are prevalent among autistic individuals, and promote increased service use within this population.<sup>1,2</sup> However, autistic individuals and their caregivers report lower satisfaction with healthcare service delivery, citing needs that are incompatible with the healthcare environment.<sup>3,4</sup> Additionally, health professionals report feeling unprepared to meet the unique needs of autistic individuals in healthcare settings.<sup>5</sup> Prior studies have described the general healthcare experiences of autistic adults<sup>6</sup>, but there is little known about health seeking and service use experiences of autistic youth.

**Objectives:** This study aimed to qualitatively describe and better understand the healthcare experiences of autistic youth receiving services at a large, urban, safety net hospital in New England.

**Methods:** We conducted four 90-minute, virtual focus groups with autistic youth between January-November 2021. Each focus group included seven participants, ages 11 to 25 years. Youth and young adult participants were not separated due to the cohesive group dynamic that has been established as most of them knew each other prior to the focus group through a teen mentoring program. Group discussions were led by the fifth author using a semi-structured group interview guide that inquired about participants' positive and negative healthcare experiences, desired accommodations during healthcare visits, and recommendations for what providers should know about autism. Audio recordings of focus groups were transcribed and verified by two research assistants. Data are being analyzed using inductive coding techniques. Three trained researchers developed qualitative memos from two transcripts to identify high-level topics that emerged from focus groups. Consensus discussions with the research team were used to generate initial codes for the codebook based on these memos and knowledge of the focus group content. Transcripts will be double-coded by two independent coders. Consensus discussion will be used to resolve any coding discrepancies, with a third coder serving as a tie breaker. Themes will be identified through a close reading of the coded data, using a thematic content approach. All analysis will be completed in Nvivo.

**Results:** At the time of submission, we have developed the consensus codebook and are in the process of coding transcripts in NVivo. Preliminary themes include: (1) Patient appreciation for providers willing to listen to their needs and frustrations with past healthcare experiences; (2) Variation in patient preferences regarding involvement in healthcare decision-making and service delivery format (e.g., telehealth vs. in-person); (3) Environmental stimuli particularly the waiting room (e.g., smells, crowds, loud sounds), are deterrents of health services use.

**Conclusions:** The type and level of specific support that autistic youth need vary across individuals. However, participants largely agreed on environmental barriers and factors that facilitate and hinder patient-provider relationships. Our findings to date support previous research that suggest the need to individualize care, disseminate individualized patient needs to all members of their care team, and increase provider knowledge about this unique patient population.

**411.105 (Poster)** Examining the Experiences of Autistic and Non-Autistic Adolescents in a Teen Mentoring Program during the COVID-19 Pandemic: A Qualitative Focus Group Study

**B. O'Hagan<sup>1</sup>, S. Foster<sup>2</sup>, A. Ursitti<sup>3</sup>, S. R. Dufresne<sup>3</sup>, L. Bartolotti<sup>1</sup> and S. Krauss<sup>2</sup>,** (1)Developmental and Behavioral Pediatrics, Boston Medical Center, Boston, MA, (2)Boston Medical Center, Boston, MA, (3)Eliot-Pearson Department of Child Study & Human Development, Tufts University, Medford, MA

---

**Background:** Social distancing policies are critical, but have also created disruptions to the lives of many children and families.<sup>1</sup> Disruptions in routine can be particularly difficult for autistic individuals, especially when compounded with the loss of access to much needed services and supports.<sup>2</sup> Our program has run a unique teen mentoring program since 2015, which involves monthly social events for autistic and non-autistic adolescents. Due to the COVID-19 pandemic, the teen mentoring program activities shifted to virtual formats to adhere with social distancing rules.

**Objectives:** This study aims to examine the perspectives of autistic and non-autistic adolescents, as well as caregivers, about their experiences participating in a teen mentoring program and maintaining social connections during the pandemic.

**Methods:** Three focus groups were conducted with seven autistic and three non-autistic adolescents ages 13-18 (7 males, 2 females, 1 non-binary). In addition, two focus groups with nine caregivers were conducted, seven of whom have an autistic child. Focus groups were audio recorded, transcribed, and verified by two research assistants. Guiding questions focused on eliciting responses about adolescents' experiences during COVID-19 in terms of adjusting to virtual formats for activities and staying connected with friends. Qualitative data are being analyzed using inductive coding as the study is exploratory in nature. We conducted qualitative memoing on two transcripts to identify high-level topics to serve as codes in the initial codebook, which was developed through consensus. Qualitative analysis is being conducted in NVivo, where each transcript is coded by two independent coders out of a team of three coders. All three coders meet to review and reach consensus in the coding, and the third coder serves as a tie breaker if the two coders disagreed. Thematic content analysis will be performed based on a close reading of the data.

**Results:** The teen mentoring program participants indicated mixed feelings about participating in virtual and in-person activities during a pandemic, which ranged from excitement to anxiety. Positive feelings about virtual settings included improved accessibility and skills (e.g., better time management, increased independence). Negative feelings about participating in virtual activities included limitations in opportunities for social interactions. Additionally, caregivers underscored routine disruption as a challenge when shifting to virtual format. Participants identified coping strategies to address challenges in virtual activities, including forming pods of individuals with similar interests and staying connected with others via social media.

**Conclusions:** The teen mentoring program participants indicated benefits and disadvantages associated with the shift to virtual activities. However, participants and caregivers agreed that the teen mentoring program monthly events, virtually or in-person, had positive effects to their social skills and relationships. Findings highlighted the importance of maintaining social connections and adapting services to ensure continuity of access, whenever possible.

**411.106 (Poster)** Evaluating Maternal Communicative Behaviors in Latina Mothers of Young Children with ASD in Low-Resource Households  
**S. Vanegas<sup>1</sup>, E. Miranda<sup>2</sup>, J. Valdes<sup>1</sup>, L. Hopp<sup>1</sup> and S. Magana<sup>3</sup>,** (1)Texas State University, San Marcos, TX, (2)University of Texas at Austin, Austin, TX, (3)Steve Hicks School of Social Work, University of Texas at Austin, Austin, TX

---

**Background:**

Research has consistently found that the quality and quantity of adult speech that children experience can positively impact their language, communication, and social development (Greenwood et al., 2018; Weisleder & Fernald, 2013). In low-resource households, the quality of early dyadic communication (mother-child), specifically fluency and connectedness, were strong predictors of expressive language in typically developing children one year later (Hirsh-Pasek et al., 2015). However, little research to date has focused on maternal communicative behaviors directed towards children with ASD from diverse racial/ethnic and socioeconomic backgrounds. Understanding maternal communication patterns in racial/ethnic minority families is important as it can impact interventions and supports. We set to explore how Latina mothers from low-resource households communicate with their children with ASD during a semi-naturalistic play interaction.

**Objectives:**

The goal of this exploratory study is to evaluate maternal communicative behaviors during a play interaction and to identify child and maternal factors that are associated with greater quality behaviors.

**Methods:**

Latina mothers and young children (18 months through 6 years) with ASD were recruited as part of a larger intervention study implemented in low-resource households in the United States. For low-resource status, families met one of the following criteria: Medicaid as insurance provider, caregiver has a high school or lower education, or household income of  $\leq 200\%$  of the federal poverty level. Child and caregiver data included the Mullen Scales of Early Learning (MSEL), Vineland Adaptive Behavior Scales-3 (VABS-3), child challenging behavior, family empowerment, and parenting stress. Mothers completed a 15-minute play interaction with their child at home using a curated toy box. The toy box included developmentally appropriate items (e.g., animal figures, blocks, bubbles, Little People ® figures, puzzles, vehicles). Coding of maternal communicative behaviors will follow established coding protocols (Conway et al., 2018; Hirsh-Pasek et al., 2015) for the following: directives,

praise, missed opportunities, expansions, imitations, responsive questions, supportive directives, labels, fluency, and connectedness. Coding will be completed by Latina, bilingual (English/Spanish) researchers.

#### Results:

We present results for 11 mother-child dyads who participated in the study prior to COVID-19. Children were about 4.00 years old ( $SD = 1.79$ ), mostly male (63.6%), and communicated in verbal language (63.6%). They had a mean MSEL Early Learning Composite score of 58.90 ( $SD = 15.53$ ), and mean VABS-3 Adaptive Behavior Composite score of 65.64 ( $SD = 10.52$ ). Mothers were on average 35.18 years old ( $SD = 5.67$ ), mostly foreign-born (81.8%), and mostly bilingual (English/Spanish, 63.6%). Preliminary analyses finds that caregiver age was positively associated with parenting stress,  $r(10) = 0.67, p = 0.024$ . We will examine if child (e.g., challenging behavior) and maternal (e.g., parenting stress) factors are associated with maternal communicative behaviors using Pearson correlation analyses.

#### Conclusions:

This exploratory study will evaluate how Latina caregivers communicate with their children with ASD during a play interaction. We will further identify how child and family factors are associated with these behaviors. These findings will inform parenting support programs to enhance the language and communication trajectories of young children with ASD from racially/ethnically and socioeconomically diverse backgrounds.

#### **411.107 (Poster)** En Español Se Siente Mas Bonito: Parent Perspective of Bilingual Language Development and Service Support for Autistic Children

**E. Zamora<sup>1</sup>, F. A. Castellon<sup>2</sup> and C. Kasari<sup>3</sup>**, (1)Psychology, University of California, Los Angeles, Los Angeles, CA, (2)University of California, Los Angeles, Los Angeles, CA

Background: Bilingualism is a growing phenomena among neurotypical and neurodiverse children alike. However, for children with disabilities, such as Autism Spectrum Disorder (ASD), both professionals and clinicians alike have perpetuated the belief that early bilingual instruction may cause further language delays in populations with already impaired communication. Recent studies are beginning to highlight a potential benefit in the preverbal communication, expressive vocabulary, and executive functions of bilingual children (Valicenti-McDermott et al. 2013; Iarocci et al. 2017; Lim et al. 2018). However, 90% of developmental psychology research is conducted on white, U.S., middle class families known as the W.E.I.R.D. population (Mistry, Contreras, & Dutta, 2013). Consequently, families from differing cultural and environmental contexts may be overlooked in these studies.

Objectives: The study aimed to explore and document the parenting practices in Spanish-speaking families that support their Autistic child's cognitive and bilingual development. The study also documented if bilingualism has been supported/promoted by service providers and parental perceptions towards the importance of bilingualism.

Methods: This study employed a two-phase, community-based participatory research (CBPR) qualitative design to accomplish the validation of research materials, recruitment, and analysis. As the research team made contact with community groups and stakeholders, they practiced *confianza*, *familismo*, and *personalismo*. Phase I consisted of a focus group (5 participants) where research materials were presented such as the research flyer, interview protocol, and feedback was received in order to ensure the questions were culturally sensitive, relevant, and appropriate within the community. Phase II consisted of two rounds of qualitative interviews with 5-6 participants who were Spanish-speaking parents of bilingual autistic youth between the ages of 5-12. The interview protocol was adapted from previous focus groups protocol to reflect the focus on language, family dynamics, and support for bilingualism.

Results: Participants included 1 Male and 5 Females, all parents of at least one bilingual autistic youth. Parent's mean age was 43 ( $SD = 4.42$ ) and mean age when youth were diagnosed was 3.33 ( $SD = 1.39$ ). The average median household income was \$41,999 ( $SD = \$35,637$ ). All participants were Latinx and identified as immigrants from either Mexico or Guatemala. Four out of five parents endorsed the importance of bilingualism but all five parents promoted dual language learning for their autistic child. Three out of five parents explicitly sought support for the promotion of bilingualism through in-home services which resulted in delayed service delivery and long wait times.

Conclusions: The growing number of bilinguals with ASD calls for extensive research on second language development, parental support for successful bilingual development, and culturally sensitive and competent services for immigrant populations.

#### **411.108 (Poster)** Understanding the Impact of the COVID-19 Pandemic on Autistic Children and Their Families: Results from an Online Survey Developed By Project Steer Stakeholders

**A. Wainer<sup>1</sup>, A. R. Borowy<sup>2</sup>, M. Beard<sup>3</sup>, R. A. Gordon<sup>1</sup> and K. M. Walton<sup>2</sup>**, (1)Department of Psychiatry, Rush University Medical Center, Chicago, IL, (2)Nisonger Center, The Ohio State University, Columbus, OH, (3)Department of Psychology, The Ohio State University, Columbus, OH

Background: Approaching stakeholders as engaged collaborators in research represents a challenging, yet critical, shift to better align autism research with the values, goals and needs of stakeholder communities. Project STEER (Stakeholders Engaging in Early Intervention Research) brings together autistic adults, parents of children with autism, community-based service providers, and autism early intervention researchers to support this shift. The COVID-19 pandemic offered a unique opportunity to partner with Project STEER stakeholders to learn more about the impact of the pandemic on children with autism and their families.

**Objectives:** The goal of this study was to co-develop an online survey with Project STEER focused on better understanding the impact of the COVID-19 pandemic on autistic children and their families.

**Methods:** Project STEER used a Participatory Action Research approach to develop an online survey consisting of questions that were identified by stakeholders as being of greatest importance to the autism community during this time.

**Results:** The survey was completed by 106 families of children with autism ages 1 to 11. Two percent of the sample identified as American Indian/Alaskan Native, 2% as Asian, 15% as Black, 2% as Hispanic, Latinx or Spanish, 1% Native Hawaiian, 2% as Middle Eastern or North African, 69% as White, and 7% as another race or preferred not to say. Most children's therapeutic and educational services were paused only briefly and then resumed either in person or via telehealth; only 14% of children experienced the complete discontinuation of a service during the pandemic. Interestingly, pandemic-related changes in children's services were experienced as mostly or completely negative for just 17% of children and 23% of parents—suggesting that a majority of families viewed these changes as neutral or positive. Twenty-one percent of parents report that their changes in household responsibilities during the pandemic were mostly or completely negative, with 38% feeling that their personal needs are not currently being met. Between 40% and 47% of children with autism experienced increases in aggression/disruptive behavior, anxiety, moodiness and sadness during the pandemic. Parents report developing a better understanding of their child's skills and behavior (62%) and improvements in the parent-child relationship (74%) during the pandemic. Parents also report spending more quality time (69%) with their child with autism as a result of the pandemic.

**Conclusions:** Although the pandemic caused many changes in services for children and their families, these data indicate that many children's academic and therapeutic needs were largely being met. However, parents themselves have experienced significant stress and unmet needs during this time. Many parents also reported increases in their children's experiences of aggression, anxiety, moodiness, and attention challenges during the pandemic. There have been longstanding calls for better mental health services and resources for children with ASD. The pandemic may have further increased the need for such services. Importantly, while the pandemic has been an unpredictable and stressful time for most, parents do report some positive impacts including developing a better understanding of their child and increases in the amount of quality time spent together.

**411.109 (Poster)** Family Echo: All Teach, All Learn Model to Build Family Knowledge and Ability to Care for Children with Autism  
*A. Hess<sup>1</sup>, E. Butter<sup>2</sup> and C. Hostutler<sup>1</sup>, (1)Nationwide Children's Hospital, columbus, OH, (2)Nationwide Children's Hospital, Columbus, OH*

---

#### Background:

From navigating a diagnosis to learning about new therapies, parents and caregivers of children with developmental disabilities, including autism need an immense amount of knowledge and support to provide best care to their loved ones. However, that information can often be difficult to access.

Project ECHO (Extension for Community Healthcare Outcomes) has proven successful as a learning framework for health care professionals to engage in best practice learning for application to patient and clinic practices. Learning is facilitated through evidence-based didactics, case-based discussion, and mentorship from a group of multi-disciplinary subject matter experts (HUB).

Family ECHO adapts the Project ECHO model to build an “all teach, all learn” environment where families, rather than health care professionals, are the targeted audience (SPOKES). The Family ECHO framework is able to connect families and HUB experts to share best practices and identify novel and emerging practices developing within the health care community.

#### Objectives:

- Describe the process of adapting the Project ECHO framework to families of children with autism
- Review initial outcomes related to changes in family autism knowledge, perceived caregiving competence, access to resources on specific topics related to autism.
- Demonstrate the reach of the program

#### Methods:

Family ECHO employs a 60-minute structure that includes a didactic, facilitated case-based discussion, and a pathway to resources, supports, and clinical service when needed. The traditional ECHO model elicits a case to discuss from participants. In Family ECHO, participants are families and caregivers of patients with autism; therefore, we modify the case presentation component to have HUB team members present a case vignette to ensure protection of protected health information. Data on the number of attendees and their locations are collected, in addition to an evaluation survey collected after the Family ECHO series.

#### Results:

In 2020, 430 attendees yielded 1507 attendances across 26 Family ECHO sessions. Participants came from Michigan, Kentucky, South Carolina, West Virginia and the US Virgin Island. Within Ohio, the primary audience, participants came from 79 out of 88 total counties.

Data from the evaluation survey (126 responses from 430 participants invited) indicates the topics offered are in line with the needs reported by participants of the series:

| Topic                                  | % of Families Endorsing Topic Was Topic Covered in FAMILY ECHO |     |
|--|--|-----|
| Irritability and Challenging Behaviors | 86%  | Yes |
| Behavior Management                    | 85%  | Yes |
| Family Support                         | 83%  | Yes |
| Anxiety                                | 74%  | Yes |
| Parenting                              | 60%  | Yes |
| ADHD                                   | 56%  | Yes |

Overall, attendees reported high satisfaction with the program (89% reporting being satisfied or very satisfied). 91% of participants reported participation in Family ECHO improved their knowledge and ability to care for children with developmental disabilities including autism.

Conclusions:

To our knowledge, Family ECHO is the first application of the Project ECHO framework to directly support families. We have successfully developed and launched a series structure including case presentation, outcome measures and didactic presentations and have enrolled participants from across many regions. Response from participants regarding topics for learning are in line with data collected by partner organizations.

#### **411.110 (Poster)** Family Experiences of Children with Autism Spectrum Disorder in Indian Context: A Parental Survey

**C. Pinto<sup>1</sup> and S. Tiwari<sup>2</sup>,** (1)Department of Speech and Hearing, Manipal College of Health Professions, Manipal, India, (2)Department of speech and hearing, Manipal academy of higher education, Manipal, India

Background: There is a dearth of tools assessing the parental measures and family life of Children with Autism Spectrum Disorder (ASD). Autism Family Experience Questionnaire (AFEQ) is a recent tool developed to assess parental priorities for outcomes of an early intervention and the impact of intervention on family experience of parents of children with ASD. AFEQ has known validity and reliability measures (Leadbitter et al., 2018).

Objectives: Our study aimed to adapt, validate the scale, and evaluate the parent-generated measure of family outcomes using the adapted AFEQ scale in the Indian context.

Methods: Permission was sought from the authors to adapt and validate the AFEQ to Indian context. The original tool was then checked for social and cultural suitability to Indian context by giving to three experienced professionals (one psychiatrist and two clinical psychologists) for content validation. A 4-point likert scale was used to rate the parameters such as 4- retain, 3-retain with minor changes, 2-retain with major changes, and 1- exclude. After incorporating modifications based on experts inputs, the adapted questionnaire was provided to 90 parents of children with ASD (age range of 3-10 years). The adapted questionnaire (like original) contained 48 items and was scored on a 5-point Likert scale: 1 to 5, where 1 indicated always and 5 indicated never. There are 4 subdomains in the questionnaire such as (1) experience of being a parent of a child with autism; (2) family life, (3) child development, and (4) child symptoms. Parents filled in the questionnaire forms, that were collected on the same day and the scores were computed.

Results: Results of content validation showed scale validity index of 0.83 indicating acceptable content validity. Minor modifications such as rephrasing of certain items (viz., 2,10,14,15,16, 18, 23, 29, 30, 32) were done as per the suggestions from the experts. We compared the parental ratings of the adapted AFEQ scale with the available norms from the original AFEQ scale. The parent ratings of the adapted AFEQ scale revealed comparable scores with the original version of the scale(see Table 1). Scores on child development and overall AFEQ was slightly lower in our study, indicating positive outcome. The scores on parent section in our data, however, revealed little higher scores or relatively lower outcome. While, the scores on family and child symptoms were similar.

Conclusions: Our study results indicate that the family outcomes in children with ASD were similar to existing reports in the literature, suggesting comparable quality of life. Findings of the study, therefore, provide support for the use of AFEQ for assessment of parental priorities for key outcomes of intervention in children with ASD and their family. The adapted version of AFEQ questionnaire provides a simple to administer and ready tool for research and clinical use.

#### **411.111 (Poster)** Family Perspectives on Behavioral Health Hospitalizations for Children with Autism Spectrum Disorder

**E. Klinepeter<sup>1,2</sup>, K. Gibbs<sup>2</sup>, J. Choate<sup>2</sup> and T. Nelson Hall<sup>1</sup>,** (1)Baylor College of Medicine, Houston, TX, (2)Texas Children's Hospital, Houston, TX

Background: Estimates suggest children with Autism Spectrum Disorder (ASD) are six times more likely to be hospitalized for behavioral health needs (e.g., aggression, self-injury, and tantrums) and incur 12.4 times greater hospitalization costs than for typically-developing children.<sup>1,2</sup> Given implications for health care systems, research on effective service delivery is critical yet very limited. Research has primarily been limited to emergency centers and outpatient hospital departments, with limited perspectives of families elicited. Among existing research, families have identified staff training and communication, knowledge of their children's behavioral and communication needs, and recognizing parental expertise as key components in service delivery, offering important implications for future training and practice.<sup>3,4</sup>

**Objectives:** The purpose of this qualitative descriptive study was to investigate family experiences with care received during behavioral health hospitalizations for children with ASD.

**Methods:** Primary caregivers of children with ASD and behavioral health needs admitted to a large pediatric hospital were purposefully recruited. Twelve total parents participated across two focus groups (six parents each). A semi-structured interview guide was utilized to elicit perspectives on children's needs and experiences with admission, personnel, and services. Data were transcribed and coded for major themes using an interpretive description approach.<sup>5</sup> Rigor was established through audit trails, saturation, member checks, reflexivity, and rich descriptions.

**Results:** Emerging themes highlighted the complexity of behavioral health hospitalizations in relation to: 1) needs of the child and 2) family experiences and variables. For the child, factors such as communication, sensory, and safety needs existed at the center of the family's experience. For the family, experiences comprised of factors such as advocacy, information-sharing with healthcare personnel, planning ahead, feelings of value or being heard by personnel, caregiver fatigue, and experiences with personal stressors during hospitalizations. Families also expressed significant variability in positive and negative experiences.

**Conclusions:** This research demonstrates the complexity of hospitalizations for children with ASD and variability in family experiences, as informed by the needs of the child and family variables. In line with current calls for research, findings point to implications for design of personnel training and development of practices to best meet the unique needs of children with ASD and families during hospitalizations. In turn, this offers the potential for improved personnel satisfaction, safety during hospital admissions, caregiver well-being, and overall outcomes for children with ASD and their families.

#### **411.112 (Poster) How Do Autistic Individuals Conceptualise and Experience Uncertainty?**

**L. Lennuyeux-Commene<sup>1</sup>, S. B. Gaigg<sup>2</sup> and J. Yates<sup>3</sup>,** (1)Department of Psychology, City, University of London, London, United Kingdom, (2)Autism Research Group, City, University of London, London, United Kingdom, (3)Psychology, City, University of London, London, United Kingdom

---

##### **Background:**

Autistic people are more likely to suffer from anxiety than their non-autistic peers (van Steensel et al., 2011) and considerable evidence implicates Intolerance of Uncertainty as a central risk factor in anxiety in autism (e.g. Maisel et al., 2016). While previous qualitative work has contributed to identifying intolerance of uncertainty as a significant source of anxiety in autism (e.g. Rodgers et al., 2018 and Hodgson et al., 2016), there has, however, been little research on what *uncertainty itself* means exactly for autistic people and/or what types of uncertainties might be particularly anxiety provoking.

##### **Objectives:**

This qualitative interview study sought to refine the construct of uncertainty by discerning what types of uncertainties might be problematic for autistic people, thereby informing better mental health practices and helping autistic people manage anxiety in their everyday life.

##### **Methods:**

The sample consisted of 15 adults (5 women), between 24 and 71 years of age with no additional learning or language impairment. Semi-structured interviews, lasting from half an hour to just over an hour, were carried out online via Zoom, to probe participants' understanding and experiences of uncertainty and possible links to feelings of anxiety. Grounded theory was applied to transcripts of the interviews, broadly following Charmaz' constructivist epistemology (Charmaz, 2014). As such, the analysis involved interaction with and interpretation of the data through successive levels of analysis, involving memo-writing, coding and the gradual construction of a theory.

Analysis was conducted in NVivo 12 Pro (QSR International Pty Ltd. (2018) NVivo (Version 12), <https://www.qsrinternational.com/nvivo-qualitative-data-analysis-software/home> ). The initial coding was done line-by-line, and the codes were then modified as the different themes were formed and questioned with each new reading. Eventually, theoretical saturation was reached, whereby the model fit the data as interpreted and no new meaning could be drawn out. The resulting theory and construct were then shared with the participants in the form of a summary of the analysis and findings for participant validation.

##### **Results:**

The main theme that recurred in people's narrative was that 'uncertainty' was 'not knowing'. This 'not knowing' however, was not always experienced as anxiety provoking. Rather, 'not knowing' became a source of anxiety only when it felt difficult to plan for, or control. The process of managing uncertainty became a process of containment: i.e., reducing the uncertainty by gathering information or planning, or simply avoiding situations where the uncertainty was likely to be unmanageable.

##### **Conclusions:**

The resulting theory that was derived from the data was that uncertainty has three different levels, ranging from the certainty of what is 'known', through the relatively manageable uncertainty of the 'known unknown', to the anxiety provoking 'unknown unknown', which is difficult to avoid or manage through planning or information gathering. The diagram illustrates this theory, which distinguishes between three different levels of

'knowing' or 'not knowing'.

**411.113 (Poster)** How Does Stigma Towards Autism Compare to Other Clinical Conditions?

**D. R. Jones, K. M. DeBrabander and N. J. Sasson, University of Texas at Dallas, Richardson, TX**

---

**Background:**

Although stigma towards autism has been well documented (Someki et al., 2018), less is known about how it compares to other stigmatized disabilities. Schizophrenia, a highly stigmatized condition (Angermeyer & Matshinger, 2003) also characterized by social disability but with other distinguishing features, may offer a useful contrast. Previous comparisons (Jensen et al., 2015; Sasson & Morrison, 2019) report that autism may be viewed more favorably than schizophrenia, but the underlying volitional thoughts contributing to these differences is unclear.

**Objectives:** The present study examines this question with a qualitative approach, allowing for a nuanced understanding of stigma towards different diagnostic labels.

**Methods:**

As part of a larger study, 533 undergraduates were randomly assigned to complete an open-ended question regarding their thoughts about, and exposure to, one of eight diagnostic labels: four related to autism (autism, autistic, autism spectrum disorder, or Asperger's), two to schizophrenia (schizophrenia or schizophrenic), and two to an unspecified clinical condition (clinical diagnosis or clinical disorder). Participants were asked "What do you think of when you hear the word(s) [label]?" A thematic analysis was conducted. Responses were aggregated and themes were identified and coded based on the six-step approach to thematic analysis outlined by Braun and Clarke (2006). This process examines response patterns, generating initial codes that are further refined and organized into themes based on the shared narrative they convey.

**Results:**

Because quantitative analysis revealed no significant differences of diagnostic label within clinical conditions, labels were aggregated into broader categories (autism, schizophrenia, and general clinical condition) for analysis. Patterns in initial codes differed across diagnostic labels. The greatest variability was found for autism, with 88 initial codes generated and the most frequently occurring code (poor social abilities) occurring in only 15% of responses. Responses to schizophrenia showed greater cohesion, with "psychotic symptoms" occurring in 38% of responses out of the 86 codes produced. General clinical condition generated 62 initial codes, with high cohesion: the most frequent code (reference to brain or behavioral conditions) occurred in 63% of responses.

The identified themes and subthemes (figure 1) contained some overlap across conditions, but also important distinctions. Excerpts from participant responses, to be included at the conference, further illuminate differences in how these conditions are perceived.

**Conclusions:**

Stigma and beliefs about autism differ from those directed toward other clinical conditions. Descriptions of autism were less cohesive across responses, suggesting that knowledge, understanding, and perceptions of autism are highly variable. Whereas attitudes toward autism (patronizing, exclusionary, and accepting) and schizophrenia (fear, prejudice, and empathy) were wide-ranging, the general clinical condition did not elicit detectable attitudes. This distinction highlights the centrality of a specific clinical identity for the development of stigma. Finally, participants reported many misconceptions about autism and schizophrenia, with uncommon features such as savant syndrome and violence perceived as core characteristics of the conditions. The detailed accounts produced by this study may aid in the development of targeted programs to improve attitudes toward autism and schizophrenia.

**411.114 (Poster)** Implementing Virtual Reality Technology for Autistic Students: Teacher's Perspective on Success Factors and Challenges.

**A. Dechsling<sup>1</sup>, O. M. Vister<sup>2</sup>, T. E. Johansen<sup>3</sup>, Y. Herikstad<sup>4</sup> and A. Nordahl-Hansen<sup>4</sup>, (1)Faculty of Teacher Education and Languages, Østfold University College, Fredrikstad, Norway, (2)Østfold University College, Halden, Norway, (3)Østfold University College, Fredrikstad, Norway, (4)Faculty of Education, Østfold University College, Halden, Norway**

---

**Background:** Virtual Reality (VR) is a term describing technology able to display artificial environments with visual and auditory stimuli, in which the user can interact. VR has shown to be an acceptable technological tool for autistic individuals (Dechsling et al., 2020). Caregivers and professionals call for accessible technological tools supporting and educating autistic individuals (Putnam, 2019). However, when implementing technology it is also important to include the teachers and school personnel (Donovan et al., 2014). The teacher's opinions and praxis are among the most important factors in succeeding with the implementation of information and communication technology in schools (e.g., Storz & Hoffman, 2013). Furthermore, the implementation is an important feature when considering treatment integrity.

**Objectives:** The aim for this study is to investigate teachers and school personnel's opinions on success factors, possible pitfalls, and challenges when implementing VR-technology for autistic students.

**Methods:** A total of 13 participants consisting of teachers, team leaders, special educators, and teaching students were interviewed. Eight participants were interviewed individually while the remaining five were interviewed as a group. We follow the qualitative thematic analysis (TA) approach as suggested by Braun and Clarke (2006), and their clarifications on reflexive TA in Braun and Clarke (2020).

**Results:** The thematic analysis resulted in themes on knowledge, network, attitudes, and technological aspects. The main findings are that (1) knowledge and sufficient training for the teachers are essential in order to utilize such tools, (2) a professional network surrounding the users (i.e., teachers and students) make sure good cooperation with developers and other users, (3) there are positive attitudes among school personnel to implement VR-tools, which they also consider a success factor, (4) technological aspects such as quality, user-friendliness, easy-to-use soft- and hardware, software updates, and flexibility is important in order to get school personnel to use the technology. In the group interview, there was a discussion whether VR could be of disturbance to other educational activities.

**Conclusions:** As various studies have looked into autistic individuals and other stakeholders' views on VR-tools (e.g., Bauer et al., 2021; Dechsling et al., 2020; Putnam et al., 2019), this study focuses on the teacher's perspective on factors related to implementation. Teachers and school personnel consider VR to be a positive pedagogical tool that can supplement traditional educational practice. Furthermore, they emphasize thorough preparations and training for the teachers, a functioning network, and easy-to-use flexible VR-technology with good quality in order to succeed with the implementation in schools and for autistic students. School personnel training, a high sense involvement and ease of use of the VR-tool is crucial for successful implementation of VR-interventions for autistic students in school.

**411.115 (Poster)** Improving Provider and Family Experiences with Telehealth Services for Children with Autism and Developmental Disabilities  
**M. L. Luu<sup>1</sup>, L. N. Berry<sup>2</sup>, R. H. Fein<sup>1</sup>, S. Cash<sup>1</sup>, R. G. Voigt<sup>2</sup> and R. P. Goin-Kochel<sup>2</sup>,** (1)Texas Children's Hospital, Houston, TX, (2)Baylor College of Medicine, Houston, TX

---

**Background:** Although research supports telehealth as a feasible tool to increase access to clinical services, there are still challenges with work flows and subsequent delivery of and/or receipt of care. This is particularly true for clinics that rely heavily on standardized, in-person assessments and behavioral observations, such as diagnostic programs for autism spectrum disorder (ASD) and related conditions. We previously reported on providers' and parents' experiences with the abrupt transition to telehealth services because of COVID-19 at a tertiary ASD/developmental center in a large metropolitan area and identified the following areas in need of improvement: technological issues, lack of family preparedness and communication, additional in-person and testing time needed by providers, and limitations of remote care. To address these needs, we developed a telehealth guide with text and pictures to consolidate all instructions, visit-preparedness information, technological resources, and contacts that was distributed to families at the time their appointments were scheduled.

**Objectives:** To evaluate pre-post telehealth-guide experiences with telehealth services from both caregiver and provider perspectives at a tertiary ASD/developmental center in a large metropolitan area.

**Methods:** The telehealth guide was distributed to all families scheduled for a telehealth visit. REDCap surveys were developed separately for caregivers and providers; these were sent via email with a request to complete the form with a given appointment in mind. Providers were emailed a survey link for every third visit, and surveys were distributed to all families regardless of whether the visit was completed, attempted, or no-showed. Post-survey distribution spanned three months (10/12/2020-1/29/2021). Pre-post guide surveys contained 10 items with Likert-type ratings to describe participants' agreement with various statements about their telehealth-visit experience (5 = strongly agree, 0 = strongly disagree). Survey responses were analyzed separately for caregivers and providers.

**Results:** A total of 108/827(13.1%) pre-guide and 74/512 (14.5%) post-guide caregiver surveys were returned; 161/829 (19.4%) pre-guide and 76/512 (14.8%) post-guide provider surveys were returned. Independent samples t-test revealed significant improvements in pre-post guide caregiver experiences in the following five areas: preparedness for visit,  $F=10.959(180)$ ,  $p = 0.001$ ; receiving helpful information from the provider,  $F=7.517(180)$ ,  $p = 0.007$ ; understanding the plan of care,  $F=11.319(180)$ ,  $p < 0.001$ ; equipment working well,  $F=26.120(180)$ ,  $p < 0.001$ ; and overall experience with the visit,  $F=6.620(180)$ ,  $p = 0.011$ . Cohen's  $d$  effect sizes ranged from 0.787 to 0.984. Comparable provider data and qualitative analyses of parent and provider post-guide open-ended feedback are underway.

**Conclusions:** Providing families with written and pictorial information prior to telehealth visits may foster more positive experiences with telehealth. Results from providers will further elucidate utility of the guide. The nature of this QI study design and the dynamic context in which the guide was introduced limit definitive conclusions. Nevertheless, given the permanency of telehealth services, it is valuable to develop and evaluate supports that facilitate this form of clinical care.

**411.116 (Poster)** Investigating Autistic Adults' Preferences for the Social Model of Disability and Identity-First Terminology  
**T. Q. Boucher<sup>1</sup>, N. E. Scheerer<sup>2</sup>, P. Hood<sup>1</sup>, V. Ly<sup>1</sup>, H. Aime<sup>1</sup> and G. Iarocci<sup>1</sup>,** (1)Psychology, Simon Fraser University, Burnaby, BC, Canada, (2)Psychology, Western University, London, ON, Canada

---

**Background:** Many autistic adults have advocated for autism to be viewed under the social model of disability, which states a person is disabled by their environment and its physical, social, and attitudinal barriers (Anderson-Chavarria, 2021). The medical model of disability is the dominant model for autism (Graby, 2016), where disability is seen as an individual problem caused by abnormalities, impairments, or deficits in one's body and/or brain. The medical model of disability is often viewed as stigmatizing by autistic individuals in that it over-pathologizes autistic traits (Woods, 2017). The medical model adopts person-first language, while the social model adopts identity first-language. Although previous research has indicated that autistic individuals prefer identity-first language, it is unclear how this preference relates to views about autism and autistic identity.

**Objectives:** Determine the model of disability that autistic adults prefer and how this relates to their views of autism.

**Methods:** Sixty autistic adults (33 women, 10 men, 10 non-binary/two-spirit/agender/gender-diverse, 7 non-disclosed;  $M_{age}=37.07$ ,  $SD=10.85$ ) were recruited through social media and completed the online study. The study was created by autistic and non-autistic researchers in consultation with eight autistic community members who provided input on question content, design, and accessibility. Participants completed the Autism-Spectrum Quotient (Baron-Cohen et al., 2001) and survey questions designed with autistic consultants. Using a slider from 0 to 100, participants indicated how much they agree with the medical and social model of disability, willingness to spend time with other autistic people, pride in being autistic, whether autism gives more challenges or strengths, the extent to which their challenges are due to autism or external barriers, and how much they would change about their autism. Definitions of the medical and social models of disability from Shakespeare (2006) were provided. Participants rated their preference for person-first and identity-first language on a 5-point Likert scale.

**Results:** Participants had an average AQ score of 37.20 ( $SD=7.26$ ). Thirty-three participants gave the social model of disability a rating of 100 (mean=75,  $SD=20.40$ ); no participants endorsed a preference for the medical model. Spearman correlations identified a positive relationship between preference for the social model of disability with participants' autistic pride, willingness to spend time with other autistic people, and the external attribution of the challenges they experience, and negatively with the desire to change anything about their autism (see Table 1). Preference for the social model of disability was negatively correlated with preference for person-first language and positively correlated with identity-first language.

**Conclusions:** There was a clear preference for the social model of disability in autistic participants. This preference is related to their sense of autistic pride, external attribution of challenges they experience, and endorsement of identity-first terminology to describe autism. These findings have implications for clinical practice; considering the high rates of loneliness and co-occurring mental health difficulties experienced by autistic individuals, it is critical that mental health professionals seek ways to cultivate connections and wellbeing in autistic clients. It may be that approaching care through the social model may represent one way that this can be achieved.

#### **411.117 (Poster) Language Interactions Among Bilingual Families and Their Children with ASD**

**S. R. Cohen<sup>a</sup>, J. Miguel<sup>b</sup> and E. Lee<sup>c</sup>, (1)University of California - San Diego, La Jolla, CA, (2)Department of Education Studies, University of California, San Diego, La Jolla, CA, (3)UCLA, Los Angeles, CA**

---

##### **Background:**

Home language interactions are among the strongest predictors of young children's language and cognitive development. For multilingual families who rear neurodiverse children and who may be minoritized for their language use, limited research examines families' daily language interactions. Strong evidence exists for bilingual families to use their multilingual interactional resources to support their children's language development (Bialystok & Craik, 2010). Yet, children's language background is not always reported as an interacting factor, in developmental and intervention research (Byers-Heinlein et al., 2019; Huerta et al., 2021), reinforcing a pervasive deficit perspective favoring middle-class, monolingual language and cultural practices (Castro, et. al., 2021; Kay-Raining Bird et al., 2012). Developmentally appropriate, linguistically diverse, and culturally responsive early interventions that support the language diversity, the educational expectations, and the cultural practices of bilingual families and their autistic children are needed (Cohen et. al., 2020; DuBay et al., 2018; Stahmer et al., 2019).

**Objectives:** This study aimed to characterize the daily language practices of monolingual and bilingual Mexican heritage families and their autistic children.

##### **Methods:**

Six Mexican heritage, bilingual, families from low-income backgrounds, who reared an autistic child video recorded their language interactions during daily routines with their child over 10 days. See Table 1 for demographic information. There were 18 hours and 56 minutes of recordings from 171 videos (i.e. average length per video: 6.61 minutes). Video recordings were analyzed by activity settings, who was present during these activities, and the language used in the activities.

##### **Results:**

Families filmed an average of 34.2 videos over ten days (Range = 9-71). The most prevalent activity was adaptive caregiving (e.g., eating, preparing/serving food, brushing teeth, getting ready for school, asking questions about the child's school day) (70% of the activities;  $N=121$ ). Across all families, videos captured the target child 95% of the time ( $N=163$ ). The mother appeared in 50% of all videos ( $N= 85$ ). Siblings appeared in 47% of all videos ( $N=81$ ). Although all families reported Spanish as their primary language, three families recorded primarily Spanish interactions, whereas the other three recorded primarily in English (See table 2).

##### **Conclusions:**

Study families used English and Spanish during adaptive caregiving tasks throughout their day. Even though all study families reported being Spanish dominant, three families video recorded their interactions in English. It is possible that Spanish dominant families who video-recorded in English may have believed that they should be speaking English. Historically, families have been counselled away from using their dominant language for ASD interventions to "eliminate confusion" (Kay-Raining Bird, et al., 2012). Previous studies have shown that Latinx families accept the use of English only interventions despite initial resistance (Cioé-Peña, 2020). Few fathers were present during everyday language interactions. It is possible that families adhered to traditional gender roles and fathers were the sole breadwinners for their families. Targeted ASD interventions should be integrated into routine caregiving activities; mothers should be included in the implementation of ASD interventions, and these

interventions should be delivered in both English and Spanish.

**411.118 (Poster) Maternal Autism: Is Wellbeing Related to Autistic Camouflaging?**

**V. S. Finke** and S. Anns, *School of Psychology, University of Sussex, Brighton, United Kingdom*

---

**Background:** Recent findings indicate that autistic mothers (including non-binary parents) may face additional challenges compared to their non-autistic counterparts (McDonnell & DeLucia, 2021). These challenges may present as difficulties maintaining social support, wellbeing, and ability to cope (Pohl *et al.* 2020). Autistic camouflaging is a social coping strategy which involves hiding autistic traits and altering behaviour to appear socially acceptable (Hull *et al.* 2017). Yet, this protective strategy may compromise effective communication with healthcare professionals. For instance, 80% of autistic mothers report fear of judgement if they disclose a formal or suspected diagnosis of autism and 40% report rarely or never disclosing their diagnosis (Pohl *et al.* 2020). Additionally, camouflaging has been shown to be implicated with mental wellbeing (Raymaker *et al.* 2020), which is impacted in autistic mothers (Acar, Slowinska, & Anns, 2021).

**Objectives:** The objective of this study was to investigate the possible link between autistic camouflaging and wellbeing in autistic and non-autistic mothers. Specifically, we expect to find that higher camouflaging scores will predict higher concurrent adverse wellbeing in autistic but not non-autistic individuals.

**Methods:** To date, 273 mothers and non-binary parents completed an online survey, self-reporting demographic information and autistic traits using the Social Responsiveness Scale-2, Revised Edition (SRS-2; Constantino & Gruber, 2012) (see Table 1). Group inclusion criteria for three groups was i) ASC: those who reported an autism diagnosis and scored above the t-score cut-off of 60 on the SRS-2; ii) SDA: those who self-diagnosed as autistic and also scored above 60 on the SRS-2; iii) Non-ASC: those who reported no formal or self-diagnosis of autism and who scored below 60 on the SRS-2. Participants completed the Camouflaging Autistic Traits Questionnaire (CAT-Q; Hull *et al.* 2019) and the Depression, Anxiety, and Stress Scale (DASS-21; Lovibond & Lovibond, 1995).

**Results:** Mean scores on the DASS-21 and the CAT-Q were significantly higher in the autistic groups than the non-autistic group (DASS-21:  $F(2,270) = 29.04, p < .001$ ; CAT-Q:  $F(2,270) = 159.98, p < .001$ ). A significant correlation between mean scores on each measure was found in the ASC and SDA group, but not the non-ASC group. Regression analyses showed that CAT-Q scores could significantly predict concurrent DASS-21 scores in both autistic groups (ASC:  $F(1,120) = 4.72, p = .032$ ; SDA:  $F(1,92) = 31.35, p < .001$ ), but not in the non-ASC group ( $F(1,55) = 1.25, p = .268$ ). Most of the variance in the data was explained in the SDA group (SDA: 25.4%; ASC: 3.8%).

**Conclusions:** Our study confirms a link between autistic camouflaging and depression, anxiety, and stress in autistic mothers, both diagnosed and self-diagnosed. Both camouflaging and threat to wellbeing were also greater amongst autistic mothers. Taken together, these findings indicate a unique parenting experience in autism which could serve as important information to healthcare professionals to tailor specific support needs for this population.

**411.119 (Poster) Mental Health and Loneliness in Mothers of Autistic Children and Mothers of Children with Fragile X Syndrome during the COVID-19 Pandemic: Associations with Caregiver Burden and Social Support**

**A. C. Hickey<sup>1</sup>, K. Banger<sup>2</sup> and J. Klusek<sup>1</sup>**, (1)Communication Sciences and Disorders, University of South Carolina, Columbia, SC, (2)University of South Carolina, Columbia, SC

---

**Background:** The COVID-19 pandemic brought about many stressful changes. Caregivers of autistic children worried about their child being out of school, were unable to receive interventions, and became more stressed (Soares *et al.*, 2021). These disruptions are also predictors of caregiver mental health (McMorris *et al.*, 2021). Mothers of children with other disabilities, such as fragile X syndrome (FXS), experienced similar struggles during the pandemic. Characterizing pandemic-related hardships, and their impact on maternal mental health and well-being, is important for developing family supports.

**Objectives:**

The questions the study addressed are as follows:

1. During the COVID-19 pandemic, did mothers of autistic children, mothers of children with FXS, and mothers of typically developing (TD) children differ in depression and anxiety symptoms, loneliness, social support, perceived decline in mental health due to the pandemic, and increased caregiver responsibilities due to the pandemic?
2. Did caregiver burden and social support during the pandemic predict mental health and well-being across mothers of children with autism, FXS, or TD?

**Methods:** Participants were mothers of autistic children ( $n=39$ ), mothers of children with FXS ( $n=54$ ), and mothers of TD children ( $n=57$ ). The mean age of the mothers was 45 years, with similar ages across groups ( $p=.420$ ). Data collection spanned 8/2020-10/2021 during the COVID-19 pandemic. Mothers completed questionnaires tapping loneliness (UCLA Loneliness Scale), anxiety (Beck Anxiety Inventory), depression symptoms (Beck Depression Inventory-II), and social support (Duke Social Support Scale). Participants also indicated on a 7-point scale how true the following statements were: "The COVID-19 pandemic has impacted my psychological health negatively" and "The COVID-19 pandemic has increased my caregiving responsibilities". A series of general linear models were conducted to test group differences. A multivariate model was used with

caregiving burden, diagnosis, and their interaction as predictors of loneliness, anxiety, depression, and decline in mental health (model 1) and then added social support as another predictor (model 2).

#### Results:

Mothers of autistic children reported higher levels of loneliness compared to both mothers of children with FXS and TD ( $p's < .015$ ). They also reported higher depression symptoms ( $p = .002$ ) and lower social support ( $p < .001$ ) compared to mothers with TD children, however, they did not differ from mothers of children with FXS on those measures ( $p's > .053$ ). In all groups, increased caregiving responsibilities during COVID-19 was associated with self-reported decline in mental health ( $p < .0001$ ), increased anxiety symptoms ( $p = .018$ ), and loneliness ( $p = .028$ ). In mothers of autistic children, increased caregiving responsibilities also predicted depression ( $p = .041$ ). When social support was added into the model it was a strong predictor for all outcome variables except for anxiety, regardless of group (all  $p's < .021$ ); more social support was associated with better mental health and well-being.

#### Conclusions:

Regardless of child's diagnosis, increased caregiving burden negatively impacted mothers' mental health and well-being during the pandemic, with social support playing a protective role. However, mothers of autistic children reported significantly lower levels of social support. Future research could look at barriers to access to social support for mothers of autistic children and potential interventions and resources, such as telehealth therapies, that could be helpful.

**411.120 (Poster)** Mental Health of Mothers and Fathers of Autistic Children during the COVID-19 Pandemic  
*N. Ekas<sup>1</sup> and C. Kouros<sup>2</sup>, (1)Texas Christian University, Fort Worth, TX, (2)Southern Methodist University, Dallas, TX*

---

**Background:** Parents of autistic children generally experience increased levels of stress and mental health problems compared to parents of children without a disability. Families were affected by the COVID-19 pandemic as parents adopted new roles, such as teacher, while continuing to balance their roles as employees, parents, and spouses. Indeed, COVID-19 stressors have been connected to high parental stress in families of neurotypical children (Brown et al., 2020). Parents of autistic children face additional stressors as their child's therapy services were shut down.

**Objectives:** This longitudinal study examined the extent to which pandemic-related experiences within the family, such as increased parental responsibility, were related to mental health outcomes for mothers and fathers of autistic children from April to October 2020.

**Methods:** This study is part of a larger, longitudinal study of families of children with ASD that started prior to the COVID-19 pandemic. Parents were contacted to complete an online survey three times (April, July, and October 2020); 93 families completed at least one survey. The surveys assessed parenting experiences during the pandemic as well as stress, anxiety, and depression.

**Results:** A series of paired t-tests were conducted to examine differences between mothers and fathers at each time point. At each time point, mothers reported significantly greater parenting responsibilities, anxiety, depression, and stress compared to fathers. Separate hierarchical linear models were performed to examine changes from April to October 2020. For mothers, there were no significant changes across time for any of the variables. Mothers consistently reported above average levels of anxiety, stress, and depression. Fathers generally reported below average levels of depression and stress, and these remained consistent over time. Levels of anxiety, however, were slightly above average, but decreased across time.

**Conclusions:** Our results suggest that mothers were more adversely impacted during the COVID-19 pandemic compared to fathers. Mothers reported significantly more parenting responsibilities, and these remained elevated even as lockdowns eased and schools reopened in our community. Mothers' levels of anxiety, depression, and stress were higher than normed averages and they remained elevated throughout the study. Fathers were less impacted by the pandemic; however, their levels of anxiety significantly declined as lockdowns eased. In the community, by the end of the study (October 2020) all businesses had resumed nearly normal operations and schools were reopened. It appears fathers were benefiting from these changes, whereas mothers were not. The findings have implications for the development of services directed to families of children with ASD. For example, focusing on parent mental health and assisting with parenting responsibilities (e.g., remote respite care) may benefit both parents and their children.

**411.121 (Poster)** Now What?: First Actions Taken By Parents after an Autism Diagnosis.  
*D. L. Limon<sup>1</sup>, K. M. Normansell-Mossa<sup>1</sup>, E. I. Hartnett<sup>2</sup>, R. A. Lundwall<sup>3</sup> and M. South<sup>4</sup>, (1)Clinical Psychology, Brigham Young University, Provo, UT, (2)Oregon Health and Science University, Portland, OR, (3)Psychology & Neuroscience, Brigham Young University, Provo, UT, (4)Psychology & Neuroscience, Emory Autism Center, Provo, GA*

---

**Background:** Parent reactions to their child receiving an autism diagnosis can be positive depending on their own background and the effectiveness of the provider's delivery of the information. Nonetheless, many parents often feel alone in navigating resources post-diagnosis.

**Objectives:** To examine the first actions taken by parents immediately following an autism diagnosis feedback session with their provider. Understanding how parents receive and process information from the feedback session will inform providers' approaches for delivering an autism diagnosis to families. Results from this study can be used to optimize supportive and psychoeducational resources for families.

**Methods:** Parents of children diagnosed with an autism spectrum disorder within the previous three years were recruited from autism-related service organizations and community groups around the United States to complete a survey regarding the feedback session where their child's diagnosis was

disclosed to them. 189 children with an autism spectrum diagnosis were included in the study (145 male) with an age range from 1 to 28 years old (mean = 4 years old). 90.5% of survey respondents identified as the mother of the child. Parents were asked to describe the first thing they did following the diagnosis, to help their child and/or to help themselves.

**Results:** Five parents indicated that they did nothing different following the diagnosis. The remaining 184 answers fell into or blended across several broad themes including: a) seeking additional information about the diagnosis; b) starting the process of seeking services for their child; c) taking steps to support their child at home; d) processing their own thoughts and feelings; e) seeking support for themselves as parents. Overall, 41% of parents report seeking informal social support first, with 73% accessing informal social support at some point. Approximately 72% of parents eventually accessed information on websites that they found on their own, while only 50% accessed information on websites recommended by their provider. Many families reported that the first thing they did after leaving the session was to cry, then went and did another initial task, such as seeking services for their child or support for themselves. Often many of these tasks were initiated at about the same time. About half of parents stated that the first thing they remember doing was seeking services for their child. Many families noted that the first thing they did to help their child was at home such as implementing new strategies into their daily routines including schedules and/or rewards.

**Conclusions:** Many parents are likely to seek out information on their own and would benefit from direction from their providers about reliable sources of information that address their child's needs. Additionally, providers should incorporate emotional support for parents in their feedback plan. Tailored recommendations during the feedback session, specific to the needs of each child and family, provide a solid foundation for parents to build on after hearing the diagnosis.

**411.122 (Poster)** Parent Perceptions about the Academic, Literacy, Social, and Behavioral Development of School-Age Children with Autism during COVID-19: A Latent Profile Analysis

**M. C. Zajic<sup>1</sup>** and **N. S. McIntyre<sup>2</sup>**, (1)Health & Behavior Studies, Teachers College, Columbia University, New York, NY, (2)School of Communication Sciences and Disorders, University of Central Florida, Orlando, FL

**Background:** The COVID-19 pandemic disrupted educational services for children across the United States, with emerging evidence highlighting the loss of clinical and educational services and supports for school-age children with autism spectrum disorder (ASD). The effects of the pandemic on learning and development in children with ASD is just now being understood, and approaches are needed to examine such impacts in broad academic development, areas of common challenge for children with ASD (e.g., literacy skills like reading and writing), social, and behavioral development.

**Objectives:** To examine latent profiles of parent perceptions about their child's academic, literacy, social, and behavioral development as measured in reference to three timepoints (TPs): 1) 2019-2020 School Year Prior to COVID-19 (5/2019-3/2020), 2) Initial COVID-19 Disruption (3/2020-8/2020), and 3) 2020-2021 School Year (8/2020-5/2021).

**Methods:** This is an online survey study that recruited participants from the Simons Foundation Powering Autism Research initiative, a national database of families and individuals with verified ASD diagnoses. Current analyses include perspectives from 350 parents and caregivers of a K-6<sup>th</sup> grade children (age=7.99[1.91], 31% non-white) with ASD (ages at pandemic onset). Participants completed questions that asked about their agreement to the statement, "I believe my child is making general progress in their [skill]", with skill representing academic, reading, and writing achievement as well as social and behavioral development. Parents rated their agreement using a Likert scale (0 = *Strongly Disagree*, 5 = *Strongly Agree*) for each skill for each TP. Latent profile analysis was used to examine for the presence of underlying, multivariate profiles based on patterns of participant responses across Likert items. Profiles were fit sequentially until model estimation failed, and selection of final models was based on theoretical support as well as multiple model fit indices.

**Results:** TP1 responses endorsed a 3-profile model: 1) *Agree/Strongly Agree Overall* (46%); 2) *Somewhat Agree/Disagree Overall* (43%); and 3) *Disagree/Strongly Disagree Overall* (11%). TP2 responses endorsed a 3-profile model: 1) *Agree Academics, Somewhat Agree Social and Behavioral* (23%); 2) *Disagree Overall* (40%); and 3) *Strongly Disagree Overall* (38%). TP3 responses endorsed a 3-profile model: 1) *Strongly Agree/Agree Academics, Somewhat Agree Social and Behavioral* (44%); 2) *Somewhat Agree/Disagree Overall* (39%); and 3) *Disagree/Strongly Disagree Overall* (17%).

**Conclusions:** Findings highlight a consistent three-profile model fitting best across all TPs. However, the profiles differed across TPs in agreement ranges and group membership. TP1 highlighted overly positive responses in general, with only 11% of responses disagreeing about their child showed general progress across items. TP2 highlighted a large drop in agreement across profiles and a much larger percentage of respondents endorsing negative perceptions. TP3 highlighted more hopeful responses similar to TP1 but with lower agreement in general more similar to TP2. Furthermore, a higher percentage of participants endorsed overall disagreement relative to TP1. Findings suggest a general negative perception to the COVID-19 educational disruption but suggest that parents were more hopeful about their child's development during the subsequent school year. Implications will be discussed in line with future research concerning academic, social, and behavioral development.

**411.123 (Poster)** Parent Stress, Emotion Dysregulation, and Depression in Parents of Children with Autism and Intellectual Disabilities during the Covid-19 Pandemic: A Mixed-Method Analysis

**S. Khawar<sup>1</sup>**, **K. Schiavo<sup>1</sup>**, **E. Fowler-Benton<sup>1</sup>**, **M. I. Cargill<sup>1</sup>**, **N. Yacoub<sup>1</sup>**, **R. G. McDonald<sup>1</sup>**, **C. Tilson<sup>2</sup>** and **E. Kang<sup>1</sup>**, (1)Department of Psychology, Montclair State University, Montclair, NJ, (2)Chicago School of Professional Psychology, Chicago, IL

Background:

Parents of children with autism spectrum disorder (ASD) have reported increased stress and anxiety during the Covid-19 pandemic (Yilmaz et al., 2021; Brown et al., 2020). Even prior to the pandemic, research suggests that mothers of youth with ASD and Down Syndrome demonstrate elevated rates of depression and parenting stress (Davis & Carter, 2008; Singer, Ethridge, & Aldana, 2002; Tekinarslan, 2013) when compared to mothers of typically-developing (TD) youth. Mothers also report more depressive symptoms than fathers (Hastings et al., 2005). Research also suggests that child behaviors may particularly increase parental stress (Hastings, 2003). Therefore, understanding factors that contribute to increased parental stress and psychopathology is especially crucial during the pandemic. Preliminary research also suggests racial/ethnic differences in family experiences during the pandemic (CDC, 2020), specifically minorities being impacted most by the health disparities (Hooper et al., 2020). It is important to contextualize these relations by identifying struggles that parents face is crucial for providing support that enhance well-being of families affected by ASD during the pandemic.

#### Objectives:

This mixed-method study assessed (1a) racial and gender differences in mental health among parents of children with developmental and intellectual disabilities (DD/ID), and (1b) the impact of child maladaptive behaviors on parent psychopathology during the Covid-19 pandemic, and (2) to qualitatively assess the main areas of struggle for parents and the potential mechanisms of supportive interventions.

#### Methods:

Forty parents (87.5% female; 60% non-white; 80% ages 35-54) of children with DD/ID (72.5% ASD; 10% Down Syndrome;  $M_{age}=11.60$ ,  $SD_{age}=5.62$ ; 77.7% male) participated in this study. Parents completed a measure of parental depression (BDI-II; Beck, 1996), parental emotion dysregulation (DERS; Gratz and Roemer, 2004), and parenting stress (PSI-4-SF; Abidin, 1995), as well as child's internalizing and externalizing behaviors (Maladaptive Behavior domain from the VABS-III; Sparrow et al., 2016). Quantitative analyses included a two-way ANOVA to examine differences in parent psychopathology by race and gender. Multiple regression examined if child maladaptive behaviors predicted parental stress, depression, and emotion dysregulation. Qualitative analyses included coding responses to open-ended questions (e.g. "What is the greatest struggle for you with your child's diagnosis during the pandemic?") to assess the perceived causes of stress and parent needs.

#### Results:

Quantitative analyses revealed an interaction between gender and race for BDI-II and DERS ( $F>4.08$ ,  $p<.05$ ) such that non-white males and white females reported higher parental BDI-II and DERS (Figures 1 & 2). Qualitative analyses revealed main areas of struggle as lack of emotional/social support, parenting needs of other children, child behaviors, and managing child's treatments.

#### Conclusions:

Our mixed-method approach indicate racial and gender differences in parental psychopathology, and identified predictors such as child maladaptive behaviors and lack of support. These findings highlight the importance of addressing emotional and behavioral problems in children with DD/ID, and considering demographic factors and other areas of perceived challenges of parents in supporting parental mental health during these challenging times.

#### **411.124 (Poster)** Parent-Reported Impact of the COVID-19 Pandemic on Autistic Traits and Mental Health Symptoms in Children and Adolescents with ASD

**L. Hooijman**<sup>1,2</sup>, **R. Van der Hallen**<sup>1,2</sup>, **S. Louwerse**<sup>1,3</sup>, **K. Visser**<sup>1,4</sup>, **D. Bastiaansen**<sup>1,5</sup>, **W. A. Ester**<sup>1,6,7,8</sup>, **L. W. ten Hoopen**<sup>1,9</sup>, **P. F. de Nijs**<sup>1,9</sup>, **S. Van Rijen**<sup>1,2</sup>, **F. Truijens**<sup>1,2</sup> and **L. P. Dekker**<sup>1,2</sup>, (1)Rotterdam Autism Consortium (R.A.C.), Rotterdam, Netherlands, (2)Department of Psychology, Education & Child Studies, Erasmus University Rotterdam, Rotterdam, Netherlands, (3)Erasmus MC - Sophia, Rotterdam, Netherlands, (4)Youz, Rotterdam, Netherlands, (5)Yulius, Barendrecht, Netherlands, (6)Sarr Expert Centre for Autism, Lucertis Child- & Adolescent Psychiatry, Rotterdam, Netherlands, Rotterdam, Netherlands, (7)Parnassia Psychiatric Institute, The Hague, Netherlands, (8)Department of Child and Adolescent Psychiatry, Curium-LUMC, Leiden University Medical Center, Oegstgeest, Netherlands, (9)Child and Adolescent Psychiatry/Psychology, Erasmus MC-Sophia Children's Hospital, Rotterdam, Netherlands

**Background:** On the 11th of March 2020, the COVID-19 outbreak was officially declared a pandemic. Some groups may be identified as vulnerable; for example, children and adolescents and individuals with pre-existing mental health issues, such as autism. Simultaneously, it seems that some individuals with ASD may actually benefit from the restrictions imposed. The pandemic presents us with a unique opportunity to look at the impact of a collective major life event on children and adolescents with ASD. This will better our understanding of the possible impact other (major) life events may have, help identify risk and protective factors, and inform policies and interventions. Most early studies lack a pre-COVID-19 measurement making it more difficult to indicate the impact of COVID-19 and the restrictions that coincide with it.

**Objectives:** The aim of the current study was to examine the short-term and longer-term effects of the pandemic on children and adolescents with ASD from pre-COVID-19 to during COVID-19, with a focus on emotional and behavioral problems and autistic symptoms. In addition, we aim to identify risk and protective factors (e.g., age, gender, and IQ).

**Methods:** In collaboration with three mental healthcare institutions specialized in autism in the region of Rotterdam all families who received care in the year prior to the pandemic were invited to partake in the current study (n=200). T0 (pre-COVID-19; 03/2019-03/2020) and T1 (2<sup>nd</sup> lockdown, 01/2021-05/2021) is available on a subset of parents/caregivers of children and adolescents with ASD (N = 55). T2 (lenient/less restrictive period;

09/202112/2021) data is currently being collected to assess long-term impact. Participants completed the Child Behavior Checklist; CBCL (i.e., the Brief Problem Monitor- Parent Form; BPM-P) and the Social Responsiveness Scale (SRS-2) at T0, T1, and T2.

**Results:** Final data collection is currently ongoing. Preliminary results indicate an overall group effect with an increase in emotional and behavioral problems from T0 to T1. Interestingly, when taking gender into account, females report less anxiety and depression complaints at T1 compared to T0, while males report more anxiety and depression complaints at T1 compared to T0. No change in autistic symptoms were identified from T0 to T1 on a group level. Results regarding CBCL and SRS comparing T0 vs T1 vs T2 are expected early 2022.

**Conclusions:** The COVID-19 pandemic has a unique effect on children and adolescents with ASD. Final results regarding the short- and long-term impact of the COVID-19 pandemic with regard to autistic symptoms and on emotional behavioral problems comparing T0 vs T1 vs T2 are expected by early 2022.

**411.125 (Poster)** Parent-Sibling Communication and Mental Health in Siblings of Children with Autism Spectrum Disorder Compared with Physical Disabilities

**S. Orm<sup>1</sup>, Y. B. Haukeland<sup>2</sup>, T. M. Vatne<sup>3</sup> and K. W. Fjermestad<sup>4</sup>,** (1)Department of Psychology, University of Oslo, Oslo, Norway, (2)University of Oslo, Oslo, Norway, (3)Frambu Resource Centre for Rare Disorders, Siggerud, Norway, (4)Psychology, University of Oslo, Oslo, Norway

---

**Background:** Siblings of children with autism spectrum disorder (ASD) are at higher risk of mental health difficulties compared with the general population and siblings of children with other intellectual and developmental disabilities. However, it is unclear whether they are at higher risk of mental health difficulties compared with siblings of children with physical disabilities. Furthermore, open and supportive parent-sibling communication has been proposed as a protective factor for mental health difficulties in siblings of children with physical disabilities but few studies have examined the relationship between parent-sibling communication and mental health difficulties in siblings of children with ASD.

**Objectives:** To compare the levels of mental health difficulties and parent-sibling communication across siblings of children with ASD, siblings of children with physical disabilities, and typically developing (TD) controls, and to examine the relationship between parent-sibling communication and mental health difficulties in siblings of children with ASD.

**Methods:** The sample comprised siblings of children with ASD (n=47), physical disabilities (n=42), and TD controls (n=44) between 8 and 16 years of age. We used a multi-informant approach where children and their mothers and fathers reported on sibling mental health using the Strengths and Difficulties Questionnaire (SDQ) and children reported on parent-child communication using the Parent-Child Communication Scale (PCCS). Data were analyzed using analysis of variance (ANOVA) with Fisher post-hoc tests and Pearson's correlation coefficient.

**Results:** There were significant differences between the three groups in both sibling-reported internalizing and externalizing difficulties ( $p \leq .007$ ), father reported internalizing and externalizing difficulties ( $p \leq .019$ ), and mother reported internalizing and externalizing difficulties ( $p \leq .003$ ). Siblings of children with ASD had more internalizing difficulties according to both child-, mother-, and father-report ( $p \leq .006$ ; Hedges  $g = .65-.94$ ) and more externalizing difficulties according to child- and father-report ( $p \leq .008$ ; Hedges  $g = .65$ ) compared with controls. Siblings of children with ASD also reported poorer mother-sibling ( $p = .021$ , Hedges  $g = -.56$ ) and father-sibling communication ( $p < .001$ ; Hedges  $g = -.92$ ) compared with controls. There were no significant differences between siblings of children with ASD and siblings of children with physical disabilities. Mother-sibling communication correlated significantly negatively with mother-reported externalizing difficulties ( $r = -.39$ ,  $p = .020$ ) and father-reported externalizing difficulties ( $r = -.47$ ,  $p = .018$ ).

**Conclusions:** Sibling of children with ASD and siblings of children with physical disabilities seems to be at equal risk of mental health difficulties and poor parent-sibling communication. Parent-sibling communication seems not to be a general protective factor of mental health difficulties in siblings of children with ASD but rather mother-sibling communication is limited to a protective factor against externalizing difficulties. This study highlights the importance of providing supportive interventions for siblings of children with ASD and suggests that targeting parent-sibling communication may not be the most effective approach.

**411.126 (Poster)** Parent-to-Parent (P2P) As an Intervention Delivery Model: A Scoping Review

**J. D. Lee<sup>1</sup>, A. Terol<sup>2</sup>, C. Yoon<sup>2</sup> and H. Meadan<sup>3</sup>,** (1)444 Minnesota Avenue Ste 300, Juniper Gardens Children's Project, Kansas City, KS, (2)University of Illinois at Urbana-Champaign, Champaign, IL, (3)University of Illinois, Champaign, IL 61820, IL

---

**Background:**

Parents of children with autism have often reported feelings of isolation and increased stress after receiving their child's diagnosis. Increasing global prevalence of autism calls for increased services and supports to meet the needs of children with autism and their families. This may also indicate the need for diversifying intervention delivery models to increase contextual fit and enhance implementation effects for different populations. Many parents of children with autism have reported parent-to-parent (P2P) model to be a source of emotional support, advocacy, and knowledge related to their child's diagnosis, and practical advice.

**Objectives:**

P2P intervention model may be especially relevant in low resource settings across the world where parents of children with autism are reported to experience inequitable access to resources and evidence-based interventions (EBI). However, there have been little efforts to examine the evidence of benefits of P2P, and there is no literature synthesizing the evidence of P2P intervention model even though this could potentially be beneficial to

many families in various low-resource settings. Therefore, the purpose of this review was to scope the evidence of the use of P2P model among parents of children with autism.

## Methods:

In this review, we conducted a systematic search process by referring to the PRISMA checklist. The initial search yielded a total of 631 articles. After screening, a total of 33 articles were selected for full-text review, and 23 articles were then selected for inclusion. We then created an online coding form that included demographic information, type of study, modality and type of intervention, dosage, target outcomes, and social validity.

## Results:

Two researchers independently coded half of the 23 total articles using the online coding form, and another independent researcher coded 38% of the 23 articles for reliability. The findings revealed that in about half of the studies included mentor-mentee system where parent mentors disseminated information about EBI or advocated for the mentees. The other half of the studies included support groups to primarily provide emotional support for other parents. Social validity data across the 23 studies revealed that most parents found the mentor-mentee system and the support group to be feasible, acceptable, and effective while some parents preferred receiving support from professionals.

## Conclusions:

Given the heterogeneity of its use, P2P intervention model poses itself as an innovative intervention delivery model, which researchers may use to disseminate information about EBP and mitigate the inequitable access to EBP. As the evidence shows that parents of children with autism may benefit from a P2P model, it is crucial to examine the mechanisms to support marginalized and minoritized parents through this model. For example, parents of children with autism who live in low-resourced communities and are experiencing limited access to EBP may especially benefit from such intervention model. There are also implications for future research on adapting this intervention delivery model to disseminate EBP with minoritized and marginalized families of children with autism.

### 411.127 (Poster) Parents' Perceptions of Genetic Testing for Their Children with Autism: What Factors Make a Difference?

**G. J. Sakyi<sup>1</sup>, C. N. Murali<sup>2</sup>, S. S. Mire<sup>1</sup> and R. P. Goin-Kochel<sup>3</sup>,** (1)Psychological, Health, and Learning Sciences, University of Houston, Houston, TX, (2)Baylor College of Medicine, Houston, TX, (3)Baylor College of Medicine, Houston, TX

---

**Background:** Strong evidence points to the role of genetic factors in the development of autism spectrum disorder (ASD), and genetic testing can provide insights on genetic contributions to ASD symptoms and guide subsequent medical care and family planning decisions. As such, the American College of Medical Genetics recommends genetic testing be offered to everyone with an ASD diagnosis. Yet not all families follow through on genetic-testing referrals. While reasons for poor follow-through on referrals vary (e.g., lack of insurance coverage/high costs of testing, parents' limited knowledge about processes and purposes, perceptions about the utility of genetic testing), it is unclear whether and how income and parents' perceptions of their child's ASD influence their opinions about genetic testing, which ultimately influences whether they complete recommended genetic testing.

**Objectives:** To ascertain (a) whether parents' etiological beliefs about ASD influence their perceptions of genetic testing; (b) whether parents' attributions of ASD-related symptoms influence their perceptions of genetic testing; and (c) whether differences in parents' perceptions of genetic testing (i.e., their causal beliefs of their child's ASD and their attributions of ASD-related symptoms) and income affect genetic testing completion.

**Methods:** Parents of children with ASD aged 12 years and younger were recruited from the Simons Foundation Powering Autism Research Knowledge (SPARK) Research Match (RM) program. Parents completed a series of questionnaires about their demographics, experiences with genetic testing, and the *Revised Illness Perception Questionnaire for Autism Spectrum Disorder* (IPQ-R-ASD), a measure of attributions related to ASD.

**Results:** 231 parents have completed the survey at the time of abstract submission, with data collection ongoing. Our sample is socioeconomically diverse with regard to income (e.g., 44% reported annual household income below the U.S. median). Participants were recruited using purposeful sampling, resulting in a relatively equal number of participants who did and did not complete genetic testing. Almost all (90%) parents expressed interest in genetic testing; however, only 137 (59%) reported their child actually received genetic testing after receiving a referral. Based on IPQ-R-ASD results, parents endorsed varied etiological beliefs related to their child's ASD on the Causal scale (e.g., genetics, stress at birth, will of God, vaccines), as well as several symptoms they attributed to their child's ASD on the Identity scale (e.g., behavioral dysregulation, social interaction difficulties, repetitive behaviors, withdrawal). Chi-squared tests of independence will permit exploration of relationships between (a) ASD etiological beliefs and positive/negative perceptions about genetic testing; and (b) observed symptom attribution and genetic testing perceptions. Forthcoming binomial logistic regression analyses will be conducted to model the relationship between the predictor variables (opinions about genetic testing, causal attributions, observed symptom attribution, income) and completion of genetic testing.

**Conclusions:** Results of this study will contribute novel insight into the relationship between parents' perceptions about ASD and their receptivity to genetic testing, as well as the influence socioeconomic factors may have upon differences in these relationships. Such results can inform providers' knowledge of parental decision-making regarding genetic testing, ultimately equipping them to better support families raising children with ASD.

### 411.128 (Poster) Effects of Anxiety and Social Impairment on Quality of Life in Autistic Children

## Background:

Quality of life (QoL), or an individual's subjective perception of their personal well-being across multiple domains, has been shown to be diminished for children on the autism spectrum. Greater severity of core autism symptoms is associated with reduced quality of life in both children and adults. Additionally, approximately 40% of ASD youth are affected by anxiety, which can further reduce quality of life. However, few studies have examined the impact of co-occurring psychopathology on QoL within ASD youth. Examining how autism and anxiety interact can inform targeted treatments and clinical care for an improved quality of life in autistic individuals.

## Objectives:

To examine the associations between quality of life and social impairment in children with ASD with co-occurring anxiety disorders.

## Methods:

Subjects included 82 children years 8-15 with ASD and comorbid anxiety disorders ( $M=11.45$ ,  $SD=1.79$ ; 63 boys, 19 girls). ASD diagnosis was confirmed using the ADOS-2 and ADI-R. Co-occurring psychopathology was assessed using the Anxiety Disorders Interview Schedule based on DSM-5 criteria. Quality of life was assessed using the parent report of the Pediatric Quality of Life Inventory 4.0 (PedsQL), which has excellent reliability and validity in autistic youth. The Social Responsiveness Scale Second Edition (SRS-2) was used as a measure of core ASD symptoms. The parent-report of the Multidimensional Anxiety Scale Second Edition (MASC-2) was used as a measure of anxiety symptoms. Multivariate regression models were conducted in R in which the severities of anxiety (MASC-2 total score) and ASD (SRS-2 total score) symptoms were modeled as continuous variables with QoL (PedsQL total score). Analyses controlled for age, IQ, and emotion control (Emotion Regulation Index scale, BRIEF-2). Given the developmental impacts of social functioning and emotional control on QoL, age-related effects were tested using SRS-2-by-age and MASC-2-by-age interactions.

## Results:

Significant negative correlations were found between total MASC-2 and PedsQL scores ( $r=-0.4$ ,  $p=0.00025$ ) and total SRS-2 and PedsQL scores ( $r=-0.39$ ,  $p=0.00037$ ) (**Figure 1**). Post hoc tests showed that these correlations were consistent across all PedsQL subscale domains (emotional, school, social, and physical functioning). Multivariate linear modeling analyses showed SRS-2 as a significant predictor of QoL across all domains with a significant interaction with age ( $\beta=-1.8$ ,  $t=-2.5$ ,  $p=0.01$ ). No significant interaction of age was observed between anxiety symptoms and QoL ( $\beta=0.22$ ,  $t=0.3$ ,  $p=0.76$ ). Supplemental analyses of the SRS-2-by-age interaction found that for older autistic children ( $\geq 12$  years of age), greater social impairment was associated with reduced QoL ( $p<0.0001$ ) but not for younger autistic children ( $<12$  years,  $p=0.7$ ) (**Figure 2**). Post hoc tests further showed that this interaction (SRS-2-by-age) was driven by the SRS-2 Social Communication and Interaction subscale, which measures social impairments, but not the Restricted Interests and Repetitive Behavior subscale.

## Conclusions:

These findings demonstrate that while anxiety contributed to reduced QoL across all ages in autistic children, social impairment indexed by SRS-2 contributed to reduced QoL only in older but not younger children. For older autistic children, social cognitive impairment may reduce QoL by hindering development of age-appropriate social perception abilities or by increasing awareness of social deficits.

### 411.129 (Poster) Stakeholder Opinions on Neurodiversity and Autism Intervention

**P. Dwyer<sup>1,2,3</sup>, S. K. Kapp<sup>4,5</sup>, K. Gillespie-Lynch<sup>6,7</sup>, D. S. Chang<sup>1,2</sup> and S. M. Rivera<sup>1,2,3</sup>**, (1)Department of Psychology, University of California, Davis, Davis, CA, (2)Center for Mind and Brain, University of California, Davis, Davis, CA, (3)MIND Institute, UC Davis Medical Center, Sacramento, CA, (4)Department of Psychology, University of Portsmouth, Portsmouth, United Kingdom, (5)Center for Interaction, Development and Diversity, University of Portsmouth, Portsmouth, United Kingdom, (6)Department of Psychology, College of Staten Island, City University of New York, Staten Island, NY, (7)The Graduate Center, City University of New York, Staten Island, NY

---

**Background:** The neurodiversity movement (NDM) is intensely controversial, a situation arguably exacerbated by confusion over its meaning. Some claim the NDM rejects all supports (e.g., Jaarsma & Welin, 2012), whereas others suggest the NDM encourages environment-focused supports and allows some individual-focused intervention (e.g., Chapman, 2021).

**Objectives:** This study aims to clarify opinions of NDM supporters and opponents, so that future debate can avoid exchanges based on false premises.

**Methods:** 501 autism stakeholders – 275 autistic adults, 159 parents (51 autistic), 75 other family members (44 autistic), 120 professionals (33 autistic), and 100 researchers (41 autistic) – completed an online survey.

NDM support was measured using 5 items (e.g., “I’m glad to be a supporter of the neurodiversity movement”) adapted from Nario-Redmond et al. (2013).

The 35-item Autism Intervention Attitudes Scale (AIAS) measured perceived appropriateness of intervention targets. Principal axis exploratory factor analysis suggested 5 factors (normalization, adaptive skills, well-being, societal reform, and supportive environments).

Participants were asked questions about whether disability-related challenges were personal or environmental (causal attributions), and whether intervention should focus on the person or the environment. Some questions were abstract (2x2 within-subjects: with/without co-occurring intellectual disability (ID), children/adults) and others followed six concrete vignettes describing specific situations (2x2 between-subjects: with/without co-occurring ID, highlighting/not highlighting environmental barriers).

Results: NDM support was elevated among autistics,  $p=.001$ , Cliff's  $\delta=.17$ .

NDM support negatively predicted endorsement of normalization, Spearman  $\rho=-.40$ , and adaptive skills goals,  $\rho=-.30$ ,  $ps<.0001$ , but was positively associated with approval of societal reform,  $\rho=.37$ , supportive environments,  $\rho=.35$ ,  $ps<.0001$ , and well-being,  $\rho=.10$ ,  $p=.02$ .

Self-identification as autistic negatively predicted support for normalization  $\delta=-.54$ , adaptive skill  $\delta=-.53$ , and wellbeing interventions,  $\delta=-.17$ , but positively predicted endorsement of supportive environments,  $\delta=.25$ ,  $ps<.0001$ . Autistic/non-autistic differences on societal reform were nonsignificant,  $p=.07$ ,  $\delta=.09$ .

In abstract questions, childhood/adulthood did not affect intervention preferences,  $p=.61$ , but participants were *less* likely to prefer person-focused interventions for autistic individuals with ID,  $p=.03$ . In concrete vignettes, ID did not influence intervention preferences,  $p=.58$ .

Respondents focused more on the environment (vs. the individual) in their *causal attributions* than in their *intervention preferences* in concrete vignettes,  $p<.0001$ , though not in abstract questions,  $p=.09$ . The magnitude of this effect grew as NDM support increased,  $p<.0001$ .

Conclusions: Autistic participants supported NDM only slightly more strongly than non-autistic respondents. Both groups were equally supportive of societal reform, but autistics more strongly opposed normalization. NDM supporters showed reduced endorsement of normalization or adaptive skills goals (i.e., changing individuals), but support for adaptive skills was higher than for normalization (see table).

Respondents viewed environment-focused interventions as relatively *more* useful for individuals with co-occurring ID, challenging the presumption that the NDM is inappropriate for people with ID.

Respondents – especially NDM supporters – appeared to believe person-focused interventions can sometimes be appropriate even when environmental barriers are the cause of challenges. This could imply greater potential for NDM supporters and opponents to find common ground on practice; however, NDM supporters' pragmatism in adopting individual solutions for societal problems suggests the enormity of social ills affecting the autism community.

#### **411.130 (Poster)** The Broader Autism Phenotype and Young Adults' Perceived Barriers to Education and Employment: The Moderating Role Parent and Sibling Dynamics

A. Jensen, Brigham Young University, Provo, UT

##### **Background:**

Research highlights that young adults with autism face significant challenges in obtaining higher education (e.g., Bakker et al., 2019) and employment (e.g., Chen et al., 2015). Based on these associations, young adults with autism may perceive greater barriers to education and employment. It may be characteristics of autism that drive these patterns rather than the diagnosis itself. Parents and siblings can play an important role in helping young adults achieve successful markers of development (e.g., Jensen et al., 2018) such as education and employment. It is possible that parent and sibling relationship dynamics may mitigate or enhance the possible links between characteristics of autism and perceived barriers to education and employment.

##### **Objectives:**

The current study extends this literature and examines the link between characteristics of autism and marked by the broader autism phenotype (BAP) and young adults' perceived barriers to education and employment. Additionally, we examined how siblings may potentially mitigate or enhance these links through sibling support and perceived parental favoritism.

##### **Methods:**

Data come from 738 young adults living in the United States, surveyed via Amazon Mechanical Turk. Participants ranged between 18 and 29 years old ( $M\ age = 25.40$ ,  $SD = 2.53$ ). The sample was mostly female (57%) and Caucasian (73%). Participants reported on their own BAP characteristics using the Autism Spectrum Quotient questionnaire (Baron-Cohen et al., 2001), perceived parental favoritism, support received from a sibling, perceived barriers to education, and perceived barriers to employment.

##### **Results:**

Analysis was conducted in separate hierarchical regression models for each dependent variable: perceived barriers to education and perceived barriers to employment. In the first step we included demographics (of the parent and participating young adult), sibling structural factors (e.g., age spacing, birth order, sex composition), support received from a sibling, perceived maternal favoritism, perceived paternal favoritism, and their BAP characteristics.

Results for barriers to education and employment revealed (see Table 1) that young adults' BAP characteristics were positively associated with perceived barriers to education and employment. In both models, this effect was qualified by an interaction with maternal favoritism (see Figure 1). For young adults who believed that they were not favored by their mother, there was no association between BAP characteristics and perceived education or employment barriers. For young adults who believed they were their mothers' favorite, BAP characteristics were positively linked with perceived barriers to education ( $b = .05$ ,  $se = .01$ ,  $p < .001$ ) and employment ( $b = .06$ ,  $se = .01$ ,  $p < .001$ ).

## Conclusions:

Overall, these results suggest BAP characteristics are linked to the perception of greater barriers to education and employment. Young adults with more characteristics of autism believe that it will be harder for them to gain an education and be employed in work they would like to do. Parents may play a role in this process as the link between BAP characteristics and perceived barriers may be stronger for those who believe they are favored by their mother.

### 411.131 (Poster) The Experience of Parents of Children with Neurodevelopmental Disorder during the First Wave of COVID-19 Pandemic: Preliminary Quantitative and Qualitative Cross-Cultural Findings

**M. Giannotti<sup>1</sup>**, **N. Mazzoni<sup>1</sup>**, **A. Bentenuto<sup>1</sup>**, **F. Filosi<sup>2</sup>**, **G. Iandolo<sup>3</sup>**, **M. Facchini<sup>4</sup>**, **L. Strathearn<sup>5</sup>**, **K. Zarei<sup>6</sup>** and **S. De Falco<sup>1</sup>**, (1)Department of Psychology and Cognitive Science, University of Trento, Rovereto, Italy, (2)University of Trento, ROVERETO, Italy, (3)Universidad Europea de Madrid., Madrid, Spain, (4)University of Trento, Rovereto, Italy, (5)Baylor College of Medicine, Houston, TX, (6)Center for Disabilities and Development, University of Iowa Stead Family Children's Hospital, Iowa City, IA

---

**Background:** Parenting a child with neurodevelopmental disorder (NDD) may have entailed additional challenges during the first wave of COVID-19 pandemic due to the sudden changes in family routines and the suspension of support from school and healthcare services. Although recent findings on this topic documented higher levels of parental burden, the role of culture and other potential predictors of parental stress in families of children with NDD remains poorly understood. Moreover, quantitative findings have been focused on negative aspects related to the pandemic, and little is known about potential family resilience factors associated with the experience of home confinement.

**Objectives:** The current study examined factors associated with parental stress during the first wave of pandemic in Italian, Spanish and American families of children with NDD. Specifically, we tested the predictive role of culture as well as the effect of parent, child, and contextual dimensions on parental stress. Second, for a better understanding of family adjustment we qualitatively explore parental responses about their experience of COVID-19 home confinement with their child.

**Methods:** Parents ( $N = 143$ ) of children with NDD aged from 3 to 17 years old from Italy ( $n = 85$ ) Spain ( $n = 27$ ) and United States ( $n = 31$ ) completed an online survey during the first wave of the COVID-19 pandemic. Data on sociodemographic characteristics, parental stress and mental health, child externalizing behaviors and contextual variables were collected using an online cross-sectional survey. In addition, a specific open question on parenting a child with NDD during the home confinement was qualitatively assessed through content analysis.

**Results:** Parents reported higher level of parental stress during home confinement compared to the period before COVID-19 home confinement ( $p < .05$ ) regardless of culture. No effect of culture was found in determining parental stress levels during COVID-19. By contrast, child age, parent mental health, child externalizing behaviors and pre-COVID-19 levels of parental stress emerged as significant predictors of parental stress during the pandemic. ( $p < .05$ ). Qualitative analysis showed that beyond negative aspect such as the perceived lack of support, the psychological and relational difficulties, parents also acknowledged the opportunity of spending more time with their children reporting higher parental self-efficacy and adaptive attitudes.

**Conclusions:** Our findings suggest paying great attention to families of children with NDD that undergo home confinement planning specific support intervention for parents and children. Ensuring continuity of care for children with NDD by activating telehealth interventions during period of lockdown and restrictions is of primary importance. Resilience factors in families of children with NDD should be also considered to tailor personalized intervention in case of future pandemic outbreaks.

### 411.132 (Poster) The Impact of the COVID-19 Pandemic on Caregivers of Autistic Children

**C. M. Perry<sup>1</sup>**, **J. E. Goldblum<sup>2</sup>**, **C. Harrop<sup>3</sup>**, **A. R. Dallman<sup>1</sup>** and **B. A. Boyd<sup>4</sup>**, (1)Department of Allied Health Sciences, University of North Carolina at Chapel Hill, Chapel Hill, NC, (2)Department of Psychology and Neuroscience, University of North Carolina at Chapel Hill, Chapel Hill, NC, (3)Department of Allied Health Sciences, University of North Carolina - Chapel Hill, Chapel Hill, NC, (4)Juniper Gardens Children's Project, University of Kansas, Kansas City, KS

---

**Background:** Given the unprecedented nature of the COVID-19 pandemic, autistic individuals and their families faced a host of challenges. Caregivers adjusted to these changes while fulfilling a multitude of caretaker roles to help their children cope with the "new normal". Caregiver stress levels increased during this time as many felt they were unable to meet the overlapping needs of both work and homelife (Waite & Creswell, 2020). Due to the uncertainty of the pandemic, routines were greatly disrupted for autistic individuals and their families who tend to rely on

structured routines to adapt to unpredictability and change (Sethi et al., 2019). Therefore, familial stress and mental health concerns for both caregivers and children increased during this time (Westrupp et al., 2015).

**Objectives:** Using a qualitative approach, we explored the impact of the COVID-19 pandemic on caregivers of autistic individuals (ages 10 to 17 years). Through examining the mental health and well-being of caretakers of autistic children, we hoped to gain a greater understanding of how to effectively support vulnerable families through times of crisis.

**Methods:** A subset of caregivers drawn from the larger Project BIDD study (Bodfish et al., 2021; Jones et al., 2021) were invited to take part in a follow-up study examining the impact of the COVID-19 pandemic on families of autistic children. Caregivers were invited to participate in one of three semi-structured virtual focus group interviews conducted via Webex. Each group was led by a primary and secondary facilitator and lasted ~80 minutes. The main topics of discussion included family routine changes, caretaker roles, homelife stress, social support, and child behaviors all in context of COVID-19. Data analysis involved several rounds of coding guided by the principles of an interpretative phenomenological analysis (IPA) framework (Smith et al., 2009). Codes were organized into themes and sub-themes using NVivo 12 Software.

**Results:** A total of 11 female-identifying caregivers of autistic children participated in our virtual focus groups. While caregivers faced challenges juggling their roles and responsibilities and adapting to disrupted routines, their biggest reported stressor was a lack of external support during the pandemic. With COVID-19 safety protocols in place, most children were unable to receive outside support from their usual special education teachers, therapists, and aides. Caregivers described how their families were also isolated from the help of any relatives or close friends. Without these support systems, caregivers were left feeling overwhelmed and alone.

**Conclusions:** The COVID-19 pandemic caused caregivers of autistic children to experience an increasing amount of homelife stress. To gain a better understanding of the caregiver experience, efforts should be placed on implementing caregiver support systems and gathering information directly from the autistic community. Researchers should use the experience of this pandemic to establish prevention and interventions efforts that can be effectively executed in future crisis situations, both at global and local support levels.

**411.133 (Poster)** The Influence of Parent Experience: Investigating the Association between Parent Experiences and Parent-Reported Behaviours of Their Autistic Child

---

**Background:**

Autism spectrum disorder (ASD) is a neurodevelopmental disorder that is characterized by social communication difficulties and restricted and repetitive behavioral patterns (American Psychiatric Association, 2013). Numerous aspects associated with parenting an autistic child have been demonstrated to influence levels of burden that may contribute to parent stress, including: impaired social communication skills (Russel & McCloskey, 2016) that influence feelings of isolation between a family and their autistic child, isolation from friends and family (Gorlin et al., 2016), problem behaviours, financial requirements, and access to care (Shepherd et al., 2018). Previous research has found that parents with an autistic child report higher levels of burden, which is associated with perceived parenting self-efficacy (Weiss et al., 2016). While many studies have investigated parental stress or efficacy of those with autistic children, few have assessed the family's experience quantitatively; this has been addressed with the recent development of the Autism Family Experience Questionnaire (AFEQ; Leadbitter et al., 2017). Further, little research has addressed the association between family experience and the autistic child's developmental skills.

**Objectives:** To address this, we focused on the relationship between parental reports of their experience as a parent of an autistic child, and their report on their autistic child's development. We hypothesized that lower parental experience scores, representing a more negative perceived experience, would be associated with lower scores in parent-reported child development.

**Methods:** This study used data from the pilot phase of the *Pediatric Autism Research Cohort (PARC) Project*. The sample recruited included 91 children diagnosed with ASD (76 boys); mean age at study enrolment was 49.01 months (SD=9.23). Assessments were completed at 5 time points: Time 1 (baseline/at enrolment) and Times 2-5 at approximately 6-month intervals post-baseline.

**Results:** Data were analyzed for children who completed the AFEQ using correlation analysis, followed by a Fisher's z transformation to assess differences between timepoints. Preliminary results indicate a significant association between parental reports on their parenting experience (AFEQ1) and their child's development (AFEQ3) at time 4 and time 5 (Table 1) and a significant difference between correlations of time 3 and 4 (Table 2). No other significant differences were found.

**Conclusions:** Results suggest that there may be an association between how parents feel about their parenting experience and parent-reported development in their autistic child; however, it may not be evident until the child is slightly older and/or has carried their ASD diagnosis for more than 2 years. Further, the significant difference between time 3 and 4 may indicate an important time period in the relationship between parent's

perceived family experience and their autistic child's development, or at least their perception of this development, that requires further investigation. Results from this study will inform the full-phase PARC study following full data collection. Additionally, results may help to further understand the relationship between family experiences of having an autistic child and the autistic child's development as perceived by their parents; this understanding may be important when adapting or developing support for these families and the autistic child.

**411.134 (Poster)** The Large-Scale Shift to Telehealth Delivery in Part C Services during the Pandemic: Provider and Caregiver Perspectives  
**A. Bravo<sup>1</sup>, L. V. Ibanez<sup>2</sup>, C. C. Dick<sup>3</sup>, S. Scott<sup>4</sup>, P. Carpentier<sup>2</sup> and W. L. Stone<sup>1</sup>,** (1)College of Education, University of Washington, Seattle, WA, (2)UW READi Lab, Seattle, WA, (3)Psychology, University of Washington, Seattle, WA, (4)University of Washington, Seattle, WA

---

#### Background:

Infants and toddlers at risk for autism spectrum disorder (ASD) are eligible for early intervention (EI) through Part C of the Individuals with Disabilities Education Act (IDEA, 2004). Telehealth shows promise for increasing access to providers who specialize in ASD; however, reported barriers to telehealth include a lack of provider training in virtual service provision and poor access to reliable and high-speed internet for families (Romsetty & Adams, 2020).

The pandemic required EI programs to pivot to telehealth as a primary service model. The rapid shift without an existing blueprint to follow did not allow for an optimally planned, phased implementation approach, which may have implications for experiences and attitudes towards telehealth in EI.

#### Objectives:

This study aimed to characterize changes to EI services brought about by the transition to telehealth from the perspective of providers and caregivers of children at-risk for ASD.

#### Methods:

Providers and caregivers from three EI agencies completed a *Pandemic Telehealth Survey* created by the second and last authors. Participants were recruited from an ongoing study about EI services for children at-risk for ASD.

EI providers ( $n=39$ ) responded to open-ended questions about pandemic-related changes in child- and caregiver-specific strategies used, session content, and recommendations to improve telehealth services. Providers rated how the frequency and duration of visits, amount of time spent working with the child and the caregiver, child progress, and perceived caregiver engagement had changed. Response options were "overall increase," "overall decrease," "mixed," and "no change."

Caregivers ( $n=14$ ) responded to open-ended questions about pandemic-related changes to session interactions with providers and their child, advantages and disadvantages of telehealth, and recommendations to improve the telehealth experience. Caregivers rated how the duration of visits, topics covered, and satisfaction with and value of services had changed. Response options were "overall increase," "overall decrease," "no change," and "not sure."

Descriptive statistics were used to examine item ratings and qualitative analysis was used to examine open-ended responses. Qualitative analysis used a systematic and iterative approach of affinity diagramming (Kawakita, 1992), codebook development, and independent coding and review.

#### Results:

Many providers reported briefer (48%) and less frequent (50%) sessions, increased time spent coaching caregivers (75%), decreased time working directly with children (93%), no change in time spent addressing child goals (54%), and increases and decreases across clients regarding child progress (56%) and caregiver engagement (54%).

Most caregivers reported briefer sessions (64%), with many indicating no change in frequency (46%). The majority of caregivers indicated that discussion of daily routines increased (55%), time spent addressing therapy goals decreased (64%), observation of providers decreased (82%), and the value of services decreased (55%).

Ten themes emerged from provider responses to open-ended questions (see Table 1) and ten themes emerged from caregivers (see Table 2).

#### Conclusions:

Providers and caregivers expressed unique points of view surrounding caregiver coaching, child improvements, and the value of telehealth services. This study provides important insight into areas of need for building EI provider capacity for and improving the quality of telehealth for caregivers and children at-risk for ASD.

**411.135 (Poster)** Exploring Factors That Contribute to the Quality of Life in Mother and Fathers of Children with Autism Spectrum Disorder  
**H. Behr<sup>1</sup>, R. Hock<sup>2</sup>, B. C. Aaron<sup>3</sup> and A. Rovane<sup>4</sup>,** (1)College of Social Work, The University of South Carolina, Columbia, SC, (2)University of South Carolina, Columbia, SC, (3)College of Social Work, University of South Carolina, Columbia, SC, (4)Psychology, University of South Carolina, Columbia, SC

---

**Background:** Parents of children with Autism Spectrum Disorder report significantly poorer quality of life (QoL) than the general population. To address this public health concern, it is necessary to examine malleable factors that contribute to quality of life (QoL) in this population. A potentially valuable area of inquiry is parents' style of interacting with their child and their co-parent. Researchers suggest that parents of children with ASD have greater difficulty resolving conflict, which is associated with lower couple relationship satisfaction and more frequent conflict. These findings could suggest that coparenting conflict resolution skills affect QoL for this population. Researchers found that parents with authoritarian and permissive parenting styles experienced greater stress than authoritative parents. An investigation of QoL must consider the different pathways for mothers and fathers of children with autism.

**Objectives:** This study explores whether dimensions of parenting style (laxness and over-reactivity) and coparent conflict communication contribute to QoL for mothers and fathers of children recently diagnosed with ASD.

**Methods:** Caregivers of children (ages 2-8) with a recent diagnosis of ASD were recruited from family support organizations. To be eligible, the parents were required to share parenting responsibilities with a coparent, and their child was diagnosed within the past 12 months. Mothers (n=30) and fathers (n=28) completed questionnaires about child characteristics, mental health, and family relationships. QoL was measured using the Quality of Life in Autism Questionnaire (Eapen et al., 2014). Coparent conflict resolution skills were measured with Psychological Aggression and Negotiation subscales of the Conflict Tactics Scale (Straus et al., 1996). Parenting Styles were measured using the laxness and over-reactivity subscales of the Parenting Scale (Arnold et al., 1993). Two hierarchical regression models were constructed to test whether parenting styles predicted quality of life in mothers (Model 1) and fathers (Model 2). In step 1 of each model, parenting style variables were included as predictors, controlling for child behavior. In step 2, coparenting conflict variables were added to the model.

**Results:** In Model 1, no parenting style variables significantly predicted QoL for mothers in step 1. In step 2, psychologically aggression ( $b = -.46$ ,  $p = .01$ ) and negotiation ( $b = .48$ ,  $p = .007$ ) conflict styles were significant predictors for quality of life, predicting 36.7% of overall variance in quality of life. In Model 2, no parenting style variables significantly predicted quality of life for fathers in step 1. In step 2, lax parenting style approached significance ( $b = -.35$ ,  $p = .09$ ), but no conflict styles were significant predictors for quality of life. Model 2 predicted 20.3% of overall variance.

**Conclusions:** Study findings highlight the differential relationships between parenting style, coparent conflict and QoL for mothers and fathers of children recently diagnosed with ASD. For mothers' higher QoL was associated with more use of negotiation tactics and lower use of psychological aggression during coparent conflict. In contrast, higher QoL for fathers was associated with less laxness in parenting. Future longitudinal and intervention research should explore the directionality of these relationships to inform future family-based service delivery.

**411.136 (Poster)** Exploring the Contributions of Child Challenging Behaviors and Coparenting on Stress in Mothers and Fathers of Children Diagnosed with Autism  
**B. C. Aaron<sup>1</sup>, R. Hock<sup>2</sup>, H. Behr<sup>3</sup> and A. Rovane<sup>4</sup>,** (1)College of Social Work, University of South Carolina, Columbia, SC, (2)University of South Carolina, Columbia, SC, (3)College of Social Work, The University of South Carolina, Columbia, SC, (4)Psychology, University of South Carolina, Columbia, SC

---

**Background:**

Researchers have found that parents of children with ASD report high levels of stress. The stress and strain of parenting can be intensified when a child has special needs and requires more time and effort (Brobst, Clopton, & Hendrick, 2009). Parents of children with ASD experience significantly more stress than parents of children who have other neurodevelopmental disabilities; furthermore, and mothers reported more stress related to their child's temperament and behavioral characteristics than did the fathers (Grebe et al., 2021). Research on families with children with ASD indicates that partner support is associated with reduced parent stress (Boyd, 2002; Dunn et al., 2001; May et al., 2015) and lower levels of child challenging behaviors and symptoms (Hock & Ahmedani, 2012).

**Objectives:**

This study seeks to explore if child challenging behaviors contribute to strain for both mothers and fathers of children with ASD; and if coparenting quality acts as a buffer against strain for both mothers and fathers of children with ASD.

**Methods:**

*Measures*

Coparenting was measured using the coparent agreement subscale of the Coparenting Relationship Scale (Feinberg et al.). Child behavior challenges were measured using the sensory/perceptual approach and aggressiveness sub-scales of the Pervasive Developmental Disorder Behavior Inventory (Cohen & Sudhalter).

*Participants*

Caregivers of children (ages 2-8) with a recent diagnosis of ASD were recruited from family support organizations, diagnostic clinics, and pediatric offices. To be eligible, the parents were required to share parenting responsibilities with a co-parent, and their child was diagnosed within the past 12 months. Mothers (n=30) and fathers (n=28) completed questionnaires about child characteristics, mental health, and family relationships.

#### Data Analysis

Two hierarchical regression models were used to predict caregiver strain for mothers (Model 1) and fathers (Model 2). In the first step, child sensory/perceptual approach and aggressiveness were added. In the second step, coparent agreement was added to the model.

#### Results:

Separate hierarchical regression models were used to predict caregiver strain for mothers and fathers separately. In the first step, child sensory/perceptual approach and aggressiveness were added. For mothers, this model was statistically significant,  $F(2, 27)=5.084$ ,  $p=.013$ ,  $R^2_{adj}=.220$ . Coparent agreement was added in the second step, which improved the model fit,  $F(1, 26)=9.497$ ,  $p<.001$ ,  $R^2_{adj}=.458$ . Child aggressiveness contributed significantly in the first step ( $Beta=.544$ ,  $p=.024$ ), while only coparent agreement contributed significantly in the final model ( $Beta=.627$ ,  $p=.001$ ). For fathers, neither model significantly predicted caregiver strain.

#### Conclusions:

This study's findings add to previous research demonstrating that mothers' and fathers' experience of caregiving strain is influenced by different factors. Challenging behaviors are associated with strain for mothers, but not fathers. Researchers have attributed higher levels of stress to the larger role mothers historically played in daily care for children with ASD (Davis & Carter, 2008). Greater coparent agreement is associated with reduced caregiver strain for mothers, after controlling for challenging child behaviors. This finding points to the potential value of attending to the coparent relationship in ASD services such as diagnosis and parent training. Additional research is needed to understand the support needs of fathers.

#### **411.137 (Poster) Service Encounters: Service Provision and Difficulty Experienced When Attempting to Access Appropriate Treatment and Educational Services in Uruguay**

**M. Montenegro<sup>1</sup>, J. Robles<sup>1</sup>, G. Garrido<sup>2</sup>, D. Valdez<sup>3</sup>, A. Rosoli<sup>4</sup>, C. Amigo<sup>5</sup>, S. H. Cukier<sup>6</sup>, C. S. Paula<sup>7</sup>, R. A. Garcia<sup>8</sup>, A. Rattazzi<sup>6</sup> and C. Montiel-Nava<sup>9</sup>,** (1)University of Texas Rio Grande Valley, Edinburg, TX, (2)Universidad de la República, Montevideo, Uruguay, (3)Facultad Latinoamericana de Ciencias Sociales sede Argentina, Buenos Aires, Argentina, (4)Projects, Organizacion Estados Iberoamericanos, Santo Domingo, Dominican Republic, (5)Clinica de psiquiatria pediátrica Facultad de medicina, UDELAR, Montevideo, Uruguay, (6)PANAACEA, Buenos Aires, Argentina, (7)Developmental Disorder Program, Universidade Presbiteriana Mackenzie, São Paulo, Brazil, (8)Clínica Las Condes, Santiago, Chile., Santiago, CHILE, (9)Psychological Science, University of Texas Rio Grande Valley, Edinburg, TX

**Background:** Even when a variety of treatment services for autistic individuals are now more widespread, caregivers are not exempt from experiencing barriers to access, especially for those that live in low- and middle-income countries like Uruguay autistic individuals oftentimes are only able to access insurance covered treatments, which are not always the most effective. It is thus imperative to understand not only type of services being provided to individuals in Uruguay, but to assess individual and contextual characteristics of those expressing difficulty accessing appropriate services for their autistic children.

**Objectives:** The present study attempts to first better understand types of services being provided to autistic individuals in Uruguay and compare them to service provision in other Latin American countries. Secondly, it tries to identify child and caregivers' characteristics and contextual factors to ascertain their effect on caregiver's endorsement of difficulty when attempting to ensure appropriate treatment and educational services.

**Methods:** The current study examines the experience of 351 caregivers of autistic individuals residing in Uruguay. Analysis included a chi-square test for association between age, functional level and type of services received. Then, a binomial logistic regression was performed to ascertain the effects of child characteristics (e.g., age, functional level, challenging behaviors), caregivers' characteristics (educational level, perceptions), and contextual factors (e.g., service payment, insurance type) on the likelihood of experiencing difficulty when attempting to access appropriate treatment and educational services for autistic children.

**Results:** In Uruguay, the service most commonly received by autistic individuals is psychomotor therapy (73.9% of the sample). When assessing predictors for likelihood of referring difficulty ensuring appropriate treatment for autistic child, the built model was statistically significant ( $X^2(27)=113.19$ ,  $p<0.001$ ). Predictors that significantly added to the model were caregiver education (primary or secondary), importance placed on accessing appropriate services, and challenging behaviors of child (aggression, daily habit difficulty, medical comorbidity, social interaction, repetitive behaviors, communication difficulties, security concerns, and sensory issues). The built model to assess predictors for difficulty ensuring appropriate educational services was statistically significant,  $X^2(22)=102.87$ ,  $p<0.001$ . Predictors that significantly added to this model were caregiver educational level (primary), importance placed on educational services, age functional level of child and child exhibiting aggression, daily habits and eating difficulties, social interaction challenges, poor safety sense.

**Conclusions:** The present study shows that the majority of services received are those financed by state institutions, regardless of their specificity for ASD and the child's specific needs. Specific treatments as well as evidence based once are available to a minority of the population due to cost limitations. Therefore, access to services in Uruguay is mediated by public health policies that offer a limited number of services for persons with ASD. The need to generate awareness and inform about evidence based interventions is crucial.

**Keywords:** ASD, Uruguay, Service Provision, Access Difficulty, Physical Therapy, Age.

**411.138 (Poster)** Baseline Parenting Stress but Not Parent Depression Predicts Growth in Parent Self-Efficacy over the Course of a Parent-Mediated Intervention

**M. Howard<sup>1</sup>, K. M. Frosch<sup>2</sup> and B. R. Ingersoll<sup>2</sup>,** (1)*Psychology, Michigan State University Psychology Department, East Lansing, MI,* (2)*Psychology, Michigan State University, East Lansing, MI*

**Background:** Research has established the important predictive role of parent self-efficacy on child development and outcomes (Albanese et al., 2019). Parent depression and parent stress have both been shown to relate to parent self-efficacy, but the causal relationships among them remain unclear (Jones & Prinz, 2005). Mothers of children on the autism spectrum are prone to higher levels of depression and stress (Baker-Ericzen et al., 2005). However, few research studies have examined predictors of change in parent self-efficacy for families of autistic children. Understanding the role of parent stress and depression on parent self-efficacy over time is important for understanding the impact of parent-mediated interventions (Wainer et al., 2017).

**Objectives:** The goal of this study is to examine the moderating effect of parent depression and stress on change in parent self-efficacy for a group of parents participating in a parent-mediated intervention.

**Methods:** Data were collected from parents of autistic children who participated in a research study examining the efficacy of a low-dose parent-mediated Naturalistic Developmental Behavioral Intervention (NDBI) delivered via telehealth. All caregivers in this study received some form of intervention, which was either self-directed or supported by a coach. Most caregivers were enrolled in additional services outside of the study. Our sample included 46 adults (37 mothers, 1 grandfather, 8 fathers). Parent stress was measured using the Parenting Stress Index-Short Form, and parent depression was assessed using the Center for Epidemiological Studies Depression Scale. Parent self-efficacy was measured using the Parenting Sense of Competence Scale. We evaluated moderators of change in parent self-efficacy using multilevel linear growth models with caregiver as the upper-level unit and trial as the lower-level unit. We hypothesized that parents with lower self-reported indicators of depression and stress at baseline would demonstrate a greater increase in parent self-efficacy over the course of a parent-mediated intervention.

**Results:** Parent depression did not significantly predict average level of self-efficacy over time, nor did it moderate the rate of change in self-efficacy over time. However, we found a significant main effect of parent stress ( $p < .001$ ) such that parents who reported higher stress levels also reported lower self-efficacy on average. There was a significant interaction between time and parent stress ( $p = .017$ ). Parents with low levels of stress (1 SD below the mean) showed no significant change in self-efficacy over time ( $p = .313$ ). Parents with high stress levels (1 SD above the mean) reported significant increases in self-efficacy over the duration of the study ( $p = .016$ ).

**Conclusions:** This research found that parent stress level significantly predicted mean levels of parent self-efficacy over the course of a low-dose NDBI, while parent depression did not. Moreover, baseline parent stress predicted rate of change in self-efficacy, such that higher-stress families reported significant increases in parent self-efficacy over time. Future research should investigate whether the improvement in parent self-efficacy among those high stressed families was a result of the intervention itself or some other factor (e.g., contact with the research team, obtaining an assessment of their child's functioning).

**411.139 (Poster)** Program Evaluation of a Cultural and Recreational Event Serving Families with Individuals on the Autism Spectrum

**G. Perez Liz<sup>1</sup>, A. T. Wieckowski<sup>1</sup>, M. Albaugh<sup>2</sup>, R. Ideishi<sup>3</sup> and D. L. Robins<sup>1</sup>,** (1)*A.J. Drexel Autism Institute, Drexel University, Philadelphia, PA,* (2)*The Philadelphia Orchestra, Philadelphia, PA,* (3)*The George Washington University / School of Medicine & Health Sciences, Washington, DC*

**Background:** Arts-based programs can positively influence psychosocial well-being of children with physical and developmental disabilities and promote opportunities for inclusion. It is important to evaluate social inclusion strategies, as experienced by the end-user, when implementing inclusive programming. Several arts organizations in Philadelphia have implemented initiatives to offer sensory-friendly programming for over a decade. Although this has been an ongoing effort, there is still need for dissemination of the evaluation outcomes of such programs. The Sensory-friendly Community Concert by the Philadelphia Orchestra, organized and executed in partnership with the Eagles Autism Challenge, is a recent initiative to create inclusive recreation and arts. The second annual event occurred in early 2020 and offered a free orchestra concert paired with a family fun event for families with individuals on the autism spectrum and other developmental disabilities; more than 1200 individuals attended.

**Objectives:** To describe and analyze the barriers and facilitators for social inclusion in the design and implementation of a sensory-friendly community concert, based on attendee's experiences.

**Methods:** A survey containing 7 mandatory multiple-option items (demographics and satisfaction with specific aspects of the event), and 6 optional open-ended question items (barriers and facilitators), was administered to concert attendees during the event. Demographic data was collected for sample characterization. Answers to the open-ended questions were categorized, as coded by two investigators. Descriptive statistics were conducted for all variables.

**Results:** A total of 79 responses were collected for the mandatory satisfaction questions, and 39 respondents completed the optional, open-ended barriers/facilitators questions. All participants were >18 years old, 74.7% were female, and 49.53% were parents/family member of individuals with a disability, 26.58% were health professionals, and 8.85% were individuals with a disability. Participants' overall assessment of the event was "Fantastic" or "Really good" (91.1%), and 96.2% responded "Agree" or "Strongly agree" when asked if the event providing a safe, accepting environment for their family. When utilized, respondents agreed that the sensory kit provided (45.6%), the quiet space in the back of the room (51.9%), and the sensory break room (49.4%) fit their families' needs, with 35.4%, 7.6%, and 36.7% indicating they did not utilize those

accommodations, respectively. The most common motivators to attend the event were the opportunity to experience music/cultural programming and factors related to people/community (i.e., having a family member on the autism spectrum, or attending with members of their autism support group). The most frequently endorsed facilitators were factors related to facilities/location. Barriers were not identified for this event; barriers reported for similar events were related to challenges inherent to the individual's disability (e.g., sensory sensitivity). Participants endorsed a sense of community, exposure to music/culture, and factors related to disability inclusion as the greatest benefits of attending the event.

**Conclusions:** Inclusive strategies in arts programming can facilitate attendance and foster participation of families with a member with disabilities. Common barriers to attendance can be addressed by tailoring to specific needs based on the disability. Facilitators to attendance can be embedded into the event's design, such as the choice of venue and its facilities.

**411.140 (Poster) "Weaponized Autism": A Discourse Analysis of Gab Posts**

**C. Welch<sup>1,2</sup>, L. Senman<sup>1</sup>, R. L. Loftin<sup>1</sup>, C. Piccolini<sup>3</sup>, J. Robison<sup>4</sup>, A. Westphal<sup>5</sup>, B. Perry<sup>6</sup>, P. Jachyra<sup>7</sup>, S. Stevenson<sup>1</sup>, J. Aggarwal<sup>1</sup>, J. Nguyen<sup>10</sup>, S. Wijekoon<sup>2</sup>, S. Baron-Cohen<sup>11</sup>, R. Slavny<sup>12</sup> and M. Penner<sup>10</sup>,** (1)University of Toronto, Toronto, ON, Canada, (2)Bloorview Research Institute, Toronto, ON, Canada, (3)Autism, Bloorview Research Institute, Toronto, ON, Canada, (4)Department of Psychiatry and Behavioral Sciences, Feinberg School of Medicine, Northwestern University, Chicago, IL, (5)Free Radicals Project Inc., Chicago, IL, (6)William & Mary, Williamsburg, VA, (7)Child Study Center and Department of Psychiatry, Yale University, New Haven, CT, (8)Ontario Tech University, Oshawa, ON, Canada, (9)Azrieli Adult Neurodevelopmental Centre, Centre for Addiction and Mental Health, Toronto, ON, Canada, (10)Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (11)Autism Research Centre, Department of Psychiatry, University of Cambridge, Cambridge, United Kingdom, (12)University of Cambridge, Cambridge, United Kingdom

**Background:** There is mounting concern that extremist groups, including the alt-right, are intentionally using online content to engage and recruit autistic people. The term "weaponized autism" is frequently used on alt-right platforms and has begun to make its way into mainstream media.

**Objectives:** To understand the meaning of the term "weaponized autism", the realities it represents, and its potential impacts on autistic people.

**Methods:** The dataset included 711 posts from Gab, an online platform known for hate-based discourse. Posts were collected by the Southern Poverty Law Center and had been posted on dates spanning 2018-2019. Posts were filtered for mentions of weaponized autism and variations on this term. The first author was deeply immersed in the data and applied a health-science-informed approach to discourse analysis. This involved examining Gab users' processes for claiming authority, this discourse's relationships with other relevant discourses, the roots and construction of the major concepts and roles enacted, and finally, potential implications for practice. We interrogated the data with specific *a priori* questions at each stage of the analysis. Our interdisciplinary team met at three junctures in the analytic process to enhance and extend the analysis, leveraging our diverse clinical, academic, and experiential knowledge base to further contextualize the findings.

**Results:** Most of the Gab users discussing weaponized autism did not themselves identify as autistic. Rather, 'weaponized autists' were generally spoken of, and sometimes spoken to. We found that the term "weaponized autism" was reflective of highly stereotyped and ambivalent views of autism. 'Weaponized autists' were described as omnipotent masters of technology, who are also socially unskilled. This resulting depiction is of a group of people who are effective weapons to exploit for the aims of the alt-right. Autistic Gab users discussed the exclusion they experience in real life and the relative sense of purpose that was offered in this space. An important limitation relevant to these results, is that the terminology used in alt-right online communities is constantly changing, and the meaning of 'weaponized autism' may have shifted since our posts were collected. Additionally, different platforms and online spaces have their distinct vernacular and so other sites, including those associated with online hate, may have different nuances associated with the term 'weaponized autism'.

**Conclusions:** Within this dataset, 'weaponized autism' is a term used by mainly non-autistic Gab users, indicative of a reductive, stereotyped, and predatory view toward autistic people. Autistic people who experience exclusion in broader society might be more vulnerable to engaging with this identity, which signals the importance of supporting truly inclusive spaces as a protective factor.

## POSTER SESSION — FAMILY ISSUES AND STAKEHOLDER EXPERIENCES

### 424 - Family Issues and Stakeholder Experiences II

**424.055 (Poster) Patterns of Maternal Communicative Behaviors Among Low-Income Chinese Immigrant Mothers of Children with ASD- an Exploratory Study**

**Y. Xu<sup>1</sup>, F. Chen<sup>2</sup> and S. Magana<sup>3</sup>,** (1)Department of Health Sciences Education, University of Illinois College of Medicine at Rockford, Rockford, IL, (2)University of Illinois at Chicago, Chicago, IL, (3)Steve Hicks School of Social Work, University of Texas at Austin, Austin, TX

**Background:**

Around the world bilingual speakers outnumber monolinguals (Kohnert, & Medina, 2009). According to recent census data in the U.S. one in five Americans speak a language other than English at home. Research with mostly monolingual children in the sample had shown that maternal communicative behaviors are associated with language development (Levickis et al., 2014; Rowe, 2012). It is also known that low-resource households, the quality and quantity of parent-child interaction are factors that significantly impact the language development in children (Roberts and Kaiser 2011; Hirsh-Pasek et al., 2015) Research is emerging on the topic of bilingualism and Autism Spectrum Disorders (ASD, Drysdale et al., 2015; Reetzke et al., 2015). However, little is known about maternal communicative behaviors among low-resourced immigrant families of young children with ASD.

## Objectives:

To fill this gap, we collected mother-child interaction video clips from low-income Chinese immigrant families of young children with ASD to explore maternal communicative behaviors in naturalistic settings.

## Methods:

Thirteen Chinese mothers and young children under the age of five with ASD from Chicago and New York metropolitan area were recruited as part of a pilot parent psychoeducational intervention study with Chinese immigrant mothers. To meet inclusion criteria, mothers need to speak Chinese fluently. We used the 138% Federal Poverty Level as the cutoff for “low-income”. We collected data on child’s social communication skills (SCQ), level and frequency of challenging behavior (SIB-R), severity of ASD (CARS-2), home and community language exposure (in English, Mandarin or other Dialect), access to speech therapy, family empowerment and parental stress. Each mother-child dyad was asked to select three daily activities from the following: play with small toys (e.g., cars, figurines, puzzles), play with larger objects (e.g., large ball), play with people, reading a book, caregiving (e.g., changing diaper, washing hands), and house chores. Coding of maternal communicative behaviors will follow Conway et al. (208)’s protocol.

## Results:

We present results for 13 mother-child dyads, who participated the study between January and March of 2021 during the COVID-19 pandemic. The majority of these mothers live in low-income households (54%). Three children were female while 10 were male. Children were on average 3.7 years old ( $SD=1.32$ ), had a mean SCQ of 20.9 ( $SD=5.85$ ), mean SIB-R of 121.3 ( $SD=12.91$ ). Mothers were on average 33.2 years old ( $SD=5.58$ ), PSI-SF had a mean score of 103.7 ( $SD=15.96$ ). Preliminary analysis shows that higher income is marginally associated with child’s higher SCQ scores ( $p=0.057$ ), and SIB-R scores ( $p=0.066$ ). We will further compare if income and other mother or child characteristics have any association with maternal communicative behavior and quality of mother-child interaction.

## Conclusions:

This study explores how Chinese immigrant mothers communicate and interact with their children during a daily activity. Further video analysis will help contribute to the gap of literature on maternal communicative behaviors among low-income Chinese immigrant families of children with ASD. These findings will inform parent educational interventions to help under-served immigrant mothers navigate strategies to support language development of their bilingual children with ASD.

## **424.056** (Poster) Play and Emotional Availability of Fathers of Young Children with ASD: Impact on Development

*S. Perzolli, A. Bentenuto, G. Bertamini and P. Venuti, Department of Psychology and Cognitive Science, University of Trento, Rovereto, Italy*

---

## Background:

Research on fatherhood has focused primarily on fathers of children with typical development, even if recent findings revealed an increasing interest in the investigation of fathers of children with Autism Spectrum Disorder (ASD). Most research on parental interaction focused on mothers, even if a healthy father-child with ASD relationship may have peculiar consequences on child development and child emotional regulation (Rankin et al. 2019; Hirschler-Guttenberg et al., 2016). Recent studies on paternal involvement during treatment showed consistent benefits concerning child’s outcomes (Flippin et al., 2011; Elfert et al., 2015). Despite this, research is still scarce, and it is not yet possible to have a consistent profile about paternal interactive behaviors.

## Objectives:

In line with this, this work wants to analyze paternal behaviors through highly standardized observative tools. Specifically, we aimed to:

1. Investigate father-child affective and play dyadic behaviors
2. Explore systematically the variables that impact on dyadic aspects of play.

## Methods:

Data of 67 fathers and their preschoolers with ASD ( $M$  chronological age= 45.47;  $SD= 12.19$ ;  $M$  mental age= 31.83;  $SD=12.88$ ) were collected through ten minutes of video-recorded play interactions. In order to assess the affective quality, the Emotional Availability Scales (EAS, Biringen et al., 2008) were used. Further, on the same interaction’s sequences, the Play code (O’Reilly & Bornstein, 1993) was employed to assess the levels of both child and fathers’ exploratory and symbolic play. Interactions were coded by two independent observers.

## Results:

Results revealed that fathers display good but non-optimal levels of EA (e.g.,  $M$  sensitivity = 5.11;  $SD=0.89$ ;  $M$  structuring=4.7;  $SD=0.86$ ) despite their children having low levels of responsiveness ( $M=3.76$ ;  $SD=0.88$ ) and involvement ( $M=3.32$ ;  $SD=0.83$ ). Fathers showed more exploratory play ( $M=169$ ;  $SD=108.49$ ) than symbolic play ( $M=37.38$ ;  $SD=46.23$ ), coherently with child’s play behaviors. Child responsiveness is associated with

child's cognitive functioning ( $r=0.39$ ;  $p=0.002$ ;  $BF=25$ ) and symptom severity ( $r=-0.44$ ;  $p<0.001$ ;  $BF=101$ ). Involvement is as well associated with child's cognitive functioning ( $r=0.47$ ;  $p<0.001$ ;  $BF=184$ ) and symptoms severity ( $r=-0.51$ ;  $p<0.001$ ;  $BF>100$ ). Currently we are implementing and evaluating a set of predictive models with validation controls for model selection. Until now, paternal levels of exploratory play seem to be predicted by child's levels of play ( $b=0.31$ ;  $t(57)=3.42$ ;  $p=0.001$ ), suggesting fathers ability to adapt to child's activities ( $F(2,57)=8.79$ ;  $p<0.001$ ).

#### Conclusions:

From a theoretical perspective this study may enhance knowledge about affective and cognitive domains of paternal dyadic characteristics. From a clinical standpoint, these findings might help clinicians in the implementation of optimized and personalized interventions for children with ASD considering paternal and maternal behaviors in a complementary way for the achievement of better developmental outcomes.

#### **424.057 (Poster)** Psychological Functioning and Resilience in Mothers and Fathers of Children with and without Autism Spectrum Disorder during the COVID-19 Pandemic

**C. A. Paisley<sup>1</sup>, R. L. Harmon<sup>2</sup>, A. B. McClain<sup>2</sup>, A. M. Birnschein<sup>2</sup> and T. S. Tomeny<sup>2</sup>,** (1)School of Medicine, University of Colorado, Aurora, CO, (2)Psychology, The University of Alabama, Tuscaloosa, AL

**Background:** Parents of children with Autism Spectrum Disorder (ASD) often experience greater levels of psychological distress than parents of typically developing (TD) children. The COVID-19 pandemic presented unique challenges for all parents due to work from home requirements and decreased childcare. However, the stress and mental health problems parents of children with ASD experience may be different and/or exacerbated during the unprecedented time of the coronavirus pandemic.

**Objectives:** This project aimed to identify how experiences and functioning may have differed for mothers and fathers of TD children and children with ASD in the United States during the COVID-19 pandemic. Specifically, this study examined group and gender differences in anxiety, depression, parental burnout, and resilience.

**Methods:** One-hundred and eighty five parents of children with and without ASD (ages 4 -16 years) self-reported on measures of psychological functioning (*Depression, Anxiety, and Stress Scale – 21*), parental burnout (*Parental Burnout Assessment*) and resilience (*Parenting Resilience Elements Questionnaire*). The ASD group included 88 parents (48 females, 38 males, one non-binary parent, and one unreported gender) and the TD group included 97 parents (55 females, 41 males, and one parent who did not to report gender).

**Results:** Independent samples *t*-test revealed that the ASD group reported higher levels of anxiety,  $t(183) = 9.36$ ,  $p < .001$ , depression,  $t(183) = 8.48$ ,  $p < .001$ , and total burnout,  $t(145.158) = 8.62$ ,  $p < .001$ , than the TD group. A two-way ANOVA showed that fathers reported more depression symptoms than mothers in the ASD group,  $F(1, 178) = 6.63$ ,  $p = .011$ , partial  $\eta^2 = .036$ , and fathers in the TD group,  $F(1, 178) = 55.74$ ,  $p < .001$ . Mothers in the ASD group reported higher depression levels than mothers in the TD group  $F(1, 178) = 24.34$ ,  $p < .001$ , partial  $\eta^2 = .120$ . There was no main effect of gender in anxiety symptoms or total burnout. However, a two-way ANOVA revealed a significant main effect of gender for parental burnout related to emotional distancing,  $F(1, 178) = 8.23$ ,  $p = .005$ , partial  $\eta^2 = .044$ , with fathers reporting higher levels than mothers in the ASD group. Lastly, a two-way ANOVA showed that fathers reported lower levels than mothers in both groups on resilience related to Knowledge of Child's Characteristics,  $F(1, 178) = 10.26$ ,  $p = .002$ , partial  $\eta^2 = .054$ , and Perceived Social Supports,  $F(1, 178) = 7.10$ ,  $p = .008$ , partial  $\eta^2 = .038$ .

**Conclusions:** This study demonstrates that parents of children with ASD reported greater psychological distress compared to parents of TD children during the COVID-19 pandemic. A high percentage of parents in the ASD group reported parental burnout indicating that it is essential for clinicians to assess parents' level of functioning and feelings related to their parenting role. Additionally, results suggest that fathers have experienced more psychological distress and burnout compared with mothers, which highlights the necessary inclusion of fathers in both research and clinical services.

#### **424.058 (Poster)** Risk for Mild Cognitive Impairment in Mothers of Autistic Children

**L. Friedman<sup>1</sup>, A. C. Hickey<sup>2</sup> and J. Klusek<sup>2</sup>,** (1)University of South Carolina, Columbia, SC, (2)Communication Sciences and Disorders, University of South Carolina, Columbia, SC

**Background:** Emerging evidence suggests that mothers of children with disabilities are at risk for accelerated age-related cognitive decline (Song et al., 2016). Mothers of autistic children, specifically, have documented challenges in working memory and verbal fluency. They also experience significant risk factors for age-related cognitive decline, such as high levels of parenting stress. Yet, research to date has not examined risk for mild cognitive impairment (MCI; a transitional zone between normal cognitive function and dementia) among mothers of autistic children, or its relation to parenting stress.

**Objectives:** Objective 1 - Compare mothers of autistic children and control mothers on performance on an MCI screener. Objective 2 - Examine associations between parenting stress and MCI screener performance within mothers of autistic children.

**Methods:** Thirty-one mothers of autistic children and 43 control mothers who were between the ages of 35 and 65 years participated in a virtual assessment as part of a larger study. All participants were fluent English speakers without existing neurological diagnoses (e.g., traumatic brain injury). Examiners completed formal training to administer the Montreal Cognitive Assessment (MoCA), which is a widely-used MCI screener. The MoCA assesses skills such as memory and attention. Test developer recommendations for remote administration were followed. The traditional cut-off for MCI is a score below 26 out of 30. However, this has been criticized as being too high, with a more conservative proposed cut-off of 23. Analyses include both cut-off scores. Parenting stress was measured using the Parenting Stress Index-4, a self-report questionnaire that assesses current life stress related to raising a child. Percentile scores were calculated using normative data. The normative mean is a score of 50; higher scores indicate higher levels of parenting stress.

**Results:** Results from a logistic regression, controlling for age and years of education, indicated that mothers of autistic children were 2.42 times more likely to fall below the cut-off for MCI at a score of 26 on the MoCA (95% CI [0.92, 6.39];  $p = .016$ ). Using the conservative cut-off of 23, mothers of autistic children were 7.13 times more likely to fall below the threshold for MCI (95 % CI [1.4, 36.45];  $p = .016$ ). Within-group analyses examined correlations between parenting stress and the dichotomous MoCA status for both cut-off scores among mothers of autistic children. Findings indicated that parenting stress was not significantly related to either cut-off outcome among the mothers of autistic children (cut-off of 26:  $p = .215$ ; cut-off of 23:  $p = .684$ ).

**Conclusions:** Mothers of autistic children may be at risk for falling below the cut-off for MCI on the MoCA. Of note, this study only used one index of cognitive impairment; though the MoCA is a sensitive measure, future work should include a comprehensive battery of neuropsychological measures to characterize the risk for mild cognitive impairment. Contrary to our hypothesis, parenting stress was not significantly associated with cut-off status. Future research should assess other risk factors of MCI that are common in mothers of autistic children, including poor sleep quality and depression.

**424.059 (Poster) Sensory Processing and Meaningful Community Participation in Autistic Adults**

*N. Bagatell<sup>1</sup>, D. V. Chan<sup>2</sup>, Y. C. Syu<sup>3</sup> and E. M. Lamarche<sup>4</sup>, (1)University of North Carolina at Chapel Hill, Chapel Hill, NC, (2)Allied Health Sciences, University of North Carolina at Chapel Hill, Chapel Hill, NC, (3)University of North Carolina - Chapel Hill, Chapel Hill, NC, (4)TEACCH Autism Program; Psychiatry, University of North Carolina, Chapel Hill, NC*

---

**Background:** Sensory processing differences, commonly reported in autistic children, have been shown to impact involvement in community activities. While research shows that sensory processing differences continue into adulthood, relatively little is known about how these differences affect participation in the community, and whether sensory processing contributes to lower overall rates of community participation (Levy & Perry, 2011; Orsmond et al., 2013; Song et al., 2021).

**Objectives:** This project uses a novel approach (i.e., integration of qualitative interview data, quantitative survey data, and GPS data) to explore how autistic adults' sensory processing patterns contribute to participation in the community, including where people go, how often they are in the community, and their preferred locations.

**Methods:** We report on data gathered from six autistic adults (see Table 1 for demographic information) and their caregivers who participated in two different studies. From Study 1 we reviewed results of the Adolescent and Adult Sensory Profile (AASP; completed by caregivers) and transcripts from a two- part interview with caregivers. The interviews included the Vineland Adaptive Behavior Scales 2 and a semi-structured interview focused on services and future plans. From Study 2, we reviewed GPS tracking data collected over one week and transcripts from structured interviews with the autistic adults focused on community participation. The analysis process for the current investigation involved creating a participant narrative linking sensory processing patterns to community participation.

**Results:** Each participant had a unique sensory processing profile that influenced where people went, the activities in which they engaged, how much time they spent in the community, and their preferred locations (see Table 2). Those whose sensory processing patterns indicated sensory sensitivity and sensory avoiding described the experience of certain environments as overwhelming and fatiguing and thus either spent less time in the community, visited fewer places, or utilized other adaptive strategies than those with other sensory processing patterns. Reviewing the sensory processing and community participation data yielded notable patterns, particularly related to sensation seeking and community involvement. Time in the community, however, was not the only factor related to sensory processing profiles; other factors such as access to transportation, employment status, and living status impacted time spent in the community and community engagement.

**Conclusions:** Results highlight the importance of sensory processing in daily life, especially as it impacts participation in the community. Sensory processing patterns should be considered along with other personal and contextual factors when assessing community participation. It is important to match personal sensory processing patterns with environmental demands. It is also critical that efforts aimed at advocating for sensory-friendly environments consider the variety of sensory processing patterns of autistic adults.

**424.060 (Poster) Stakeholder Input on Opportunities and Challenges Related to Inclusion in Research**

*S. Furukawa<sup>1</sup>, K. Fitzpatrick<sup>1</sup>, A. Wyatt<sup>1</sup>, E. McMillan<sup>1</sup>, E. Turner<sup>1</sup>, C. Taylor<sup>1</sup>, J. Neul<sup>1</sup> and B. A. Malow<sup>2</sup>, (1)Vanderbilt University Medical Center, Nashville, TN, (2)Sleep Disorders Division, Department of Neurology, Vanderbilt University Medical Center, Nashville, TN*

---

**Background:**

Inclusion of people on the autism spectrum in ongoing health research (e.g., trials in vaccines, cardiovascular disease, diabetes, obesity and other areas) is critical to the success of these studies given that they have unique characteristics and add diversity to the study population. To generalize results to the autism community, being inclusive of people with autism is paramount. However, challenges remain related to including this population in research.

**Objectives:** The goal of this initiative was to solicit feedback from community members as well as professionals in an open forum to discuss the opportunities and challenges of representation of people with autism and other intellectual and developmental disabilities (IDD) in research. The findings from this initiative were used to enhance our consultations with researchers at our institution who were interested in including more participants with IDD in their work.

**Methods:** Our Vanderbilt Kennedy Center held a virtual dinner that included medical professionals, researchers, self-advocates, caregivers, and the general public.

Questions were discussed in virtual breakout rooms with small numbers of participants to facilitate input, paired with moderators and notetakers in each room. The questions were:

1. What are the opportunities you see in including individuals with IDD in research?
2. What are the potential barriers?
3. What ideas do you have that might increase people with disabilities in research?

## **Results:**

*For Question 1*, participants emphasized the following opportunities:

- Inclusion is the ideal way to create a more comprehensive understanding of a condition.
- Inclusion in decision-making processes allows for increased awareness and engagement by study participants.
- Diversity of individuals with different characteristics allows for better assessment of how effective study treatments will be.

*For question 2*, participants emphasized the following barriers:

- Participating in research requires effort—including transportation and parking to the research facility, availability of social supports (e.g., childcare, time off from work), and other factors.
- Research protocols may limit flexibility for those with behavioral challenges and anxiety. One parent stated:

"I don't know how our son would sit still in for an MRI or EEG."

- Convincing families that a study is worth their investment.
- Effectively communicating the study details in the consent or assent documents.

*For question 3*, participants provided the following ideas on increasing the number of people with IDD in research:

- Understand the possibility of conducting visits more virtually to decrease the burden of distance, transportation, and availability. COVID-19 restrictions helped advance this possibility.
- Using community networks to recruit, support, and gain public awareness
- Exploring reasonable incentives both in the short term and the long term, such as offering a direct service during recruitment (e.g., clinical consultation), or providing assistance for the entire family to attend (e.g., siblings).
- Equipping researchers with tools to communicate with individuals with IDD, including providing photos and toolkits to show what to expect during a visit or a procedure

## **Conclusions:**

Several points emerged from the discussions to promote inclusion as outlined above. We are incorporating these points into our consultations with researchers to strengthen their inclusive efforts.

**424.061** (Poster) Systematic Review: Parent-Mediated Interventions and Their Impact on Parent's Stress.

**M. Z. Hassan<sup>1</sup>, J. Y. Talbot<sup>2</sup> and C. E. McCormick<sup>1</sup>, (1)Human Development and Family Studies, Purdue University, West Lafayette, IN, (2)Speech, Language, and Hearing Sciences, Purdue University, West Lafayette, IN**

**Background:** Parent mediated interventions (PMIs) are recommended as part of best practices for early intervention programs for children with autism (Zwaigenbaum et al., 2015). PMIs train parents in techniques and strategies that they in turn use to teach their own children. Although there is considerable evidence that PMIs are effective for improving child outcomes, less is known about how this model effects parents and how factors like delivery modality impact parent experiences. This review provides an overview of parent outcomes in the context of PMIs, with a focus on the impact of PMIs on parental stress.

**Objectives:** This review addresses the following questions: 1) Do PMIs improve measures of parental stress? 2) Are parental stress outcomes consistent across cultural contexts? 3) Are parental stress outcomes influenced by intervention delivery modality?

**Methods:** To identify eligible studies, a comprehensive search was conducted on the following databases: PsycINFO (EBSCO), Child Development & Adolescent Studies (EBSCO), CINAHL (EBSCO), PubMed, ProQuest Dissertations & Theses (ProQuest) and World Cat Dissertations Theses (OCLC). Peer reviewed journal articles and dissertations and theses published were included in the search process. Literature in the final review met the following criteria: experimental design, implementation of a PMI, at least one child diagnosed with an Autism Spectrum Disorder between the

age of 0-5 years, and one parental wellbeing measure reported as an intervention outcome measure. Extracted variables included: study design, participant characteristics (e.g., race/ethnicity), intervention model, intervention delivery (modality, dosage, duration), and types of reported outcomes.

**Results:** The search identified 1785 manuscripts on electronic databases and grey literature, of which 79 were included in this review from between the years 1998-2020. Among the 79 manuscripts, 47 measured parental stress as an outcome. Preliminary results indicate parental stress was reduced in 34 (72%) of the manuscripts that measured stress. Eleven manuscripts (14%) reported no change in stress after participating in a PMI and one study from Australia found an increase in stress in the home-based intervention group and a decrease in stress in their center-based intervention group. Parental stress results did not differ for remote and in-person interventions. From the 79 manuscripts, 56 (71%) were conducted in North America, 12 (15%) were conducted in Europe, 9 (11%) were led in Asia, and 2 (3%) were conducted in Australia. Given these demographics, cultural differences were not found in the stress outcomes of parents after participating in a PMI.

**Conclusions:** Despite parents taking on an additional role of an interventionist when participating in a parent-mediated intervention, evidence shows there to be a positive impact on their overall well-being. An increase in knowledge and techniques to understand their child's autism symptoms and behaviors may have given parents more confidence to handle stressful situations and reduce their feeling of stress. Thus, greater involvement by parents in the intervention improves their overall quality of life and wellbeing (Koly et al., 2021). This was also found to be consistent across cultures indicating that when PMIs are translated and tailored to other cultures, they can produce similar positive parental outcomes.

---

**424.062 (Poster)** The Association between COVID-19 Impact and Barriers to Healthcare for Autistic Youth and Their Families

**E. A. DeLucia<sup>1</sup>, M. Fok<sup>2</sup>, J. R. Bertollo<sup>3</sup>, C. G. McDonnell<sup>3</sup> and A. Scarpa<sup>1</sup>,** (1)Department of Psychology, Virginia Polytechnic Institute and State University, Blacksburg, VA, (2)Department of Psychology, Virginia Tech, Blacksburg, VA, (3)Department of Psychology, University of Wyoming, Laramie, WY

---

**Background:** The COVID-19 pandemic has had broad and long-lasting impacts on physical and mental health across communities. Autistic youth and their families may be disproportionately impacted by the increased structural challenges created during the pandemic, such as barriers to accessing healthcare. While autistic youth typically face difficulties accessing healthcare, it is possible that the COVID-19 pandemic may have exacerbated such barriers due to factors such as clinic closures, increased provider waitlists, and a rapidly changing health services landscape.

**Objectives:** The current study aims to 1) examine differences in the impact of the COVID-19 pandemic for caregivers of autistic versus non-autistic youth, 2) evaluate whether caregivers of autistic youth report significantly more barriers to healthcare during compared to before the pandemic, and 3) explore whether the impact is associated with healthcare barriers prior to the pandemic or changes in self-reported healthcare barriers during the pandemic.

**Methods:** Caregivers of autistic ( $n=117$ ) and non-autistic ( $n=125$ ) youth ages 2 to 17 ( $M=8.58$  years) were asked to report on barriers to healthcare for their child before and during the pandemic and to complete the Coronavirus Impact Questionnaire (CIQ), which assessed psychological, financial, and resource impacts of COVID-19. We conducted independent-samples  $t$ -tests to examine group differences on the CIQ subscales and a paired-samples  $t$ -test to determine whether parents of autistic youth reported more barriers to healthcare during compared to before the start of the pandemic. Finally, using Pearson  $r$  correlations, we explored the association between the CIQ scales, pre-pandemic barriers to healthcare, and change in barriers to healthcare during the pandemic.

**Results:** Caregivers of autistic youth reported significantly greater impacts of the COVID-19 pandemic than caregivers of non-autistic youth across all three CIQ subscales (Table 1). Caregivers of autistic youth did not report differences in barriers to healthcare access before ( $M=158.24$ ,  $SD=52.10$ ) compared to during ( $M=155.15$ ,  $SD=46.90$ ) the pandemic,  $t(66)=-.81$ ,  $p=.419$ . All CIQ scales were moderately correlated with level of pre-pandemic barriers to healthcare in the autistic group (psychological  $r=.33$ , resource  $r=.38$ , financial  $r=.37$ ,  $ps \leq .002$ , Figure 1). Additionally, changes in barriers to healthcare were not correlated with any CIQ scale ( $ps > .320$ ).

**Conclusions:** Caregivers of autistic youth reported greater impact of the COVID-19 pandemic compared to caregivers of non-autistic youth across psychological, financial, and resource-related domains. Pre-pandemic barriers to healthcare were correlated with COVID-19 impact, suggesting that families with greater difficulties accessing healthcare prior to the pandemic were also more likely to experience higher levels of COVID-19 impact. Caregivers of autistic youth did not report increased barriers to healthcare services during the pandemic as compared to before. This may reflect high levels of barriers pre-pandemic; alternatively, it is possible that treatment approaches such as telehealth served to decrease some barriers to healthcare during the pandemic. Additional research should continue to evaluate the impact of COVID-19 on the wellbeing and care access of autistic youth and their families; future interdisciplinary work is needed to consider policy outcomes that would benefit youth and families particularly impacted by pandemic-related stress.

---

**424.063 (Poster)** The Effect of Training and Experience on Preservice Teachers' Knowledge Related to Autism and Language Development

**L. J. Avery,** Special Education, University of Missouri - Columbia, Columbia, MO

---

**Background:** The increasing number of students being identified with autism, the trend towards an inclusive education model, and the consistently poor academic and post-secondary outcomes for individuals with autism necessitates an examination of teacher preparedness to meet the learning needs of this population. Research suggests that special education preservice and in-service teachers are more knowledgeable about autism than general educators. However, teachers across both categories demonstrate knowledge deficits and do not feel adequately prepared to meet the learning needs of their students with autism. Furthermore, social and structural language difficulties are prevalent in this population of students, and learning

depends on successful language use. However, research has not examined what preservice teachers know about language development in general or the specific language characteristics typically associated with autism spectrum disorders.

**Objectives:** This pilot study examined the effects of autism-specific instruction and experience interacting with individuals with autism on preservice teachers' knowledge of autism, language development, and language characteristics typically found in the autism population.

**Methods:** This descriptive study utilized the Autism and Language Knowledge Questionnaire (ALK-Q) to gather data on participants' training and experiences and measure their knowledge in three distinct areas: autism, language development, and language characteristics associated with autism. Analysis of variance (ANOVA) was used to identify variables that influenced preservice teachers' knowledge scores. In addition, analysis of individual questions identified trends in knowledge gaps and misconceptions.

**Results:** Preservice teachers studying special education had higher average knowledge scores than those studying general education. General education teachers also demonstrated greater knowledge gaps and more misconceptions. While ANOVA did not determine a significant effect between the number of courses and knowledge scores, those students who took more courses that addressed autism had better scores across all three knowledge scales. Participants who received outside training in addition to their teacher preparation program outperformed peers without additional training. ANOVA and GLM model fit analysis indicate that level of experience has a significant effect on knowledge scores. Those with more experience interacting with individuals with autism had higher levels of knowledge across all three scales.

**Conclusions:** This preliminary research supports the existing literature and has important implications for Institutes of Higher Education that prepare future educators. The results support the need for autism-specific instruction during teacher preparation programs to improve preservice teacher knowledge of autism. They also support the need for increased opportunities for preservice educators to interact with individuals with autism as a part of their training.

**424.064 (Poster)** The Effect of an Etiologic Genetic Diagnosis on Family Adjustment and Parental Stress Among Families of Children with Autism Spectrum Disorder (ASD)

**C. N. Murali<sup>1</sup>, G. J. Sakyi<sup>2</sup>, S. S. Mire<sup>2</sup> and R. P. Goin-Kochel<sup>3</sup>, (1)Baylor College of Medicine, Houston, TX, (2)Psychological, Health, and Learning Sciences, University of Houston, Houston, TX, (3)Baylor College of Medicine, Houston, TX**

---

**Background:** Genetic diagnoses are a widely known etiology for autism spectrum disorder (ASD). In order to identify genetic diagnoses, the American College of Medical Genetics, American Academy of Pediatrics, and other professional organizations recommend that all children with ASD undergo genetic evaluation and appropriate testing. Identification of a genetic etiology for ASD can assist with prognosis and recurrence risk counseling as well as medical management. However, the effects of a causal genetic diagnosis on family adjustment and parental stress among families of children with ASD remain unknown.

**Objectives:** To explore the potential effects of receiving an etiologic genetic diagnosis upon family adjustment and parental stress among families of children with ASD.

**Methods:** Parents of children with ASD aged 12 years and younger were recruited through the SPARK (Simons Foundation Powering Autism Research for Knowledge) Research Match (RM) program. Participants responded to a multi-part survey including a custom survey regarding their experiences with genetic evaluation and testing for their child with ASD, the *Family Adjustment Measure* (FAM; measure of family's adjustment to the ASD diagnosis) and *Parenting Stress Index™, Fourth Edition, Short Form* (PSI™-4-SF; measure of parenting stress), and other validated measures.

**Results:** A total of 282 participants (93.6% female, 97.9% in the role of parent, grandparent, or non-family caregiver) began the multi-part survey and reported on 76.9% male children. 49.5% reported that their child with ASD received genetic testing, 8.7% were referred but did not receive testing, and 41.2% were never referred. Of those who completed genetic testing, parents reported whether the results definitely did (25.4%), possibly did (26.2%), or definitely did not (48.4%) provide an etiological diagnosis for the ASD. There were no significant differences among these three groups on any subscales of the FAM, although a trend emerged for parents of children with a genetic diagnosis to score higher on the Family-Based Support and Social Support subscales and lower on the Parental Distress and Positive Coping subscales. Likewise, there were no significant differences among these three groups on any subscales of the PSI™-4-SF; however, there was a trend for parents of children with an etiological genetic diagnosis to score lower across all subscales and total PSI™-4-SF score.

**Conclusions:** Compared with those whose children's genetic test results were ambiguous or negative, families of children for whom a genetic etiology was confirmed tended to have more support in their family and other social circles. They reported lower distress, but also less positive coping. On measures of parenting stress, caregivers of children with an identified genetic etiology tended to have decreased distress and improved parent-child interactions. Though these differences were not statistically significant, these trends warrant further investigation since our outcomes suggest that finding genetic causes for children's ASD may influence whole family outcomes. Future work will focus on the impact of families' perception of genetic test results in comparison to medical providers' perception; as well as differences between families of children who did and did not undergo genetic testing, regardless of testing outcome.

**424.065 (Poster)** The Lived Experience of Gender Dysphoria in Autistic Young People: A Phenomenological Study with Young People and Their Parents

**K. Cooper<sup>1</sup>, C. Butler<sup>1</sup>, A. Russell<sup>2</sup> and W. Mandy<sup>3</sup>, (1)University of Bath, Bath, United Kingdom, (2)Psychology/Centre for Applied Autism Research, University of Bath, Bath, United Kingdom, (3)Department of Clinical, Educational and Health Psychology, University College London, London, United Kingdom**

## Background:

*Gender dysphoria* means distress due to an incongruence between an individual's gender and sex assigned at birth. Gender clinics offer support for people who are exploring their gender, and who are experiencing gender dysphoria. There is a higher prevalence of autism in young people attending gender clinics than in the general population.

## Objectives:

We aimed to explore the lived experiences of autistic young people who have experienced gender dysphoria, and their parents, using a multiperspectival Interpretative Phenomenological Analysis (IPA).

## Methods:

Young autistic people aged 13-17 (n=15), and their parents (n=16), completed in-depth interviews about the young person's experience of gender dysphoria. We analysed each individual transcript using IPA to generate individual themes, and for each of the dyads, we developed themes which acknowledged the similarities and differences in the perspectives of parents and young people.

## Results:

The first overarching theme was *coping with distress* which had two subthemes: (a) *understanding difficult feelings* and (b) *focus on alleviating distress with external support*. This theme was about young people being overwhelmed by negative feelings which they understood as being about gender incongruence. Young people then looked to alleviate these feelings through a gender transition. The second overarching theme was *working out who I am* which had two subordinate themes: (a) *the centrality of different identities and needs* and (b) *thinking about gender*. This theme was about how young people and their parents focused on different needs; while young people more often focused on their gender-related needs, parents focused on autism-related needs.

## Conclusions:

We conclude autism and gender dysphoria were seen as intersecting in meaningful ways by parents and young people. A key finding is that while autistic young people tended to see their needs as mostly linked to gender dysphoria, parents more often saw their difficulties through the lens of autism.

**424.066 (Poster)** The Oral Health Knowledge, Attitudes, and Practices of Black Caregivers of Children with and without Autism Spectrum Disorder  
**D. H. Como<sup>1</sup>, L. I. Florindez<sup>1</sup>, L. I. Duker (Stein)<sup>2</sup> and S. Cermak<sup>3</sup>,** (1)Division of Occupational Science and Occupational Therapy, University of Southern California, Los Angeles, CA, (2)Chan Division of Occupational Science and Occupational Therapy, University of Southern California, Los Angeles, CA, (3)USC Mrs. T.H. Chan Division of Occupational Science and Occupational Therapy, University of Southern California, Los Angeles, CA

---

## Background:

Oral health is vital to overall physical and psychological health. However, some pediatric populations, such as children from underserved minoritized groups (e.g., Black/African American [B/AA]) and children with special health care needs (e.g., autism spectrum disorder [ASD]), are at greater risk for oral health disparities (e.g., increased caries and oral-related chronic diseases, poorer overall oral health status and access to care). Gaps in oral care knowledge, attitudes, and practices may contribute to oral health disparities in these populations.

## Objectives:

The purpose of this study was to identify the oral health knowledge, attitudes, and oral care practices of B/AA caregivers of children with and without ASD.

## Methods:

Participants were 125 caregivers (e.g., parents, grandparents, guardians) of children 4-14 years who self-identified as B/AA or mixed (including B/AA) and identified their children similarly (B/AA or mixed), with (n=65) or without ASD (n=60). Caregivers completed a 120-item culturally-tailored survey to examine the oral health knowledge, attitudes, access, and practices in minoritized populations.

## Results:

Significant correlations were found for both groups combined between caregiver oral care knowledge and child daily oral care practices ( $p=0.016$ ), caregiver daily oral care practices and child's daily oral care practices ( $p<0.001$ ), and caregiver oral care knowledge and caregiver oral care attitudes ( $p<0.001$ ). For the ASD group, a significant correlation was found between child's daily oral care practices ( $p=0.014$ ) and access to care. For the non-ASD group, significant correlations were found between access and caregiver oral care knowledge ( $p=0.001$ ), and access and

maternal/caregiver education ( $p=0.004$ ). Nearly half of respondents reported that they and their child are fearful of dentists, although 90% indicated they trust their child's dentist. Despite that trust, 74% of the ASD group and 28% of the non-ASD group stated that they believe their race/ethnicity negatively influences how their child is treated at the dentist. Although caregivers of children without ASD reported more years of education, they also exhibited significantly less oral care-related knowledge than caregivers of children without ASD ( $p<0.001$ ). Regardless of ASD status, an overwhelming number of caregivers (89%) reported they would like to learn additional ways to improve their child's oral health.

#### Conclusions:

This study highlights the relationship between caregiver oral health knowledge, attitudes, and oral care practices. B/AA caregivers of children without ASD have some foundational knowledge about oral health and basic practices, but parents of children with ASD have significantly less. This is an area that needs to be addressed, and fortunately most caregivers report their interest in learning more. Given the inconsistency between families' reported trust of their child's dentist alongside a feeling that their child's treatment is negatively impacted by their race/ethnicity, it is important to develop and implement culturally-tailored oral health education and behavioral interventions to mitigate oral health disparities for B/AA families. Therefore, it is important to explore the intersection of culture and oral health for this population.

**424.067 (Poster)** The Role of Autistic Features in Parental Mental Health and Quality of Life: Comparison between Parents of Children with Idiopathic Autism, Phelan Mcdermid Syndrome (PMS) and Other Copy Number Variants (CNVs)

**J. Cooke<sup>1</sup>, B. Rankasz<sup>2</sup>, B. Oakley<sup>2</sup> and E. Loth<sup>2</sup>, (1)Forensic and Neurodevelopmental Sciences, Kings College London, Institute of Psychiatry, Psychology & Neuroscience, London, United Kingdom, (2)Forensic and Neurodevelopmental Sciences, Institute of Psychiatry, Psychology, and Neuroscience, King's College London, London, United Kingdom**

---

#### Background:

Parents of autistic children sometimes report more mental health issues and lower quality of life (QoL) than parents of non-autistic children. Contributing factors include strength of their child's autistic features, level of care need, and strength of autistic features within the parent. Rare genetic conditions associated with autism, such as Phelan McDermid Syndrome (PMS) and other copy number variants (CNVs) that involve multiple and profound disabilities, may pose a unique challenge to parents.

#### Objectives:

- Identify differences in parental anxiety, depression, and QoL based on child's diagnosis (idiopathic autism [iASD], PMS or other CNV, or typical development [TD])
- Examine the relationship between parental anxiety, depression, QoL and the strength of their child's autistic features
- Examine the relationship between parental anxiety, depression, QoL and the strength of autistic features within parents

#### Methods:

32 parents (20 mothers/12 fathers) of iASD children, 34 parents (21 mothers/13 fathers) of PMS or other CNV children, and 28 parents (17 mothers/11 fathers) of TD children completed the Becks Anxiety and Depression Inventories, the QoL for Adult Carers Questionnaire (AC-QoL), and the Social Responsiveness Scale (SRS). Parents also completed the Sensory Experience Questionnaire (SEQ), Child Routines Inventory (CRI), and the Vineland Adaptive Behaviour Scales (VABS-II) about their child.

#### Results:

No difference in levels of anxiety, depression, or QoL were observed between parental groups based on child's diagnosis. Parental anxiety was positively associated with parental depression ( $r(94) = 0.583, p < .001$ ), strength of parental autistic features ( $r(94) = 0.456, p < .001$ ), and child's level of motor behaviours/compulsions (cMBC) ( $r(53) = 0.337, p < .05$ ). Parental depression was positively associated with strength of parental autistic features ( $r(94) = 0.337, p < .001$ ), cMBC ( $r(53) = 0.380, p < .01$ ), and negatively associated with child's level of social adaptive functioning ( $r(86) = -0.271, p < .05$ ). Parental QoL was negatively associated with child's level of sensory experience ( $r(18) = -0.670, p < .01$ ), cMBC ( $r(17) = -0.634, p < .01$ ), and child's rigidity/insistence on sameness (cRIS) ( $r(17) = -0.645, p < .01$ ).

Linear regression found 55.9% of variance in parental anxiety levels was explained by level of parental depression, strength of parental autistic features, and cMBC ( $F(3,52) = 20.745, p < .001$ ). 45.1% of variance in parental depression levels was explained by level of parental anxiety, strength of parental autistic features, and child's MBC and social adaptive functioning ( $F(4,47) = 8.828, p < .001$ ). Levels of parental depression accounted for the most variance in levels of parental anxiety (33.9%) and visa versa (37%). 63.7% of variance in parental QoL could be explained by child's level of sensory experience, cMBC and cRIS ( $F(3,16) = 7.588, p < .01$ ). Child's level of adaptive functioning was not predictive of parental anxiety, depression, or QoL.

#### Conclusions:

Parental mental health was better predicted by parent's own mental state than the strength of their child's autistic features or level of adaptive functioning. Parental QoL was negatively impacted by the strength of their child's sensory experiences and restricted and repetitive behaviours (RRBs).

**Background:** Children with autism spectrum disorder, a pervasive developmental disorder, have been shown to potentially increase levels of parental stress when compared to children with no psychological disorders (Rao & Beidel, 2009). Additionally, extant literature demonstrates a relationship between parental stress and judgements on one's own parenting abilities, including limit setting (Fong, 1991; Reed et. al., 2017). When analyzing which factors contribute the most to parental stress, Faulk, Norries, and Quinn (2014) found that parental cognitions were a better predictor of stress over child-centric variables.

**Objectives:** This study investigates the role of parent's self-reported stress and psychopathology as a predictor for limit setting abilities in families with a child with autism spectrum disorder.

**Methods:** There were a total of  $n = 31$  parents of children with ADOS-confirmed ASD. This sample was 76.5% male, 47.1% white, 47.1% African American, 5.9% Asian with an average age of  $M = 5.21$  years ( $SD = 2.591$ ). All assessments were collected by parent report during an evaluation at a university autism spectrum disorder clinic. Parental stress was assessed using the validated and reliable Parental Stress Scale (PSS; Algarvio et al., 2018; Zelman et al., 2018). Parental psychopathology was rated using the Hopkins Symptoms Checklist (Derogatis et al., 1974). Additionally, self-perceived limit setting was rated using the Parent-Child Relationship Inventory Limit Setting subscale (PCRI; Gerard, 1994). Linear regression analyses were conducted to determine the influence of psychopathology and parent stress on limit setting abilities.

**Results:** Limit setting was significantly correlated with parental stress ( $r = -.56, p = .001$ ) and parent-rated psychopathology ( $r = -.38, p = .046$ ). Analysis indicated that parental stress significantly predicted limit setting abilities, but parents self-rated psychopathology did not significantly predict limit setting. A linear regression analysis model was demonstrated to be significant ( $p = .004$ ) and explains about 30% of the variance (adj  $R^2 = .301$ ). Parent self-rated psychopathology did not significantly predict limit setting ( $B = -9.319, p = .129$ ), but parent stress did significantly predict limit setting ( $B = -.488, p = .009$ ).

**Conclusions:** Parental stress, but not psychopathology, significantly predicts a parent's limit setting. Lower parental stress is associated with higher limit setting abilities with their autistic child. This finding is consistent with previous research on the relationships between parental stress and limit setting abilities. These findings have the potential to impact parent support resources and parent training modules. When looking to reduce parental stress, it may be important to help parents effectively set limits with their children. Additionally, future research should look to understand underlying mechanisms within this relationship and ways to improve parental stress.

**424.069 (Poster)** Time Is Not Money—Examining the Relationships between Parental Stress and Family Resources after the Clinical Support Withdraws for Lower Resourced Families and Their Children with Autism  
**L. M. Chiang<sup>1</sup>, W. I. Shih<sup>2</sup> and C. Kasari<sup>3</sup>,** (1)*UCLA, Los Angeles, CA,* (2)*University of California - Los Angeles, Los Angeles, CA,* (3)*University of California, Los Angeles, Los Angeles, CA*

---

#### **Background:**

Parenting stress in caregivers of children with ASD has been well documented (e.g., Benson & Kersh, 2011; Hayes & Watson, 2013; Zaidman-Zait et al., 2017). Core deficits of ASD were found to significantly predict maternal depressed mood (Benson & Kersh, 2011; Davis & Carter, 2008). Maladaptive behaviors could hinder the parents' daily routines, social engagement, such that parents may reduce time running errands or socializing with friends and family, feeling withdrawn from the community (Harper et al., 2013). As parenting stress negatively impacts both parental and child outcomes (Neece et al., 2010) and potentially counteracts the effectiveness of early interventions (Osborne et al., 2008), it is imperative to understand the parenting stress that caregivers experience and the supporting resources available within their ecological system.

#### **Objectives:**

To extend previous work by Kasari et al. (2014) by investigating how parenting stress changed over the active treatment course and after the clinical support had been withdrawn, between the two treatment groups that received either an individual coaching version of a manualized intervention (i.e., JASPER; Kasari et al., 2010) or a group-based caregiver education module (i.e., CEM) that covered similar materials.

#### **Methods:**

This secondary analysis included 31 children with ASD ( $M_{age} = 42.3$  months) and their caregivers who were lower resourced and part of a multi-site RCT trial (Kasari et al., 2014). The Parenting Daily Hassles (PDH; Crnic & Greenberg, 1990) was administered at entry, exit, and 3-month follow-up to assess parenting stress. Linear mixed-effect models were utilized to examine the PDH score changes over time by treatment group, specifically before and after the clinical support was withdrawn. Income, family resources (FRS; Leet & Dunst, 1987), and Mullen Scale of Early Learning (MSEL; Mullen, 1995) score at entry were examined as predictors of the parental stress.

#### **Results:**

Parental stress scores changed specifically before and after exit. The CEM group reported significantly worsened stress from entry to exit [ $t = 3.79, p < .01$ ] though the change was not significant from exit to follow-up. Whereas JASPER group reported no significant change in stress from entry to exit but experienced significantly higher stress from exit to follow-up [ $t = 4.14, p < .01$ ]. Higher level of family resources significantly predicted lower parenting stress [ $F(1,19) = 38.37, p < .001$ ] over time for both groups. Such significance was not present at exit, but only from exit to follow up [ $F(1,10) = 59.26, p < .001$ ]. No significant group by time interactions.

#### **Conclusions:**

Family resources were a significant predictor of parental stress for both treatment groups, especially after the families exited the study. Sources are not limited to tangible capital, such as money, housing, and transportation, but also include intangible assets, like social support and private time for self-care. Having such resources could alleviate the daily hassles perceived by parents of children with ASD. To reiterate, different treatment modules may be differentially suitable for families with various levels of resources. For lower resourced families, intensive treatment modules could improve outcomes at exit but instill latent ramifications, such as aggravated parental stress, if the clinical support ceases abruptly from exit to follow-up.

**424.070 (Poster)** Tracking Outcome of Early Career Researchers in ASD

A. Halladay<sup>1,2</sup>, K. Madgett<sup>1</sup> and A. T. Singer<sup>1</sup>, (1)Autism Science Foundation, Scarsdale, NY, (2)Rutgers University, Piscataway, NJ

---

**Background:**

Many private and public funding agencies offer fellowships to scientists at the beginning of their careers. In addition to supporting rigorous scientific training and high-quality research, there is often a further goal of encouraging retention of these early-career scientists within the autism field past their funding period. However, very little data has been collected on the impact of this funding on career trajectories.

**Objectives:**

Our objective is to explore the potential impact of early career research funding on retention and productivity through an analysis of five and ten-year outcomes among applicants to Autism Science Foundation's (ASF) pre- and postdoctoral fellowship programs. This analysis was designed to determine the impact of fellowship training support on a number of scientific measures as well as those more directly relevant to community impact.

**Methods:**

We utilized publicly available data resources and databases (iCite, LinkedIn, Google, Dimensions) to capture information on researchers who applied to the ASF's pre and postdoctoral fellowship programs from 2010-2016 (n=400). We determined the career trajectories of all applicants at 5 years after their initial application, and where data was available from the earliest cohorts, at 10 years. This analysis examined the differences in retention in autism and publications who were funded by ASF and those who applied but were not funded.

**Results:**

At 5 years follow up, we found a higher percentage of those who were funded (80%) stayed in the autism field compared to those who applied but were not funded (57%). ( $\chi^2 = 9.89$ ,  $p = .001$ ). However, when the subset of applicants funded in 2010-2011 were tracked to 10 years post award, the difference in autism retention was no longer significant.

Regardless of whether or not the fellows stayed in autism research, funded and non-funded researchers were equally as productive in terms of publications at 5 years post award. This suggests that both groups were publishing in academic journals in whatever scientific career they chose.

**Conclusions:**

This study design allowed for rigorous tracking of funded researchers in a non-biased way (not relying on individual progress reports) with the presence of a control group (non-funded applicants). Funding the training of early career researchers improved the retention in the autism field at 5 years. There are a number of factors which may influence the 5 year retention that are not directly related to ASF funding. Funded and non-funded researchers published in scientific journals at the same rates. Future analyses will also include citation ratios and a measure of networking. These findings suggest that support to early career researchers that includes a strong training component is critical to recruit and retain scientists into autism research.

**424.071 (Poster)** Trust Takes Times: Using a Patient-Centered Outcomes Research (PCOR) Approach to Build and Sustain Engagement with Transition-Age Autistic Youth and Stakeholders

S. N. Brasher<sup>1</sup>, L. Coleman<sup>2</sup> and M. J. Segall<sup>3</sup>, (1)School of Nursing, Emory University, Atlanta, GA, (2)Marcus Autism Center, Atlanta, GA, (3)Emory Autism Center, Emory University, Atlanta, GA

---

**Background:** The transition to adulthood is fraught with challenges as individuals depart familiar systems of care and begin to navigate new and unfamiliar systems. This transition is particularly difficult for autistic youth, who often present with co-occurring psychiatric and medical conditions, in addition to the core symptoms of autism spectrum disorder (ASD). There is great concern regarding how the intersection of these co-occurring conditions and core symptoms impact their overall health, healthcare decision making, and health outcomes. Recent data suggests that the transition to adulthood disproportionately impacts autistic individuals compared to neurotypical peers and individuals with other chronic conditions. This amplifies the need to better understand the challenges encountered during the transition to adulthood for transition-age autistic youth.

**Objectives:** The purpose of this study was to build and sustain engagement with transition-age autistic youth, their caregivers, and other stakeholders to better understand the challenges encountered during the transition to adulthood and identify meaningful ways to address these challenges.

**Methods:** A Patient-Centered Outcomes Research (PCOR) approach was used to form partnerships among transition-age autistic youth ages 14-36, their caregivers, and stakeholders (e.g., clinicians, educators, researchers). These individuals met monthly within their respective communities over the course of three years to identify barriers to the transition to adulthood for transition-age autistic youth, as well as facilitate the identification of patient-centered solutions. Appointed leaders from these groups attended a monthly advisory board consisting of autistic adults, caregivers, and stakeholders to further share this information and develop PCOR and comparative effectiveness research (CER) questions. Partnerships were created through local autistic self-advocacy and community organizations to provide a sustainable infrastructure.

**Results:** Outcomes of this study included the identification of seven key areas of transition for autistic individuals (e.g., healthcare, self-advocacy, safety, education, employment, social relationships, and daily living). A total of 30 PCOR/CER questions were identified to be executed in future research. Additionally, outcomes included knowledge of how best to build and sustain engagement with autistic individuals, caregivers, and stakeholders. Included in these outcomes were lessons learned on best practices on creating an inclusive environment for authentic engagement and strategies to ensure engagement is equitable.

**Conclusions:** Transition-age autistic youth face many challenges as they embark on the transition to adulthood, even more so than their neurotypical peers or other individuals with chronic conditions. This often results in poorer transition outcomes. This study demonstrated the need and ability to build and sustain engagement with transition-age autistic youth, caregivers, and other stakeholders to better understand these challenges from a PCOR perspective. This type of approach allows for not only a better understanding of their unique needs, but also provides a means of developing patient-centered solutions to address these needs. Many lessons were learned over the course of the study, including that although trust takes time to build and sustain engagement, the outcomes that result from this investment have the potential to make a meaningful impact on the lives of autistic youth embarking on the transition to adulthood.

**424.072 (Poster)** What Are the Experiences of Primary to Secondary Transition for Children with Autism? an Exploration of the Experiences of Primary to Secondary School Transition for Children with Autism in One East London Borough.

**E. Valizadeh**, Support for Learning Service, London Borough of Tower Hamlets, London, United Kingdom

---

**Background:**

This research acknowledges that there is a lack of literature specifically focused on the views of children with autism with regards to primary to secondary transition. As Makin, Pellicano and Hill (2017) note this transition is often reported as problematic and existing literature considering the views of parents and teachers reveals a number of difficulties related to primary to secondary transition. Despite this, there is little research capturing the voice of the children themselves. A literature review will provide an overview of other relevant research focused on the experiences of children with autism transitioning from primary to secondary school, the wider experiences of children with autism in secondary school more generally as well as reviewing methods used in other research to elicit views of young people with autism. E.g. Fayette and Bond (2018).

An extensive literature review has revealed that there is a considerable need for more research exploring the voices of children with autism, particularly with a view to using these views to improve practice going forward.

**Objectives:**

The aim of the research is to explore the experiences of children with autism in their transition from primary to secondary school. The research aims to explore these experiences from the perspective of the children themselves, capturing their authentic voice with a view to improving practice going forward.

**Methods:**

The research used a qualitative participatory approach within a phenomenological framework. Sixteen children in year 7 with a diagnosis of autism were individually interviewed using semi structured interviews in the summer term of year 7. With regards to methodology and approach of capturing the authentic voice of the children with autism considerations must be given to methods which allow for the most credible capture of the views and experiences of the sample group. Therefore this research used an innovative approach, the Three Houses tool, in all interviews as a flexible interview schedule

**Results:**

Overall the children described negative experiences moving from primary to secondary school. The data, thematically analysed, confirmed that transition to secondary school and experiences once there were problematic. These difficulties related to a number of school level factors. Peer relationships, academic pressure and teachers understanding appeared to be key difficulties experienced by all the children interviewed.

**Conclusions:**

This research identified predominantly negative experiences of the primary to secondary school transition for the children interviewed. This research revealed that a number of school and system related factors need to be addressed to improve the transition experiences of children with autism. Additionally, the findings point towards the need for greater research which captures the authentic voices of children with autism and further considerations regarding the methods used to capture those voices. The research makes a number of recommendations of changes to practice moving forward to support improved experiences of children with autism moving from primary to secondary school.

**424.073 (Poster)** Participants' and Researchers' Perceptions of Effective Recruitment Strategies: Lessons Learned through SPARK

**R. P. Goin-Kochel**, Baylor College of Medicine, Houston, TX

---

**Background:** Recruitment for clinical studies remains one of the biggest challenges to performing studies of all sizes. As many as 75% of studies are unable to enroll the proposed number of participants and 90% fail to enroll within the original timeframe (Kost et al., 2015). Understanding which recruitment methods are most likely to facilitate participant enrollment is of utmost importance financially, scientifically, and ethically.

**Objectives:** To identify (a) the most commonly endorsed research-recruitment strategies through which SPARK participants learned about the study, (b) which strategies participants rated as most influential in their decisions to enroll, and (c) the strategies that SPARK research staff endorsed as the most successful in increasing participant enrollment.

**Methods:** In study one, 52 of 150 research staff from 23 SPARK clinical sites (35%) were surveyed about the recruitment strategies that their site had used for the SPARK study and which they felt were most successful in influencing families to enroll. Staff were invited via email to complete a REDCap questionnaire and were incentivized with a chance to receive one of five \$100 gift cards. In study two, 4,144 of 26,997 primary account holders enrolled in SPARK (15%) were surveyed about all ways they heard about SPARK prior to enrollment, which was most influential in their decisions to enroll, and their understanding of what participation entailed. Participants were incentivized with a chance to receive one of 25 portable chargers. For both studies, up to three reminders were sent to nonresponders.

**Results:** In study one, the most frequently cited recruitment methods that study personnel believed were most influential in families' decisions to participate included *speaking with a SPARK study-team member* (36.5%), *speaking with a medical provider* (19.2%), *word of mouth* (11.5%), and *a live TV news story* (11.5%). Table 1 shows the methods that they would/would not repeat/recommend. In study two, the most common methods by which families learned about SPARK were through *social media* (46.8%), *speaking with a medical provider* (22.9%), *online search* (20.0%), *hearing about SPARK from a friend/family member* (13.2%), and *a flyer/printed material* (12.7%). Among all the ways they heard about SPARK, the strategies that most influenced their decisions to enroll were *social media* (30.5%), *speaking with a medical provider* (17.5%), *online search* (12.8%), *hearing about it from a friend/family member* (7.8%), and through an *email from the SPARK research team* (5.8%). Figure 1 illustrates the proportion of recruitment strategies that families rated as most influential in their decision to enroll. For example, among all those who reported learning about SPARK from their medical providers, 72% rated medical providers and 28% rated some other strategy as the most influential in their decision to enroll.

**Conclusions:** The most common and influential ways families learned about SPARK were through social media and medical providers. The strategies that research staff would repeat/recommend often differed from those that families indicated were most influential. Findings have implications for the selection of recruitment strategies that have the greatest reach and most influential impact.

#### **424.074 (Poster) Mental Health of Siblings of Children with Autism Spectrum Disorder**

**T. Brahim<sup>1</sup>, R. H. Trabelsi<sup>2</sup>, A. Guedria<sup>3</sup> and N. Gaddour<sup>4</sup>, (1)PSYCHIATRY, UNIVERSITY OF MONASTIR, MONASTIR, Tunisia, (2)university of Monastir, Monastir, Tunisia, (3)University of Monastir, Monastir, Tunisia, (4)University Hospital F. Bourguiba, Monastir, Tunisia**

---

**Background:**

ASD is a complex neurodevelopmental disorder. This disorder can cause a major modification in the family routines and interactions. Its clinical peculiarities can be life-threatening for neurotypical siblings.

**Objectives:**

To describe the emotional and psychosocial disorders of neurotypical siblings of children with ASD and the factors associated with

**Methods:**

This is a correlational descriptive study conducted among 94 normally developing siblings of children with ASD, collected by sampling for convenience within the child psychiatry out-patient unit of Monastir, Tunisia. Data collection was carried out using two measurement instruments validated in Arabic (CBCL 6-18 and safety scale) over a period of three months.

**Results:**

Over 98% of sibling had a pathological score in at least one domain of the CBCL: 75% of sibling had anxiety / depression, 32% had somatic complaints, 74% had social integration problems, 30% thoughts problems, 71% had attention problems, 11% had delinquent behaviors and 60% had aggressive behaviors. In 95% of cases, sibling had internalized disorders and in 84% had externalized disorders. Being a sister, the first born, having more than one sibling and the presence of family violence were associated to higher score in the anxiety / depression domain. Attention problems were associated to moral violence exposure. Delinquent and aggressive behaviors were associated to male gender.

**Conclusions:**

Siblings of children with ASD suffer from multiple emotional and psychological problems. Anxiety and depression seem to be the most frequent. Developing a special program for this population could help improve their quality of life and may, the evolution of the ASD children.

#### **424.075** (Poster) Parent Perceptions of Autism and Policing: Similarities and Differences By Race

*M. Leuzzi<sup>1</sup>, A. S. Russell<sup>1</sup>, A. Zitter<sup>1</sup>, J. Pacheco<sup>2</sup>, K. G. Tena<sup>1</sup>, M. R. Pelella<sup>1</sup>, A. Knox<sup>1</sup>, M. L. Cola<sup>3</sup>, R. Solorzano<sup>4</sup>, S. Turnacioglu<sup>4</sup>, J. S. Miller<sup>4</sup>, V. Ravindran<sup>4</sup>, J. Parish-Morris<sup>1</sup> and J. McCleery<sup>1</sup>, (1)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (2)Saint Joseph's University, Philadelphia, PA, (3)The Children's Hospital of Philadelphia Center for Autism Research, Philadelphia, PA, (4)Floreo, Inc., Washington DC, DC*

**Background:** Individuals with disabilities – such as ASD – are at high risk of negative outcomes during police interactions, including injury and death (Bronson et al., 2015; Perry & Carter-Long, 2016; Swaine et al., 2016). This problem stems from a combination of historically dysfunctional police expectations, tactics, and procedures, as well as challenges associated with autistic individuals' abilities to rapidly respond to unusual demands of law enforcement interactions (Rava et al., 2016). Police interactions are typically unexpected, include unusual sensory stimulation, require novel problem solving, and necessitate rapid processing of social situations, which can make them particularly difficult for autistic people (Channon et al., 2001; Salerno-Ferraro & Schuller, 2020; Vanmarcke et al., 2016). Extensive evidence also suggests that police interactions differ significantly in under-served neighborhoods and communities of color, further increasing the risk of serious negative outcomes (Brunson, 2007). Given the dearth of formalized education about this topic, parents play a critical role in educating their children about police interactions. Due to high risk of negative outcomes, it is imperative to explore how parents of autistic individuals perceive police interactions.

**Objectives:** (1) Query parents of children with autism about their perceptions of law enforcement, particularly with regards to their own child; (2) Compare perceptions of policing among White and Black or African American parents of autistic children.

**Methods:** One hundred and twenty-eight parents of individuals with ASD were emailed a link to an anonymous 10- to 15-minute online survey. Most participants were White (66%), female (89%), non-Hispanic (93%), and lived in the suburbs (47%). A substantial subgroup of participants were Black or African American (27%). The majority of participants had a Bachelor's degree or higher education (70%). Most parents reported incomes greater than \$91,000 per year (Table). Answers to four questions were compared between parents who self-reported being Black or African American, and parents who self-reported being White.

**Results:** The majority of parents in both racial groups expressed concern that police lack the skills necessary to interact safely with their autistic children (86% overall), and were worried that their child's autistic symptoms might be misinterpreted by police (89% overall). Black and White parents of individuals with autism had very different views on equitability and justice in policing (31% of Black parents agreed that their police department works to provide justice equally to all people vs. 69% of White parents). The majority of both subgroups agreed that police officers need to change how they interact with Black and Brown individuals (94% of Black parents, 76% of White parents).

**Conclusions:** Parents of autistic children are deeply concerned about the safety of police interactions, especially in the case of Black and Brown people. This highlights the need for better police officer training, including targeted skills development and benchmarks for interacting safely with autistic individuals. Current research efforts include querying police officers about their knowledge of autism, with the goal of developing a pilot intervention to improve police officers' knowledge about autism, empathy toward autistic individuals, and ability to interact safely with autistic people.

### **VIRTUAL POSTER SESSION — FAMILY ISSUES AND STAKEHOLDER EXPERIENCES**

#### **511 - Family Issues and Stakeholder Experiences I --- (V)**

#### **511.063** (Virtual Poster) A Mixed-Methods Systematic Review of Community Involvement in Autism Research

*D. W. Tan<sup>1</sup>, J. den Houting<sup>1</sup>, Y. Guan<sup>2</sup>, H. Winspear-Schillings<sup>1</sup>, M. Rabuka<sup>1</sup>, T. Haar<sup>1</sup> and E. Pellicano<sup>1</sup>, (1)Macquarie School of Education, Macquarie University, Sydney, NSW, Australia, (2)University of Western Australia, Perth, WA, Australia*

**Background:**

Participatory autism research describes an approach in which autistic people are involved in the research process including in study conceptualisation, design, implementation, interpretation, and dissemination. To date, community participation has taken various forms in autism research, ranging from autistic people having no say at all in the research process (e.g., as participants), to tokenism (e.g., providing inputs as consultants without affecting outcomes), to having decision-making power that is equal to, or even greater than, researchers. In a scoping review published in 2014, Jivraj et al. identified only two published papers reporting community involvement in autism research. They also revealed limitations in the reporting of the depth of community involvement across research in neurodevelopmental conditions.

**Objectives:**

Given the increasing calls for participatory research to be more widely adopted in autism, we sought to conduct a comprehensive mixed methods systematic review to provide an overview of participatory autism research published to date. This review addresses the following questions: (a) Has community involvement in autism research increased over time? (b) What is the level and breadth of community participation in autism? (c) What is the quality of reporting of community involvement in autism research? (d) What are some factors that may be associated with greater involvement of community members in autism research (e.g., funding source, type of research)?

**Methods:**

A pre-registration of this review has been submitted to PROSPERO. A search strategy that utilised a combination of searches through titles, abstracts, keywords, and full texts related to 'autism' and 'participatory research' was devised in consultation with the broader team and a university librarian. Search terms were entered into seven databases, namely, PsychINFO, Scopus, PubMed, MEDLINE, EMBASE, ERIC, and ProQuest Dissertations and Theses. Electronic database searches have been conducted on 9-Aug-2021 and were limited to articles published in English. We also adopted a participatory approach for this study, in which autistic advocates and researchers were involved in the design, search and coding stages, and interpretation of the findings.

#### Results:

Our searches yielded a total of 3,855 records. After removing 1,534 duplicates, the titles and abstracts of 2,321 records were screened to determine their eligibility using a double-blind review process by autistic and non-autistic team members. The full-text screening of 1,058 records is currently underway and data extraction and synthesis will be completed by February 2022. We are using a convergent integrated approach to synthesise and integrate findings from the included studies based on the four review questions. Findings will also be visualised using tables and figures.

#### Conclusions:

This systematic review will yield important findings on changes in the extent and nature of participatory research in the field of autism. It will also provide an opportunity to take stock and reflect on the progress that has been made in increasing community involvement in autism research, and its potential impact.

**511.064** (*Virtual Poster*) A Qualitative Study Exploring Autistic People's Experiences of Stigma at Universities in Australia  
**D. W. Tan, M. Rabuka, T. Haar and E. Pellicano, Macquarie School of Education, Macquarie University, Sydney, NSW, Australia**

---

#### Background:

In recent years, the number of autistic people entering university has doubled. While an encouraging trend, autistic students' completion rates remain much lower than non-autistic students in Australia (35% vs. 51-67%). Autistic people's low completion rates have been attributed to non-academic challenges of university life, such as social isolation and loneliness. But autistic people are also more vulnerable to stigma compared to non-autistic students. Across several qualitative studies investigating university experiences of autistic people, experiences of stigma consistently emerged as one of the main themes underlying their university lives. To date, there are no qualitative studies that have been designed specifically to understand the experiences of autism stigma in universities.

#### Objectives:

In this project, we seek to understand the contexts and circumstances under which autistic students felt stigmatised or experienced discrimination across a variety of settings, including their transition into university life, social environment, interactions with teaching and professional staff, and navigations through the university systems and physical environment. We also aim to determine the psychological, social, and practical impacts of stigma.

#### Methods:

Semi-structured interviews are being conducted with three groups of autistic people: 1) Ten autistic adults who have completed at least one university course in Australia, 2) ten autistic adults who have enrolled in but discontinued at least one university course in Australia, and 3) ten autistic adults who are currently studying a university course in Australia. Participants are being recruited through purposive sampling via social media posts. This project adopts a participatory approach and is co-produced with autistic researchers, who are involved in the study design, execution, interpretation, and dissemination of this research.

#### Results:

Data collection for this project is ongoing and will be completed by February 2022. We are analysing the data using reflexive thematic analysis, adopting an inductive approach to identify key features of the semantic content of the data within an essentialist framework. All members of the study team will independently familiarise themselves with the data and meet regularly to review coding, themes, and subthemes.

#### Conclusions:

The study findings will lead to a better understanding of autistic people's experiences of stigma within the university environment. It will also inform the design of further studies to develop ways in which such stigma can be reduced or prevented, as well as policy changes to improve social inclusivity for autistic and other neurodivergent students attending universities.

**511.065** (*Virtual Poster*) Associations between Parental Stress and Quality Time Spent with Youth on the Autism Spectrum  
**I. Vengurlekar<sup>1</sup>, G. Staples<sup>1</sup>, R. Bradley<sup>1</sup>, L. B. Quetsch<sup>1</sup>, C. Brown<sup>2</sup>, L. Aloia<sup>3</sup> and S. M. Kanne<sup>4</sup>, (1)University of Arkansas, Fayetteville, AR, (2)Pacific University, Hillsboro, OR, (3)Communication, University of Arkansas, Fayetteville, AR, (4)Center for Autism and the Developing Brain, White Plains, NY**

---

**Background:** Parents of youth with autism spectrum disorder (ASD) experience high levels of stress due to their caregiving role. While research indicates that parental stress may decrease when positive interactions between parents and their children increase, little is known about this relationship or the nature of these interactions.

**Objectives:** This study aimed to explore the relationship between parental stress, time parents and children spent together, shared enjoyment, and synchronicity in a nationally representative sample of parents of youth with ASD.

**Methods:** Caregivers ( $N = 511$ ) of youth ages 4 – 18 completed the Parenting Stress Index-Short Form (PSI) and a survey of parent-child quality time developed by the research team. Mean youth age was 10.81 years ( $SD = 4.50$ ). Most children in the sample were male ( $N = 393$ ; 77.2%) and White ( $N = 448$ ; 77.0%). Caregivers were between the ages of 22 – 66 ( $M = 40.4$ ,  $SD = 7.73$ ) and two-thirds were married ( $N = 353$ ; 69.2%).

**Results:** Results indicated that as parental stress increased, amount of time parents and children spent together ( $r = -.098$ ,  $p = .027$ ) and shared enjoyment during these interactions decreased significantly ( $r = -.331$ ,  $p < .001$ ). Further, parents with clinically significant levels of stress reported engaging in shared activities and experiencing synchronicity with their child less often than parents below the clinical threshold ( $X^2 = 12.37$ ,  $p < .001$ ;  $X^2 = 16.32$ ,  $p < .001$ , respectively). Significant associations between demographic factors (e.g., child age, race, family income) and stress, shared enjoyment, and synchronicity are also presented.

**Conclusions:** The primary aim of the current study was to explore the relationship between parental stress, quality time, and shared activities among parents of youth with ASD. Results indicated parental stress was negatively associated with the amount of time parents spent with their child during the weekday, but not the weekend. These findings suggest the routine of weekday and weekend days may have differing impacts on the relationship between parent-child quality time and stress. Further, parental stress was negatively associated with both parent and child enjoyment during shared activities. These findings suggest that parents with higher stress spend less time with their child with ASD and their interactions tend to be less enjoyable for both parties. This study contributes to the body of work exploring shared enjoyment and quality time among families of youth with ASD and has implications emphasizing parent-child interactions in ASD clinical practice.

**511.066 (Virtual Poster)** Autism in the Context of Humanitarian Emergency: The Lived Experiences of Syrian Refugee Parents  
A. S. Bernier<sup>1</sup>, S. Nsair<sup>2</sup>, H. Hans<sup>2</sup> and A. McCrimmon<sup>1</sup>, (1)Werklund School of Education, University of Calgary, Calgary, AB, Canada, (2)University of Calgary, Calgary, AB, Canada

**Background:** The Syrian Crisis emerged due to various sociopolitical factors, including an authoritarian regime, finite resources, and proxy involvement (Musarurwa & Kaye, 2016). There is a dearth of literature investigating the impact of the Syrian Crisis, which is scarcer for families resettling with autistic children. Indeed, autistic children are tremendously susceptible to the adverse impacts of war and displacement as influenced by their diagnostic profile (Jabri, 2015), which includes impairments with social communication (American Psychiatric Association [APA], 2013). That is, war-related circumstances may elicit withdrawal or aggressive behavioural responses, and/or exacerbate already existing symptomatology (Jabri, 2015). Considering the resettlement experiences of refugee populations is important to enhance adjustment, adaptation, service acquisition, and well-being outcomes (Hynie, 2018; Ryan et al., 2008). Indeed, pre-migration experiences that consist of stigma, a lack of psychological resources, and reduced professional support (e.g., Hedar, 2019) can impact refugee adjustment (Ryan et al., 2008).

**Objectives:** The aim of this study was to obtain a comprehensive understanding of families' migration and resettlement experiences, which can serve to inform and enhance future service provision. The following research question guided this study: How has the lived experience of resettling in Alberta, Canada, and accessing supports/services been for Syrian refugee families with an autistic child? Despite the current study being framed within a Canadian province, it has several international implications and applications to broader theories.

**Methods:** The qualitative analytical approach of interpretive phenomenological analysis (Smith et al., 2009) was used with careful consideration of ontology, epistemology, and axiology. In line with literature guidelines, purposeful sampling was conducted with three participants meeting inclusion criteria and, subsequently, undergoing in-depth semi-structured interviews (Smith et al., 2009). A professional Arabic interpreter was used during data collection, which aligned with established rationale in the literature (e.g., Croot et al., 2011). This study established trustworthiness through peer debriefing, triangulation, and thick contextual description (Amin et al., 2020). Additionally, credibility and validity were enhanced through use of Yardley's four metrics of qualitative rigor (sensitivity to context, commitment and rigour, transparency and coherence, and impact and importance). Transcribed interviews underwent systematic analysis.

**Results:** Each participant's interview rendered 11 unique emergent themes. These themes contributed to the superordinate conceptual thematic structure that accounted for cross-participant experiences. Seven superordinate conceptual themes were derived: (1) Crises Affecting Autism; (2) Cultural Importance and Relevance; (3) Impactful Perceptions; (4) Support and Service Gaps; (5) Positive Attributions; (6) Quotidian Resettlement Difficulties; (7) Vital Relational Networks. All participants described barriers with resettlement, positive experiences with supports/services, and areas of continued need.

**Conclusions:** The results of this study were situated within existing theoretical frameworks for contextualization and elucidation of the results. Such theoretical frameworks include models for migrant adaptation (Ryan et al., 2008), psychosocial adjustment (Georgis et al., 2017), and stress (McCubbin & Patterson, 1983). Implications for practice included informing effective support and service practices, bolstering culturally responsive practice, and addressing crisis-sensitive practice. This study also aimed to address gaps in autism-related research, such as the importance of attending to diverse populations with complex layers of vulnerability.

**511.067 (Virtual Poster)** Understanding the Experiences of Autistic Working Mothers in Australia: An Exploratory Study

#### Background:

The lives and experiences of autistic women, including parenthood and employment, is an emerging area of research. Autistic females have historically been misdiagnosed and/or diagnosed with autism later in life and have higher levels of co-occurring mental health conditions than autistic males and the general population. Managing employment and parenthood are factors that influence female mental health and quality of life. Research has demonstrated a decrease in Australian female life satisfaction in recent decades, attributed to increased stressors through juggling work and family roles, contributing to a greater share of unpaid household labour, and other aspects of gender inequity including the gender pay gap. Studies investigating employment have identified that autistic adults experience greater unemployment and underemployment than non-autistic populations and require specific supports in finding and maintain employment. This prior research leads us to question whether autistic women require specialised supports for managing work and motherhood. To the best of our knowledge, there is no current research focused on autistic working mothers; thus better understanding of the experiences of autistic women who are working and caring for children is imperative.

#### Objectives:

This study aimed to understand the benefits of employment and being a parent/caregiver for autistic mothers, to determine the challenges in being an autistic working mother, and to identify whether there are specific supports that are needed for autistic mothers who manage caring and work responsibilities.

#### Methods:

A qualitative methodology was adopted, utilising a phenomenological research design. An advisory group of five autistic adults reviewed participant materials. Ten autistic working mothers aged between 28 and 49 years of age were recruited via social media advertisements, and participated in a 45-60-minute semi-structured interview. The resulting data was analysed using an inductive thematic analysis approach. A second rater recoded 20% of the data, with fair to good inter-rater agreement (Kappa = 0.51). Member checking occurred with participants to improve trustworthiness of results prior to finalisation of key themes.

#### Results:

Three key themes were identified: 'Work gives me purpose' - how employment supports mental wellbeing, financial independence, and provides important social interaction; 'Everyone thinks I look okay' - autistic working mothers balance challenges in addition to those typically experience by non-autistic working mothers, which include supporting the needs of their, often, neurodiverse children, managing workplace accommodations, and autistic burnout; 'Self-sufficiency out of necessity' - the lack of specialised supports is a key issue which leads to many autistic working mothers no longer asking for assistance and coping as best they can.

#### Conclusions:

Autistic working mothers experience unique challenges in addition to the stressors typically encountered by non-autistic working mothers, which impact their mental and physical wellbeing. These findings support the need for specific supports for autistic working mothers to enable greater workforce participation and mental wellbeing in this under-researched population.

#### **511.068** (Virtual Poster) Caregiver Concerns during Prodromal Autism; A Qualitative Study

**F. Avila<sup>1</sup>, M. R. Talbott<sup>2</sup>, S. Dufek<sup>3</sup> and G. S. Young<sup>4</sup>**, (1)Psychiatry and Behavioral Sciences, University of California at Davis MIND Institute, Sacramento, CA, (2)Psychiatry and Behavioral Sciences, UC Davis MIND Institute, Sacramento, CA, (3)Psychiatry, University of California, Davis, Sacramento, CA, (4)University of California at Davis, MIND Institute, Sacramento, CA

---

#### Background:

Despite progress in early identification, the average of diagnosis for autism spectrum disorder has remained around four years for decades (CDC, 2020). Parents often notice developmental differences as early as the first year of life, but face long waitlists when seeking early evaluations and services (Kanne and Bishop 2020; Zuckerman et al., 2015). Better understanding the specific behaviors that drive parents to seek early services may help to improve early screening and identification tools and help to guide the future development of supportive interventions for this early period.

#### Objectives:

Our aim is to understand specific concerns parents have during the prodromal period that lead them to seek out early specialized evaluations, using a qualitative approach that identifies shared themes from parents' open-ended text responses.

#### Methods:

Thirty-seven (n = 37) participants from an ongoing study evaluating the feasibility of telehealth evaluations for infants completed three questionnaires that prospectively asked parents about their current concerns. These questionnaires were qualitatively analyzed for themes within six broad domains: social communication, repetitive and restrictive behaviors, motor, general, medical, and family history. Participants' open-ended responses to each questionnaire were coded individually. Codes were then tallied across all three questionnaires for each participant, without duplicating reappearing codes. Codes were used to generate qualitative themes based on the similarity of the reported concerns within each domain and within each questionnaire. The frequency of each theme was tallied and used to calculate averages, standard deviations, and percentages of parents reporting a given theme within each category. Finally, illustrative quotes were chosen from the questionnaires, and organized per theme.

#### Results:

With a total of 231 concerns reported across all 3 questionnaires, on average parents reported 6.24 concerns (SD = 3.89). Across all domains, 47.61% of reported concerns were for social communication, 24.24% for RRB, 6.92% for motor, 14.71% for general, 4.76% for medical, and 1.73% for family history.

Themes occurring with a frequency over 20% are considered highly prevalent. For the social communication domain, the most prevalent parent concern themes were reduced eye contact. For RRB the most prevalent themes were around repetitive movements, sensory stimulation, and other unusual movements or behaviors. Motor concerns included fine and gross motor delays, and specific motor delays concerns. General concerns included temperament, overall care, and general developmental delays. For medical, neurodevelopmental concerns were reported. And family history concerns only included an older sibling already being diagnosed with ASD.

An illustrative quote describing reduced eye contact from the social communication domain: "I started to notice a shift before he turned 6 months, such as decrease in eye contact;" for repetitive movements: "Repetitive playing with taking objects out of a container and putting them back in."

#### Conclusions:

In this sample of caregivers, concerns around social communication development and restricted and repetitive behaviors were highly prevalent. The identified themes point to future directions for developing assessments and supportive interventions to better address families needs during a prodromal period of development by guiding specialists to heed social communication and restrictive and repetitive behaviors concerns from caregivers.

#### **511.069** (Virtual Poster) Caregiver Experiences Related to Employment of Their Adult-Aged Children with Autism

**K. Wilson<sup>1</sup>, C. Marsack-Topolewski<sup>2</sup>, G. Knollman<sup>1</sup> and D. Smith<sup>1,3</sup>**, (1)*Towson University, Towson, MD*, (2)*School of Social Work, Eastern Michigan University, Ypsilanti, MI*, (3)*Temple University, Philadelphia, PA*

**Background:** Meaningful and lasting employment has been difficult for many individuals with autism spectrum disorder (ASD) to obtain. Caregivers are often highly involved in the employment process for their adult children with ASD (Nicholas et al., 2018). Caregivers develop deep relationships with their adult children with ASD, often making them most familiar with their characteristics and how they might impact training and potential employment (Gal et al., 2013; Hand et al., 2018). Although highly credible and central to the employment process of many adults with ASD, parental caregiver experience is particularly absent in the literature on employment for adults with ASD.

**Objectives:** The objective of this study was to examine caregivers' experiences and perceptions surrounding employment for their adult-aged children with ASD.

**Methods:** The authors used phenomenological methodology to explore caregivers' experiences surrounding employment for their adult-aged children with ASD. Criteria for participation in the study included: Caregiver of an adult-aged child with ASD (18+ years), 50+ years of age, and able to read and comprehend English. Caregivers were recruited throughout the United States through autism support groups and organizations.

Interviews focused on caregivers' quality of life, social support networks, and experiences related to caregiving adult children with ASD. Interviews were transcribed and redacted of identifying information. Accuracy of each transcript was reviewed by the principal investigator and interpretation was confirmed for accuracy by 10 participating caregivers. Line-by-line coding was completed using a phenomenological approach that employed the following steps (Polkinghorne, 1989): (1) dividing text into units, (2) transforming units into meaning by identifying themes, and (3) bringing together meaning-based themes to describe caregivers' experiences on the topic. The last step in the coding process involved independent coders coming to consensus about the final set of themes and representative quotes from caregivers.

**Results:** Fifty-one caregivers participated, with 66% between 50-59 years (range: 50-70 years), 82% female, and 90% Caucasian/white. Additional demographic information will be presented. Three themes emerged with findings depicting caregivers' perceptions of a shared experience with their adult-aged children with ASD surrounding motivation and challenges related to employment pursuits. The overarching themes were (1) motivation for employment and independence, (2) variability of job training experiences and (3) negative experiences surrounding employment. Each of the themes will be described with quotations to add context and depth.

**Conclusions:** Results add to the growing body of research on the perspective of caregivers in transition and employment processes for adults with ASD. Caregivers interviewed for this study indicated a critical role in helping their adult child locate and secure employment, especially as school-based support faded. Caregivers' contributions went beyond financial capital to include investment of social capital through networking and building

of relationships to expand opportunities. Further examination of concerns surrounding long-term interdependence could be explored as both the caregiver and adult with ASD age and enter new stages of transition.

**511.070** (*Virtual Poster*) Characterizing the Accommodations Made By Parents of Young Children with Autism: A Mixed Methods Analysis  
**Y. G. Dai** and A. S. Carter, *Department of Psychology, University of Massachusetts Boston, Boston, MA*

---

**Background:** Social communication challenges, inflexible adherence to routines, and heightened response to sensory input often interfere with an autistic child's participation in activities (Bonis, 2016). Accordingly, their parents frequently make changes to their daily routines (i.e., accommodations). Few studies have explored the types of accommodations caregivers make to their *family's* routines after their young child is diagnosed with autism.

**Objectives:** (1) Characterize the frequency and domains of accommodations by parents of children with autism; (2) Explore whether child characteristics predict the number of accommodations; (3) Identify themes within accommodation domains.

**Methods:** One hundred seventy-four parents (166 mothers) of a child with autism (17-38 months old;  $M = 28\text{mo.}$ ) completed the family accommodations interview. The interview was developed by Seltzer and Krauss to assess accommodations in six domains (household routines, social activities, work schedule, finances, religious activities, and engagement with family members) over the past 18 months. Parents were interviewed using the Vineland Adaptive Behavior Scales (Sparrow et al., 1984) to assess child adaptive skills and children were tested with the Mullen Scales of Early Learning (Mullen, 1995) and Autism Diagnostic Observation Schedule (Lord et al., 2000) to assess cognitive skills and autism symptom severity respectively. We used a mixed methods analysis to characterize the frequency and types of parental accommodations.

**Results:** 158 participants (91%) made accommodations in at least one domain, 98 (56%) made accommodations in at least three domains, and 11 (6%) endorsed accommodations in all domains. The number of accommodations made by caregivers was not predicted by the child's cognitive functioning,  $F(4,167) = 1.75, p = .14$ , autism symptom severity,  $F(4,161) = 0.16, p = .96$ , or adaptive skills,  $F(4,168) = 0.74, p = .57$ . Parents most often reported accommodations in social activities ( $N = 118$ ; 67.82%) followed by household routines ( $N = 110$ ; 63.22%), work ( $N = 101$ ; 58.05%), communication with family ( $N = 70$ ; 40.23%), finances ( $N = 62$ ; 35.62%), and religious activity ( $N = 39$ ; 22.41%).

Thematic analysis was used to qualitatively explore themes within accommodation domains. Examples of predominant themes include: (a) having to quit ( $N = 29$ ) or cut-back ( $N = 22$ ) on work; (b) participating in fewer social activities (e.g., gatherings, parties, restaurants;  $N = 75$ ), (c) experiencing disruptions to errands ( $N = 54$ ); (d) withdrawing from religious services ( $N = 29$ ); and (e) having fewer interactions with family members ( $N = 57$ ). Children's disruptive behavior in community settings, intensive early intervention schedules, and a perceived lack of understanding from others about their child's behavior, contributed to accommodations across domains. Positive themes emerged in the social and family contact domains: seven parents reported socializing more (e.g., through support- and play groups) and 10 parents reported increased support from family members since their child's diagnosis.

**Conclusions:** Characterizing accommodations may (a) illuminate when accommodations support optimal child development and when they negatively impact parent and child wellbeing, and (b) inform policy changes, including improving family leave and adding psychoeducation to religious institutions to support parents who are raising children with autism.

**511.071** (*Virtual Poster*) Child Disruptive Behavior and Parenting Stress: The Moderating Role of Shared Enjoyment in Parent-Child Activities  
**R. Bradley<sup>1</sup>**, E. A. del Rosario<sup>1</sup>, L. B. Quetsch<sup>1</sup>, C. Brown<sup>2</sup>, L. Aloia<sup>3</sup> and S. M. Kanne<sup>4</sup>, (1)University of Arkansas, Fayetteville, AR, (2)Pacific University, Hillsboro, OR, (3)Communication, University of Arkansas, Fayetteville, AR, (4)Center for Autism and the Developing Brain, White Plains, NY

---

**Background:** It is well-documented that caregivers of youth with ASD experience increased rates of parenting stress. Child problem behavior emerges in the literature a key factor implicated in increased parenting stress among these caregivers, with recent prominent research indicating that this relationship is likely bidirectional. Research among families in the general population suggests that parenting behavior plays a role in the transactional relationship between parenting stress and child problem behaviors, such that maladaptive parenting behaviors (e.g., increased criticism, decreased enjoyment) are associated with both parenting stress and child externalizing behavior. However, qualities of the parent-child relationship in families of youth with ASD have rarely been examined in this context. Given the significant global family impacts of both child problem behavior and parenting stress, examining familial factors that can potentially buffer this relationship is of clinical importance.

**Objectives:** The present study assessed the potential moderating effect of parental enjoyment during parent-child shared activities on the relation between child problem behavior and parenting stress.

**Methods:** Caregivers ( $N = 511$ ) of youth ages 4 – 18 completed the Parenting Stress Index-Short Form (PSI) and two measures of child problem behavior (Eyberg Child Behavior Inventory; ECBI; Children's Scale of Hostility and Aggression; C-SHARP). The ECBI and C-SHARP together produced four total scores measuring child disruptive behavior that were used in the present analyses: the ECBI Intensity scale, the ECBI Problem scale, the C-SHARP Verbal Aggression scale, and the C-SHARP Physical Aggression scale. Parents also reported on their level of enjoyment during shared activities with their child. Four moderation models were conducted to determine whether the association between child problem behavior and parenting stress was moderated by parental enjoyment.

**Results:** Results indicated that greater child disruptive behavior and lower self-reported parental enjoyment during shared activities were both associated with increased parenting stress in all models ( $p$ -values  $< .001$ ). However, the interaction between child problem behavior and parental

enjoyment was only significant in the models assessing the C-SHARP Verbal Aggression and ECBI Problem scales. Results suggest parental enjoyment moderates the relationship between child behavior problem and parenting stress in the context of parent-perceived verbal aggression and broad severity of child disruptive behavior problems ( $\beta = 1.63$ ,  $SE = .82$ ,  $p < .05$ ;  $\beta = .28$ ,  $SE = .13$ ,  $p < .05$ ) but not in the context of physical aggression or parent-reported frequency of problem behavior ( $\beta = .78$ ,  $SE = .97$ ,  $p = .42$ ;  $\beta = .72$ ,  $SE = .83$ ,  $p = .39$ ).

**Conclusions:** This investigation found support for an interaction between parental enjoyment in parent-child interactions and child problem behaviors, such that parents with low enjoyment experience increased parenting stress even in the context of low child problem behavior. This relationship differed by problem behavior index, suggesting that specific problem behaviors may impact the family in distinct and clinically meaningful ways. These findings demonstrate the importance of examining the quality of the parent-child relationship as a potential treatment target among families endorsing child problem behavior and parenting stress.

**511.072 (Virtual Poster) Child Disruptive Behaviors As a Mediator of the Impact of Child Sleep Quality and Parental Stress**

**E. Thorpe<sup>1</sup>**, H. Onovbiona<sup>1</sup>, L. B. Quetsch<sup>1</sup>, C. Brown<sup>2</sup>, L. Aloia<sup>3</sup> and S. M. Kanne<sup>4</sup>, (1)University of Arkansas, Fayetteville, AR, (2)Pacific University, Hillsboro, OR, (3)Communication, University of Arkansas, Fayetteville, AR, (4)Center for Autism and the Developing Brain, White Plains, NY

---

**Background:** Over 50% of children with autism spectrum disorder (ASD) experience sleep disturbances (Liu et al., 2006). The high prevalence of sleep problems in children with ASD has been associated with greater levels of child disruptive behaviors (Mazzone et al., 2018). In addition, prior findings reveal that increased sleep problems in children with ASD predict higher levels of parental stress. Further, the presence of child disruptive behaviors can also lead to increased levels of parental stress (Ward, 2020). However, the role of child disruptive behaviors in the association between child sleep quality and parental stress remains unclear – especially as it relates to families of children on the autism spectrum.

**Objectives:** The primary objective of this study was to examine the role disruptive behaviors in children with ASD have on the relationship between child sleep quality and parental stress. Examining this relationship may help to better understand the mechanisms underlying child disruptive behaviors in children with ASD.

**Methods:** In this study, participants were a sample of families of children ages 4-18 years with ASD and disruptive behaviors ( $N = 502$ ). Bootstrap mediation analyses (using 5,000 samples) were used via PROCESS in SPSS (Hayes, 2013) to examine if disruptive behaviors (measured by the Eyberg Child Behavior Inventory; ECBI) mediated the impact of child sleep quality (measured by the Children's Sleep Habits Questionnaire; CSHQ) on parental stress (measured by the Parenting Stress Index: Short Form). Higher scores on the CSHQ indicated poorer sleep quality. Indirect effects were considered significant when zero was not contained in the 95% confidence intervals.

**Results:** The results revealed that controlling for disruptive behaviors, the regression of child sleep quality on parental stress was significant,  $\beta = 1.9$ ,  $t(500) = 10.7$ ,  $p < .01$ . The regression of child sleep quality on child disruptive behaviors was also significant ( $\beta = 3.46$ ,  $t(500) = 9.63$ ,  $p < .01$ ). Controlling for the mediator (disruptive behaviors), child sleep quality predicted parental stress to a lesser extent ( $\beta = 1.12$ ,  $t(499) = 6.77$ ,  $p < .01$ ), indicating that disruptive behaviors partially mediated the relationship between child sleep quality and parental stress,  $\beta = 0.71$ , 95% CI= [.5145, .9414].

**Conclusions:** Child disruptive behaviors mediated the relationship between child sleep quality and parental stress. The results suggest that increased sleep disruptions may result in increased child disruptive behaviors, which may lead to increased parental stress. Interventions targeting sleep difficulties in children with ASD and child disruptive behaviors concurrently may be helpful to reduce parental stress. Future directions will be discussed in the poster.

**511.073 (Virtual Poster) Community Participation Challenges of Minority Transitioning Adults with Autism Spectrum Disorder (ASD); Parental Perspective**

**A. P. Davidson<sup>1</sup>**, B. Pfeiffer<sup>2</sup> and M. Salzer<sup>3</sup>, (1)Health and Rehabilitation Sciences, Temple University, Philadelphia, PA, (2)Rehabilitation Sciences, Temple University, Philadelphia, PA, (3)Temple University, Philadelphia, PA

---

**Background:** Individuals with Autism Spectrum Disorder (ASD) face challenges with community participation. Black or African Americans with ASD experience additional barriers to community participation. Parents of Black or African American individuals with ASD experience extra concern when their child participates in the community.

**Objectives:** The purpose of this research was to determine parents perceived barriers with community participation for Black or African American individuals with ASD.

**Methods:** Focus group and Photovoice design. Demographic Survey of Parents of Self-identified Black or African American individuals with ASD completed on-line. Photovoice data and narratives were collected to describe their concerns. Data was analyzed using grounded theory methodology. Data was coded into themes and subthemes and relationships between themes were identified.

**Results:** Seven (87%) women, and one (13%) man participated in the study. Results identified to two major themes: 1.concerns with community participation and 2. strategies for emergency responses. Five subthemes emerged from those two main themes: 1. disability related 2. race related 3. negative experiences 4. caregiver burden 5. community participation strategies. Parents of Black or African American individuals report vulnerabilities associated with disability as their greatest concern when participating in the community. Race was a close second.

**Conclusions:** This study identified important considerations to understand perceived challenges of community participation for minority individuals with ASD. Targeted research to collect information about barriers and facilitators to community participation, emergency response, safety, and race education is necessary to increase access to participation for this population. Focus groups are ongoing.

**511.074 (Virtual Poster)** Comparisons of Parental Stress and Child Behavior in Families Seeking Behavioral Treatment: A Diverse Sample of Children with Autism Spectrum Disorder

**H. Onovbiona<sup>a</sup>, L. B. Quetsch<sup>a</sup>, C. Brown<sup>a</sup>, L. Aloia<sup>a</sup> and S. M. Kanne<sup>a</sup>,** (1)University of Arkansas, Fayetteville, AR, (2)Pacific University, Hillsboro, OR, (3)Communication, University of Arkansas, Fayetteville, AR, (4)Center for Autism and the Developing Brain, White Plains, NY

---

**Background:** Approximately 50% of children with autism spectrum disorder (ASD) exhibit disruptive behaviors (DB; Bearss et al., 2013). While evidence-based treatments in community settings to reduce DBs in youth with ASD are continuing to grow, the evidence that exists to support these services rests on outcomes from White middle- to upper-class families. Little is known about the characteristics of families of children with ASD among systemically racial and ethnic minoritized groups. Exploring the family characteristics for multicultural families of children with ASD who use DB treatments may help researchers and clinicians better understand pressing treatment concerns.

**Objectives:** The goal of this present study was to examine characteristics in a sample of ethnically and racially diverse families of children with ASD who utilize treatments for child DBs. The primary aim of this study was to compare parental stress and behavior characteristics between families who endorsed using services ( $N = 69$ ) and those who do not endorse using treatments for DB ( $N = 95$ ). Frequency of the types of services used will also be reported.

**Methods:** The sample consisted of families living in the United States who identified as Latinx ( $N = 90$ ), Black ( $N = 50$ ), Asian ( $N = 24$ ), Native Americans ( $N = 16$ ), and Pacific Islander ( $N = 6$ ). Some of the families identified with multiple racial and ethnic groups. Analyses were conducted to examine whether families differed on parent (Parenting Stress Index: Short Form) and behavioral measures (Eyberg Child Behavior Inventory; ECBI) based on whether they endorsed using DB therapy.

**Results:** The results revealed that families who endorsed using services reported significantly greater ECBI Problem scores ( $t(162) = 3.244, p = .001, d = .51$ ) and parental stress ( $t(162) = 3.609, p < .001, d = .55$ ). No significant differences in ECBI Intensity scores were found between the two groups ( $t(162) = 1.929, p = .055$ ). The highest endorsed DB treatments included medications, Applied Behavior Analysis, and general therapy.

**Conclusions:** The findings from this study suggest that multicultural families of children with ASD who use treatment for DBs are likely to perceive their child's behaviors as more problematic and are likely to present with higher levels of parental stress. This either suggests that families of children with ASD who use treatments for DB may benefit from services that target parental stress as well as help parents feel more confident in addressing child DBs (e.g., Parent-Child Interaction Therapy) or families are currently participating in services that are not addressing their needs, resulting in parental stress and views of child DB as more of a problem. The results also demonstrated that non-White families of children with ASD are using alternative approaches to treatment more frequently than parent training programs.

**511.075 (Virtual Poster)** Describing the Experience of Suicidal Thoughts and Behaviours in Autistic Youth

**S. J. Howe<sup>a</sup>, K. Turner<sup>a</sup>, H. D. Sanguino<sup>a</sup> and C. McMorris<sup>a</sup>,** (1)University of Calgary, Calgary, AB, Canada, (2)Department of Paediatrics, University of Calgary, Calgary, AB, Canada

---

**Background:**

Suicidal thoughts and behaviours (STBs) are exceptionally common in autistic youth, with suicidal thoughts being about 3-5 times higher than in non-autistic youth. Untreated STBs can have detrimental impacts not only on the youth but also their family. Research has focused primarily on prevalence of STBs in autistic youth, with very little known about the lived experience. Although suicide is often viewed as a solitary act, STBs profoundly impact the entire family, with caregivers often playing a crucial role in suicide prevention. Thus, when considering experiences of STBs and related support needs for autistic youth, it is critical to include the perspectives of caregivers.

**Objectives:**

Although STBs are highly prevalent in autistic youth, the unique characteristics of STBs in these individuals is largely unknown. This study 1) describes *past and present experiences of STBs in autistic youth*, and 2) discusses *caregiver experiences of providing care and obtaining support for the family*.

**Methods:**

Seven semi-structured interviews were conducted with caregivers ( $n=6$  female) of autistic youth (12-20 years,  $M = 15.4$  years old) who experienced STBs. Purposive sampling was used to recruit caregivers through social media advertisements and autism-specific community agencies. Themes were generated using Interpretative Phenomenological Analysis.

**Results:**

Four core themes emerged each with related subthemes. In theme 1, caregivers described *reasons for wanting to die as diverse and varied among youth*. Subthemes indicated youth wished to die: to *take control* (e.g., when not offered choice); as a *strong emotional response in a difficult moment*

(e.g., angry, frustrated, build up and explode); after a *major life event* (e.g., traumatic event); due to *overwhelming sensory or physical experiences* (e.g., auditory stress); when *longing for social connection*; when *feeling not enough* (e.g., letting others down); and to *end emotional pain* (e.g., don't want to live this way anymore). In theme 2, caregivers viewed youth to benefit from *external support to manage suicidal thoughts* (e.g., caregiver intervention to distract, electronics). In theme 3, caregivers expressed *hesitation around emergency services* where they were concerned *emergency medical care might escalate their youth further* or would not offer added support. Finally, in theme 4, caregivers indicated *available support lacked accessibility and was incomplete*. Specifically, caregivers felt support *underemphasized their own caregiver needs*, was *reactive and not preventative*, and included *systemic barriers* (e.g., too many hoops, too much energy, long waitlists, too expensive).

#### Conclusions:

This study offers a preliminary description of the experience of STBs in autistic youth as well as of their caregivers' experience of supporting them through crisis. Caregivers offered rich insight and attributed a wide range of reasons for their autistic youths wish to die, suggesting that a highly individualized approach to assessment and intervention is required. Caregivers played a significant role in supporting their youth to manage thoughts of self-harm. They were ambivalent about traditional medical crisis services and deemed support difficult to access due to barriers. Further investigation of how mental health crisis intervention and prevention strategies can be tailored to meet the needs of autistic youth and their caregivers is needed.

#### **511.076** (Virtual Poster) Developing Screen Time Guidelines for Children and Youth with Autism Spectrum Disorder: Using the Knowledge to Action Framework

**M. Cohen Eilig<sup>1</sup>**, A. Glodjo<sup>2</sup>, T. Jarus<sup>3</sup>, Y. Mayer<sup>4</sup>, J. Chan<sup>1</sup> and N. Kuzyk<sup>1</sup>, (1)Developmental Pediatrics, Sunny Hill Health Centre at BC Children's Hospital, Vancouver, BC, Canada, (2)Sunny Hill Health Centre at BC Children's Hospital, Vancouver, BC, Canada, (3)UBC, Vancouver, BC, Canada, (4)UBC, Vancouver, BC, Canada

---

#### Background:

Over the past decade, screen-based usage among children and youth has increased significantly, particularly among those with Autism Spectrum Disorder who are more susceptible to the potential detrimental effects on health and development. Current screen time guidelines exist for typically developing children and youth. However, these guidelines do not address the specific needs of autistic children and youth.

#### Objectives:

To develop population-specific guidelines that are agreed upon by caregivers and expert clinicians.

#### Methods:

The first stage was an exploratory qualitative study in which experienced clinicians working with children with autism participated in semi-structured in-depth focus groups. The results highlighted a lack of knowledge and awareness, concerns regarding addictions, and a lack of evidenced based and population specific guidelines. In the second stage, based on these results and an extensive literature review on screen time, a survey was created that included different statements regarding the management of screen time. Using the Delphi method, 30 expert researchers, clinicians, and caregivers who have experience working with or caring for children with Autism Spectrum Disorder were invited to complete a series of three surveys. In each round, participants had to rate their agreement on a series of statements. The consensus level was set to 75%. Finally, knowledge translation methods were used to disseminate the final product to stakeholders.

#### Results:

The final guidelines were accepted by more than 80% of the panel in the first and second rounds of the survey. The guidelines included a few sections with the following contents: (1) Special considerations in screen time management for children and youth with Autism Spectrum Disorder (2) Recommendations for caregivers and clinicians to support monitoring and regulating time and content of screen time use (3) Additional resources including a) behaviors to monitor for screen time problematic use b) websites with general information about screen time use. In the third survey, the panel was asked about the best ways to disseminate the new guidelines. 82% of experts agreed that a booklet (online or printed) would be a "good way" to share the guidelines. Experts also reached an agreement that accessibility, organization and structure, clarity, relevance, knowledge, and delivery are important aspects to consider within the knowledge translation product for the next phase of this project.

#### Conclusions:

Providing guidance to parents and clinicians regarding the use of screen time with children with Autism Spectrum Disorder is timely. These guidelines include the best ways to use screen time, the benefits and limitations of screen time, and strategies for mediating screen time conflicts. The agreed-upon guidelines developed in this study could be the steppingstones for clinical interventions for screen time overuse of children with Autism Spectrum Disorder, addressing the screen time crisis that many families are experiencing.

#### **511.077** (Virtual Poster) Differences in Parenting Stressors, Family Resilience, Cognitive Appraisals, and Perceptions of Psychological Crisis Among and within Parents of Children with Developmental Disabilities

**E. Suzukida<sup>1</sup>** and T. Yamane<sup>2</sup>, (1)Graduate School of Developmental and Environment, Human Development and Environment, Kobe University, Kobe, Japan, (2)Graduate School of Developmental and Environment, Kobe University, Kobe, Japan

---

**Background:** There are some differences in perceptions of psychological crisis and family relationships among parents of children with developmental disabilities. For example, mothers of children with autism perceive lower family adaptation than mothers of children without disabilities. However, there is no difference between fathers (Gau et al., 2012). Moreover, Otsuka & Hotta (2013) revealed that mothers of children with developmental disabilities experienced higher stress levels than the fathers. Therefore, it is assumed that parents of children with developmental disabilities perceive their stress and family relationships differently.

**Objectives:** This study was designed to examine (a) differing of parenting stressors, family resilience, cognitive appraisal of parenting stress, psychological stress, mental health, and family adaptation between parents, and (b) the difference of these variables in parental pairs.

**Methods:** A questionnaire was administered to 136 parents (42 fathers and 94 mothers) of children with developmental disabilities. The mean ages of the parents was 44.53 years (30-57 years old;  $SD = 5.50$ ). The mean age of the children was 12.71 years old (5-18 years old;  $SD = 3.95$ ). Thirty-six parent pairs were used for dyadic data. The questionnaire assessed parents' age, child's age, relationship to the child, sex, diagnosis, parenting stressors, family resilience, cognitive appraisal of parenting stressors, psychological stress, mental health and family adaptation.

**Results:** Unpaired  $t$ -tests between parents showed that "difficult understanding and coping" ( $t(128)=2.09, p < .05, d=.40$ ) and "inadequate understanding of child's disability" ( $t(128)=2.43, p < .05, d=.46$ ) in parenting stressors, "appraisal of threat" ( $t(133)=2.57, p < .05, d=.48$ ) in cognitive appraisal, "depression/anxiety" ( $t(129)=2.31, p < .05, d=.43$ ) and "lethargy" ( $t(129)=2.41, p < .05, d=.45$ ) in psychological stress were higher in mothers than fathers. The results also showed that "trust in the power of family" ( $t(122)=1.99, p < .05, d=.38$ ) was higher in fathers than mothers. Intra-class correlation coefficients showed that "conflict caused by child's disability", "cohesion", "trust in the power of family", "balance of individuals and family", "appraisal of impact", "commitment", "moodiness/anger", "mental health", "family adaptation" were slightly or moderately similar ( $ICC=.39-.60$ ) between parents. Paired  $t$ -tests between parents showed "difficult understanding and coping" ( $t(34)=2.15, p < .05, d=.42$ ) and "inadequate understanding of child's disability" ( $t(33)=2.47, p < .05, d=.49$ ), "lethargy" ( $t(35)=2.04, p < .05, d=.48$ ) were higher in mothers than fathers. The results showed that "cohesion" ( $t(35)=2.31, p < .05, d=.37$ ) and "trust in the power of family" ( $t(32)=2.73, p < .05, d=.50$ ) was higher in fathers than mothers. These results indicate differences in perceptions of each variables between parents, and some similarities in perception of each variables in the father-mother pairs.

**Conclusions:** Our findings suggest that fathers and mothers perceive their stress and family resilience differently, while parental pairs were comparable in how they perceived these factors. In the future, it is necessary to consider how the difference influences mutually between parents.

**511.078 (Virtual Poster) Echo Autism STAT: Caregiver Satisfaction and Needs**

**V. Wong<sup>1</sup> and K. Soh<sup>2</sup>,** (1)*Clinical Excellence Research Center, Stanford University, Stanford, CA*, (2)*ECHO Autism Communities, Child Health, Columbia, MO*

---

**Background:**

Evidence has shown that the systems of autism care are fragmented, and children with ASD are four times more likely to experience unmet health care needs compared to children without disabilities (Karpur, 2019). Some commonly reported challenges include delayed diagnosis (Zuckerman et al., 2017), insufficient care coordination (Vohra, 2013), or long waitlists for therapy (Dimian et al., 2021).

These challenges are further exacerbated for underserved groups, such as racial and ethnic minorities (Travers et al., 2013), people with public health insurance (Kuhn et al., 2021), and people living in rural areas (Antezana et al., 2017).

ECHO Autism STAT was developed to solve the aforementioned problems and is growing rapidly to enable primary care physicians to reliably diagnose autism and connect families with the right resources (Mazurek et al., 2019).

**Objectives:** To preliminarily evaluate caregiver satisfaction about the ECHO Autism STAT evaluation and their needs.

**Methods:** We surveyed fourteen caregivers whose children received an autism diagnosis through ECHO Autism STAT.

**Results:**

### **Demographic Information**

A majority of caregivers were white (72%); the rest of the caregivers were Black (7%) and Latinx/Hispanic (21%). The average age of the caregivers was 29.1 years old. Approximately 60% of caregivers reported a household of less than or equal to \$20,000 or \$20,000 to \$40,000. Approximately 64% of the caregivers had a high school GED or some college education.

All children were enrolled in an insurance health plan, and approximately 57% of them enrolled in the state Medicaid health plan.

### **Caregiver satisfaction**

A hundred percent of caregivers reported their STAT PCP providers explained things in a way that was easy to understand, listened carefully to them, showed respect for what they had to say, spent enough time with their child, knew important information about their child's medical history, and followed up with them to help them get connected with services that would help with their child's development. The average caregiver rating of providers was 9.9 out of ten.

### Caregiver support

86% of parents reported that they had not received parent training on how to deliver autism-specific strategies to support their children at home. 92% reported that they were not connected with a parent support group.

### Conclusions:

Empirical evidence has shown that caregivers were satisfied with ECHO Autism STAT providers, and that ECHO Autism STAT positioned well to support the unmet caregiver needs.

### 511.079 (Virtual Poster) Effects of COVID-19 on the Transition Services for Autistic Youth: A Qualitative Analysis

J. Albright<sup>1,2</sup>, E. A. DeLucia<sup>1</sup>, M. Fok<sup>3</sup>, K. Bernstein<sup>1</sup>, L. Sejas<sup>1</sup> and A. Scarpa<sup>1,2</sup>, (1)Department of Psychology, Virginia Polytechnic Institute and State University, Blacksburg, VA, (2)Virginia Tech Autism Clinic & Center for Autism Research, Blacksburg, VA, (3)Department of Psychology, Virginia Tech, Blacksburg, VA

---

**Background:** Previous literature has shown that adequate transition planning for autistic students can increase the likelihood of attending postsecondary education, and other adaptive, prosocial outcomes (e.g., employment, independent living). The COVID-19 pandemic has pervasively impacted human and social services that support the ASD community. In March 2020, Virginia declared a state of emergency which ceased all in-person K-12 instruction. This change brought unprecedented challenges for students with disabilities including reduced or paused school-based therapeutic services. Our qualitative study is the first to examine the effects of the pandemic on transition services for autistic students.

**Objectives:** Elucidate the disparities in transition services for transition-age autistic students following the COVID-19 pandemic.

**Methods:** Caregivers ( $n=5$ ) of children aged 14-21 with an autism classification who received special education services and special education school providers ( $n=5$ ) were interviewed. Autistic students were invited but not required to participate alongside their caregiver in the interviews. Demographic information is reported in Table 1. Participants completed an online demographic survey and a 1-hour virtual interview to describe how transition services have been impacted by the COVID-19 pandemic. Participants received a \$25 gift card upon completion.

Two research assistants transcribed video recordings of the interviews and three separate coders analyzed data using a data-driven thematic approach. Coders initially read the interview transcripts to discuss content and identify preliminary codes. They, then, independently coded each transcript and resolved discrepancies through discussion to achieve consensus to generate and refine content themes.

**Results:** *Misalignment* (e.g., between student skills/interests, parent feedback/concerns, transition services) and resulting *dissatisfaction* were common themes that emerged from caregiver interviews regarding their child's transition services. These conflicts were present prior to COVID-19 and continued as the pandemic persisted. While IEP and transition planning meetings were easily shifted to a virtual format, caregivers and teachers described a *dearth of integrated community-based transition-related experiences* (e.g., on-site job skills training, public transportation practice) and a *lack of access to typical transition-related resources* (e.g., state and local community services). This resulted in an *added burden* on caregivers, who attempted to supplement services at home, as well as teachers, who attempted to adapt to virtual teaching. Interviews with school personnel revealed that *learning opportunities were lost* as virtual skills training (e.g., social skills) remained a challenge for students. As students returned to in-person schooling, social distancing mandates continue to complicate transition planning services.

Despite these challenges, *post-transition goals remain unchanged* for interviewed families. Additionally, caregivers emphasized many *positive effects* of the shift to virtual learning, including improved behavior, gains in adaptive living skills, and decreased family conflict.

Several areas for improvement regarding transition services emerged, including *use of evidence-based behavioral approaches* and an emphasis on *individualized services* that are based on student strengths and interests.

**Conclusions:** These initial qualitative observations show that families and school providers across Virginia have experienced both negative and positive effects on transition services following COVID-19. Future research will provide in-depth analysis of participant's qualitative responses. Data collection is ongoing and will be complete by the time of presentation.

### 511.080 (Virtual Poster) Examination of the Correlation between Physical and Psychological Measures in Parents of Individuals with Autism Spectrum Disorder

N. Johnson<sup>1</sup>, A. Bekhet<sup>1</sup>, E. Zint<sup>2</sup>, J. Wang<sup>2</sup>, S. Pena<sup>1</sup>, A. V. Van Hecke<sup>3</sup>, M. Garnier-Villarreal<sup>4</sup> and A. Ng<sup>2</sup>, (1)Nursing, Marquette University, Milwaukee, WI, (2)Physical Therapy, Marquette University, Milwaukee, WI, (3)Psychology, Marquette University, Milwaukee, WI, (4)Sociology, Vrije University, Amsterdam, Netherlands

---

## Background:

Autism Spectrum Disorder (ASD) impacts the health of the whole family. The World Health Organization recommends adults participate in aerobic physical activity (PA) that is moderate- intensity for 150-300 minutes a week or vigorous-intensity for 75-150 minutes, or a combination of the two intensities. Parenting is associated with declines in physical activity from the pre-parent state due to lack of time, motivation, and need for child care. While exercise improves autistic individuals' health, no literature was located on exercise interventions for parents of individuals with ASD, or on the correlation of physical and psychological health of parents.

## Objectives:

The purpose of this study was to assess baseline physical and mental health of parents of individuals with ASD to tailor a exercise intervention program to their needs. A second purpose was to estimate the relationship of physiologic correlates with psychological correlates of health for parents of individuals with autism spectrum disorder.

## Methods:

As part of a mixed methods pilot study to assess barriers to exercise, and baseline physical and psychological health correlations, N=44 English-speaking parents [n=39 female, n= 5 male; mean age= 46.6 years; n=33 white, n=6 Black, n=3 Hispanic, n=1 Asian, n=1 other] of individuals with ASD (n=31 male, n=13 female) participated in this descriptive, correlational, cross-sectional study, in a Midwest USA city. Physiologic measures included body mass index (BMI), weight, waist and hip measures, sit -stand test, grip test, 2-minute walk test (timed), sit/stand test (timed), and time in sedentary, moderate, and vigorous activity over the course of 7 days from a hip-height accelerometer. Psychological and demographic measures included the (1) Parenting Stress: Autism subscales (Likert scales ranging from "1" not stressful to "5" extremely stressful), for (i) behavior and communication (bc: 6 questions), (ii) advocating for child needs (an: 4 questions), (iii) personal family life (pfl: 10 questions), (iv) parental caregiving (pc: 8 questions); (2) Parent state anxiety (stai: 20 questions) (Likert scale from "1" not at all to "4" very much so), (3) parent positive thinking (pts: 9 questions) (Likert scale from "0" never to "3"always), parent depression (Phq-9: 9 questions) (Likert scale from "0" not at all to "3" nearly every day), and 10 demographics questions to describe the sample. All the composite variables for psychological scales were calculated as the average across items.

## Results:

Parent's median body fat was high (39.2 % (min/max, 20.3-59.1%). The median for parents' time in moderate physical activity was 152.5 minutes (mins)(min/max, 4- 496.8 mins), thus individuals were meeting requirements, yet there was a large range where many were sedentary. Further the parenting stress of advocating for the child's needs ( $p=0.043$ ) was inversely correlated with moderate physical activity. Positive thinking was related to less depression ( $p=0.002$ ).

## Conclusions:

Results of this pilot showed that some parents had a low amount of activity. Low activity correlated to increased stress of advocating for child's needs. Parents need supports to be able to prioritize exercise. Future studies should include a larger sample to verify these effects.

## **511.081** (Virtual Poster) Examining the Impacts of Stress on Parent Emotion Regulation Abilities

**S. Constant<sup>1</sup>, S. H. Kim<sup>2</sup> and D. Swain<sup>3</sup>, (1)Psychiatry, Center for Autism and the Developing Brain Weill Cornell Medicine, White Plains, NY, (2)Psychiatry, Center for Autism and the Developing Brain, White Plains, NY, (3)Virginia Polytechnic Institute and State University, Blacksburg, VA**

## Background:

Parents of children with Autism Spectrum Disorder (ASD) consistently report higher levels of stress compared to parents of children with neurotypical and delayed development (Hayes and Watson, 2012). Parent-mediated interventions (PMIs) necessitate parents to learn therapeutic techniques to maximize and generalize child gains, adding to the burden of parenting. While several PMIs for young children with ASD target challenging child behaviors, parent factors that may play an important role in successful adoption of strategies, such as emotion regulation (ER) abilities, are often overlooked. As a first step, we aim to explore the impacts of stress on parent ER abilities.

**Objectives:** (1)Examine parent stress profiles and changes in parent stress over 6-month period of time.(2)Evaluate the effects of parent stress on parent ER abilities.

## Methods:

Participants included 43 dyads of toddlers with ASD ( $M_{age}=32.6$  months,  $SD_{age}= 7.8$ ) and a primary caregiver ( $M_{age}=37.8$  years,  $SD=5.3_{age}$ ). Parents self-reported on their levels of stress as it relates to multiple domains (Parenting Stress Index-Short Form subscales: Parental Distress [PD], Parent-Child Dysfunctional Interaction [PCDI], and Difficult Child [DC], with higher values indicating more stress) and ER abilities (cognitive reappraisal and emotion suppression [Emotion Regulation Questionnaire subscales] and psychological inflexibility [Action and Acceptance Questionnaire]). A subset of families (n=11) completed stress measures 6 months later. Separate regressions were run for each parent ER strategy with all three parent stress subscales entered as predictors. There were no significant correlations between parent age, child age, child NVIQ and parent ER abilities;

therefore, these parent and child factors were not included as covariates in regression analyses. Paired sample t-tests were run to examine changes in parent stress over 6 months.

#### Results:

In the current sample, the percentage of parents who reported clinically elevated levels varied across stress domains ranging from 11.9% ( $n=5$ ) for PD to 16.7% ( $n=7$ ) for PCDI and 21.4% ( $n=9$ ) for DC. For the subset of parents with two timepoints, no significant changes were noted in regard to any parenting stress subscales. The model predicting cognitive reappraisal was not significant. The model predicting parent emotion suppression use was significant; however, no parent stress predictors were significant. Parental Distress ( $\beta=.66$ ,  $p<.001$ ) and Difficult Child ( $\beta=-.39$ ,  $p=.03$ ) significantly predicted psychological inflexibility, such that higher report of distress regarding the parenting role and lower perception of child difficulty corresponded with increased inflexibility toward negative or unwanted emotions.

#### Conclusions:

The current study sheds light on the importance of examining the role of parenting stress on parent ER known to impact parenting abilities. Parenting stress, especially as it relates to the parenting role and child characteristics, significantly impacted parents' psychological inflexibility, or the unwillingness to experience unwanted thoughts and emotions even when valued goals are identified. PMIs may benefit from the inclusion of interventions that specifically target psychological inflexibility, such as Acceptance and Commitment Therapy. Interestingly, the current sample consisted of lower rates of clinically significant stress compared to previous studies (Padden and James, 2017) and results should be replicated with larger, more diverse samples to better understand the influences of these factors.

#### **511.082** (Virtual Poster) Exploring Nutrition, Physical Activity, and the Role of Pet Dogs in Households with a Child with Autism Spectrum Disorder: The Dane Study

**S. C. Foltz<sup>a</sup>**, C. Mule<sup>a</sup>, D. Linder<sup>a</sup>, A. Must<sup>a</sup>, S. Cash<sup>a</sup>, J. Adkins<sup>a</sup> and E. Halbreich<sup>a</sup>, (1)Tufts University, Boston, MA, (2)Center for Children with Special Needs, Tufts Medical Center, Boston, MA, (3)Cummings School of Veterinary Medicine, Tufts University, Grafton, MA, (4)Tufts University School of Medicine, Boston, MA, (5)Friedman School of Nutrition Science and Policy, Tufts University, Boston, MA, (6)Tufts University, Medford, MA

---

**Background:** Children with autism spectrum disorder (ASD) have unique risk factors that can impact healthy eating and physical activity behaviors. However, few obesity prevention interventions take into consideration the attributes of ASD, and fewer still offer family-based lifestyle programming. Incorporating pet dogs already living with families may enhance healthy eating and physical activity behaviors among children with ASD through several potential mechanisms, such as patience with gross-motor skill challenges or an indirect approach to modeling healthy eating. Notably, little is known about the experiences of children with ASD and their families with respect to dog ownership and the potential approaches through which an animal-assisted intervention (AAI) might work.

**Objectives:** The overall goal was to conduct a formative, qualitative study to gain an understanding of the role of pet dogs in the lives and lifestyle habits of families with ASD.

**Methods:** We conducted interviews with ten parent-child dyads. Eligibility criteria were living with a pet dog, English-speaking, child between 8-18 years of age with an ASD diagnosis, and IQ greater than 70. Dyads were recruited via postings to listservs and social media and by sharing study information with healthcare providers. The interview guides were designed to explore the relationship between children with ASD and their pet dogs; the role of the dog in family life; attitudes and practices related to physical activity and nutrition; and thoughts about intervention strategies. Interviews were conducted from August-December 2020 using Zoom videoconferencing. All interviews were audio-recorded and transcribed verbatim. We used a directed qualitative content analysis approach. NVivo 12 was used to assist with the analysis.

**Results:** Both parents and children described a strong and loving bond between the child and dog. Parents felt that the relationship benefitted the child socially because of the dog's attention and companionship. Parents stated that the dog integrates well with the family's routine, although negative impacts included added responsibilities and financial concerns. With respect to nutrition and physical activity, children felt that healthy eating and exercise were important for both them and their dog. Most parents said that they make healthy eating a priority for the whole family but mentioned challenges such as rejection of new foods. Parents described physical activities that the family does together, but expressed challenges that included inconvenience and added effort when the dog is involved. In terms of programming that would incorporate their dog to help teach children about nutrition and physical activity, most children expressed interest in learning more, either from their parents or by reading about it. Almost all parents were favorable toward this type of program, although some were concerned about having the bandwidth to implement it.

**Conclusions:** This exploratory work suggests that while pet dogs present some challenges to a family with a child with ASD, overall the dog integrates well and provides benefits for the child. AAIs to improve nutrition and physical activity could build on the strong bond that children can have with their pet dogs, but it may not be feasible for parents to deliver such programs.

#### **511.083** (Virtual Poster) Exploring Occupational Balance and Quality of Life in Primary Caregivers of Autistic Children: A Qualitative Study **G. Davy**, K. L. Unwin, J. Barbaro and C. Dissanayake, Olga Tennison Autism Research Centre, La Trobe University, Melbourne, VIC, Australia

---

**Background:**

Occupational balance (i.e., subjective experience of engaging in sufficient occupations/activities) has been shown to have a positive influence on health, well-being, and life satisfaction in the general population. Parents of autistic children, particularly primary caregivers, often modify their participation across leisure, social, and workforce contexts to meet the caregiving needs of their child. Past research suggests that changes to occupational balance may play a role in the subjective quality of life (QoL) in parents of autistic children. However, few studies have examined the occupational experiences of caregivers and the impact that participation may have on their QoL.

#### Objectives:

The aim in the current study was to examine caregiver experiences, perceptions, and beliefs in relation to parenting their autistic child/ren with a particular focus on their QoL in relation to their ability to participate in leisure, workforce, and community related activities.

#### Methods:

An experiential qualitative approach was adopted where 20 primary caregivers aged 29–48 years (all female) of children (7–11 years) diagnosed with autism participated in individual semi-structured interviews regarding participation and QoL. Additional questions were included to capture the impact of the COVID-19 pandemic (e.g., “*How has COVID-19 impacted your participation both at home and in the community?*”). Audio recordings were transcribed verbatim via Otter.ai software and analysed utilising a reflexive approach to thematic analysis in NVivo.

#### Results:

A number of themes were identified capturing the parenting experience of *balancing caregiving responsibilities* with occupational needs and QoL. While many benefits were identified with parenting an autistic child, primary caregivers also acknowledged challenges such as accommodating the child’s needs and organising and attending their child’s appointments. These challenges were exacerbated for single parents and parents of children who needed added vigilance and support in daily activities.

A broader theme of *achieving occupational balance* suggests the importance of participation for the caregivers own QoL and identity. While a range of meaningful activities were reported, re-engaging in the workforce was commonly identified, particularly for the caregiver’s identity outside of the parenting role. Finding the time for participation was often complex due to the increased time pressure and fatigue experienced by the parents and the planning/support required, often resulting in parents avoiding occupational participation beyond that which was necessary.

Themes relating to *living through the COVID-19 pandemic* captured the additional challenges to daily life reported by parents, such as balancing home schooling while working from home. However, positives were also identified such as the forced time at home providing new opportunities for self-care, leisure, and family activities.

#### Conclusions:

The responsibilities associated with raising an autistic child impacts the occupational balance of primary caregivers. Advocating/laiaising with services and/or supports for the child, and the vigilance required outside of the home environment increases the mental load for parents of autistic children, limiting the time available to engage in meaningful activities. The findings highlight that additional consideration and support is needed for caregivers of autistic children, particularly single parents, to improve their ability to meet and maintain their occupational balance and QoL needs.

#### **511.084** (Virtual Poster) Family-Centered Care in ABA: Parent and BCBA Perspectives

**M. Held<sup>1</sup>**, A. Witwer<sup>2</sup>, G. Hilbrands<sup>1</sup>, J. Thomas<sup>1</sup> and L. Delfunt<sup>1</sup>, (1)*The Ohio State University Nisonger Center, Columbus, OH*, (2)*The Ohio State University, Columbus, OH*

Background: In recent decades, the autism field has embraced family-centered care (FCC), with several studies demonstrating the positive impact of FCC on families. FCC involves offering care to families that is aligned with their needs, wishes, and values. However, parents of children with ASD are less likely to report receiving FCC than parents of children with other health care needs. Treatment providers often spend significant amounts of time with parents and children with ASD and as such have ample opportunities to implement FCC. Applied Behavior Analysis (ABA) is the most commonly utilized category of treatment for ASD, giving providers of ABA the opportunity to have a particularly significant impact on families. No known studies have examined the state of FCC in ABA, and FCC is not a required component of training for Board Certified Behavior Analysts (BCBAs). In order to improve FCC in ABA, it is necessary to first explore the current implementation of FCC

Objectives: To examine the current state of FCC in ABA and identify training needs for BCBAs.

Methods: Separate national focus groups were conducted with a) parents of children with ASD receiving ABA intervention and b) BCBAs providing ABA intervention to children with ASD. Focus groups followed a semi-structured format and were guided by a moderator. Parent Focus Groups focused on communication and interactions with BCBAs and the impact of BCBAs on parental stress. BCBA Focus Groups focused on professional topics in which additional training is desired and communication and interactions with parents. Focus groups were conducted until data saturation was reached. In total, three Parent Groups (n=16) and three BCBA Groups (n=10) were conducted. A two-step qualitative data analysis process was conducted in order to determine themes. First, open coding was completed by two coders who independently reviewed the transcripts from each focus group and labeled “codes,” representing themes. Axial coding was then completed, during which each code and corresponding text was examined to identify subthemes. Discrepancies in coding were settled by a third coder.

Results: For the Parent Groups, the open coding process revealed 13 broad themes: Role of the BCBA, Barriers, Interdisciplinary Collaboration, Family Considerations, Stigma, Parental Stress and Mental Health, Transition and Future Planning, Rapport/Relationship, Communication, Parental Preferences, Treatment Goals, Comorbidity, and Child-Centered Focus. Definitions of these 13 broad themes as well as subthemes will be presented. Additionally, the themes and subthemes identified during the BCBA Groups will be presented.

Conclusions: Although parents report many positive experiences with BCBAs, they also identify several areas in which additional training for BCBAs would improve the quality of care received. BCBAs also identify areas in which they do not feel adequately trained and would like additional resources and support. Many of the training needs identified by parents and BCBAs overlap, including parental stress, mental health comorbidities, the diagnostic process, and communication skills. BCBAs identified additional training needs, such as trauma-informed care and family-centered care in general. These identified needs should be considered for academic programs, continuing education opportunities, and professional development opportunities.

**511.085** (Virtual Poster) "I Was Done with the Volcanoes in Me": Exploring the Perspectives of Young Autistic People with Lived Experience of Suicidal Ideation/Behaviour and Self-Harm

*L. Taimre, University of Melbourne, Melbourne, VIC, Australia; Orygen Youth Health, Melbourne, VIC, Australia*

---

Background: Young people with autism spectrum disorder (YP-ASD) experience high rates of suicidal ideation/behaviour, with risk factors including being female and masking ASD traits. Evidence suggests that current clinical practices and theories of suicidality may not adequately serve YP-ASD due to differing needs and experiences, however this has not yet been qualitatively explored.

Objectives: This project aimed to explore how YP-ASD experience suicidal behaviour and self-harm, the relationship between suicidal ideation/behaviour and self-harm for autistic young people, their experience of seeking help from mental health services, and whether their experience is influenced by their gender.

Methods: Five young people (four identifying as female including one who was identified as male at birth; one identifying as male) aged 15-25 (M = 17.6) with diagnoses of ASD or self-identifying as autistic were recruited from the Orygen Youth Health Clinical Program and headspace centres in Melbourne, Australia. Data were collected from semi-structured interviews and analysed using reflexive thematic analysis

Results: Three main themes and three further subordinate themes were described:

- 1) Interpersonal and Intrapersonal Understanding Facilitates Connection to the Self and Others;
- 2) Suicide and Self-Harm can fill a Need for Emotional Expression (with subordinate themes: 2.1) Suicidal or self-harm actions tend to be quick and impulsive; 2.2) Suicide and self-harm can cause meta-distress);
- 3) The Duality of Relating to Others (with subordinate theme 3.1) Connection within the therapeutic relationship tends to be slow and complex).

Conclusions: The implications of these findings are discussed with reference to clinical practices including safety planning and ASD-inclusive therapy, with consideration given to limitations and directions for future research.

**511.086** (Virtual Poster) "I'm the Family Ringmaster and Juggler": Autistic Parents' Experiences of Parenting during the Early Phase of COVID-19  
*M. Heyworth<sup>1,2</sup>, S. Brett<sup>1</sup>, J. den Houting<sup>1</sup>, I. Magiati<sup>1</sup>, R. Steward<sup>1</sup>, A. Urbanowicz<sup>3</sup>, M. Stears<sup>4</sup> and E. Pellicano<sup>1</sup>, (1)Macquarie School of Education, Macquarie University, Sydney, NSW, Australia, (2)Reframing Autism, Sydney, NSW, Australia, (3)School of Psychological Science, University of Western Australia, Perth, WA, Australia, (4)Wellcome Trust, London, United Kingdom, (5)Social and Global Studies Centre, RMIT University, Melbourne, VIC, Australia, (6)Sydney Policy Lab, University of Sydney, Sydney, NSW, Australia*

---

Background: There is a dearth of research on autistic parenthood. The limited literature that does exist suggests that autistic mothers are more likely to experience prenatal and postnatal depression than non-autistic mothers, and can find it difficult to manage the everyday demands of parenting and domestic life, including heightened sensory experiences. While emerging research has also highlighted more positive autistic parenting experiences, there is a need to understand autistic parenthood in greater depth.

Objectives: Using qualitative methods, the current study sought to understand what parenting was like for autistic and non-autistic parents of autistic children during a particularly unsettling time: the initial phase of the COVID-19 pandemic.

Methods: Our participants included 35 Australian autistic parents (95% women) of autistic children (aged 4 – 25 years). Each took part in semi-structured interviews about their experiences of life during the initial phase of the pandemic (interviews ranged between 21.80 and 86.30 mins). Once transcribed, the interviews were subjected to reflexive, thematic analysis using an inductive (bottom-up) approach to identify patterned meanings within the dataset. We also adopted a participatory approach, in which non-autistic academics, autistic researchers and advocates, including an autistic parent of autistic children as lead author, were actively involved as partners in the research – in the design and implementation of the methods, and in the analysis, interpretation and dissemination of the results.

**Results:** We identified four themes (Figure 1). Parents repeatedly spoke of how life before COVID-19 could “be really hard” and that the lockdown brought some initial relief from the intensity of their usual lives and from “the obligations to be social” (Theme 1). Nevertheless, most parents felt that the “cumulative stress” of trying to juggle everything – home-learning, working from home, maintaining the house – proved very challenging (Theme 2). These challenges eventually took their toll on parents’ mental health (Theme 3). Parents were aware they needed support but found it difficult to reach out to their usual (autistic) social supports for help and formal support was virtually non-existent. Consequently, they felt “very much forgotten”. Despite all of this, many described how their connections with their children grew stronger over lockdown as they focused on nurturing their children’s “mental health ahead of everything else” (Theme 4).

**Conclusions:** Our analysis clearly shows how unsatisfactory normal life can be for autistic parents. Research has already documented these challenges for autistic adults, but parenting requires grappling with a distinctive set of demands, including juggling and transitioning between multiple commitments and dealing with different social expectations and obligations. These challenges are usually at least partially overcome as a result of the informal supports that many autistic parents draw upon. But the relative absence of informal supports during the pandemic left them reliant on more formal supports, many of which were not forthcoming. Nevertheless, parents kept going, in part because of the deep attachments and love they had with their children. Urgent research is needed to identify the most effective formal supports for autistic parents, ideally in partnership with autistic parents themselves.

**511.087** (Virtual Poster) Autism and Bilingualism: A Thematic Analysis of Practitioner Perspectives and Experiences

**R. V. Davis<sup>1</sup>** and **F. Binti Mohd Zaki<sup>2</sup>**, (1)Department of Psychiatry, University of Edinburgh, Edinburgh, United Kingdom, (2)University of Edinburgh, Edinburgh, United Kingdom

---

**Background:** Around 25% of autistic children worldwide have the opportunity to learn multiple languages and access the plethora of cultural, familial and community connections that come with this. However, many autistic children are being denied opportunities to access additional languages in and outside of the home. There is little evidence identifying the barriers to language learning and access, and in particular, no research addressing the perspectives of practitioners, who are crucial in supporting parents to make informed choices about bilingualism for their child.

**Objectives:** The aim of this research is to understand the experiences of practitioners working with autistic bilingual children and their families. Specifically, this work identified barriers to best practise relating to family understanding, the knowledge base of practitioners and the relationship between socio-cultural factors and practise and recommendations.

**Methods:** Twelve speech and language practitioners from across the UK were recruited for this study. All participants had significant experience (M=7 years, Range 4-23 years) working with autistic bilingual children and their families. Semi-structured interviews were conducted and focused on attitudes and beliefs of practitioners regarding family bilingual experiences, the effect of socio-cultural factors of practise, and the general work barriers.

**Results:** Inductive thematic analysis was conducted on the interview data. A total of 25% of first level codes were checked for consistency by a second coder, with 100% intercoder reliability. Three central themes arose from the interviews (see figure 1).

The majority of practitioners described a number of recurring barriers to optimally support parents and children: Practitioners do not have confidence in the tools available to conduct diagnostic or language assessments with autistic bilingual children and described a lack of emphasis on cultural factors during their training period as a challenge when supporting families. Many were concerned at the limited options for resources and interventions available in other languages, which could be challenging for parents who were less proficient or confident communicating in English, and practitioners highlighted a lack of understanding of autism from many families as an additional barrier. Furthermore, practitioners reported having limited opportunities to access additional cultural training after they qualified or to keep up to date with relevant research.

**Conclusions:** This is the first study to understand the perspectives of speech and language practitioners working with autistic bilingual children, and identifies a number of key difficulties in supporting access to language learning. These findings will have important implications for practitioners and in turn, the families and children they support.

Practitioner concerns mirror previous research showing that findings regarding the potential positive effects of bilingualism are not trickling down to parents or specialists. This study also highlights the need for culturally relevant resources and training, and for practitioners to be provided with opportunities to receive up-to-date and accessible findings from research.

It is clear that families of autistic bilingual children will also benefit from evidence-based resources about autism and the interplay with bilingualism, to ensure that stakeholders can make informed decisions about language use at home.

**511.088** (Virtual Poster) Autistic Teens Show Greatly Reduced Self-Determination Compared to Their Typically Developing Peers

**R. Handsman<sup>1</sup>**, **J. R. Linde<sup>2</sup>**, **B. B. Maddox<sup>3,4</sup>**, **L. Kenworthy<sup>5</sup>**, **A. Verbalis<sup>5</sup>**, **J. F. Strang<sup>5</sup>** and **C. E. Pugliese<sup>5</sup>**, (1)Center for Autism Spectrum Disorders, Childrens National Medical Center, Washington, DC, (2)Georgetown University, Washington, DC, (3)University of North Carolina-Chapel Hill, Chapel Hill, NC, (4)Psychiatry, UNC TEACCH Autism Program, Chapel Hill, NC, (5)Center for Autism Spectrum Disorders, Children's National Hospital, Washington, DC

---

**Background:**

Self-determination (SD) can be described as the skills someone has to become a primary causal agent in one's own life. This includes making decisions regarding one's own goal in areas a person feels is important. The small amount of prior research with autistic youth has shown that parents rate SD to be significantly lower than their typically developing (TD) peers. However, prior research in this area has not distinguished between autistic youth with and without intellectual disability (ID); furthermore, almost no research has examined differences in SD specifically between autistic teens without ID and TD peers.

### Objectives:

Examine differences between autistic teens and their TD peers in SD skills and opportunities to practice SD as reported by both parents and students.

### Methods:

Participants included 99 adolescents aged 14-20 ( $M = 16.05$ ,  $SD = 1.39$ ) with  $FSIQ \geq 70$  ( $M = 106.38$ ,  $SD = 13.74$ ). Autistic participants ( $n = 68$ ) met DSM-5 criteria supported by the SCQ and/or ADOS, and TD participants ( $n = 31$ ) had no diagnoses or active treatment. Parent- and self-reported SD was assessed using the American Institutes for Research Self-Determination Scale (AIR-SDS). The AIR-SDS measures SD skills (e.g., I/My child set their own goals to satisfy wants or needs) and opportunities to practice SD at home and school with higher scores indicating greater SD. Independent samples t-tests and chi-squared analyses were calculated to determine group differences on SD skills, and opportunities to practice SD at home and school for both parent- and self-report forms. Bivariate correlations examined the relationship between parent and self-report SD in both groups.

### Results:

There were no significant differences in age ( $t = -1.32$ ,  $p > .11$ ), IQ ( $t = 0.81$ ,  $p > .37$ ), or gender ( $X^2 = 2.5$ ,  $p > .11$ ) between ASD and TD groups. Parents of TD teens reported significantly higher SD skills when compared to autistic teens' parents ( $t = 7.49$ ,  $p < .001$ ). The same relationship was seen regarding opportunities to practice SD at home ( $t = 2.35$ ,  $p = .02$ ) and school ( $t = 2.25$ ,  $p = .01$ ), with autistic teens having fewer parent-reported opportunities. When examining self-report of SD, TD teens reported greater opportunities to practice SD at home compared to autistic teens ( $t = 2.56$ ,  $p = .01$ ). SD opportunities at school were trending towards significance ( $t = 1.75$ ,  $p = .08$ ;  $t = 1.84$ ,  $p = .07$ ). There were no significant differences between autistic and TD teens' report of overall SD skills ( $t = 1.20$ ,  $p > .01$ ). Bivariate correlations for the ASD group show parent and student agreement on opportunities to practice SD at school ( $r = .278$ ,  $p = .04$ ). In the TD group parents and students agreed on SD skills ( $r = .438$ ,  $p = .03$ ) and overall level of SD ( $r = .378$ ,  $p < .001$ ).

### Conclusions:

Results indicate that autistic teens have great impairments in SD when compared to their TD peers. Understanding SD in TD teens helps to further understand the differences seen in autistic teens.

### 511.089 (Virtual Poster) Classroom Practices and General Autism Awareness of Faculty Among Three California Public Universities

**G. B. Salinas<sup>1</sup>**, Y. Bolourian<sup>2</sup>, S. Zeedyk<sup>3</sup> and J. Blacher<sup>2,4</sup>, (1)School of Education, University of California Riverside, Riverside, CA, (2)School of Education, University of California, Riverside, Riverside, CA, (3)Department of Child and Adolescent Studies, California State University, Fullerton, Fullerton, CA, (4)Department of Psychology, University of California, Los Angeles, Los Angeles, CA

**Background:** In recent years, there has been an influx in research focused on college students with autism. Studies have found that these students may face challenges related to mental health, social relationships, and academic aspects in college. Self-reported experiences of neurodiverse students also indicate specific difficulties with disclosure of diagnosis to faculty (Bolourian et al., 2018), and research on faculty perspectives demonstrates that many professors view autism as an invisible disability (Zeedyk et al., 2019). Findings from these studies highlight the need to identify the classroom practices and knowledge base in autism that faculty members possess for working with this population.

**Objectives:** The present study aims to describe the teaching practices and knowledge in autism of faculty from three large state universities in California.

**Methods:** An online survey was disseminated across three public universities (U) in Southern California; 214 faculty members (U1 n=78; U2 n=47; U3 n=89) responded to the survey. Survey questions included basic demographics for describing the sample, five questions on classroom practices, and 14 autism knowledge questions. Descriptive statistics, frequencies, and Chi-square or Fisher's exact tests were used to describe the findings and compare across the three institutions.

**Results:** The majority of participants were female (69.9%), predominantly White (68.2%), and most held a doctorate degree (58.4%). The average years of experience teaching was 12.88 ( $SD=9.11$ ). A total of 207 participants responded to five classroom practices questions. Overall, responses indicated that the three universities employed similar teaching practices. Statistically significant differences were found for only 2/5 statements asked: (1) More participants from U1 included a statement in their syllabus regarding disability services/accommodations compared to U2; (2) More U1 participants reported being approached by a student with documentation from student disability services than those from U2. As for general autism knowledge, faculty respondents shared similar views, though significant differences in proportions across the three universities were observed on two items related to genetic and dietary information specifically. For example, when asked if autism runs in families, significant differences were found across the three universities: 40.3% participants from U1, 17.1% participants from U2, and 37.2% participants from U3 *disagreed* with this

statement. When asked if changing a child's diet would lessen the severity of autism symptoms 40.3% participants from U1, 15.0% participants from U2, and 24.4% participants from U3 agreed with this statement.

**Conclusions:** Although faculty at the three universities expressed some differences in classroom practices and autism knowledge, there were more similarities than differences. These findings suggest that overall faculty members from these public universities possess a strong understanding of autism within and outside of the classroom. These survey results, particularly regarding classroom practices, can be used for preparing future faculty training in autism. A simple act of including a statement on accessing disability services/accommodations within course syllabi may help open the door to communication and normalize the accommodation process for neurodiverse students.

**511.090 (Virtual Poster)** Efficacy of Coping Mechanisms Used during COVID-19 As Reported By Parents of Children with Autism  
*E. Furrar<sup>1</sup>, I. Memis<sup>1</sup>, F. Wang<sup>1</sup>, R. S. Eshraghi<sup>2</sup>, J. Durocher<sup>3</sup>, A. Ahn<sup>4</sup>, A. C. Samson<sup>5</sup>, J. Van Herwegen<sup>6</sup>, D. Dukes<sup>6</sup>, M. Alessandri<sup>6</sup>, R. Mittal<sup>6</sup> and A. A. Eshraghi<sup>6</sup>.* (1)University of Miami Miller School of Medicine, Miami, FL, (2)University of Miami, Coral Gables, FL, (3)Institute of Special Education, University of Fribourg, Fribourg, Switzerland; Faculty of Psychology, Unidistance Suisse, Brig, Switzerland, Switzerland, Switzerland, (4)Institute of Education, University College London, London, United Kingdom, (5)Special Education, University of Fribourg, Fribourg, Switzerland, (6)Otolaryngology, Neurological Surgery and Pediatrics, University of Miami Miller School of Medicine, Miami, FL

---

**Background:** The COVID-19 pandemic's disruptions and alterations to daily life have been especially challenging for families with Autism Spectrum Disorder (ASD). Adapting to new daily routines, environmental changes, and uncertainty related to the pandemic have been determined to be causing distress in autistic children, worsening both the core features of ASD and their overall mental health. There is a need to develop different coping mechanisms and determining their efficacy in reducing anxiety in individuals with ASD.

**Objectives:** This study aims to evaluate various coping strategies employed by autistic children and their efficacy in mitigating stress and anxiety during the COVID-19 pandemic.

**Methods:** For this study, we used the data from a survey regarding alterations in children's behaviors and concerns throughout the COVID-19 pandemic as reported by their parents. We performed comprehensive analysis regarding how often a child with autism is using a certain coping strategy in mitigating stress and anxiety during pandemic (frequency) on a scale of 1 to 5 where 1 is very rarely and 5 is very frequently. We also determined to which extent child benefits from a particular strategy (efficacy) on a scale of 1 to 5 where 1 is not at all and 5 is extremely. Using Spearman's rank-order correlations and repeated measures ANOVAs, correlation coefficients between the frequency and efficacy of each coping mechanism, as well as significant differences between the two measures, were determined.

**Results:** Based on the Spearman's correlations, the "positive" coping mechanisms of distraction, focusing on positive aspects, and telling jokes had strong correlations amongst all age groups. Younger children managed stress by changing their way of thinking about the situation, while older children either avoided information about the pandemic or talked about it as much as possible. Amongst the "negative" behaviors, isolation was a common highly correlated behavior for all three age groups, however, all "negative" behaviors in the over 15 years old group had strong correlations in contrast to the two younger groups. Regardless of the child's age group, all parent behaviors had high associations between frequency and efficacy. Repeated measures ANOVAs revealed significant differences in frequency and efficacy ratings across the coping mechanisms. Interactions between the behaviors and age groups indicated variations in frequency and efficacy based on the child's age group, yet establishing a routine was rated as the most frequently and effectively used for all age groups.

**Conclusions:** The coping mechanisms defined as "positive" had stronger correlations between frequency and efficacy than the "negative" ones at all three age groups. The results of this study will lay the foundation to develop novel coping strategies that will help in alleviating stress in autistic children especially during this era of COVID-19 pandemic. Further studies using large cohort are warranted to develop effective coping mechanisms for individuals with ASD, especially for future public health emergencies.

**511.091 (Virtual Poster)** Experiences and Perspectives of Parents of Children with Autism Spectrum Disorder in Lima-Peru  
*M. Asencio Pimentel<sup>1</sup> and C. H. Qi<sup>2</sup>.* (1)University of New Mexico, Albuquerque, NM, (2)Special Education, University of New Mexico, Albuquerque, NM

---

**Background:** Most research on autism spectrum disorder (ASD) has been conducted in developed countries, which have extensive available resources to address the needs of children with ASD (Samadi & McConkey, 2011). However, there are limited studies in the field of ASD in developing countries, and specifically in Peru. Specially, few studies have examined the experiences and perspectives of parents of children with ASD regarding access to ASD service and ASD services in Peru.

**Objectives:** The purpose of this study was to examine (a) the experiences and perspectives of parents regarding accessing services for their child with ASD, the services their child received, and parental involvement. This study seeks to better understand parents' experiences and perspectives to inform the development of policies and services that will help improve the lives of children with ASD and their parents in Peru.

**Methods:** This study employed a multiple case design to explore the experiences and perspectives of parents of children with ASD in Peru. Criterion sampling was used to select potential participants. Parents were recruited from centers that provide services for individuals with ASD. Ten parents of young children with ASD participated in the study. This study was conducted virtually via Zoom. Data collection methods included 60-min semi-structured individual interviews, five diaries, 10 photos and 30-min interviews regarding the photos that were taken. Each session was audio and video recorded. Each interview was transcribed verbatim in written Spanish and then translated into English. NVivo software was used to organize, analyze and visualize the data. First cycle coding and second cycle coding were conducted to find patterns and themes. Finally, cross-case analysis was employed to compare commonalities and differences among participants.

**Results:** The results of this study revealed that the cost of the services for children with ASD in Lima, Peru, was high, taking into account the average income in the Peruvian Capital. Costs ranged from 35 to 100 Peruvian Nuevos Soles per 45 minutes each therapy session. Six major themes emerged from the preliminary results of this study: Service access, service experience, parental involvement, parental empowerment, discrimination, and parental expectations.

**Conclusions:** Parents of children with ASD experience greater challenges in Peru due to an inadequate health care system and scarce public services. Only financially stable caregivers can access private services, and those who are financially unstable can only access a limited amount of private services due to the high cost of their services. Overall, this study provides an understanding of barriers children with ASD, and their parents encounter regarding service access.

**511.092 (Virtual Poster)** How Can We Effectively Engage Autistic Teens in Online Learning Opportunities?: Use Universal Design but Remember It Is a Process and Should be Student Interest Driven

**E. Grossman<sup>1</sup>, J. Herrell<sup>2</sup>, A. Riccio<sup>3</sup>, S. Biswas<sup>4</sup>, E. Pak<sup>5</sup>, C. Ulerio<sup>6</sup>, J. Delos Santos<sup>6</sup>, P. Dwyer<sup>7</sup>, S. Shevchuk-Hill<sup>8</sup>, S. Dave<sup>8</sup>, L. Hwang-Geddes<sup>9</sup>, B. Kofner<sup>10</sup>, K. Gravitch<sup>1</sup>, R. Faye Concepcion<sup>11</sup>, T. Major<sup>8</sup>, B. Rosenberg<sup>12</sup>, W. Martin<sup>1</sup>, A. Hurst<sup>13</sup> and K. Gillespie-Lynch<sup>14</sup>,** (1)Psychology, CUNY Graduate Center, New York, NY, (2)CUNY School of Professional Studies, New York, NY, (3)Education Development Center, New York, NY, (4)Tech Kids Unlimited, Brooklyn, NY, (5)College of Staten Island, Staten Island, NY, (6)Hunter College, City University of New York, New York, NY, (7)Department of Psychology, University of California, Davis, Davis, CA, (8)Pace University, New York, NY, (9)Cornell University, Ithaca, NY, (10)CUNY, NY, NY, (11)Ossining High School, Ossining, NY, (12)Technology, Culture, Society, New York University Tandon School of Engineering, Brooklyn, NY, (13)New York University, New York, NY, (14)Department of Psychology, College of Staten Island, City University of New York, Staten Island, NY

**Background:** Autistic people are often chronically underemployed (Burgess & Cimera, 2014) despite interest in computers (Murray & Lesser, 1999) and the growing need for computing professionals (Bureau of Labor Statistics, 2015). Efforts to improve autistic people's employment outcomes should not *just* focus on computing, given their diverse career aspirations (Cheriyen et al., 2021). However, computing is a path toward employment for *some* autistic people. Universal Design (UD; providing multiple options to engage diverse learners) and informal learning opportunities may help disabled students succeed in technology-related careers (Moon et al., 2012), and thus, could help autistic youth develop employment-related skills. However, research with non-autistic people suggests that UD may overwhelm learners with redundant information (Mayer, 2001).

**Objectives:**

1. Iteratively develop instructional strategies to engage autistic learners.
2. Assess the validity of online assessments (we shifted to online instruction/assessment due to COVID-19).

**We hypothesized that:**

1. Students with more focused attention would prefer unimodal instruction; those with less focused attention would prefer multimodal instruction.
2. Workshops would lead to improved STEM self-efficacy and self-determination.

**Methods:** Assessments were piloted with autistic teens and revised by a participatory team. Two virtual 2-week game design workshops were conducted with an informal technology education non-profit (July 2021:  $n=20$ , Mage=17.2; 63% White; August 2021:  $n=19$ , Mage=16.5; 65% White). Students made games and discussed career opportunities and social justice issues. Students rated engagement with probed activities including varied group sizes, activity types, and modalities (Table 1), using an adapted picture-based engagement scale, assessing interest and understanding (Riccio et al., 2020). Pre- and post-tests assessed video game self-efficacy, self-determination (Shogren et al., 2020), and computational thinking (CT: Román-González et al., 2017). Cambridge Brain Sciences games assessed inhibition, spatial planning, deductive and grammatical reasoning, and memory. Workshop 1 informed adaptations for Workshop 2.

**Results:**

Across workshops, CT was positively associated with inhibition and memory, but *not* video game self-efficacy (Table 2). Unexpectedly, CT and inhibition were uncorrelated with engagement while self-efficacy and self-determination were correlated with each other and often with engagement.

At pre-test, Workshop 1 students reported more interest in game design ( $p = .045$ ) and learning how to make things ( $p = .035$ ) than Workshop 2 students.

Engagement did *not* vary across workshops. Students rated video+voice more engaging than voice only and video+voice+text instruction ( $ps < .05$ ). Self-determination improved across workshops ( $p = .003$ ). Unexpectedly, planning also improved ( $p = .003$ ). Video game self-efficacy did not improve ( $p = .36$ ), but trended toward being higher in Workshop 1 ( $p = .057$ ).

**Conclusions:** Self-report measures aligned with *self-reported* engagement while skills-based measures often cohered, suggesting that both types of information are needed. Self-determination improvements are promising as self-determination is associated with numerous positive outcomes. However, data-driven adaptations in Workshop 2 did *not* lead to improved outcomes, likely because Workshop 1 students were more interested in game design. Findings suggest that UD *can* overwhelm learners. Instructional adaptations should be iteratively revised guided by students' interests

and feedback. We are also evaluating if engagement and/or pre-test skills align with the games students made.

**511.093** (Virtual Poster) Inequities in Identification and Access to Services between Spanish-Speaking and English-Speaking Caregivers in California

*P. Luelmo and L. J. Hall, Special Education, San Diego State University, San Diego, CA*

---

**Background:** Access to autism identification, diagnostic and intervention services are not equal, with the most vulnerable families receiving a late identification and unequal access to services. In this study we gathered caregivers' perspectives in a large district in southern California with identified inequities in autism identification (i.e., disproportionality of autism for White children). Specifically, the school system identified for the study had a documented overrepresentation of White students with autism and a documented under identification of Latinx/Hispanic students with autism.

**Objectives:** RQ: What are the experiences of caregivers related to their navigating the special education system for their children with autism? Are there any differences in knowledge about the IEP between English-speaking and Spanish speaking Latinx/Hispanic families?

**Methods:** A caregiver online survey was developed and approved by the Institutional Review Board of a large university in Southern California. We distributed the online survey to all parents of children with disabilities via a personalized email in the district. The survey was distributed in English and Spanish. The survey took 10-15 minutes to complete. Two previously published measures were used in the survey. **Caregiver Identification/Diagnosis Questionnaire.** Participants completed a short questionnaire (4- item) about the child's initial identification of a disability (e.g., Who first noticed the red flags of disability in your child). The questionnaire was adapted from a previous study gathering facilitators and barriers for racial/ethnic minority families (Stahmer, et al., 2019). **IEP Advocacy Knowledge Scale.** A community-developed 10-item multiple choice assessment of basic facts about special education parents' rights in special education. The items assessed basic knowledge of the IEP: zero reject, least restrictive environment, and Free and Appropriate Public Education (e.g., the least restrictive environment). Each item on the test has one correct response and was graded as correct or incorrect (0,1).

**Results:** Several differences were observed between the English-speaking parents and the Spanish speaking parents across all measures in the online survey responses (N=79). The results of the IEP Advocacy Knowledge Scale showed significant differences between the Spanish speaking and English-speaking respondents. Specifically, Spanish speaking parents had lower scores on IEP advocacy knowledge on average (M=4.73 SD=1.71) than the English speaking caregivers, (M=7.42, SD=2.5),  $t(44) = -6.89, p < .001$ . Additionally, 77% of English speaking parents reported they were the ones to identify "red flags" of autism, compared to only 14% of Latinx/Spanish speaking families. At the same time, Spanish speaking caregivers reported greater satisfaction with the IEP system when compared to English speaking caregivers.

**Conclusions:** The results showed that while Spanish speaking caregivers have a more positive assessment of the school system and its services, they might not be advocating as much as English speaking caregivers, who showed greater advocacy skills in navigating the special education process.

**511.094** (Virtual Poster) The Impact of COVID-19 on Individuals with ASD in the US: Parent Perspectives on Social and Support Concerns  
*E. Furar<sup>a</sup>, F. Wang<sup>a</sup>, J. Durocher<sup>a</sup>, A. Ahn<sup>a</sup>, I. Memis<sup>a</sup>, L. Cavalcante<sup>a</sup>, L. Klahr<sup>a</sup>, A. C. Samson<sup>a</sup>, J. Van Herwegen<sup>b</sup>, D. Dukes<sup>c</sup>, M. Alessandri<sup>d</sup>, R. Mittal<sup>e</sup> and A. A. Eshraghi<sup>f</sup>, (1)University of Miami Miller School of Medicine, Miami, FL, (2)University of Miami, Coral Gables, FL, (3)Miller School of Medicine University of Miami, Miami, FL, (4)Institute of Special Education, University of Fribourg, Fribourg, Switzerland; Faculty of Psychology, Unidistance Suisse, Brig, Switzerland, Switzerland, Switzerland, (5)Institute of Education, University College London, London, United Kingdom, (6)Special Education, University of Fribourg, Fribourg, Switzerland, (7)Otolaryngology, Neurological Surgery and Pediatrics, University of Miami Miller School of Medicine, Miami, FL*

---

**Background:** COVID-19 pandemic related lockdown measures and disruptions to services and daily routines for children with ASD and their families have resulted in a lack of access to the daily resources they have through school and private therapies. In addition, children with ASD and their families are experiencing a loss of support networks and social connections due to the pandemic.

**Objectives:** The current study aimed to determine the impact of the COVID-19 pandemic's social environmental changes on parental ratings of personal and child concerns about family conflict, opportunities for social interaction, and loss of institutional support.

**Methods:** The impact of COVID-19 on the concerns of families of individuals with ASD in the US was evaluated using surveys. The survey consisted of questions regarding parental concerns before, at the start of and during the COVID-19 pandemic, as well as parents' perception of children's concerns at these same three time points. Four specific areas of concern were evaluated in caregivers: concern that their child had fewer opportunities for social contact and interactions, concern that their child was not able to approach others, concern about family conflict, and concern about the loss of institutional support, including interventions, for their child. Parents also rated the degree to which they felt that their child was concerned about these issues. Changes in the level of concerns/worries were evaluated at 3 different time points (before or pre-COVID-19), at the start or beginning of the pandemic, and several months into the pandemic for 3 distinct age groups (2 – 9 years old, 10 – 15 years old, and over 15 years old) among children who were "aware" or "not aware" of the pandemic. This investigation specifically looked at trends in how concerns evolved over time, as well as whether there were any significant differences between the age groups or awareness status at each time point.

**Results:** The comprehensive analyses of the responses from families with ASD in the US determined differences in concerns across all three time points. Parents reported clear and significantly increased levels of concern over the course of pandemic regarding their child's loss of opportunities for social interactions, restrictions on being able to approach others, family conflict, and loss of institutional support. Parent ratings of perceived child concern also increased significantly in all areas during the course of the pandemic.

**Conclusions:** The information gathered from this study can be useful in determining effective techniques to support individuals with ASD and their families during health emergencies. By using this data, specialists can place a focus on the areas of increased stress delineated through this study, such as family conflict and access to social opportunities, in order to guide stress-mitigation techniques and inform modifications to autism therapies and services. The high levels of concerns highlighted in the current study provide support for the need to assess families' priorities and tailor services to best meet families' needs. This will potentially increase the quality of life of family members, and improve ASD services across the lifespan, and improve outcomes.

**511.095 (Virtual Poster) Maternal Factors Influencing Anxiety in Children with Developmental Disorders Compared to Children with Typical Development in Japan**

**K. Nogami<sup>1</sup>** and **T. Yamane<sup>2</sup>**, (1)Human Development, Graduate School of Human Development and Environment, Kobe University, Kobe, Japan, (2)Graduate School of Developmental and Environment, Kobe University, Kobe, Japan

---

**Background:**

Anxiety symptoms are common in children with developmental disorders (CDD). Studies have indicated that maternal anxiety and overprotection are associated with the anxiety of children with typical development (CTD). Thus, the same factors may influence the anxiety of CDD. There is a need to examine the mechanisms through which maternal factors impact children's anxiety between CDD and CTD.

**Objectives:**

We aimed to examine a model of the influence of maternal factors, adding Sense of Coherence (SOC), on anxiety symptoms in CDD and CTD. We hypothesized a multi-group model in which maternal SOC (comprehensibility, manageability, and meaningfulness), maternal anxiety, and maternal overprotection influence anxiety symptoms in CDD and CTD (Figure 1).

**Methods:**

From October 2020 to May 2021, mothers of children aged 6 to 15 participated in a survey. The sample comprised 105 mothers of CDD (mean age = 41.77 years,  $SD = 5.19$ ) and 292 mothers of CTD (mean age = 40.41 years,  $SD = 5.46$ ). The mean age of CDD was 9.56 years ( $SD = 2.58$ ), with 80 boys (76.19%) and 25 girls (23.81%); 69 of these were children with autism spectrum disorders (ASD) (65.71%). For CTD, the mean age was 9.56 years ( $SD = 2.58$ ), with 148 boys (50.68%) and 144 girls (49.32%).

The questionnaire measured their child's total anxiety, maternal SOC, maternal anxiety, and maternal overprotection. Moreover, since COVID-19 had a significant influence on the lifestyles of residents of Japan, we added questions regarding children's and mothers' anxiety about COVID-19 and set them as control variables. We utilized SPSS Version 27.0 and M-plus Version 8.5 for the analysis.

**Results:**

Multi-group path analysis was utilized to examine the hypothetical model. Comparing the configural invariance model, the partially constrained model (the path of maternal anxiety to child anxiety was constrained), and the fully constrained model, the partially constrained model yielded an adequate fit to the data ( $CFI = 1.00$ ,  $RMSEA = .03$ ) (Figure 2). After controlling for anxiety regarding COVID-19, there were negative paths from comprehensibility to maternal anxiety and from meaningfulness to overprotection ( $\beta = -.28$ -.50,  $p < .05$ ) in the CDD group. Moreover, in the CDD group, there was a positive path from maternal anxiety to child anxiety ( $\beta = .26$ ,  $p < .001$ ). In contrast, for the CTD group, there were negative paths from comprehensibility and manageability to maternal anxiety ( $\beta = -.17$ -.33,  $p < .05$ ), a path from maternal anxiety to overprotection ( $\beta = .29$ ,  $p < .001$ ), and paths both from maternal anxiety and overprotection to child anxiety ( $\beta = .23$ ,  $p < .01$ ).

**Conclusions:**

Our results suggest that maternal comprehensibility and meaningfulness influence maternal anxiety and overprotection, and maternal anxiety directly influences child anxiety in the CDD group. In the CTD group, however, lower comprehensibility and manageability influence maternal anxiety, and maternal overprotection mediated by maternal anxiety influences child anxiety. These findings suggest that assessment and treatment for anxiety of CDD should measure maternal SOC and maternal anxiety. There may be a need to treat anxiety of mothers of CDD.

**511.096 (Virtual Poster) The Wellbeing and Support Needs of Australian Caregivers of Neurodiverse Children.**

**E. D'Arcy<sup>1,2</sup>**, **T. Burnett<sup>1</sup>**, **E. Capstick<sup>1</sup>**, **C. Elder<sup>1</sup>**, **O. Slee<sup>1</sup>**, **S. J. Girdler<sup>1,2,3,4,5</sup>**, **M. T. Scott<sup>1,3</sup>** and **B. T. Milbourn<sup>2,6</sup>**, (1)School of Allied Health, Curtin University, Bentley, WA, Australia, (2)Curtin Autism Research Group, Curtin University, Bentley, WA, Australia, (3)Cooperative Research Centre for Living with Autism (Autism CRC), Brisbane, QLD, Australia, (4)School of Allied Health, University of Western Australia, Crawley, WA, Australia, (5)Karolinska Institutet, Stockholm, Sweden, (6)School of Allied Health, Curtin University, Perth, WA, Australia

---

**Background:**

Neurodiverse children have individual support needs across various areas of life, including home life, school, and extracurricular activities. In Australia, most disability-related supports are provided through the National Disability Insurance Scheme (NDIS). The NDIS aims to provide

individualised, person-centred supports to people with disabilities of all ages (NDIS participants). However, with supports required to be directly related to the participant, there is a risk that caregiver supports are disappearing. Caregiver supports are important for supporting caregivers' health and mental wellbeing. These supports also allow caregivers to support their neurodiverse children to the best of their capacity, reducing reliance on external, paid support. To date there has been little understanding of how the introduction of the NDIS has affected caregivers' wellbeing and their support needs.

#### Objectives:

This study aimed to a) explore the wellbeing of Australian caregivers of neurodiverse children (0-12), b) understand how their caregiver role impacts their wellbeing, and c) identify the support needs of Australian caregivers of neurodiverse children (0-12 years).

#### Methods:

An online survey of multiple-choice questions and open-ended questions was conducted. The survey included four sections: a) demographic information; b) caregiving responsibilities; c) caregiver wellbeing (including the personal wellbeing index and parenting stress index); and, d) Support needs. Qualitative information was analysed using content analysis, and the quantitative information was analysed descriptively (with published measures scored according to their manuals). Participants were recruited through social media and disability-related organisations from across Australia. Ethical approval was granted for this research.

#### Results:

A total of 66 participants completed the survey, with the majority being female (n=63, 95.5%) and biological parents to their care recipients (n=64, 97%). Just under a quarter (n=14) identified as being neurodiverse themselves. The majority of the care recipients were male (n=59, 69%), with a diagnosis of ASD (n=80, 82%), and were an average of eight years old. Caregivers spent an average of 16.3 hours per day caring for their neurodiverse children (SD=6.6 hours), and their responsibilities included managing their daily routine (n=66, 100%), meal times (n=65, 98.5%), organising health appointments (n=65, 98.5%) and protective behaviours (n=65, 98.5%). The samples' average Personal wellbeing index score was 55 (SD=12.8), significantly lower than the Australian population average of 75. On the Parenting Stress Index, the average score fell in the 92<sup>nd</sup> percentile, indicating clinically significant levels of stress. In the qualitative responses, themes included significant mental health concerns, impact on relationships and self-identity, barriers to community participation, financial hardship, and lack of or barriers to needed supports (including therapy and diagnostic services).

#### Conclusions:

These results have identified significant wellbeing and mental health concerns for caregivers of neurodiverse children in Australia. The results identify a wide range of negative impacts on these caregivers' wellbeing and gaps in the available supports. More support is needed from various sources for these caregivers to support their wellbeing and allow them to support their children.

**511.097 (Virtual Poster)** Autistic Women's Experience - or the Dynamic Interaction between the Characteristics Associated to the Activities They Engage in and Their Environment with Their Own Personal Characteristics.

**M. Désormeaux-Moreau<sup>1</sup>**, A. Grondin<sup>2</sup>, M. Couture<sup>3</sup>, F. Watier<sup>2</sup> and A. Paradis<sup>4</sup>, (1)*École de réadaptation, Université de Sherbrooke, Sherbrooke, QC, Canada*, (2)*Université de Sherbrooke, Sherbrooke, QC, Canada*, (3)*Rehabilitation, Université de Sherbrooke, Sherbrooke, QC, Canada*, (4)*Education, Université du Québec à Montréal, Montreal, QC, Canada*

**Background:** While it used to be considered that the prevalence of autism was of 1 girl for every 4 boys, research now tends to paint a different picture. Indeed, many Autistic women are not formally identified as such until adulthood (compared to men, which are more likely to be identified during childhood), as their experiences and functioning deviate from the traditionally male representation of autism. Indeed, very few studies have focused on the lived experience of Autistic women, hence an important knowledge gap. Moreover, emerging research shows that Autistic women's late identification may negatively impacts their identity-building processes (Baldwin, S. et al., 2016; MacLeod, et al., 2013).

**Objectives:** This research aimed to understand the experiences of Autistic women and how their personal characteristics manifest themselves in their daily lives (i.e., through their activities and in their environment, whether physical, social, cultural or institutional).

**Methods:** A qualitative strategy and a descriptive design were used. Data were collected via an electronic questionnaire (sociodemographic) and written life stories/ storytelling (Burrick, 2010). More specifically, Autistic women from Québec (Canada) were invited to reflect on their story, by sharing significant events and/or perceived difficulties, as well as what, evokes her perceived differences. Data analysis relied on descriptive statistical analyses and Paillé's grounded theorizing analysis, which was supported by the theoretical basis of the Person-Environment-Occupation (PEO) theoretical model (Law et al., 1996).

**Results:** 38 Autistic women participated in the study. All of them had been identified as autistic as adults and they were between 24 and 59 years of age. The life stories' narrative content was associated to three main categories, namely the interaction between the participants' personal characteristics (related to autism) and the characteristics of: i) the environment in which they evolve; ii) the occupations in which they engage; and iii) the particular environments in which they perform given occupations. Results show that, among participants, camouflage is a common strategy that is used to promote a better fit with their environment. Such a strategy is used at their own expenses since it generates significant cognitive and

sensory load. Results also show that in the end, it is often the mismatch between the autistic women characteristics and their environment that leads them to initiate steps to obtain a formal diagnosis.

**Conclusions:** The analyzed life stories' narrative attests of a great capacity in terms of introspection and environments' observation. Findings show that for the participants, recognizing and considering themselves as Autistic contributes to a better understanding of themselves and their daily functioning, while conferring a sense of belonging to a group. While the challenges and obstacles reported being essentially related to the mismatch between their profile and the contexts (environmental and occupational) in which they evolve, this knowledge of themselves can guide choices to promote their well-being and development.

**511.098 (Virtual Poster)** The Importance of Contexts on the Experience of a Fulfilling Life - What Can We Learn from a Comparison of COVID-19 Lockdown's Impact on Life Satisfaction of Autistic and Non-Autistic Adults

**M. Désormeaux-Moreau<sup>1</sup>, M. Couture<sup>2</sup> and A. Grondin<sup>3</sup>,** (1)*École de réadaptation, Université de Sherbrooke, Sherbrooke, QC, Canada,* (2)*Rehabilitation, Université de Sherbrooke, Sherbrooke, QC, Canada,* (3)*Université de Sherbrooke, Sherbrooke, QC, Canada*

**Background:** Public health measures taken to limit the spread of COVID-19 led to changes in all individuals' lifestyle (e.g., personal, and professional roles and routines, way to carry out activities). These changes have led to the interruption, modification, or replacement of some or even several of the activities that people perceived as important, enriching, necessary or significant to them. The unpredictability of events and the loss of reference points that we have been experiencing had an impact on the life satisfaction of a large segment of the population (Brown, 2021). The major changes experienced since March 2020 has been said to pose an even greater threat to the mental health and life satisfaction of Autistics, who are thought to have higher rates of anxiety (Wright, Spikins & Pearson, 2020). However, several Autistic adults have expressed on social media their appreciation of home confinement, due to reduced exposure to certain potentially anxiety-provoking contexts (Asperger au féminin - Québec, 2020; Aspie Québec, 2020), either related to social interactions or to sensory stimuli.

**Objectives:** This research aimed to assess the life satisfaction of Autistic and non-autistic individuals ( $\geq 16$  years old) living in Québec (Canada) before and during the COVID-19 lockdown.

**Methods:** A survey was launched using an online questionnaire between July 1 and October 31, 2020. Participants were those capable of completing the online survey offering an introspective perspective at their lived experience of the sanitary crisis. The questionnaire comprised the Satisfaction with Life Scale as well as questions on the impacts of the pandemic on occupations & social relationships. Data analysis relied on descriptive statistical tests.

**Results:** Slightly under 400 adults responded to the survey, one quarter of which being Autistic. In both groups, more than half of the participants were between 26 and 45 years of age. While both groups reported a decreased of their life satisfaction during the COVID-19 lockdown, the discrepancy (before – during the lockdown) was lower in Autistic adults. In fact, once the initial shock overcame, autistic participants coped well with the pandemic context. They were satisfied with their living conditions and their interpersonal relationships improved, while they reported an increase in the significance and the importance given to their activities. Among non-autistic adults, there was an overall decrease in life satisfaction, as well as a decrease in the importance and meaning of their occupations.

**Conclusions:** Results show that the Autistic participants were able to adapt and benefit from the new context, compared to non-autistic adults who had difficulty coping with the changes and perceived loss during the COVID-19 pandemic period. This finding highlights the influence of environmental and occupational contexts on life satisfaction in Autistic and non-autistic adults, thereby reinforcing a socio-environmental understanding of autism. It also shows that while contexts that are appropriate to people's characteristics allow for fulfilling lives, such contexts differ among the Autistic adult and the non-autistic adult population.

## VIRTUAL POSTER SESSION — FAMILY ISSUES AND STAKEHOLDER EXPERIENCES

### 524 - Family Issues and Stakeholder Experiences II --- (V)

**524.023 (Virtual Poster)** Trends in U.S. Autism Research Funding: Interagency Autism Coordinating Committee Autism Research Portfolio Analysis Report

**S. Daniels<sup>1</sup>, O. Celestin<sup>2</sup> and K. Ferrara<sup>3</sup>,** (1)*National Institute of Mental Health (NIMH), Rockville, MD,* (2)*OARC, NIH/NIMH, Bethesda, MD,* (3)*National Institute of Mental Health (NIMH), ROCKVILLE, MD*

**Background:**

The Office of Autism Research Coordination (OARC) of the U.S. National Institutes of Health (NIH) will present findings from the upcoming 2019-2020 *Interagency Autism Coordinating Committee (IACC) Autism Research Portfolio Analysis Report* that describes autism research investments made by both government and private funders.

OARC/NIH coordinates and manages the IACC, a federal advisory committee composed of federal officials and public stakeholders. The Committee was established by Congress to coordinate federal agency activities and to provide advice to the Secretary of Health and Human Services related to autism spectrum disorder (ASD). The IACC's *Strategic Plan* provides a framework to guide the efforts of U.S. federal agencies and partner organizations. OARC conducts an annual portfolio analysis of U.S. research projects to help guide the IACC's strategic planning efforts and inform

the IACC of progress toward implementation of the *Strategic Plan*. The *Portfolio Analysis* is also used by agencies and organizations to better understand trends in ASD research funding.

#### Objectives:

OARC will present findings from its *2019-2020 IACC ASD Research Portfolio Analysis Report*, which provides information on autism research investments made by U.S. federal and private funders of ASD research.

#### Methods:

Data including project description, institution, and funding amount were collected from U.S government and non-government funders of autism research. All projects included in the *Portfolio Analysis* were coded according to the seven research questions and 23 objectives outlined in the *2016-2017 IACC Strategic Plan*. Each of the questions in the *Strategic Plan* address general topic areas that are represented as community-focused questions (e.g., How can I recognize the signs of ASD, and why is early detection so important?). Each question includes three to four objectives; there is also one cross-cutting objective that focuses on ASD in females. The data were analyzed in several ways to provide information on the types of research being funded and the research topic areas supported by each funder. This report also assesses the composition of research projects that are investigating racial and ethnic disparities in ASD.

#### Results:

OARC collected U.S. ASD research project data for 2019 and 2020 and aligned research projects with the 23 objectives in the *Strategic Plan*. The analysis provides an overview of the distribution of research projects and funding across the seven *Strategic Plan* Question areas, analysis of projects across multiple scientific subcategories, a breakdown of federal and non-federal funders' contributions to ASD research investments, geographical distribution of research projects, and trends in research funding over time. The data provide information on the degree to which the objectives and budget recommendations described in the *IACC Strategic Plan* are being met. These data will be made available to the public through the Autism Research Database on the IACC website: <https://iacc.hhs.gov/funding/data/>.

#### Conclusions:

These analyses of ASD research funding provide a broad overview of the autism research landscape in the U.S. and the roles of government and non-government funders in supporting ASD research.

#### **524.024 (Virtual Poster) Multiple Perspectives Regarding Barriers to Minoritized Populations' Participation in Genetic Research: Examining Practitioner and Community Responses on This Critical Issue**

**M. J. Oyeyemi<sup>1</sup>, Z. Algaze<sup>2</sup>, V. Ranganathan<sup>3</sup>, A. Quinones<sup>2</sup>, S. Horner<sup>4</sup>, E. LaSasso<sup>2</sup>, A. Daniels<sup>5</sup>, K. Diehl<sup>1</sup>, J. K. Law<sup>6</sup>, N. Nagpal<sup>1</sup>, R. T. Schultz<sup>1</sup>, J. Pandey<sup>1</sup> and S. Consortium<sup>1</sup>, (1)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (2)Center for Autism Research at the Children's Hospital of Philadelphia, Philadelphia, PA, (3)CHOP, Philadelphia, PA, (4)CHOP Center for Autism Research, Havertown, PA, (5)Simons Foundation, New York, NY, (6)Maryland Center for Developmental Disabilities, Maryland Center for Development Disabilities, Kennedy Krieger Institute, Baltimore, MD**

Background: Individuals with Autism Spectrum Disorder (ASD) who belong to communities of color are often underrepresented in autism research, which contributes to further disparities in healthcare (Maye et al., 2021). The Simons Foundation Powering Autism Research for Knowledge (SPARK) study, a nationwide genetic study, has reviewed their recruitment efforts and report that 6% of participants are Black and 3% are Asian, significantly less than national demographic data (13.4% Black, 5.9% Asian) and that of Philadelphia (42.1% Black, 7.2% Asian; U.S. Census Bureau, 2020).

Objectives: To (a) better understand the barriers ASD families, especially those from underrepresented communities, face in genetic autism research and (b) to discover and improve strategies to ethically recruit families from underrepresented communities based on the perspectives of ASD community members and healthcare providers who serve ASD families.

Methods: The Children's Hospital of Philadelphia (CHOP)-SPARK team developed two surveys for distribution to Philadelphia ASD community members and healthcare providers. The surveys included 21 multiple choice and open-ended questions about genetic research participation and recruitment efforts, with the community survey addressing the responder's concerns and the provider survey focusing on that of their minoritized patients. A randomized sample of community responses were compared with healthcare provider responses.

Results: Both groups identified logistical issues and lack of awareness as the biggest barriers to genetic research participation, also citing privacy concerns and the possibility for misuse of information (Tables 2 & 3). One community member noted that "doctors...[should] give out some sort of flyer" about SPARK to increase participation, an idea shared by 66% of providers, who stated that they would discuss SPARK more if provided with recruitment materials. However, the groups had different views on what resources ASD families need. The top choices for community members were research finding updates and relevant webinars, while 65% of providers recommended social service access, a resource only 46% of community members selected (Tables 4 & 5).

Concerns and needs of underrepresented communities seemed to differ from that of white community. A majority (85%) of survey respondents identified as white, followed by 10% and 4% from the Black and Asian communities, respectively (Table 1). Black community members saw the fear

of being taken advantage of and mistrust of clinical/research staff as significant barriers to genetic research participation, while less than 10% of white respondents shared these concerns (Table 2).

Providers believed that having research staff present in healthcare settings would be the most effective tool to increase minoritized family participation. Underrepresented communities supported this method, as 60% felt most comfortable meeting with researchers in a CHOP clinic. In the total sample, community members felt more comfortable scheduling at-home visits than meeting with research staff in healthcare settings.

Conclusions: ASD families from underrepresented groups have unique experiences that guide their hesitancy to participate in genetic research. Acknowledging specific needs through targeted recruitment strategies and provider partnership may help reduce racial disparities in autism research. Additional findings that highlight the significance of comparing community and provider perspectives on this issue will be presented.

**524.025 (Virtual Poster)** Representation Counts: Assessing the Needs, Barriers, and Fears of Minoritized Populations' Participation in Genetic Research

**M. J. Oyeyemi<sup>1</sup>**, Z. Algaze<sup>2</sup>, V. Ranganathan<sup>3</sup>, A. Quinones<sup>4</sup>, L. Malloch<sup>5</sup>, A. Daniels<sup>6</sup>, K. Diehl<sup>7</sup>, R. P. Goin-Kochel<sup>8</sup>, A. Gulsrud<sup>9</sup>, J. K. Law<sup>10</sup>, N. Nagpal<sup>11</sup>, D. E. Sarver<sup>12</sup>, R. T. Schultz<sup>13</sup>, J. Pandey<sup>14</sup> and S. Consortium<sup>15</sup>, (1)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (2)Center for Autism Research at the Children's Hospital of Philadelphia, Philadelphia, PA, (3)CHOP, Philadelphia, PA, (4)University of Mississippi Medical Center, Jackson, MS, (5)Simons Foundation, New York, NY, (6)Baylor College of Medicine, Houston, TX, (7)UCLA Semel Institute for Neuroscience & Human Behavior, Los Angeles, CA, (8)Maryland Center for Developmental Disabilities, Maryland Center for Development Disabilities, Kennedy Krieger Institute, Baltimore, MD

---

Background: Simons Foundation Powering Autism Research for Knowledge (SPARK) is a nationwide genetic study recruiting individuals with Autism Spectrum Disorder (ASD) and family members. In 2020, 6% of SPARK participants were Black and 3% were Asian, showing a clear disparity compared to national demographics (13.4% Black; 5.9% Asian; U.S. Census Bureau, 2020). Black families within the ASD community often distrust research because of the history of ethical violations, while Asian parents cite struggles with language barriers (Jones & Mandell, 2020; Roman-Urrestarazu et al., 2021). Four SPARK sites distributed surveys to local ASD community members to understand barriers to genetic research participation, with the goal of addressing racial disparities across the SPARK network.

Objectives: To (a) identify participation barriers in genetic-autism research, including the SPARK study, from the perspectives of individuals with strong ties to their local ASD communities and (b) inform the development of new recruitment strategies, especially those targeting underrepresented communities.

Methods: The SPARK team at the Children's Hospital of Philadelphia (CHOP) developed a 21-question survey to collect feedback from ASD community members regarding genetic research participation concerns and recruitment strategy opinions. Four SPARK clinical sites, CHOP, University of California, Los Angeles (UCLA), University of Mississippi Medical Center (UMMC), and Baylor College of Medicine (BCM), distributed this survey electronically to their local networks/ASD community stakeholders. Total survey responses from UCLA, UMMC and BCM were added to a random sample from CHOP and analyzed for prominent trends and themes.

Results: Most (55%) responses came from white ASD community members, followed by 21%, 13%, and 2% from the Black, Asian, and Native American communities, respectively (Table 1). Eighty percent of community members from the four sites stated that SPARK is beneficial for individuals with ASD. However, concerns about information misuse and privacy were referenced by 25% of respondents. Some community members questioned the direct benefit to their family members with ASD, as well as long delays in return of genetic results.

Priorities and concerns about genetic research differed significantly between racial groups (Tables 2 & 3). Together, 63% of Black and Asian community members preferred that research studies offer support in gaining access to services, while 54% of white community members showed interest in this. Asian community members were more interested in support groups and webinars and more concerned about logistical barriers to participation than non-Asian respondents. Black community members identified the fear of being taken advantage of and mistrust of clinical/research staff as key barriers to participation more than non-Black respondents. This may reflect "concerns about bias" and "distrust [of]... the medical community" cited by multiple Black community members. Native American community members also cited mistrust of clinical staff and information security as key concerns.

Conclusions: To increase research participation in underrepresented communities, researchers need to build trust through clear messaging about information protection and data usage, as well as providing families with the resources they need to improve their daily lives. Further comparison across racial/ethnic groups will be presented, highlighting the importance of these perspectives.

**524.026 (Virtual Poster)** Parent-Perceived Parental Stress, Relationship Closeness, and Relationship Satisfaction: Comparison of Simplex and Multiplex Families

**E. Mitchell<sup>1</sup>**, H. Onovbiona<sup>2</sup>, L. B. Quetsch<sup>3</sup>, C. Brown<sup>4</sup>, L. Aloia<sup>5</sup> and S. M. Kanne<sup>6,7</sup>, (1)Psychological Science, University of Arkansas, Fayetteville, AR, (2)University of Arkansas, Fayetteville, AR, (3)Pacific University, Hillsboro, OR, (4)Communication, University of Arkansas, Fayetteville, AR, (5)Center for Autism and the Developing Brain, White Plains, NY, (6)Weill Cornell Medical College and New York-Presbyterian Hospital, New York, NY

---

Background: Parents of children with autism spectrum disorder (ASD) experience higher stress when compared to those with neurotypical youth (Hayes & Watson, 2013). However, little is known about stress may change when families have one child (simplex) versus more than one child with

ASD (multiplex). Furthermore, research rarely explores the strengths of families of youth with ASD (e.g., closeness, satisfaction) and how family composition may impact these experiences.

**Objectives:** The current study aims to examine if parental stress, relationship closeness, and relationship satisfaction differ between simplex and multiplex families.

**Methods:** Eight-six multiplex families and 86 simplex families of children with ASD between the ages of 4 to 17 years were compared. Independent samples t-tests were conducted to examine if parental stress (Parenting Stress Index: Short Form), relationship closeness, and relationship satisfaction differed between family groups.

**Results:** Analyses revealed no significant differences between the groups on parental stress ( $t(170) = -.726, p = .469$ ), parent perceived relationship closeness ( $t(170) = .129, p = .449$ ), or parent perceived relationship satisfaction ( $t(170) = -.918, p = .360$ ).

**Conclusions:** Stress, relationship closeness, and relationship satisfaction between the samples were statistically nonsignificant. Our findings suggest that families are able to connect with their children at similar levels regardless of the number of children with neurodiversity in the house. This suggests that families may experience certain levels of stress (e.g., from concerns for the child's future, family finances, autism stigma) or connection that are not impacted significantly by having multiple children with the same diagnosis (Papadopoulos, 2021). Further discussion and future directions will be presented on the poster.

**524.027 (Virtual Poster)** Perspectives of Caregivers and Youth with Developmental Disabilities on Physical Activity: A Qualitative Study  
*S. Srinivasan, A. Athreya, M. Kaba, S. S. Glenney and D. Bubela, Kinesiology, University of Connecticut, Storrs, CT*

---

**Background:** Youth with developmental disabilities (DD) are more likely to be obese compared to their non-disabled peers and suffer from associated adverse physical and psychological consequences. Individuals with DD are three times more likely to be sedentary compared to healthy peers and 56% of individuals do not participate in any physical activity (PA).

**Objectives:** The present study involved focus group discussions with youth with DD and their caregivers to understand their perceptions regarding PA and identify facilitators and barriers influencing PA participation in youth with DD.

**Methods:** 13-to-26-year-old, verbal, males and females with DD (including ASD, Cerebral Palsy, Down syndrome and Intellectual Disability) and their caregivers were recruited. Two separate focus groups in each stakeholder group were conducted virtually via Webex with youth and their caregivers, with group sizes ranging from 4-8 participants. Each focus group lasted for about 1.5 hours and was audio recorded. During the focus group, an experienced moderator facilitated the discussion. For youth with DD, we asked about PA they pursued recently, frequency and duration of PA engagement, how PA made them feel, their favorite activities, barriers they face in being active, and general suggestions they had to promote PA in youth with DD. Similar questions were also posed to caregivers about their children with DD. In addition, they were asked to share perspectives about the importance of PA for their family, impact of COVID on their child's PA, and PA opportunities they plan to access for their child as they transition out of school. Focus group sessions were transcribed and three researchers read the transcripts to identify themes emerging from the discussions.

**Results:** All youth reported engaging in some PA such as recreational activities (e.g. walking, swimming, bike riding, horse riding, Unified Sports, Wii, etc.) or chores (e.g. yard work) for PA. They were more likely to engage in PA that was fun, not too challenging or competitive, and that provided opportunities for interactions with healthy peers or family. Over 90% youth also highlighted the importance of having trained personnel to motivate them and help them with the activities if needed. A majority of caregivers emphasized an unmet need for more accessible, adapted programs and facilities with flexible timings, transportation support, affordable costs, appropriate equipment, and trained empathetic personnel to help promote PA in youth. They also highlighted the dearth of state-run PA programs beyond the age of 21 years, and emphasized the burden on families to advocate for PA and scout for appropriate programs to provide their children access to PA opportunities across their lifespan. A 100% of youth and caregivers reported a significant decrease in PA during COVID-19 due to closures of programs and facilities.

**Conclusions:** Youth with DD are an underserved population especially as they transition into adulthood. There is a need for focused adult-oriented programs with trained personnel to promote PA and fitness throughout the lifespan. Our study serves to highlight family perspectives on PA and provides insights to guide the development of programs to promote PA in youth with DD.

**524.028 (Virtual Poster)** Perspectives of Clinicians and Special Educators on Physical Activity in Youth with Developmental Disabilities: A Qualitative Study  
*A. Athreya, M. Kaba, S. S. Glenney, D. Bubela and S. Srinivasan, Kinesiology, University of Connecticut, Storrs, CT*

---

**Background:** Youth with developmental disabilities (DD) including Autism Spectrum Disorder (ASD) are at high risk for obesity due to lower levels of physical activity (PA) compared to healthy peers. According to the National Survey for Child Health, less than 20% youth with DD meet the PA recommendations issued by the US department of Health and Human services.

**Objectives:** This study involved focus group discussions with physical therapists and special educators working with youth with DD to understand their perspectives on PA in their clients/students and factors associated with PA participation in this population.

**Methods:** Inclusion criteria included (1) physical therapists working with youth with DD from 13-26 years in school, hospital, outpatient, or other settings, and (2) special educators/paraprofessionals working with youth within school settings. Two separate focus groups were conducted virtually via Webex with each stakeholder group, with group sizes ranging from 4-8 participants. The discussion, facilitated by an expert moderator, lasted about 1.5 hours and was audio recorded. We asked clinicians about the amount of PA they recommend for youth with DD, the types of activities that youth enjoy, strategies used to motivate them, barriers faced in getting youth to be active especially as they transition out of school systems, and suggestions on program development to promote PA in youth. Educators were additionally asked about PA opportunities offered to students in schools and the extent to which PA-related goals are part of students' Individualized Education Program (IEP) and transition plans. Focus groups were transcribed and three researchers read transcripts to identify major themes.

**Results:** The majority of stakeholders reported that youth with DD prefer activities that are fun, allow them to experience success, afford integration with peers, and are adapted to their needs (e.g. individualized based on interest and ability level, non-competitive, etc.). Although 100% clinicians recommended incorporating some form of PA daily within their client's schedule, ultimately, engagement in PA depends on multiple factors such as availability of energetic staff/healthy peers to motivate students, family values/priorities, etc. Over 75% stakeholders highlighted the need for a holistic approach to health by emphasizing both nutrition and PA. They recommended that efforts be made as part of transition programs to teach youth to access available fitness options within their local communities and different life skills/chores that will promote lifelong PA. Finally, 100% participants underscored the need for family education to ensure integration and carryover of activity habits outside school and therapy settings. Barriers identified for PA engagement included financial constraints, family beliefs, COVID-related program disruptions, lack of space and equipment, and lack of properly trained personnel and programs especially for youth over 21 years.

**Conclusions:** Clinicians and educators highlighted the critical need for programs and services to support families in the promotion of PA in youth transitioning into the adult world. Our findings call for more research on youth- and adult-centric programs to promote PA in young adults DD. Findings may have implications for policy-level changes to improve access to resources aimed at improving overall health of youth with DD.

**524.029 (Virtual Poster)** Post-Diagnostic Stress Among Parents of Children Diagnosed with Autism Spectrum Disorder: A Qualitative Study  
**P. Malhi<sup>1</sup>, A. S. Shetty<sup>2</sup>, B. Bharti<sup>3</sup> and L. Saini<sup>4</sup>,** (1)Department of Pediatrics, Post Graduate Institute of Medical Education and Research, Chandigarh, India, (2)Dept of Pediatrics, Post Graduate Institute of Medical Education and Research, Chandigarh, India, (3)Pediatrics, Post Graduate Institute of Medical Education and Research, Chandigarh, India, (4)Department of Pediatrics, All India Institute of Medical Sciences (AIIMS), Jodhpur, India

---

**Background:** Research indicates that cultural variables influence family experiences of disability and western findings may not be able to guide policy and clinical practice in traditional and conservative nations. Research in India has seldom studied caregivers' perceptions, experiences, and needs for information after an autism diagnosis. Indeed, research in this area is dominated by evidence from the western countries and neglected in the low- and middle-income countries (LMICs) leading to a substantial gap in the literature with regard to the specific issues associated with the care of a child with autism spectrum disorder (ASD).

**Objectives:**

The present study attempts to understand the perceived barriers experienced by parents of children with autism in the context of their situation and lifeworld.

**Methods:**

Twenty-eight parents with a diagnosed child with ASD (3-8 years) was recruited from a tertiary care teaching hospital in North India. An interview guide elicited information about experiences regarding obtaining an autism diagnosis, perceived barriers and facilitators, reactions to diagnosis, post-diagnostic family and community experiences, and stress experienced by parents. The interviews were audio-recorded, transcribed, and analysed. An inductive, descriptive thematic analysis was utilized to extract broad themes and sub-themes from each of the interviews conducted. The ethics clearance was provided by the institutional review board.

**Results:** Parents discussed a range of issues, including the arduous process of getting a diagnosis, their emotional responses to diagnosis disclosure, financial and relationship struggles, lack of emotional and financial support, significant challenges of parenting a child with autism, and coming to terms with autism. Parents recalled that they were unaware that some of the early signs of autism were aberrations of normal development. Delayed development, particularly in the language sector, was generally ignored or not considered severe enough to warrant medical attention. Many parents reported a high amount of post-diagnosis stress, poorer parental functioning, greater marital conflict, family socialization difficulties, and feelings of inadequacy. Parental stress was primarily related to the burden of childcare, difficulty in managing family relationships, limited support systems, financial concerns, and stigma associated with childhood disability. Overall, nine themes were identified from the qualitative analysis of the interviews: two before the diagnosis (delayed help-seeking and experiences with healthcare), one at the time of diagnosis disclosure (heightened emotional response to diagnosis), and six themes after the diagnosis (increased stress, behavioral challenges, deterioration in family relationships, negative attitudes of the family, seeking support, and moving forward with hope for the future).

**Conclusions:** There are several barriers and gaps in the autism-related available services in the country and there is a need to provide inclusive, supportive, and culturally sensitive support to caregivers. Child health professional can play a salient role in helping parents navigate the complex health care system, weigh the pros and cons of various intervention strategies, and make decisions that best suit their individual needs. Clinical implications of the study highlight the need for more family-centred physician-parent communication that is strengths-based, sensitive to families' emotional needs, and individualized to a family's unique context.

**524.030** (Virtual Poster) The Effect of Affiliate Stigma on Family Quality of Life Among Parents of ASD Children: The Chain Mediating Roles of Social Support and Self-Compassion

C. Wang<sup>1</sup> and T. Yu, (1)Department of Social Psychology, Nankai University, Tianjin, China, (2)Nankai University, Tianjin, China

---

**Background:** Parents of ASD children were reported to have higher level of affiliate stigma than that parents with other disabilities (Werner & Shulman, 2015). According to a study by Afia (2012), affiliate stigma increases parental pressure and burden on caregivers of children with disabilities, hence reducing the quality of life.

**Objectives:** This study aims at investigating family quality of life among parents of ASD children and its association with other variables, including affiliate stigma, social support, and self-compassion.

**Methods:** A survey of parents of ASD children was conducted during November 2020 to February 2021. There were 506 participants enrolled, among whom 418 were mothers of children with ASD and 88 were fathers. The measures were Family Quality of Life Scale, Affiliate Stigma Scale, Self-compassion Scale, Social Support Scale. The descriptive statistics, *t*-test, analysis of variance, correlation and regression were used to analyze the data.

**Results:** There were significant gender differences on affiliate stigma ( $P < 0.001$ ), family quality of life ( $P < 0.01$ ), social support ( $P < 0.01$ ) but not on self-compassion ( $P > 0.05$ ). Self-compassion and social support play a significant role in the chain intermediary between stigma and family quality of life. In the mediation model of affiliate stigma → self-compassion → family quality of life, affiliate stigma has a significant negative predictive effect on self-compassion ( $\beta = -0.26$ ,  $P < 0.01$ ), and self-compassion has a significant positive predictive effect on family quality of life ( $\beta = 0.19$ ,  $P < 0.05$ ). In the mediation model of affiliate stigma → social support → family quality of life, affiliate stigma significantly negatively predicts social support ( $\beta = -0.36$ ,  $P < 0.001$ ), and social support predicts family quality of life significantly positively ( $\beta = 0.56$ ,  $P < 0.01$ ). In the chain mediation model of affiliate stigma → self-compassion → social support → family quality of life, self-compassion has a significant positive predictive effect on social support ( $\beta = 0.22$ ,  $P < 0.001$ ).

**Conclusions:** In summary, compared with self-compassion, social support has a large mediating effect between the affiliate stigma of parents of ASD children and the family quality of life; self-compassion and social support of parents of ASD children play a chain mediating role between affiliate stigma and family quality of life.

**524.031** (Virtual Poster) Quiet Ego and Post-Traumatic Growth in Caregivers of Special Children: A Mediating Model for Regulation

C. Wang<sup>1</sup> and Q. Bai<sup>2</sup>, (1)Department of Social Psychology, Nankai University, Tianjin, China, (2)Nankai UNIVERSITY, TIANJIN, China

---

**Background:** Previous studies showed that quiet ego reflects a quiet self-consciousness, which allows individuals to re-establish their understanding with a more positive self-attitude, thus effectively encouraging individuals to choose positive treatment and coping styles, and thus effectively promoting the development of post-traumatic growth. However, there is little research on the characteristics of quiet self and post-traumatic growth of caregivers of special children, and the mechanism of quiet self 's effect on the post-traumatic growth is not clear.

**Objectives:** The study aims to examine the relationship between quiet ego, post-traumatic growth, positive response and social support of caregivers of special children, and further investigate the mediating role of active response between quiet ego and post-traumatic growth, as well as the regulating role of social in order to provide advice for effective post-traumatic growth and positive coping strategies.

**Methods:** Two hundred and seventy-eight caregivers of special children (42 fathers, 216 mothers and 20 other caregivers) were recruited to participate an online survey during December 2020 to March 2021. The demographic information of both caregivers and their children (Male: Female = 195:83) were collected. The measures were the Quiet Ego Scale (QES), Post-traumatic Growth Inventory (PTGI), Simplified Coping Style Questionnaire (SCSQ) and Social Support Rating Scale (SSRS). The descriptive statistical analysis, the *t*-test and variance analysis are used to analyze the demographic differences. The relationship among the variables is tested by Process, and the significance of the mediating effect is tested.

**Results:** It was found that caregivers of special children had high post-traumatic growth ( $M = 62.85$ ,  $SD = 15.96$ ). The total mean score of their social support is 37.89 ( $SD = 7.76$ ) with subjective support (Mean = 22.31,  $SD = 5.12$ ), objective support (Mean = 8.56,  $SD = 2.87$ ), and utilization of social support (Mean = 7.01,  $SD = 1.83$ ). Mothers were found to have high level of quiet ego than fathers ( $P < 0.05$ ). A significant positive correlation was found between quiet ego and post-traumatic growth of caregivers of special children ( $r = 0.266$ ,  $P < 0.01$ ), positive coping style and post-traumatic growth and its subscales ( $r = 0.64$ ,  $P < 0.01$ ), social support and post-traumatic growth ( $r = 0.328$ ,  $P < 0.01$ ), quiet ego and positive coping style ( $r = 0.191$ ,  $P < 0.01$ ), positive coping style and social support ( $r = 0.437$ ,  $P < 0.01$ ). Quiet ego can not only directly predict post-traumatic growth but also predict it through the mediating role of positive coping style.

**Conclusions:** In summary, the stronger the quiet ego of caregivers of special children, the higher the ability to respond positively and the more obvious post-traumatic growth. The increase of their quiet ego and positive response level will be helpful in improving the level of post-traumatic development of caregivers of special children.

**524.032** (Virtual Poster) Neurotypical Adult Siblings' Perceptions of Pressure: Examining Birth Order and Affect Toward the Sibling Relationship

J. Maga<sup>1</sup>, S. Guadarrama<sup>2</sup> and J. N. Phung<sup>3</sup>, (1)California State San Marcos, San Marcos, CA, (2)California State University San Marcos, San Marcos, CA, (3)Psychology, California State University San Marcos, San Marcos, CA

---

## Background:

Neurotypical (NT) individuals who grow up with an autistic sibling face high rates of stress and negative sibling attitudes (Tomeny et al., 2017). Birth order, whether the NT individual is younger or older than their autistic sibling, may influence one's experience. Among children, NT siblings who were younger than their autistic sibling showed more behavior problems when the autistic child was older than them and had behavior problems themselves (Tomeny et al., 2014). These childhood difficulties may continue into adulthood, which could worsen mental health and sibling relationship quality.

## Objectives:

This study examined birth order differences in questionnaire-report of mental health, and frequency of affective words used during a semi-structured interview.

## Methods:

Participants were 24 NT adults ( $M_{age}=24.13$  years; 79.2% women) with at least one autistic sibling. Participants completed the Depression, Anxiety, and Stress Scale (DASS; Lovibond & Lovibond, 1995) and a 1-hour semi-structured interview wherein the researcher asked open-ended questions centered on pressures/responsibilities concerning the autistic sibling. The interview transcripts were run through Linguistic Inquiry and Word Count (LIWC; Pennebaker et al., 2015), which counts the percentage of words that reflect categories of affect/thinking styles. Participants were then grouped for analysis:  $n=7$  (29%) younger than their autistic sibling,  $n=10$  (42%) between 1-6 years older than their autistic sibling, and  $n=7$  (29%) 7 or more years older than their autistic sibling.

## Results:

Standard regression models were run on the DASS questionnaire to examine birth order differences (younger, older, and much older) in depression, anxiety, and stress. When controlling for participant sex at the first level, birth order accounted for a significant F-change in DASS anxiety ( $p=.048$ ) and stress ( $p=.037$ ). For both anxiety and stress ratings, the much older group had lower ratings than the older and younger groups (Table 1). There was no significance in birth order difference for depression ratings ( $p=.112$ ).

Standard regression models were run on the LIWC anxiety, affect, positive emotion, and negative emotion categories to examine birth order differences in the percentage of words used. When controlling for participant sex at the first level, birth order accounted for a significant F-change in the percentage of words that focused on anxiety ( $p=.039$ ), affect ( $p=.009$ ), and negative emotion ( $p=.019$ ); the much older group had lower percentage of words than the older and younger groups (Table 2). There was no significant difference in positive emotion ( $p=.362$ ).

## Conclusions:

Being much older than an autistic sibling may protect against the pressures one may face as a NT sibling. Possibly, the resourcefulness that comes from having a larger upper-age-gap with one's autistic sibling allows for better coping skills. Individuals who are either younger or less than 6 years older than their autistic sibling may be at greater risk to experience anxiety, stress, and negative attitudes toward their sibling. Future work is needed to further elucidate the resilience factors held by much older siblings, as such skills could potentially be taught to individuals closer in age to their autistic sibling to better support mental health and sibling relationship outcomes in adulthood.

**524.033** (Virtual Poster) Speech Language Pathologists' Perspective on Speech Language Communication Therapy Practices for Autism Spectrum Disorder Population: An Online Indian Survey

**R. M. K. D. Veena, A. Menon and V. Aithal**, Department of Speech and Hearing, Manipal College of Health Professions, Manipal Academy of Higher Education, Udupi, India

---

## Background:

Autism Spectrum Disorder (ASD) is a growing population in the world as well as in India, estimated prevalence of autism in rural part of India is 0.11 (1-18 years) and urban part of India is 0.09 (0-15 years) (Chauhan et al., 2019). Intervention of ASD is always been a challenging task for professionals, because of its heterogeneous nature (Motttron & Bzdok, 2020). ASD children exhibits varied difficulties in terms of social interaction, communication, restricted interests, repetitive or stereotypic behaviors and sensory issues, based on the degree of severity (Waizbard-Bartov., et al 2021). Despite the fact that researchers have investigated a variety of strategies to improve speech, language, and social communication skills in children with ASD, the heterogeneous nature of autism makes it difficult to generalize one type of intervention to all autism children because it may not yield similar results. As a result, it is critical to understand the trend of speech language therapy practices followed by speech language pathologists (SLPs) in the intervention of autism. This information is likely to aid SLPs in developing a thorough intervention strategy that will have an appreciable impact on children with ASD.

## Objectives:

The objective of the study is to understand SLPs perspective on speech language communication therapy practices in India for ASD children.

## Methods:

The questionnaire's contents were validated by five SLPs with at least five years of experience working with ASD population. It was prepared in Google form and was circulated online to 150-200 practicing SLPs across India. The questions ranged from which is the best suited intervention approach, how many intervention approaches are they aware of, how intense an intervention approach should be, who should be part of an active team of professionals for intervening children with autism. The responses were obtained in Yes/No, closed set and open set format. The Yes/No and closed set responses were analyzed quantitatively by taking the mean of the responses and open set responses were analyzed qualitatively.

## Results:

Applied behavior analysis a behavioral intervention (80%), and functional communication training a naturalistic intervention strategy (68.2%) were chosen by Indian speech language pathologists as the best suited interventions for children with ASD. Literacy abilities were taught with little effort, according to 59.1% of SLPs, while social communication was the most challenging skill to master in children with ASD. PECS (85%), applied behavior analysis (80%), functional communication training (68.2%), social stories (43%), AVAZ (15%), video modeling (2%) were the interventions preferred to teach social communication skills in ASD populations. 60% of SLPs uses COMDEALL an Indian structured program for children with ASD.

## Conclusions:

Indian SLPs believed that a team of specialists (SLPs, occupational therapists, psychologists and special educators), rigorous and structured intervention in terms of time, frequency, home training, and counseling to parents or caregivers are necessary requirements for having a positive impact on overall improvement in children with ASD. Also observed, few SLPs were apprehensive in using new intervention strategies, as they were unaware regarding its implementation.

**524.034** (Virtual Poster) Speech Language Pathologists' and Psychologists' Perspective on Assessment of Autism Spectrum Disorder: An e-Survey  
**C. A. A. Sreelakshmi<sup>1</sup>** and **K. D. Veena<sup>2</sup>**, (1)Department of Speech & Hearing, MCHP, MAHE, Manipal College of Health Professions, Manipal Academy of Higher Education, Udupi, India, (2)Department of Speech and Hearing, Manipal College of Health Professions, Manipal Academy of Higher Education, Udupi, India

---

**Background:** Speech Language Pathologists (SLPs) and psychologists play a key role in the evaluation of communication and behavioral aspects of children with autism spectrum disorder (ASD). The assessment practice adopted by these professionals has considerable influence on the evaluation and intervention procedures that follow.

**Objectives:** The aim of the e-survey was to understand the different views of SLPs and psychologists in India regarding assessment and diagnosis of ASD.

**Methods:** Participants included SLPs and psychologists working with ASD clients in India. The e-survey comprised of questions on the background information of respondents, their views, and opinions on the best age for screening, assessing, and diagnosing ASD, developmental screening, early identification before two years of age, issues related to ASD differential diagnosis and prospect of a universal screening protocol for ASD in Indian scenario. Google form with the set of questions was shared.

**Results:** Though the majority of SLPs and psychologists agreed with the possibility of identifying children with a risk for developing ASD during infancy and early toddlerhood, they still preferred to make a provisional diagnosis after 2 to 3 years. This points to the fact that early identification of ASD using infant screening tools is less common than presumed in the Indian scenario. Half of the participants preferred to do a differential diagnosis of ASD from attention deficit hyperactivity disorder (ADHD) only at 3 to 4 years of age but quite a few consider making a differential diagnosis even at the age of 2 to 3 years owing to the specific and distinct features of ASD. The possibility of using parental surveillance, developmental monitoring, and behavioral analysis for early identification of ASD was supported by most of the participants. The potentiality of a Universal Screening Protocol for early identification of ASD in India was also agreed upon.

**Conclusions:** The results help to relate how diverse the Indian SLPs' and psychologists' perspective on ASD assessment and diagnosis is, from the international practicing community. The study also signifies the need to develop culturally adapted, affordable, and easy to use ASD assessment tools. Such a tool would be more popular among the professionals, could be included in universal screening programs and thereby encourage early and effective identification of ASD in low- and middle-income countries (LMIC) such as India.

**524.035** (Virtual Poster) Preparing for the Next Disaster: Lessons Learned from the Early Experiences of Autistic Adults during the COVID-19 Pandemic

**A. P. Davidson<sup>1</sup>**, **C. Feeley<sup>2</sup>**, **B. Pfeiffer<sup>3</sup>** and **M. Salzer<sup>4</sup>**, (1)Health and Rehabilitation Sciences, Temple University, Philadelphia, PA, (2)School of Engineering, Rutgers CAIT, Piscataway, NJ, (3)Rehabilitation Sciences, Temple University, Philadelphia, PA, (4)Temple University, Philadelphia, PA

---

**Background:** Disasters, such as the worldwide COVID-19 pandemic, create significant disruptions for individuals and their communities. Understanding these disruptions is a first step towards planning for future events and disaster recovery. This research aims to explore how the initial COVID-19 restrictions, including lockdowns, impacted adults with Autism (ASD).

**Objectives:** To understand how community participation was disrupted from the perspectives of the individual themselves and to identify areas that could be improved with a more rapid response when a future disaster occurs, we asked the following question: 1) What Knowledge do you have about the COVID-19 pandemic?, 2) How are you getting your information about COVID-19?, and 3) How has the pandemic in real-time affected your community participation?.

**Methods:** Using semi-structured interviews to understand individuals with ASD experienced the early months of the COVID-19 pandemic. **Participants:** Twelve participants were interviewed: six individuals with ASD (ages 20-38), three parents of individuals with ASD, and three support staff for individuals with ASD. **Analysis:** Using grounded theory methods to analyze the impacts of COVID-19 based on the knowledge, challenges, activities, resources, and support needs of individuals with ASD.

**Results:** Interviews were coded. The questions generated three themes with eleven subthemes 1) COVID Knowledge: Understanding COVID, Preventative behaviors, Information resources; 2) Pre-COVID activities: social, work/day-program/school, environment, physical activities, and 3) During COVID activities: social, work/day-program/school, environment, and physical activities.

**Conclusions:** Individuals with ASD's understanding of COVID-19 is similar to the general public and display adequate, timely knowledge. They adopted new behaviors, including transitioning from structured physical schedules to less structured virtual schedules. Caregivers and support staff expressed concerns about preventative behaviors in the community.

#### **524.036 (Virtual Poster) The Effect of Siblings on Empathy in Autistic People**

**Y. Rum<sup>1</sup>, C. Allison<sup>1</sup>, P. Smith<sup>2</sup>, S. White<sup>2</sup>, O. Golan<sup>1</sup> and S. Baron-Cohen<sup>1</sup>, (1)Autism Research Centre, Department of Psychiatry, University of Cambridge, Cambridge, United Kingdom, (2)University of Cambridge, Cambridge, United Kingdom, (3)Bar-Ilan University, Ramat-Gan, Israel**

---

##### **Background:**

Growing up with siblings builds opportunities for social-cognitive growth for autistic children, such as shared imaginative play, handling conflicts, and practising reciprocal interaction, all associated with enhanced Theory of Mind development. Siblings may thus function as a valuable social resource and positively affect the social functioning of their autistic brothers or sisters (Ben-Ytzhak et al., 2016; Rum et al., 2020).

##### **Objectives:**

We aimed to investigate the effect of having siblings on empathic abilities in autistic children, adolescents and adults. We hypothesized that autistic people with siblings would score higher on empathy measures compared to those with no siblings.

##### **Methods:**

The Cambridge Autism Research Database (CARD) was used to retrieve previously collected data for secondary analyses. Cohorts of autistic children and adolescents ( $n=1,392$ ; 18.5% females; 3-15 years old, mean age=8.5 ( $sd=1.99$ ); 22% had no siblings); and adults ( $n=727$ ; 52% females; 18-81 years old, mean age=37,  $sd=12.42$ ; 15.3% had no siblings) were each divided into two groups: with siblings (Sibs group) and without siblings (No-sibs group). For children and adolescents, empathy was measured using the parent-reported version of the Empathy Quotient (EQ-Child and Adol). For adults, empathy was measured using the self-report version of EQ, and the Reading the Mind in the Eyes Test (RMET). For each cohort, the Sibs and the No-sibs groups were compared on each measure, with reference to sex and the interaction between group and sex.

##### **Results:**

Autistic children with no siblings scored significantly higher on the EQ than autistic children with siblings ( $t_{(350)} = 4.558, p < 0.001$ , Cohen's  $d = 0.344$ ). A 2-way ANOVA (group $\times$ sex), indicated main effects of group ( $f_{(1, 1096)} = 23.751, p < 0.001$ ) and sex ( $f_{(1, 1096)} = 7.265, p < 0.001$ ) but no interaction effect (see Figure 1). For adults, no differences were found between the Sibs and No-sibs groups on either EQ or RMET. Two-way ANOVAs revealed significant main effects for sex on the EQ ( $f_{(1, 723)} = 4.299, p < 0.05$ ) and on the RMET ( $f_{(1, 723)} = 5.687, p < 0.05$ ) (females performed better than males overall). On the RMET a significant interaction between sex and group was also found ( $f_{(1, 723)} = 3.81, p = 0.05$ ) (see Figure 2).

##### **Conclusions:**

Contrary to our hypothesis, autistic children who grow up as only children in their families were reported by their parents to be more empathic in comparison to autistic children who grew up with siblings. However, autistic adults with or without siblings did not differ in their self-reported empathy or on a performance measure of cognitive empathy, and adult males who grew up with siblings scored higher than males who grew up as only children on the cognitive empathy measure. These results indicate a positive effect of growing up with a sibling on social-cognitive functioning of autistic male adults. Autistic children's empathic abilities may be underestimated by their parents when they have siblings to whom they are compared, perhaps due to a contrast effect.

#### **524.037 (Virtual Poster) The Experience of Camouflaging in Autistic Women**

**Background:** Despite decades of research suggesting that autism is rare in women and that autistic individuals have limited theory of mind, the past decade has seen an explosion of research on camouflaging in autistic women<sup>1</sup>. Literature suggests that autistic women often camouflage their obvious autistic traits (i.e., stimming) to achieve personal goals such as more school success or employability improvements<sup>2</sup>. Although camouflaging can be beneficial in many ways, the lack of acceptance for autistic identity may promote a sense of urgency to camouflage, often resulting in experiences of exhaustion, poor mental health and increased risk of suicide<sup>3,4</sup>.

With COVID-19 impacting millions worldwide, for some, the environmental expectations for socializing with others have changed exponentially. Many neurotypical and neuro-divergent individuals camouflage regularly; however, it is challenging when environmental expectations change. Therefore, we hypothesized that changing public-health restrictions could negatively impact camouflaging routines, resulting in higher cognitive loads necessary to camouflage successfully. Additionally, we hypothesized that reducing in-person socializing could lessen the intensity and duration of camouflaging techniques, benefitting the well-being of individuals who camouflage regularly.

**Objectives:** Due to camouflaging being seldom explored in the context of COVID-19, this qualitative research study examined the camouflaging experiences of autistic women during COVID-19.

**Methods:** The study was conducted with the collaboration of an Autistic Advisory Committee (AAC). The AAC consisted of three autistic women who co-developed the study materials, objectives, and dissemination projects for the current study. The study invited four autistic women aged 18-35 to complete three journal entries of their camouflaging experiences and a semi-structured interview. We used interpretative phenomenological analysis, a qualitative research method that highlights the lived experience of the participants, to address our research objective. Specifically, participants were asked: (i) how their camouflaging experiences have changed throughout the pandemic; (ii) how the impacts of camouflaging have changed since the pandemic; and (iii) their thoughts of returning to post-pandemic social interactions.

**Results:** Thematic analysis resulted in three themes extracted from the data:

- **Reduced camouflaging:** camouflaging is consistently used in social environments where autistic individuals are encouraged to meet neurotypically social expectations. However, with an environmental shift that resulted in wearing a mask, spending more time at home, and increased social interaction done behind a screen or over the phone, the utilization of specific camouflaging strategies, such as mimicking facial expressions or body language, was significantly reduced.
- **Access to supports and services:** Before COVID-19, the accessibility of supports and services was less than ideal for the participants. Participants suggested that accessing services was still not easy but more accessible within the pandemic because social interactions focused on social distancing rather than presumed social deficits.
- **Re-learning how to camouflage:** Concerns about re-learning how to camouflage and what processes would support the successful integration of additional cognitive load post-pandemic are discussed.

**Conclusions:** The COVID-19 pandemic has brought attention to how experiences of camouflaging change when social expectations change. By hearing the participants' experiences, continued movement towards neurodiversity views within society can reduce camouflaging and alleviate concerns about re-learning how to camouflage autistic traits.

#### 524.038 (Virtual Poster) The Impact of COVID-19 on Older Autistic Adults: A Mixed-Methods Analysis

K. Koffler Miller<sup>1</sup> and L. Shea<sup>2</sup>, (1)Policy and Analytics Center, A.J. Drexel Autism Institute, Philadelphia, PA, (2)A.J. Drexel Autism Institute, Philadelphia, PA

---

**Background:** Autism most often persists throughout the lifespan, but little is known about the outcomes among autistic adults (Hategan, Bourgeois, & Goldberg, 2017). Increasing calls to action from the research community and advocacy bodies to focus on adults on the spectrum as they age have been amplified by the COVID-19 pandemic (Baghdadli *et al.*, 2020; Hotez *et al.*, 2021). Because individuals on the spectrum are more vulnerable to severe complications from COVID 19 (Schott, Tao, & Shea, 2021), understanding how older autistic adults are managing during the COVID-19 pandemic is critical to informing service access and delivery design to ensure older autistic adults are kept safe while also considering the whole of quality of life including socialization, community engagement, employment, and health.

**Objectives:** There has also been minimal research that has directly engaged older adults on the spectrum and their family members. The research will describe how the COVID-19 pandemic has impacted multiple life domains of older autistic adults including community engagement, employment, relationships and socialization, and health.

**Methods:** Autistic adults over 40 years old and their family members who had previously participated in the 2018 Pennsylvania Autism Needs Assessment (PANA) and consented to future contact were recruited for this study. The 2018 PANA is a large survey of autistic individuals and their family members in Pennsylvania. This study included analysis of semi-structured interviews and interviewee's survey data from the 2018 PANA. Interviews were recorded, transcribed, and uploaded into NVivo12 along with the data from the quantitative aim for analysis within the concurrent nested design. The interview data is being coded using the inductive framework without predetermining themes. Thematic analysis was designated as the coding methodology method for this study as it permits the study team to categorize the themes and subthemes that emerged from the interviews.

The quantitative data (i.e., demographic and survey data) was used as attribute data to classify each of the transcripts. This technique allows the researcher to see, demographically, which themes were more common. This aids in the transferability of the findings and enhances qualitative method as the priority and quantitative method as the supplemental information (Terrell, 2012; Watkins, 2012).

**Results:** Twenty-eight interviews were completed with autistic adults and their parents, siblings, partners, or other family members in Spring of 2020 during the COVID-19 pandemic. Data analysis for this study is ongoing, however preliminary themes have included feelings of disrupted routines, decreased community engagement, minimized social opportunities, isolation, and negative health outcomes.

**Conclusions:** Findings from this study will be impactful for the field of research on autism and aging, specifically within the context of the COVID-19 pandemic. This study provides the opportunity for older autistic adults and their family members to have their voices, perspectives, and opinions be at the forefront an exploration of this understudied area and will provide valuable insight in both the domains of research as well as policy and practice including proactive planning for needed services and supports to protect older autistic adults during the COVID-19 pandemic and beyond.

**524.039 (Virtual Poster)** The Impact of COVID-19 on the Employment and Mental Health of Adults on the Autism Spectrum and/or with Intellectual Disabilities

**C. Di Francesco<sup>1</sup>, T. Flanagan<sup>1</sup> and A. Nadig<sup>2</sup>,** (1)Educational and Counselling Psychology, McGill University, Montreal, QC, Canada, (2)School of Communication Sciences and Disorders, McGill University, Montreal, QC, Canada

---

**Background:** Under usual economic conditions, individuals on the autism spectrum and/or with intellectual disabilities (ID) struggle to obtain and maintain employment (Berrigan et al., 2020) and are at greater risk of developing mental health conditions that negatively impact quality of life (Croen et al., 2015; Hughes-McCormack et al., 2017). The economic, social and psychological challenges evoked by the COVID-19 pandemic may therefore exacerbate unemployment rates and mental health issues among these individuals. Most emerging research on the negative impact of COVID-19 on the employment and well-being of adults on the autism spectrum or with ID focuses on early stages of the pandemic, uses quantitative methodology, and studies many domains (e.g., school, social life, work) together. Here, we investigate how COVID-19 has impacted the employment and mental health of adults on the autism spectrum and/or with ID, and identify supports that were beneficial for this population during the pandemic.

**Objectives:** We are using a multiple case study design (n = 9) to follow participants on the autism spectrum and/or with ID over time, using data collected before (2018-2019) and during the pandemic (2021), to examine how COVID-19 has impacted their mental health, employment experience, job satisfaction, and satisfaction of employment supports, and to identify the type of supports that were available and deemed helpful to them during the pandemic.

**Methods:** Participants were employees on the autism spectrum and/or with ID receiving employment support services from a community organization in Montreal, Canada. In Phase 1 (2018-2019), employees completed two questionnaires rating their (1) job satisfaction and (2) satisfaction of employment support services received on a Likert scale. In the current Phase 2 participants will be invited to complete both questionnaires again, and participate in a semi-structured interview regarding employment experiences and mental health during the pandemic.

**Results:** Prior to COVID-19, employees assigned job satisfaction ratings of 3.89 or higher on a 5-point scale (with 1 indicating strongly disagree and 5 indicating strongly agree) for the ten positive items (e.g., my job is enjoyable), and ratings of 3 and lower for the four negative items (e.g., my job is frustrating). All employees indicated that they would recommend employment support services to other individuals with disabilities seeking employment, with 89% indicating that they were either satisfied or very satisfied on every item rated for satisfaction.

To analyze change in satisfaction, questionnaire responses obtained in Phase 2 will be compared to those obtained in Phase 1. To examine in greater depth the impact of the pandemic, semi-structured interviews will be recorded, transcribed, and analyzed through qualitative analysis to identify themes.

**Conclusions:** Data prior to COVID-19 shows high satisfaction among employees. Data collected in this study will allow us to analyze change in participant satisfaction and will shed light on the experiences of these individuals. The knowledge gained will inform the supports and services required to promote job success and well-being throughout and beyond COVID-19.

**524.040 (Virtual Poster)** The Relationship between Pivotal Response Treatment for Children with Autism Spectrum Disorder and Parental Stress  
**D. J. Magin<sup>1</sup>, S. Terroso<sup>2</sup>, D. G. Sukhodolsky<sup>3</sup> and P. E. Ventola<sup>3</sup>,** (1)Yale Child Study Center, New Haven, CT, (2)Child Study Center, Yale University, New Haven, CT, (3)Yale Child Study Center, Yale University School of Medicine, New Haven, CT

---

**Background:** Parents of children with autism spectrum disorder (ASD) present with particularly high levels of stress when compared with parents of typically developing children and parents of children with other developmental disabilities (Dumas, Wolf, Fisman & Culligan, 1991; Sanders & Morgan, 1997; Taylor & Warren, 2012). There is evidence to support the idea that effective behavioral therapies for children with autism can help to alleviate this stress (Rollins, John, Jones, & Froy, 2019). Pivotal Response Treatment (PRT) is an empirically supported and naturalistic behavioral treatment focused on improving children's social communication skills (Koegel & Koegel, 2006).

**Objectives:** This project had two objectives. First, we examined the relationship between parenting stress and externalizing behaviors in their children with ASD. Secondly, with a subset of these parents, we examined the change in parental stress following the completion of a trial using pivotal response treatment.

**Methods:** Seventy-eight parents completed a measure of parenting stress (Parenting Stress Index, PSI-4) as well as a questionnaire to assess behavioral and emotional problems in their child (Child Behavior Checklist 1.5-5 and 6-18, CBCL 1.5-5 and 6-18). A subset of these parents (and their child) ( $n = 34$ ) participated in an intervention study using PRT. The trial included 7 hours of weekly individual work with the child and parent training over 16 weeks. Parental stress and child behavior symptoms were assessed in this group at both baseline and at the end of treatment.

**Results:** Scores for parenting stress on the PSI-4 and externalizing behaviors on the CBCL were positively correlated at baseline ( $r(76) = .360, p = .002$ ). Higher externalizing symptoms were related to higher levels of stress. For the group that received PRT, there was a significant decrease in parenting stress as measured on the PSI-4 following the completion of the PRT trial (Baseline Total Stress Score,  $M = 91.15$ ) (End of Treatment Total Stress Score,  $M = 83.12$ ).

**Conclusions:** There is a significant positive relationship between child externalizing behaviors and parental stress. This is consistent with prior work, yet is an important finding, as it speaks to the need to treat social communication deficits in children, while simultaneously supporting families. Pivotal response treatment may help to achieve these goals. In this study, there was a significant decrease in parenting stress following their participation in the PRT trial. Parents who participate in PRT may feel empowered and better equipped to manage their child's maladaptive behavior, which could lead to reduced parental stress. This conclusion reinforces the importance of including parent training components in children's treatment plans.

**524.041 (Virtual Poster)** Transitioning Together: Evaluation of a Multi-Family Group Psychoeducation Program for Parents and Youth with Autism  
**S. Mills<sup>1</sup>, Q. Wan<sup>1</sup>, N. E. Walker<sup>2</sup>, J. Seymour<sup>3</sup>, L. E. Smith DaWalt<sup>4</sup> and P. Burnham Riosa<sup>1</sup>, (1)Brock University, St. Catharines, ON, Canada, (2)Kerry's Place Autism Services, Aurora, ON, CANADA, (3)York ASD Partnership, Toronto, ON, Canada, (4)University of Wisconsin-Madison Waisman Center, Madison, WI**

**Background:** The transition to adulthood is a time when young people experience many changes across various life domains; transition-aged youth (TAY) without disabilities experience adjustments in schooling, relationships, and independence (Arnett, 2001). For TAY with autism spectrum disorder (ASD), these transitions are markedly difficult; they are intensified by challenges associated with their diagnosis (e.g., social difficulties resulting in isolation; skill losses after secondary school). Furthermore, the family is affected. Research has indicated that parents of youth with ASD experience significantly greater stress than parents of children without ASD (Smith et al., 2010), which has been shown to impact parents' well-being (Smith et al., 2012). Current research indicates that family support for TAY with ASD is critical. One empirically supported program, *Transitioning Together* (TT), is a manualized 8-week group psychoeducational program for youth with ASD and their families. The program's goal is to prepare TAY with ASD and their families for the transition to adulthood by exploring topics such as employment, self-advocacy, and relationships. Following promising results for parents and youth from their pilot study (Smith et al., 2012), researchers examined the effectiveness of the TT curriculum to improve key parent, youth with ASD, and relationship outcomes (DaWalt et al., 2018). DaWalt et al.'s (2018) effectiveness trial data indicated a significant decrease in parental depression and increases in their problem-solving and feelings of pride toward their child. While the intervention did not reduce ASD symptoms, youth were reported to experience increased social interactions (DaWalt et al., 2018).

**Objectives:** Given the promising results of the TT program to date, the purpose of the current study was to examine the effectiveness of TT at improving the parent, youth, and parent-child relational outcomes among families living in York Region, Toronto, Ontario.

**Methods:** The current study was a pre-post with a 1-month follow-up design delivered across four partnering community agencies involving 17 program facilitators. Among 38 eligible families, 29 parent-youth dyads enrolled, and 26 families completed the study. At study entry, the majority of our parent sample included mothers (88.5%;  $n = 23$ ). The majority of TAY were male (84.6%;  $n = 22$ ); with a mean age of 15.9 years (14-17;  $SD = 0.78$ ), with an average Social Communication Questionnaire (Rutter et al., 2003) score of 19.8 ( $SD = 7.0$ ). Parents and youth completed various outcome measures at baseline, post-intervention, and at the 1-month follow-up (e.g., family empowerment, life stress, depressive symptoms, well-being, social functioning, autistic symptoms, parent-child relationship).

**Results:** All data have been collected and are in the process of being prepared for analysis. A repeated measures ANOVA will be used to examine changes in parent-reported (e.g., family empowerment, parent well-being, perceived stress, depressive symptoms, resilience coping, parent-child relationship) and TAY-reported variables (e.g., youth empowerment, youth well-being, social functioning) over time.

**Conclusions:** Our findings will add to the relatively limited knowledge of empirically-based programs to support families with autistic youth transitioning to adulthood. Study implications on services for families and autistic youth transitioning to adulthood will be discussed.

**524.042 (Virtual Poster)** Underage Alcohol Use and Non-Use Among Autistic Youth  
**L. Graham Holmes<sup>1</sup>, C. B. Hologue<sup>2</sup> and E. F. Rothman<sup>3</sup>, (1)Hunter College, City University of New York, New York City, NY, (2)Center for Autism and Related Disorders, Kennedy Krieger Institute, Baltimore, MD, (3)Community Health Sciences, Boston University, Sargent College, Boston, MA**

**Background:**

Although historically researchers assumed few autistic people developed substance use disorders (SUDs), emerging evidence suggests that autistic people without intellectual disability may be at increased risk for SUD, and alcohol use disorder (AUD) specifically, compared to non-autistic peers. Autistic youth may drink alcohol to reduce loneliness, cope with trauma, or due to co-occurring disorders. More information about why autistic youth choose to use or abstain from alcohol can inform the development of preventive interventions.

**Objectives:**

The purpose of this study was to uncover correlates of alcohol use and abstinence in a sample of U.S. autistic youth versus non-autistic youth.

#### Methods:

186 individuals participated in an online survey. Eligibility criteria were (1) 16-20 years old; (2) English-speakers; (3) diagnosed with autism by a professional or not autistic; and (4) could complete a survey without help. Half of each group (autistic, non-autistic) had  $\geq 1$  drink in the past year. Participants completed a 10-minute phone eligibility screen before completing the survey. Completers received a \$40 gift card. Table 1 includes demographics by group.

#### Results:

One fifth of underage autistic youth reported drinking in the past month ( $n=21$ ). Of these, 29% had  $>2$  drinks in a sitting. Of those who drank in the past year ( $n=47$ ), 28% reported having six+ drinks on one or more occasions (similar to non-autistic drinkers,  $p=.08$ ). In general, autistic drinkers drank less frequently than non-autistic drinkers: they were more likely to drink monthly or less frequently ( $p=.02$ ), and more likely to say that they drank only 1-2 drinks when they did drink ( $p=.01$ ).

Despite this, half of autistic drinkers had experienced a negative consequence such as hangover, vomiting, blackout, or passing out due to drinking and four (9%) felt they needed to cut down on their drinking. While autistic drinkers were less likely than non-autistic drinkers to say that they did something they regretted while drinking ( $p=.002$ ), they were as likely as non-autistic drinkers to say that they had unprotected sex while drinking (autistic 14% vs. non-autistic 8%,  $p=.37$ ). Furthermore, autistic drinkers were four times as likely to say that they seriously considered suicide while drinking (autistic 9%, non-autistic 2%).

Reasons for drinking differed by autism status. Compared to non-autistic drinkers, autistic drinkers were less likely to say that they drank for social reasons ( $p<.01$ ), to conform ( $p=.04$ ), or to enhance their experience ( $p=.04$ ). However, 64% of autistic drinkers reported feeling more socially at ease when drinking. Autistic drinkers were just as likely as non-autistic drinkers to say that they drank to cope with emotional stressors and most (66%) reported feeling more relaxed when drinking. Compared to non-autistic participants, autistic drinkers and non-drinkers were less likely to report that they abstain from drinking because they thought it would interfere in their life or cause weight gain ( $p=.04$ ), and autistic non-drinkers were less likely to report abstaining due to legal concerns ( $p=.02$ ).

#### Conclusions:

Youth alcohol prevention programs need to be inclusive of autistic youth. Prevention programs designed to address the specific drinking profiles of autistic youth are needed.

#### **524.043 (Virtual Poster)** What Is a “Good Mother of a Children with Autism”? a Comparison between the US and Japan

**N. Porter<sup>1</sup>, K. A. Loveland<sup>2</sup>, T. Yamane<sup>3</sup> and H. F. Porter<sup>4</sup>,** (1)Department of Human Development, Washington State University, Pullman, WA, (2)Louis A Faillace, MD, Department of Psychiatry and Behavioral Sciences, McGovern Medical School, The University of Texas Health Science Center at Houston, Houston, TX, (3)Graduate School of Developmental and Environment, Kobe University, Kobe, Japan, (4)Nozomi Child Care Center, Kanazawa, Japan

---

#### Background:

Different cultures have expectations about mothering. Mothers of children with ASD may have different ideas about mothering their children compared to mothers of typically developing children. In addition, the construction of these ideas may be influenced by the sociocultural context of the family. Few studies have examined motherhood from the perspectives of mothers of children with ASD across cultures.

#### Objectives:

The goal of this research is (1) to compare the characteristics of “a good mother in general” (GMG) and “a good mother of a child with ASD” (GMA) according to mothers raising children with ASD, (2) to examine how mothers of children with ASD evaluate themselves as mothers, and (3) to compare the findings from these two questions between mothers of children with ASD in the US and Japan.

#### Methods:

One hundred four mothers of children ages 2 to 12 diagnosed with ASD participated in the study (US:  $n = 53$ , Japan:  $n = 51$ ). Using a semi-structured interview, we asked the mothers to describe characteristics of GMG (Q1) and GMA (Q2), and evaluate themselves as a mother of a child with ASD (Q3). We conducted a thematic analysis using MAXQDA and identified main themes. Theme frequencies GMG and GMA were compared using either Pearson’s Chi-Square Test or Fisher’s Exact Test. Finally, the frequencies of themes related to GMG and GMA between the countries were compared using either Pearson’s Chi-Square Test or Fisher’s Exact Test.

#### Results:

Fourteen main themes emerged regarding traits of a good mother (GMA, GMA) (Table 1). In the US sample, “Advocates” “Knows child well” “Seeks help” were mentioned significantly more for GMA than for GMG, while “Nurtures child” was mentioned more for GMG than for GMA. There were no statistically significant differences between themes for GMG and GMA in the Japanese sample. Comparing the frequencies of themes for GMG between the US and Japan, “Balances needs” “Guides” “Nurtures” “Is selfless” were mentioned significantly more in the US sample while “Cheerful” was mentioned significantly more in the Japanese sample. Comparing the frequencies of themes for GMA between the US and Japan, “Advocates” “Balances needs” “Guides” “Does her best” “Seeks help” “Is patient” were mentioned significantly more in the US sample. Eight themes emerged on mothers’ self-evaluation (Table 2). US mothers had higher frequencies for “I am a good mother” while Japanese mothers had higher frequencies for “It varies.” There were no significant differences between Japan and the US in negative evaluations, such as “I could have done more”, “I have failed as a parent.”

#### Conclusions:

These findings suggest that US mothers of children with ASD have distinct ideas about good mothers of children with ASD compared with their counterparts in Japan. In addition, US mothers had more positive self-evaluations. These differences may be associated with greater resources intended to support mothers of children with ASD in the US as well as with differences in values. Lower frequency of positive self-evaluation in Japan may be associated with low maternal self-efficacy and cultural norms that value modesty.

#### **524.044** (Virtual Poster) A Phenomenological Approach to Understanding the Experience of Telehealth Assessments

**J. Ferguson<sup>1</sup>**, **E. McQueen<sup>2</sup>**, **G. Binion<sup>3</sup>**, **H. Tokish<sup>4</sup>**, **A. Rudrabhatla<sup>4</sup>**, **S. P. White<sup>5</sup>**, **C. Klaiman<sup>6</sup>** and **S. Sivathasan<sup>6</sup>**, (1)*Clinical Assessment and Diagnostics, Emory University School of Medicine, Marcus Autism Center, Atlanta, GA*, (2)*Department of Allied Health Sciences, Marcus Autism Center, Children's Healthcare of Atlanta & Emory School of Medicine, Chapel Hill, NC*, (3)*Marcus Autism Center, Emory University School of Medicine, Atlanta, GA*, (4)*Marcus Autism Center, Children's Healthcare of Atlanta and Emory University School of Medicine, Atlanta, GA*, (5)*Marcus Autism Center, Emory University, Atlanta, GA*, (6)*Educational & Counselling Psychology, McGill University, Montreal, QC, Canada*

**Background:** Given health guidelines onset by the global COVID-19 pandemic, many providers have considered telehealth assessments to provide diagnostic services. Across various healthcare fields, it has been theorized that telehealth may be a viable alternative to in-person appointments and make services more accessible. While availability of telehealth appears to expand access in certain contexts, less is known about the family experience navigating telehealth for assessment of children with complex needs, including ASD. As such, there is a need to evaluate the acceptability of telehealth for families seeking ASD assessment.

**Objectives:** The goal of this study focuses on a central thematic question: How do families experience telehealth assessments for ASD? To answer this overarching research question, the following questions were explored:

1. How does the use of telehealth procedures impact the assessment process?
2. What barriers impact access to telehealth assessment?

**Methods:** Participants: The current study is part of a larger study assessing the validity of telehealth and adapted in-person ASD assessments. Families were eligible if their child received an ASD diagnosis following a standard diagnostic evaluation between January-March 2020. Procedure: Participants completed a 15-item survey that explored the impact of the COVID-19 pandemic. Included were 5 qualitative about their families experience with telehealth assessment. Analysis: Data were read and coded using Interpretative Phenomenological Analysis (IPA; Smith, 1996; Smith & Osborn, 2004).

**Results:** Of 25 families who completed the larger study, n=10 completed the follow-up survey. After coding and analyzing the data, the following themes emerged as salient to participants: (1) Access, (2) Comfort, (3) Involvement, and (4) Validity.

**Access:** Participants discussed the impact of telehealth on their access to assessment and therapeutic services. Many shared examples of how telehealth reduced barriers to service such as travel, availability, and childcare, whereas others cited new barriers such as connectivity issues.

**Comfort:** Many participants expressed sentiments of comfort when discussing their experience. Given the COVID-19 pandemic, many mentioned increased feelings of safety, using telehealth services and others discussed the benefits of their child(ren) feeling comfortable in their home.

**Involvement:** Participants felt more involved in the assessment process using telehealth procedures.

**Validity:** Participants shared experiences that may impact the validity of telehealth assessments. Concerns were raised about assessment materials, focus of the children, and different behavior at home than in-clinic. Conversely, participants also mentioned that telehealth assessment allowed clinicians to see more of their child’s authentic behavior and others shared minimal concerns regarding validity because the clinician still had a presence.

**Conclusions:** This study provides initial insights into caregivers’ experience of accessing ASD diagnostic services through telehealth. While telehealth procedures may increase accessibility by making scheduling more convenient and allowing families/patients to feel more comfortable and involved in the process, more work is needed to identify and reduce additional barriers and concerns about providing access to high quality, personalized care.

**524.045 (Virtual Poster) Autism Voices: Perspectives of the Needs, Challenges, and Hopes for the Future of Autistic Youth**

**R. Tesfaye<sup>1</sup>, V. Courchesne<sup>2</sup>, P. Miranda<sup>3</sup>, W. Mitchell<sup>4</sup>, D. B. Nicholas<sup>5</sup>, I. Singh<sup>6</sup>, L. Zwaigenbaum<sup>7</sup> and M. Elsabbagh<sup>8</sup>,** (1)Neuroscience, McGill University, Montreal, QC, Canada, (2)Autism Research Group, CIUSSS du Nord-de-l'Île-de-Montréal, Montréal, QC, Canada, (3)University of British Columbia, Vancouver, BC, Canada, (4)Sinneave Family Foundation, Calgary, AB, Canada, (5)University of Calgary, Edmonton, AB, Canada, (6)Department of Psychiatry, Oxford University, Oxford, United Kingdom, (7)University of Alberta, Edmonton, AB, Canada, (8)Neurology and Neurosurgery, McGill University, Montreal, QC, Canada

---

**Background:** Our understanding of the adolescent period for autistic youth has rarely relied on the first-person experiences of autistic youth. Moreover, the limited number of studies attempting to capture the experiences of autistic youth have favored a subset of the spectrum and tend to exclude minimally verbal and intellectually disabled youth. The active involvement of autistic youth in decision making is not only related to facilitating optimal transition outcomes from adolescents to adulthood, but can also be used to empower community belonging and optimize research and health policies. To broaden the inclusion of diverse autistic adolescents in qualitative research the Autism Voices protocol — a novel method suited to all language and intellectual levels — was developed in collaboration with researchers and community members.

**Objectives:** To obtain the first-person experiences of autistic adolescents with a range of cognitive and verbal abilities using the Autism Voices protocol (Courchesne et al., 2021).

**Methods:** Thirty-two autistic youths aged 11 to 18 years old (M=15.41, SD= 2.26; 81% males) were interviewed using the Autism Voices protocol. Dynamics between youth and their environments at home, school and the community were explored. Youth were questioned about their interests, plans for the future, experiences with emotions, and experience of autism. Questions were asked following universal design principles to allow participation of youth of all language and intellectual ability levels. Participants could then respond using various responses modalities suited to their abilities (writing, verbal answer, pointing to picture cards, etc.).

**Results:** Six themes emerged from the results of a thematic analysis applied on interview transcripts containing both verbal and non-verbal content: 1) autism identity, 2) thinking about the future, 3) seeking social connection on their own terms, 4) seeking autonomy, 5) school as both a stressor and social facilitator, and 6) experiences of stress and anxiety. Of the topics discussed youth identified school and the future as their primary concerns. Many described the school environment as unwelcoming, a detriment to their well-being, and a barrier to future aspirations. Despite being a stressful environment, most youth highlighted that school was enjoyable because they could meet and spend time with their peers. Similarly, while it was a stressor, most participants had considered what they wanted or did not want in their future. We identified three common pathways that guided youths' decisions about their future: practicality, familiarity and interests. Overall, youth had nuanced and complex perspectives regarding their experiences, identity and society.

**Conclusions:** This Autism Voices study highlights continuity in the challenges and aspirations of autistic adolescents and those commonly encountered by their non autistic peers (Adam & Berzonsky, 2008). Youth voiced their interests in forming social connections, their aspirations for their future, and their desire for autonomy. We discuss how these insights shared by autistic youth can facilitate active involvement in their communities, promote well-being, and optimal transition into adulthood. We further outline how the development and approaches used in the Autism Voices protocol can be tailored and applied by researchers, clinicians, and community members to partner with autistic youth

**524.046 (Virtual Poster) Reflections on Experiences in the Schools: Young Adults on the Autism Spectrum and Their Parents**

**C. M. Anderson<sup>1</sup>, C. I. Wood<sup>1</sup> and C. Sarsony<sup>2</sup>,** (1)Health Sciences, Towson University, Towson, MD, (2)Forward Together Counseling, Silver Spring, MD

---

**Background:** Although young adults (YAs) with autism spectrum disorder (ASD) have left their school days behind, many of them and their families have vivid memories and lasting concerns about experiences they had in school.

**Objectives:** To explore the past school experiences of young adults with ASD and any lasting effects.

**Methods:** Qualitative interviews were conducted with 35 parents and 12 young adults with ASD. School-focused material was segregated, then analyzed using the constant comparative method.

**Results:** Four major themes emerged. (1) **School Success and "Angels."** Success during the school years led to confidence and skills that scaffolded future achievements. Gifted teachers who "got" autism were usually involved. *The main thing was that he cared. He understood that although she was a kid who sometimes had tantrums...there was more to the picture... If she didn't turn in a paper and was supposed to go and talk to the teacher about it...he would step in...he'd help her get it to that teacher.* (2) **Dropping the Ball.** Incidents where schools had failed a student with ASD were frequently described. These ranged from playing a role in a delayed diagnosis to failing to follow an Individualized Education Program (IEP). *We always had the IEP, and it looked good on paper, but when it came to implementation, there was a gap between what they said they were going to do...and the translation of it. Or they would start off great... and then slack off. I would find out he was not getting language and speech on a regular basis.* (3) **Crises, Battles, and Exile.** Students with ASD could struggle with self-regulation or psychiatric challenges. These were sometimes misinterpreted as willfully bad behavior, followed by a non-ASD sensitive response. Crises could ensue, leading to a combative relationship between family and school. *In senior year, she was pretty much permanently suspended. This is total mismanagement on the school's part... They should have been pushing for residential treatment or another school. But they...could not afford to lose that tuition that the state is paying. So of course they are trying to do everything and they made this horrible deal where basically, we are going to give her a diploma but she is not coming back here.* (4) **Belonging vs. Isolation and Bullying.** An important theme was whether a student had felt a sense of community or isolation at school; the latter was often associated with bullying. *When he was in middle school... somebody had kicked him so hard...It left the mark of a foot. They stole his watch, flushed it down the toilet. Just anything that they could do to torment him.*

Conclusions: Children and teens with ASD spend a great deal of their time in school and receive many interventions there. It is important to understand how schools have supported or failed students with ASD, and with what long-term effects. Future research should further explore the dynamics discussed herein as well as solutions to school practices that are not serving students with ASD.

**524.047** (*Virtual Poster*) Strengths, Barriers, and Needs to Improve Acute Psychiatric Care in General Hospital-Based Crisis Settings for Autistic Persons: Findings from a Multi-Stakeholder Evaluation

**J. Fodstad<sup>1</sup>, J. Mehringer<sup>2</sup>, N. Scheive<sup>2</sup> and Y. Saadeh<sup>3</sup>**, (1)*Indiana University School of Medicine, Indianapolis, IN*, (2)*Indiana University Purdue University - Indianapolis, Indianapolis, IN*, (3)*Indiana University Purdue University Indianapolis, Indianapolis, IN*

---

**Background:** Individuals with Autism Spectrum Disorder (ASD) are more likely to receive emergency-based care for acute psychiatric needs than the general population. Providing care in non-specialized hospital settings (e.g., emergency department, behavioral psychiatric unit) to autistic persons often results in longer hospital stays, greater healthcare costs, and staff burnout. While ASD-specialized inpatient pediatric psychiatry units are effective, few exist and are unlikely to be widely adopted by large healthcare systems. Guidelines are published for improving ASD acute psychiatric care, yet minimal research has been done to develop ASD-specific programming for hospital-based general acute-care settings..

**Objectives:** The goal of this analysis is to better understand the perceived strengths, barriers, and needs to providing high quality acute psychiatric care to autistic persons in general hospital-based settings. Utilizing qualitative interviews, we collected data from relevant stakeholders.

**Methods:** Participants from one of three types of stakeholder groups were recruited: 1) a parent of an ASD individual who previously presented to an emergency room or was admitted to a general psychiatry unit for acute psychiatric needs; 2) an autistic person who received acute psychiatric care in an emergency room or general psychiatry unit; or 3) a staff member, physician, or other allied/mental health professional working in an emergency room or general psychiatry unit providing care to an ASD person. Each participant completed a recorded 60–90-minute semi-structured Zoom interview. Participants were asked a mix of closed- and open-ended questions on perceived strengths, barriers, and needs in providing acute psychiatric care in general hospital-based settings. Targeted questions were also asked to gather information unique to each stakeholder group type. The transcribed interviews were analyzed using NVivo software. Using thematic content analysis, interview responses were examined for independent themes by each stakeholder group as well as across all stakeholder groups – first through identifying broad themes, and then subsequently differentiating subthemes.

**Results:** Thirty-two stakeholders participated: 12 parents/legal guardians, 10 ASD persons, and 10 hospital staff or providers. Key themes found across stakeholders included (1) complexity beyond usual patients seen, (2) limited knowledge of autism or appropriate interventions, (3) training and experience, (4) teamwork and communication, (5) need for more information, training, or resources, and (6) need for care coordination and system-wide changes. Stakeholder specific themes emerged highlighting the importance of ensuring that care received is uniquely matched to the needs of the patient and their family and is feasible to be embedded within face-paced and complex hospital-based patient care settings.

**Conclusions:** Outcomes suggest that the needs of autistic persons who receive non-specialized acute psychiatric care and their families, and the hospital staff or providers who render crisis care are vast but are not insurmountable. More research should be done to understand the complex structure of healthcare systems where autistic individuals receive acute psychiatric care in general crisis settings. Finally, developing and testing a focused care pathway that aligns with evidenced-based ASD-specialized care and incorporates the needs of relevant stakeholders could be a well-suited model to improve acute care for autistic individuals with significant psychiatric needs.

**524.048** (*Virtual Poster*) Using the Nominal Group Technique to Investigate Experiences of Students with ASD in Online Postsecondary Education

**C. M. Nelson<sup>1</sup>, S. W. White<sup>2</sup>, L. Stoppelbein<sup>3</sup>, M. L. Armstrong<sup>4</sup>, M. L. Paul<sup>1</sup> and L. Moret<sup>5</sup>**, (1)*Educational Studies in Psychology, Research Methodology, and Counseling, The University of Alabama, Tuscaloosa, AL*, (2)*Psychology, The University of Alabama, Tuscaloosa, AL*, (3)*The University of Alabama, Tuscaloosa, AL*, (4)*Psychology, St. Louis University, St. Louis, MO*, (5)*University of Alabama, Tuscaloosa, AL*

---

Background:

Autism Spectrum Disorder (ASD) is a neurodevelopmental disorder characterized by deficits in social skills and communication. Disability theorists claim that this deficit model of ASD is not helpful in advocating for or supporting postsecondary students with ASD because it allows universities to label them and their behavior as problematic. Indeed, much of the burden of orientation to postsecondary education is placed on students with ASD by asking them to assimilate to neurotypical postsecondary classroom culture. Further, due to the COVID-19 pandemic, many traditional postsecondary students, including those with ASD, were abruptly forced into online education. Despite evidence suggesting college students with ASD prefer online courses, online learners—including those with ASD—often wish that universities offered additional services (e.g., academic and social clubs, access to mental health services) to better equip them for success and diminish feelings of isolation. Research specifically investigating the challenges students with ASD face in online postsecondary education is limited, however. Therefore, it is increasingly important to examine the lived experiences of postsecondary students with and without ASD in online learning environments.

Objectives:

We aimed to investigate the challenges students with and without ASD face in online postsecondary education and the resources that would be helpful in aiding their success.

Methods:

Quantitative and qualitative data from postsecondary students with ASD ( $n = 8$ ) and without ASD ( $n = 11$ ) were gathered. To examine quantitative differences between diagnostic groups on loneliness, self-determination, and other demographic variables (e.g., age, GPA), surveys were administered and analyzed using Welch's t-tests. To examine qualitative differences between diagnostic groups regarding challenges they face and resources they need in postsecondary online education, nominal group technique (NGT) interviews were implemented.

#### Results:

While participants with and without ASD did not differ significantly in age ( $p = 0.43$ ) or GPA ( $p = 0.13$ ), participants with ASD reported significantly greater loneliness ( $p < 0.05$ ) and less capacity for, opportunities to practice, and total self-determination ( $p < 0.05$ ) than participants without ASD. Emergent themes indicated that participants with ASD face challenges with distractions, engagement, communication, and understanding and desire consistent communication and more accessible resources in their online classes. Participants without ASD reported facing challenges with forming social connections, communication, and learning and desire resources such as virtual meetings and study rooms and increased professor support in their online courses.

#### Conclusions:

These findings highlight challenges that postsecondary students with and without ASD face in online education and demonstrate supports that would be helpful in their online educational experiences. Notably, this is the first consensus-building study to identify challenges and supports experienced by postsecondary students with ASD in relation to online learning. Our hope is that the findings will spur more research in this area and ultimately facilitate optimization of online postsecondary education, particularly for students with ASD.

**524.049** (Virtual Poster) View of the Work Community and Vocational Rehabilitation Services Among Adults with Autism Spectrum Disorder  
**J. D. Doran<sup>1</sup>** and **D. V. Chan<sup>2</sup>**, (1)Pediatric School Psychology, East Carolina University, Greenville, NC, (2)Allied Health Sciences, University of North Carolina at Chapel Hill, Chapel Hill, NC

---

#### Background:

Adults with autism spectrum disorder (ASD) face unique challenges in establishing and maintaining competitive employment (Hayward et al., 2019). These difficulties may be related to the symptoms of ASD (Muller et al., 2003) or employer attitudes (Rashid et al., 2017). Although estimates differ, adults with ASD are often under and unemployed at higher rates compared to the general population (Ohl et al., 2017) and other disability groups (Chen et al., 2015). Because autistic adults often struggle with employment, vocational rehabilitation (VR) services can provide useful resources for this population to find and maintain employment (Alverson & Yamamoto, 2017). However, even those who achieve employment through VR services often earn low wages and work few hours per week (Chen et al., 2015). Few qualitative studies have examined how autistic adults find a sense of belonging in their work communities, and to our knowledge, no qualitative studies have been published regarding autistic adults' view of VR services.

#### Objectives:

The current study sought to understand: 1.) the views and preferences among adults with ASD regarding their workplace communities; 2.) how this population can be best integrated into the workplace from their perspective; and 3.) how autistic adults view VR services.

#### Methods:

Qualitative data was collected by interviewing adults with ASD in the context of a larger study examining their community integration. Two semi-structured interviews were conducted in person or online. Participants were questioned about their current and past work environments and preferences, the processes through which they integrated into the work community, and their views and experiences of VR services. Interviews were audio recorded and transcribed verbatim for line-by-line coding. As part of the analysis, two independent reviewers coded the transcripts and identified themes with high agreement between coders.

#### Results:

The sample consisted of 20 participants all of whom had an IQ above 70 and ranged in age from 28 to 62 years ( $x = 42$ ); 65% ( $N = 13$ ) were male, 60% ( $N = 12$ ) were employed at the time of study participation, and most were white ( $N = 18$ ). Qualitative analysis revealed themes related to the importance of making a contribution in the workplace, a preference for engaging in interesting work, and the importance of establishing independence. Themes related to positive working relationships and self-disclosure and advocacy contributed to feeling integrated into the workplace community. In some cases, VR services were described as providing helpful support and connections to other community agencies, and other times were described as ineffective.

#### Conclusions:

Adults with ASD prefer supportive work environments where they are confident, mentally stimulated and can self-advocate. Despite potential difficulties with social interaction at work, positive coworker and employer relationships emerged as important to feeling a sense of belonging at work. Possible areas for improvement in VR service provision include increasing the speed of service provision, providing individualized

interventions and follow-along services to explore opportunities for growth in current positions. Attending to individual preferences in the workplace can allow for successful support of adults with ASD and potentially reduce the high under and unemployment rate in this population.

**524.050** (Virtual Poster) Youth Feedback on a Virtual Mind-Body Group Intervention for Teen Siblings of Children with Autism Spectrum Disorder  
**L. A. Fell<sup>1</sup>, B. Goshe<sup>2</sup>, L. Traeger<sup>3</sup>, G. K. Perez<sup>4</sup>, D. Iannuzzi<sup>5</sup>, E. Park<sup>6</sup>, K. Kuhlthau<sup>7</sup> and C. M. Luberto<sup>7</sup>,** (1)Division of Academic Pediatrics, Massachusetts General Hospital, Boston, MA, (2)Psychiatry, Mass General Hospital, Boston, MA, (3)Psychiatry, Massachusetts General Hospital, Boston, MA, (4)Health Policy Research Center at Mongon Institute, Mass General Hospital/Harvard Medical School, Boston, MA, (5)Department of Psychiatry, Brigham and Women's Hospital, Boston, MA, (6)Massachusetts General Hospital, Boston, MA, (7)Health Policy Research Center at Mongon Institute, Mass General Hospital, Boston, MA

---

**Background:** According to the American Psychological Association, teenagers and young adults (ages 15-21) report high levels of stress, anxiety, and depression, and overall worse mental health than any other age group. Teenage siblings of children with autism spectrum disorder (ASD) often face additional challenges and are at higher risk for social and emotional difficulties than their peers. For many teen siblings, these difficulties have been exacerbated by the COVID-19 pandemic and related restrictions. There have been few interventions focused on improving the psychosocial wellbeing of these teens. We adapted an 8-session, virtually delivered resiliency intervention (the Stress Management and Resiliency Training-Relaxation Response Resiliency Program [SMART-3RP]), for teenage siblings of children with ASD and conducted a randomized waitlist-controlled pilot trial.

**Objectives:** In order to better understand the program's acceptability, we conducted a mixed methods secondary analysis of participant feedback data. The goal of this analysis was to explore participants' feedback with respect to the intervention.

**Methods:** From May – July 2020, we enrolled teens from across the United States and randomized 40 participants to either the intervention (N=20) or waitlist control group (N=20) (51% Female, 80% White, 11% Hispanic/Latino, Mage = 15 years). We analyzed quantitative and qualitative post-intervention feedback data for all participants who completed the survey following the intervention (N=35).

**Results:**

The majority of participants reported that the intervention had the right amount of sessions (86%), the right session duration (89%), and the right amount of structure (74%). Most participants also reported that they felt comfortable during the group sessions (74%), found it helpful to learn mind-body relaxation exercises (74%), and that the intervention helped with their ability to cope with life stressors (71%). Since beginning the intervention, 80% of participants reported practicing relaxation exercises on their own at least a few times a week. Themes from qualitative feedback included satisfaction with virtual delivery and its convenience, appreciation that the intervention facilitated meeting peers with similar experiences, and desire for the program to provide additional opportunities for social connections among participants.

**Conclusions:**

The adapted SMART-3RP intervention demonstrates good potential for improving self-care skills of teenage siblings of children with ASD. The content and structure of the virtual mind-body group intervention was acceptable to teen participants, and they found it helpful in managing stress. Though they were satisfied with the opportunity to meet peers with shared experiences (and its ease in a virtual context), they emphasized the desire for the intervention to facilitate more social connection amongst participants. The results of this study contribute to the existing literature on the acceptability of content, structure, and delivery of interventions for teen siblings, and could help inform the development and administration of virtual interventions in the future.

**524.051** (Virtual Poster) Resilience in the Face of the COVID-19 Pandemic Is Associated with Age, Gender, and Coping Self-Efficacy: Insights from Children with Developmental Delays and Disabilities

**A. Yusuf<sup>1,2</sup>, N. J. Wright<sup>3</sup>, M. Steiman<sup>4</sup>, M. Gonzalez<sup>1,2</sup>, A. Karpur<sup>4</sup>, A. Shih<sup>5</sup>, K. Shikako-Thomas<sup>6</sup> and M. Elsabbagh<sup>1,2</sup>,** (1)Neurology and Neurosurgery, McGill University, Montreal, QC, Canada, (2)Azrieli Centre for Autism Research, Montreal Neurological Institute-Hospital, Montreal, QC, Canada, (3)Biostatistics & Health Informatics, Kings College London, London, United Kingdom, (4)Autism Speaks, Princeton, NJ, (5)Autism Speaks, New York, NY, (6)School of Physical and Occupational Therapy, McGill University, Montreal, QC, Canada

---

**Background:** Resilience is defined as achieving better than expected outcomes in the face of adversity. Substantial research on resilience has been conducted in cases of exposure to environmental threats. Resilience is influenced by factors like age, gender, and parenting self-efficacy. Little is known about resilience among children suspected with or diagnosed with developmental delays and disabilities (DDD) including autism spectrum disorder in the face of the COVID-19 adversity. Understanding resilience among children with DDDs can offer insights for targeting groups at highest risk to help promote optimal outcomes.

**Objectives:** We aim to identify the extent to which a resilience profile during the COVID-19 pandemic is associated with child age, gender, and parenting self-efficacy among children with DDDs.

**Methods:** We used data from the Canadian sample of the *UNICEF-World Health Organization Global Report on Developmental Delays, Disorders, and Disabilities*. An online survey was designed to assess the impact of the COVID-19 pandemic on health, wellbeing, and access to services. Data were collected during June-July 2020, resulting in a convenience sample of caregivers across Canada (n=883). Caregiver-reported changes on 12 domains of functioning (rated as 'worsening,' 'no change,' or 'improving') were subjected to latent class analysis which identified a subgroup of children consistently exhibiting improvements, labeled as 'resilient', in contrast with a stable subgroup endorsing mostly 'no change,' or one

endorsing worsening across domains. Parenting self-efficacy was indexed by parents' confidence in helping their child cope during the pandemic. Multinomial logistic regression was used to test associations between the resilience profiles and candidate predictors: child age, gender, and parenting self-efficacy.

**Results:** The resilience profile was more likely to be reported in children aged 0-5 years ( $n=194$ ), relative to older children and youth ( $OR=1.75$ ,  $p=.032$ ) and was prominently reported in relation to daily living skills, repetitive behaviour, and communication. We identified an age gradient in resilience, with each decreasing year of age associated with an increased odds ( $OR=1.01$ ,  $p=.003$ ) of belonging to the resilient compared to worsening profile and an increased odds ( $OR=1.07$ ,  $p=.039$ ) of belonging to the stable compared to worsening profile.

Parenting self-efficacy was a significant predictor of the resilience profile in the whole sample. The association was stronger in children above 6 years of age ( $OR=2.15$ ,  $p<.001$  for resilient,  $OR=1.6$ ,  $p<.001$  for stable) compared to children aged 0-5 years ( $OR=1.2$   $p=.327$  for resilient,  $OR=1.3$ ,  $p=.046$  for stable). Gender was not associated with resilience in the whole sample, but in children 0-5 years, male gender was more strongly associated ( $OR=2.30$ ,  $p=.006$  for resilient,  $OR=1.22$ ,  $p=.261$  for stable) than female gender ( $OR=2.16$ ,  $p=.086$  for resilient,  $OR=1.33$ ,  $p=.357$  for stable).

**Conclusions:** Our findings indicate that younger age, male gender, and parenting self-efficacy are associated with resilience in children with DDDs in the context of the COVID-19 pandemic. Our findings signal the importance of exploring potential factors related to decreased resilience, as well as increasing awareness of at-risk groups, addressing pandemic-related sequelae for both parents and children, and 'building-back better' after the COVID-19 pandemic.

**524.052** (Virtual Poster) Locked Down - Locked in : Understanding Experiences of Families of Children with Autism Spectrum Disorders in Delhi, India

M. Kakra Abhilashi<sup>1</sup>, G. Lall<sup>1</sup>, L. Naithani<sup>2</sup>, S. Johri<sup>3</sup>, R. Roy<sup>4</sup>, C. A. Taylor<sup>5</sup>, K. Leadbitter<sup>6</sup>, V. Patel<sup>7</sup>, J. Green<sup>8</sup>, G. Divan<sup>6</sup>, A. Kaur<sup>7</sup> and A. Singh<sup>8</sup>, (1)Sangath, New Delhi, India, (2)Sangath Society, New Delhi, India, (3)University of Manchester, Manchester, United Kingdom, (4)Harvard Medical School, Boston, MA, (5)University of Manchester, Manchester, United Kingdom of Great Britain and Northern Ireland, (6)Child Development Group, Sangath, New Delhi, India, (7)Sangath, Delhi, India, (8)Sangath India, Delhi, India

#### Background:

The COVID-19 pandemic and associated lockdowns since March 2020 have disrupted life for all families, including families of children with Autism Spectrum Disorders (ASD). Sangath, a not-for-profit organization, is leading an ongoing randomized control trial with families of children with ASD in the National Capital Region (NCR) in India. During engagement with these families, many primary caregivers shared their feelings of being impacted by the pandemic and reported high levels of stress during this period. Within the population of caregivers, it has been noted that parents of children with autism experience even higher parenting stress (Hayes & Watson, 2013) and psychological distress (Estes et al., 2009). Hence, detailed exploration of their experiences throughout this unprecedented period has been undertaken.

#### Objectives:

To understand the experiences of families of children with ASD during the COVID-19 pandemic and the associated lockdowns in an urban setting in India.

#### Methods:

The current study involves conducting 20 In-Depth Interviews (IDIs) with primary caregivers of children with ASD in the age group 2-10 years old. Families of children with ASD will be purposively sampled from an existing database ensuring a diversity of backgrounds and levels of ASD support required.

The contacts with the participants will include the following based on their stated preference: Contact 1: Providing information from Parent Information Sheet and sharing it electronically with the participant. Contact 2: Review of information, audio recorded consenting process and documentation of demographic information if consent is obtained. Contact 3: Conducting IDI. A semi-structured guide is being used, exploring the impact of the pandemic and lockdowns on the child with ASD with respect to daily routines, behaviors and access to services, the impact on primary caregiver's mental health and well-being and the family's experiences during the pandemic period including on employment and financial security. Interviews will be conducted until data saturation is reached and no new findings emerge. A thematic framework analysis will be conducted to identify emerging themes.

#### Results:

The themes emerging from the analysis are expected to provide insights on bearings of the pandemic and associated lockdowns on children with ASD and their families. Early themes reveal that vulnerable families have had significant impact on, 1. Routine healthcare access including management of seizures, 2. Financial security resulting in requiring loans from employers and restricting essential purchases, 3. Loss of access to special education services. However, positive influences of sibling's home schooling has allowed the child with ASD to imitate behaviours have also been reported.

#### Conclusions:

Since children with ASD and their families remain one of the most vulnerable groups in the society, this research intends to provide information to researchers, clinicians and policy makers on how best to support vulnerable families in the midst of future unexpected crises.

**524.053** (Virtual Poster) Influence of Social Support on Parenting Stress in Parents of Children with Autism Spectrum Disorders: Multiple Mediating Effect of Family Resilience and Parenting Sense of Competence

**C. Wang<sup>1</sup>** and **Y. Liu<sup>2</sup>**, (1)Department of Social Psychology, Nankai University, Tianjin, China, (2)Nankai University, Tianjin, China

---

**Background:** Parents of children with autism spectrum disorder (ASD) often face greater parental pressure in raising their children than the typically developing children's parents, and the current social support system is far more enough to meet the needs of ASD families.

**Objectives:** This study aims to study the impact of social support on parental stress in ASD children and to provide recommendations for parents of ASD children to reduce their stress and reshape their healthy mental health.

**Methods:** A survey of parents of ASD children was conducted during November 2020 to February 2021. There were 443 participants enrolled, among whom 346 were mothers of children with ASD and 97 were fathers. The measures were Social Support Appraisal Scale (SSRS), Parenting Stress Index / Short form (PSI/SF), Parenting Sense of Competence Scale (PSOC), The Family Resilience Assessment Scale (FRAS). The descriptive statistical analysis, the t-test and variance analysis are used to analyze the demographic differences. The relationship among the variables is tested by Process, and the significance of the mediating effect is tested by the Bootstrap to build a parallel mediation model for multi-mediation effect analysis.

**Results:** There were significant effect of symptom severity of ASD children on parents' social support ( $F(2,440)=4.09$ ,  $P < 0.05$ ), sense of competence ( $F(2,440)=3.55$ ,  $P < 0.05$ ), family resilience ( $F(2,440)=8.26$ ,  $P < 0.001$ ) and stress ( $F(2,440)=15.20$ ,  $P < 0.001$ ). Social support ( $\beta=-0.10$ ,  $P < 0.05$ ), sense of competence ( $\beta=-0.46$ ,  $P < 0.001$ ), family resilience ( $\beta=-0.19$ ,  $P < 0.001$ ) all significantly negatively predict the parenting stress. Social support was significantly negatively associated with parenting stress ( $P < 0.01$ ), and positively associated with sense of competence and family resilience ( $P < 0.01$ ). Sense of competence was significantly negatively associated with parenting stress ( $P < 0.01$ ) and positively associated with family resilience ( $P < 0.01$ ). family resilience was significantly negatively associated with parenting stress ( $P < 0.01$ ).

**Conclusions:** The results confirm that social support affects parenting stress and family resilience, and can provide suggestions on how to reduce parenting. In the future, the government, social organizations, rehabilitation institutions, families, friends, colleagues, neighbors and other stakeholders should jointly build social support networks, providing financial, emotional and information support to ASD children's parents and help decrease the pressure on their parents and restore their mental health

**524.054** (Virtual Poster) Subjective Experiences and Felt Needs of the Adolescents with Autism Spectrum Disorder and Their Parents – an Interpretative Phenomenological Analysis

Jayarajan<sup>3</sup>**, (1)Child and Adolescent Psychiatry, National Institute of Mental Health and Neuro Sciences (NIMHANS), Bangalore, Bangalore, India, (2)Clinical Psychology, National Institute of Mental Health and Neuro Sciences (NIMHANS), Bangalore, Bangalore, India, (3)National Institute of Mental Health and Neuro Sciences (NIMHANS), Bangalore, Bangalore, India

---

**Background:**

There is a rising trend in the prevalence of Autism Spectrum Disorder (ASD), globally. Global interventional research on ASD has predominantly focused on early interventions, catering to the needs of young children, over the last few decades. In the Indian context, there is a substantial understanding of the experiences of the families of young children with Autism, their perception of the disorder and disability, the stress of parenting, utilization of treatment services, and felt needs.

The transition from adolescence to adulthood in individuals with ASD has unique challenges. While a life span approach for neurodevelopmental disorders is essential to provide continued support, there is a paucity of systematic research on interventions for adolescents with ASD. A systematic review reports that very few adolescents with ASD are included as research participants, and their felt needs and aspirants are less known.

**Objectives:**

The goal of the current study was to understand the i) subjective experiences of adolescents with ASD, ii) experiences of parents in raising the adolescent with ASD, challenges in navigating through the services and their felt needs in the Indian context.

**Methods:**

In-depth interviews were conducted with 11 parents (8 mothers and 3 fathers) and 5 adolescents (who belonged to the same families), to understand their subjective experiences. Interviews with adolescents focused on their experiences at home, school, peers, and expectations related to the future. Parent interviews focused on parenting experiences, experiences related to health care utilization, schooling, handling unique changes related to adolescence, transition-related concerns, and their felt needs. The interview guides were kept flexible to suit the needs and abilities of adolescents with ASD. All interviews were conducted in English; interviews were recorded and transcribed verbatim.

**Results:**

Using interpretative phenomenological analysis, the following themes were illuminated from the parental interviews 1) Parental perception about the adolescent - Having come a long way, yet a long way to go. 2) Diagnosis and process of understanding ASD 3) Challenges for parents 4) Rewarding experiences 5) Impact of ASD 6) Coping with challenges 7) Envisioning the future. The following themes emerged from the adolescent interviews 1) Awareness of the self, 2) Valued relationships 3) Feeling (un)supported. Triangulation was attempted to understand the concordance and discrepancies of experiences between the parents and adolescents, specific to parental perceptions about adolescent experiences (awareness of the differences, peer relationships).

Conclusions:

Understanding issues of relevance from the adolescent's and family's perspective and their felt needs will help design and implement developmentally and culturally appropriate interventions to cater to the needs of this population. Implications for interventions will be discussed.

## Genetics

### PANEL — GENETICS

#### 219 - Autism Genetics – Moving from Identification to Validation to Treatment

**Panel Chair: M. Daniele Fallin**, *Wendy Klag Center for Autism and Developmental Disabilities, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD*

**Discussant: Tychele Turner**, *Department of Genetics, Washington University in St. Louis, St. Louis, MO*

**219.001 (Panel)** Sparking New Insight into Autism Genetics

**W. K. Chung**, *Department of Pediatrics, Columbia University, New York, NY*

Background:

Autism is highly heritable.

Objectives:

To identify the genetic contributions to autism and how genetic contributions are correlated with clinical characteristics.

Methods:

To capture the spectrum of ASD genetic risk, we performed a two-stage analysis of rare *de novo* and inherited coding variants in 42,607 ASD cases, including 35,130 new cases recruited by SPARK.

Results:

In the first stage, we analyzed 19,843 cases with one or both biological parents and found that known ASD or neurodevelopmental disorder (NDD) risk genes explain nearly 70% of the genetic burden conferred by DNVs. In contrast, less than 20% of genetic risk conferred by rare inherited loss-of-function (LoF) variants are explained by known ASD/NDD genes. We selected 404 genes based on the first stage of analysis and performed a meta-analysis with an additional 22,764 cases and 236,000 population controls. We identified five new risk genes (*NAV3*, *ITSN1*, *MARK2*, *SCAF1*, and *HNRNPUL2*). ASD individuals with LoF variants in the four moderate risk genes (*NAV3*, *ITSN1*, *SCAF1*, and *HNRNPUL2*,  $n = 95$ ) have less cognitive impairment compared to ASD individuals with LoF variants in well-established, highly penetrant ASD risk genes (*CHD8*, *SCN2A*, *ADNP*, *FOXP1*, *SHANK3*) (59% vs. 88%,  $p = 1.9e-06$ ).

Conclusions:

These findings will guide future gene discovery efforts and suggest that much larger numbers of ASD cases and controls are needed to identify additional genes that confer moderate risk of ASD through rare, inherited variants.

**219.002 (Panel)** Massively Parallel Approaches to Identifying Which ASD Non-Coding Variants Have CNS Consequences

**J. Dougherty**, *Genetics, Washington University School of Medicine, St. Louis, MO*

Background: Whole genome sequencing studies are identifying thousands of mutations that are unique to patients with autism, with numerous mutations identified in each individual. While deleterious protein coding mutations are relatively easily interpreted, >99% of identified mutations are non-coding, and it is unclear which of these mutations might be functional and thus potentially causal in disease. In addition, unlike protein coding mutations, the consequences of non-coding mutations are often highly specific to each cell type: since non-coding mutations alter binding sites for gene expression regulators such as transcription factors or RNA binding proteins, and these are expressed in a cell type specific manner, to identify the consequences of non-coding mutations the function of each one must be assessed in the cell types relevant to disease (e.g., neurons and neural progenitor cells).

**Objectives:** Therefore, combining massively parallel oligonucleotide synthesis, Cre-dependent adeno associated vectors, and targeted RNA sequencing we have developed assays to measure the consequences of thousands of non-coding mutations in parallel in specific cell types of the living mouse brain.

**Methods & Results:** Focusing on 3' and 5' UTR mutations, we characterize the consequences of hundreds of UTR mutations and define several from patients that strongly alter RNA abundance and/or translational profiles.

**219.003 (Panel)** Chromatin and Gene-Regulatory Dynamics of the Developing Human Cerebral Cortex at Single-Cell Resolution  
**A. Trevino, Stanford, San Francisco, CA**

---

**Background:**

Genetic perturbations of cortical development can lead to neurodevelopmental disease, including autism spectrum disorder (ASD). Distinguishing disease-causing mutations from benign genetic variation remains challenging, partly due to a lack of functional genomic annotation in relevant cell types.

**Objectives:**

The objectives of the study were: (1) To identify non-coding genomic regions involved in regulating and coordinating human corticogenesis; (2) To associate non-coding genomic regions with cells, genes, and developmental pathways in corticogenesis; (3) Using the above information, to validate and prioritize de novo, noncoding mutations identified by whole-genome sequencing of ASD-affected individuals, parents, and unaffected siblings (the Simons Simplex Collection).

**Methods:**

We mapped the activity of noncoding gene-regulatory elements by generating a single-cell atlas of gene expression and chromatin accessibility both independently and jointly. Putative ASD-associated mutations were prioritized by training base-pair-resolution neural network models to predict cell-type specific chromatin accessibility patterns from DNA sequence. These models were used to predict the disruptive impact of de novo mutations on gene regulation.

**Results:**

The molecular atlas revealed waves of gene regulation by key transcription factors (TFs) across a nearly continuous excitatory neuron and glial differentiation trajectories and identified lineage-determining TFs that exhibited strong correlation between linked gene-regulatory elements and expression levels. Neural network models identified strong, cell-type-specific enrichment of noncoding mutations predicted to be disruptive in a cohort of ASD individuals, identified frequently disrupted TF binding sites, and localized predicted mutation effects to specific cell types and time points in development.

**Conclusions:**

This approach illustrates how cell-type-specific mapping of gene regulatory elements can provide insights into the programs governing human development and disease.

**219.004 (Panel)** CRISPR Based Gene Therapy for Angelman Syndrome  
**J. M. Wolter, The University of North Carolina - Chapel Hill, Chapel Hill, NC**

---

**Background:** Angelman syndrome is a severe autism spectrum disorder caused by mutation or deletion of maternal allele of *UBE3A*. In neurons, expression of the paternal allele of *UBE3A* is disrupted by a long-noncoding RNA, *UBE3A-ATS*, which is transcribed in antisense orientation to *UBE3A*. Interfering with expression of *UBE3A-ATS* can “unsilence” the paternal allele to normal levels, suggesting a potential therapeutic strategy for Angelman syndrome. Indeed, antisense oligonucleotides targeting *UBE3A-ATS* are currently in Stage I clinical trials, but will likely require regular intrathecal injections.

**Objectives:** We sought to develop a CRISPR-Cas9 based approach which would disrupt *Ube3a-ATS*, permanently unsilence paternal *UBE3A*, and provide therapeutic benefit in preclinical mouse model of Angelman Syndrome

**Methods:** We performed high-throughput gRNA screening in primary mouse neuron culture, adeno-associated virus (AAV) delivery of Cas9 to an Angelman Syndrome mouse model, and testing of this Cas9 approach in primary human neuron cultures.

**Results:** We identified a region in *UBE3A-ATS* that, when targeted by Cas9, unsilenced the paternal allele of *Ube3a* in mouse and human neurons. Treating Angelman mice *in utero* with Cas9 delivered via AAV restored *Ube3a* throughout the central nervous system, and rescued Angelman associated anatomical and behavioral deficits. Mechanistically, the most common editing event in these mice was integration of the entire AAV genome at the Cas9 target site. This integration carried with it regulatory elements that caused premature transcription termination of *UBE3A-ATS*.

Surprisingly, we also found that catalytically dead Cas9 can unsilence paternal *UBE3A* by directly interfering with *UBE3A-ATS* transcription, reducing safety concerns surrounding the mutagenic activity of Cas9.

Conclusions: These studies highlight multiple therapeutic approaches, informed by basic understanding of molecular deficiencies, that can reverse Angelman associated phenotypes from a single treatment.

## ORAL SESSION - 7A — GENETICS

### 313 - Rare Genetic Variants Associated with ASD

#### **313.001** (Oral) Genomic Architecture of Autism Spectrum Disorder from Comprehensive Whole-Genome Sequence Annotation

**B. Trost<sup>1</sup>**, B. Thiruvahindrapuram<sup>1</sup>, A. J. Chan<sup>1</sup>, W. Engchuan<sup>1</sup>, E. J. Higginbotham<sup>1</sup>, J. L. Howe<sup>1</sup>, L. O. Loureiro<sup>1</sup>, M. S. Reuter<sup>1</sup>, D. Roshandel<sup>1</sup>, J. Whitney<sup>1</sup>, M. Zarrei<sup>1</sup>, M. Bookman<sup>2</sup>, M. Fiume<sup>3</sup>, R. K. Yuen<sup>1</sup>, J. Sebat<sup>4</sup>, T. W. Frazier<sup>5</sup>, N. Sondheim<sup>1</sup>, D. Glazer<sup>2</sup>, D. Hartley<sup>6</sup> and S. Scherer<sup>1</sup>, (1)The Hospital for Sick Children, Toronto, ON, Canada, (2)Verily Life Sciences, San Francisco, CA, (3)DNASTack, Toronto, ON, Canada, (4)University of California - San Diego, La Jolla, CA, (5)Psychology, John Carrol University, Cleveland, OH, (6)Autism Speaks, New York, NY

Background: Autism spectrum disorder (ASD) is extremely heterogeneous in both clinical presentation and genetic architecture. Fully understanding ASD genetics requires whole-genome sequencing (WGS), which theoretically allows the genome-wide detection of all sizes and types of variants.

Objectives: Our objective was to leverage the power of WGS to assess the contribution to ASD of a wide range of genetic variation, including common and rare, sequence-level and structural, coding and non-coding, and nuclear and mitochondrial.

Methods: We used WGS data from three cohorts: MSSNG ( $n=11,312$ , including 5,102 with ASD), the Simons Simplex Collection (SSC) ( $n=9,205$ , including 2,419 with ASD), and the 1000 Genomes Project (1000G) ( $n=2,504$  unrelated population controls). Sequence-level variants were detected using an industry-standard BWA/GATK pipeline; copy number variants (CNVs) were identified using our previously described workflow involving the algorithms ERDS and CNVnator, and structural variants (SVs) were detected using a novel pipeline involving Manta and DELLY. Polygenic risk scores (PRSs) were calculated using summary statistics from the recently published iPSYCH genome-wide association study. Whole-exome sequencing (WES) data from the SPARK and ASC cohorts were used along with the WGS data to derive a high-confidence ASD gene list using the TADA+ method.

Results: By combining all available WGS and WES data from individuals with ASD ( $>18,000$  trios plus additional cases and controls), we generated a list of 135 ASD-associated genes with  $FDR < 10\%$ . This gene list was then used to guide the interpretation of all types of variants, including CNVs and other types of SVs, in MSSNG, SSC, and 1000G. Frequently detected genomic disorder syndromes in ASD-affected individuals included 15q11-q13 duplications, 16p11.2 deletions, and 1q21.1 duplications. ASD-risk genes commonly affected by SVs included *AUTS2*, *MBD5*, *NRXN1*, *SHANK1*, and *PTCHD1-AS*. We identified several ASD-relevant SVs that could only have been characterized with WGS, including an inversion disrupting *SCN2A* and a complex rearrangement impacting *KCNQ2*. Polygenic risk was significantly over-transmitted from parents to ASD-affected children ( $p < 4 \times 10^{-7}$ ) but not to their unaffected siblings. No significant difference in mean PRS ( $p > 0.05$ ) was observed between ASD-affected children in multiplex families (where ASD is more likely to be caused by inherited rather than *de novo* variation) versus simplex, suggesting that rare inherited variation may have a more prominent role in multiplex ASD. ASD-affected individuals without a known clinically significant rare variant had significantly higher PRS. Despite these aggregate trends, PRS was not predictive at the level of individuals or families. Transmission tests involving non-coding genomic features showed that rare sequence-level variants affecting transcription factor binding sites targeting the 135 ASD-associated genes were over-transmitted to ASD-affected individuals ( $FDR < 0.1$ ) but not to unaffected siblings. Several individuals with ASD had pathogenic mitochondrial variants, but contrary to previous findings, we detected no increased heteroplasmy transmission or enrichment of particular haplogroups in ASD-affected individuals.

Conclusions: By examining many types of genetic variants, we present what we believe to be the most comprehensive analysis of genetic variation in ASD thus far, providing new insights into the genetic heterogeneity of ASD.

#### **313.002** (Oral) Optimized Fragile X Protein Analysis in Context of EEG and Single-Dose Challenge Study in Fragile X Syndrome

**L. M. Schmitt<sup>1,2</sup>**, E. V. Pedapati<sup>3,4</sup>, R. Liu<sup>3</sup>, A. Boggs<sup>5</sup>, C. Gross<sup>5,6</sup>, J. A. Sweeney<sup>6</sup> and C. A. Erickson<sup>3,6</sup>, (1)Developmental and Behavioral Pediatrics, Cincinnati Children's Hospital Medical Center, Cincinnati, OH, (2)Pediatrics, University of Cincinnati College of Medicine, Cincinnati, OH, (3)Psychiatry, Cincinnati Children's Hospital Medical Center, Cincinnati, OH, (4)Psychiatry and Behavioral Neuroscience, University of Cincinnati College of Medicine, Cincinnati, OH, (5)Cincinnati Children's Hospital Medical Center, Cincinnati, OH, (6)University of Cincinnati College of Medicine, Cincinnati, OH

Background: The Fragile X mental retardation 1 (FMR1) gene-specific protein product, Fragile X protein (FXP), is critical for brain development and its absence plays a causal role in full mutation Fragile X Syndrome (FXS). Elevated gamma ( $> 30$  Hz) power, thought to reflect neural hyperexcitability, is a consistent and replicated finding in FXS research across studies in mouse, human, and in vivo brain slices. Identifying the relationship between FXP levels and EEG biomarkers may be critical to better underlying pathophysiological mechanisms and treatment development and planning.

Objectives: To examine the relationship between FXP levels and EEG phenotypes in late adolescents and adults with FXS, including during an acute single-dose drug study of baclofen.

**Methods:** Forty individuals with full mutation FXS (27 males (FXS(M)) and 13 females (FXS(F)) aged 13-45 years completed blood collection for FXP processing and high-density resting state EEG. Participant whole blood samples were analyzed using an optimized Luminex-based blood spot assay that allowed us to detect very low levels of FXP. A subset of these individuals (n=16) completed an acute single-dose challenge drug study comparing baclofen and placebo on resting state EEG target engagement. Drug study participants also completed a social preference eye tracking task.

**Results:** Overall, FXP levels were higher in females than in males, and a subgroup of full mutation FXS males had trace amounts of FXP. On resting state EEG measures, lower FXP levels significantly correlated with lower peak alpha frequency and increased relative alpha1 power. In addition, correlations between higher FXP and decreased gamma1 power trended towards significance. Following single-dose baclofen, individuals with FXS with lower FXP levels demonstrated greater reductions in resting state gamma1. Among FXS(M) with trace levels of FXP, we found that greater reductions in gamma2 power were associated with greater increases in time spent looking at social compared to geometric scenes. However, this result was not found in FXS(M) without FXP, and the opposite relationship was found in FXS(F).

**Conclusions:** We provide novel evidence linking peripheral FXP levels and translational EEG biomarkers in FXS, such that increased FXP levels are associated with less severe neurophysiological phenotypes. We also found that males with FXS with trace levels of FXP may demonstrate the greater reductions in gamma1 following a single dose of baclofen, and this relationship may mediate improvement in social attention. Taken together, our findings demonstrate that optimized FXP assay has clinical utility and may be critical to treatment planning and trial stratification for future drug studies.

### **313.003 (Oral) Gene Functional Impairment and Its Correlation with the Phenotypic Profile of ASD in a National Cohort of UK Children with Intellectual Disability**

**D. H. Skuse<sup>1</sup>, M. Rallison<sup>2</sup>, J. Wolstencroft<sup>3</sup> and I. D. Imagine<sup>3</sup>,** (1)Institute of Child Health, London, United Kingdom, (2)UCL, London, United Kingdom, (3)UCL GOS Institute of Child Health, London, United Kingdom

**Background:** Monogenic *de novo* mutations (DNM) are, cumulatively, an important cause of severe developmental disorders (DD), and many are associated with an increased risk of ASD too. In this genetics-first study, participating children had been ascertained for DD of unknown origin, and whole-exome sequencing (WES) had revealed a pathogenic DNM. Previous research has categorised DNMs associated with ASD by functional group, but none has investigated whether the phenotypic profile can be distinguished by genetic etiology.

**Objectives:** The cohort under investigation was drawn from IMAGINE-ID, a national UK study of children with DD of known genetic aetiology. We aimed to test the hypothesis that there would be a significant association between specific functional groups of DNMs and the risk of ASD, and/or with ASD-related symptom clusters.

**Methods:** Children with developmental delay of genetic etiology, not associated with any recognisable clinical syndrome, were enrolled from NHS Regional Genetics Centres throughout the UK (n=3400). We identified *de novo* causal variants from WES in 808 participants, 4-19 years of age (49% female). Participating families completed a standardized child psychiatric interview, measures of functional adaptation and behavioural/emotional adjustment, and a medical history questionnaire. We focus here on 202 genes with pathogenic *de novo* mutations, categorised into five functional groups: Gene Expression Regulation (GER – 58 genes); Neuronal Communication (NC – 26 genes); Cytoskeletal (Cyt – 19 genes); Chromatin Remodelling (CR – 7 genes); Other (Oth – 92 genes). ASD phenotypic characteristics were classified into clusters: socio-emotional reciprocity (SER); non-verbal communication (NVC); developing relationships (DR) and repetitive stereotypic behaviors (RSB). Mental Age (MA) was estimated from the General Adaptive Composite (GAC) score of the ABAS-3.

**Results:** ASD was diagnosed in 191 participants (32%) for whom sufficient clinical information was available. Prevalence by functional genetic disorder was 33% (GER & Cyt), 44% (ST), 38% (CR) and 23% (Oth). Adjusting for MA revealed odds ratios for risk of ASD: 1.7 (GER), 2.5 (NC), 2.7 (Cyt) and 2.4 (CR) compared with Other gene functions. Overall, variation in gene function category was associated with just two ASD subscale scores, socio-emotional reciprocity (p<0.001) and non-verbal communication (p=0.04) as well as with mental age (p=0.02) but accounted for only a small proportion of variance. Statistically significant differences did not survive adjustment for multiple testing.

**Conclusions:** There is currently growing interest in the relevance of genomic functions such as gene expression regulation and neuronal communication to potential differences in ASD symptom profiles. Unlike previous genomic studies of ASD risk, we took a genetics-first approach to ascertainment. Our findings indicate that pathogenic DNMs in the categories NC, GER, Cyt and CR have a similar impact on the clinical features of ASD irrespective of their association with DD.

### **313.004 (Oral) Sleep Problems in Children with Rare Genetic Variants Associated with Autism and Developmental Disabilities**

**A. Holbrook<sup>1</sup>, E. Brooks<sup>1</sup>, L. Green Snyder<sup>1</sup>, J. Tjernagel<sup>1</sup> and W. K. Chung<sup>1,2</sup>,** (1)Simons Foundation, New York, NY, (2)Department of Pediatrics, Columbia University, New York, NY

**Background:** Disruptions to sleep are well known in autism (Buckley et al., 2020), and specific genetic variants have been associated with both autism and sleep disorder, with common pathways proposed (Abel et al., 2020, Missig et al. 2020, Yang et al. 2016). Although high rates of sleep problems are reported in neurogenetic syndromes (Blackmer & Feinstein, 2016; Dosier et al., 2017; Richdale & Baker, 2014; Robinson-Shelton & Malow, 2016; Smith-Hicks et al., 2021; Trickett et al., 2019) there is relatively little research on sleep across the broader spectrum of neurodevelopmental disabilities with known genetic etiologies.

**Objectives:** To examine sleep problems in children with rare genetic disorders enrolled in the Simons Searchlight study.

**Methods:** Simons Searchlight is an online research registry collecting data on genetic variants related to autism and neurodevelopmental disorders. Participants assessed included 355 children (51% male) between the ages of 2 and 18 years ( $M=9.34$ ,  $SD=4.28$ ) with pathogenic or likely pathogenic sequence or copy number variations. Gene groups with 20 or more participants who completed the Children's Sleep Habits Questionnaire (CSHQ; Owens et al., 2000) were included in this study: 16p11.2 deletion ( $n=90$ ), 16p11.2 duplication ( $n=39$ ), 1q21.1 duplication ( $n=30$ ), *CSNK2A1* ( $n=23$ ), *CTNNA1* ( $n=31$ ), *GRIN2B* ( $n=24$ ), *PPP2R5D* ( $n=30$ ), *SCN2A* ( $n=39$ ), *SLC6A1* ( $n=24$ ), and *STXBP1* ( $n=25$ ). The CSHQ is a 33-item standardized questionnaire; a total score of greater than 41 indicates significant sleep problems. The CSHQ has eight subscales reflecting medical and behavioral sleep disorders: bed-time resistance, sleep onset delay, sleep duration, sleep anxiety, night awakenings, parasomnias, sleep disordered breathing, and daytime sleepiness. Subscale thresholds are met if a participant's score is more than one SD above the community mean. Ninety-six percent of caregivers also completed the Sleep Supplement Survey, a questionnaire designed with input from members of the Simons Searchlight community, which asked about sleep hygiene and the impact of sleep on behavior problems.

**Results:** Forty-eight (16p11.2 deletion) to 80% (*STXBP1*) of children met cutoffs for risk of clinical sleep disorder on the CSHQ (Fig. 1); however, over 75% report no formal sleep disorder diagnosis. Across groups, bedtime resistance and sleep duration are most problematic. Between 44% (*STXBP1*) and 74% (*CSNK2A1*) of children exhibit increased behavioral problems the day after a night of poor sleep. In eight of the 10 genetic groups, a consistent bedtime routine was the most frequently endorsed method to address sleep problems. Medical complications impact sleep in 24% (*CTNNA1*) to 88% (*STXBP1*) of children, including gastrointestinal disorders, seizures, and medication side effects. Seizures specifically disrupt sleep in up to 64% of children (*STXBP1*).

**Conclusions:** Despite the high proportion of children at risk for clinical sleep disorders, most caregivers report no formal sleep disorder diagnosis. Many caregivers of children with rare genetic disorders utilize interventions such as sleep routines, but a large proportion of children display significant sleep problems, which are related to increased negative behaviors. Complicating this is the impact of medical conditions and medications on sleep. These findings suggest the need to address sleep problems to improve related behavioral concerns and overall quality of life.

## POSTER SESSION — GENETICS

### 412 - Genetics

**412.141 (Poster)** An Epigenome-Wide Association Study of Social Responsiveness Scale Score in the Study to Explore Early Development **E. M. Howerton<sup>1</sup>**, J. Daniels<sup>2</sup>, A. Y. Song<sup>3</sup>, K. S. Benke<sup>4</sup>, H. E. Volk<sup>5</sup>, H. Farzadegan<sup>1</sup>, A. Alexander<sup>6</sup>, A. Tapia<sup>5</sup>, G. S. Dichter<sup>6</sup>, J. Daniels<sup>7</sup>, L. A. Croen<sup>8</sup>, G. L. Wojcik<sup>1</sup>, L. Wiggins<sup>9</sup>, M. D. Fallin<sup>2</sup> and C. Ladd-Acosta<sup>2</sup>, (1)Epidemiology, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (2)Wendy Klag Center for Autism and Developmental Disabilities, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (3)Mental Health, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (4)NCBDDD, Centers for Disease Control and Prevention, Atlanta, GA, (5)Epidemiology, University of North Carolina at Chapel Hill, Chapel Hill, NC, (6)Psychiatry, University of North Carolina, Chapel Hill, NC, (7)University of North Carolina at Chapel Hill, Chapel Hill, NC, (8)Division of Research, Kaiser Permanente Division of Research, Oakland, CA, (9)Centers for Disease Control and Prevention, Atlanta, GA

**Background:** Autism spectrum disorder (ASD) is a neurodevelopmental disorder characterized by impaired social communication and repetitive and restrictive behaviors and interests. Quantitative measures of ASD-related traits can provide insight into severity and impairment across the population. Previous studies have identified epigenomic variation associated with ASD diagnosis (dichotomous), but few have evaluated associations with ASD-related quantitative traits (continuous).

**Objectives:** To identify DNA methylation patterns in child peripheral blood associated with scores on the Social Responsiveness Scale, Second Edition (SRS-2).

**Methods:** We conducted an epigenome-wide association study of autistic traits in the Study to Explore Early Development, a case-control study of ASD in the United States among children born between 2003-2006 and aged 2-5 years at the time of enrollment. Peripheral blood samples were collected at an average age of 5 years. DNA methylation was measured using the Illumina Infinium Human Methylation 450K BeadChip. Quantitative autistic traits were measured in ASD cases and population controls using the SRS-2, preschool or school-age form. After robust quality control, 857 samples were included in our final analytic sample. We performed linear regression to identify DNA methylation single sites (CpGs) or differentially methylated regions (DMRs) associated with SRS-2 scores, using surrogate variables to adjust for sources of biological and technical variation.

**Results:** No single CpG site reached genome-wide significance ( $p < 1 \times 10^{-7}$ ) using established SRS-2 T-score cutoffs for ASD symptoms (none [ $\leq 59T$ ], mild [ $60T - 65T$ ], moderate [ $66T - 75T$ ], severe [ $\geq 76T$ ]) or SRS-2 T-score as a continuous variable; however, multiple CpG sites reached a suggestive significance threshold ( $p < 1 \times 10^{-5}$ ), with eight CpG sites suggestively associated with SRS-2 T-score as a categorical variable when comparing the severe versus no ASD symptom groups, and eight CpG sites suggestively associated with SRS-2 continuous T-score. A region about 3.5kb upstream of *ZFP57* on chromosome 6 was identified as differentially methylated (family-wise error rate [fwer]  $< 0.1$ ) by SRS-2 T-score as a continuous variable in the full sample ( $n = 857$ ; fwer = 0.066) and ASD-only analyses ( $n = 390$ ; fwer = 0.016). *ZFP57* encodes a transcription factor involved in imprinting regulation and maintenance, and this DMR has been previously identified as associated with ASD in post-mortem temporal cortex samples.

**Conclusions:** One DMR near *ZFP57* was associated with continuous SRS-2 T-score in the full sample and ASD-only analyses. Future directions of study include sensitivity analyses regarding the ASD case definition and SRS-2 form type, exploration of methylation quantitative trait locus annotations near *ZFP57*, and pathway analyses. Findings from our study may provide insights into the epigenomics of autistic traits, including

whether associations differ between ASD cases and controls and among ASD cases, informing the use of ASD-related quantitative traits in future epidemiologic studies.

#### **412.142 (Poster) Attention Problems and Expressive Language in Adnp Syndrome**

**K. Kangas-Dick<sup>1</sup>, T. Levy<sup>2</sup>, L. Tang<sup>2</sup>, I. Giserman-Kiss<sup>3</sup>, J. Zweifach<sup>2</sup>, D. Halpern<sup>2</sup>, A. Kolevzon<sup>2</sup>, J. D. Buxbaum<sup>1</sup>, P. M. Siper<sup>2</sup> and J. H. Foss-Feig<sup>2</sup>,** (1)Seaver Autism Center for Research & Treatment Ichan School of Medicine at Mount Sinai, New York, NY, (2)Seaver Autism Center for Research and Treatment, Department of Psychiatry, Icahn School of Medicine at Mount Sinai Hospital, New York, NY, (3)Neurodevelopmental and Behavioral Phenotyping Service, National Institutes of Mental Health, Bethesda, MD, (4)Psychiatry, Icahn School of Medicine at Mount Sinai, New York, NY

---

**Background:** Emerging research has begun describing phenotypes in children and adolescents with activity dependent neuroprotective protein (ADNP) syndrome (Siper et al., 2021), an autosomal dominant neurodevelopmental disorder associated with autism spectrum disorder (ASD), intellectual disability (ID), speech and motor delays, and a myriad of medical comorbidities (Arnett et al., 2018; Helsmoortel et al., 2014; Van Dijck et al., 2019). One half to two thirds of individuals with ADNP syndrome present with ASD (Siper et al., 2021), and a large majority present with speech delays (98.6%) and behavioral problems (77.6%; Van Dijck et al., 2019). In one sample of individuals with ADNP syndrome, 47.4% of caregivers reported clinically significant externalizing problems, including attention problems (68.4%), ADHD (52.6%), aggressive behavior (47.4%), and oppositional defiant problems (21.1%) (Tang et al., 2020).

A larger body of literature has investigated the relationships between clinical characteristics in idiopathic ASD. Findings suggest that externalizing behaviors, including hyperactivity and aggression, are negatively associated with language ability and communication skills (Maskey, Warnell, Parr, Couteur, & McConachie, 2013; Neuhaus et al., 2020; Rattaz, Michelon, Munir, & Baghdadli, 2018; Rodas, Eisenhower, & Blacher, 2017). This information may be useful for treatment aiming to decrease externalizing behaviors in ASD. Whether this relationship holds in ADNP syndrome is unknown.

**Objectives:** This study investigated the relationship between language skills and parent-rated attention and behavior problems among children and adolescents with ADNP syndrome. Specifically, we hypothesized that child attention problems are negatively related to expressive language skills.

**Methods:** Twenty-two individuals with ADNP syndrome (10 females; age 2-17,  $m=7.18$ ,  $sd=3.92$ ; 50% ASD) participated in comprehensive clinical evaluations, including caregiver interviews and standardized assessments. Participants completed the Expressive Vocabulary Test, 2<sup>nd</sup> Edition (EVT-2) to measure expressive language skills. Externalizing problems were assessed by parent ratings on the Child Behavior Checklist (CBCL) 1.5-5 or 6-18 version, depending on the child's chronological age. Relationships between language skills and behavioral functioning were examined.

**Results:** Twelve participants were unable to respond to the EVT-2. For those participants who had EVT-2 raw scores  $>0$ , parent-rated attention problems ( $n=11$ ,  $m=68.27$ ,  $sd=5.98$ ) were significantly negatively correlated to expressive language skills ( $n=12$ ,  $m=49.83$ ,  $sd=19.18$ ,  $r=-.70$ ,  $p=.02$ ). Specifically, for children able to participate in the EVT-2, expressive language skills explained 48% of the variance in attention problems,  $R^2=.48$ ,  $F(1,9)=8.42$ ,  $p<.05$ . Step-wise ordinary least squares (OLS) regression analysis revealed that ASD diagnosis did not explain additional model variance. There was no relationship between attention problems and expressive language when including children without speech.

**Conclusions:** In this sample of children and adolescents with ADNP syndrome, attention problems were significantly negatively related to expressive language skills, for individuals with speech, even when controlling for ASD diagnosis. For children with ADNP syndrome and at least some speech, language skills may be a potential target for intervention, as decreased expressive language was linked to increased attentional problems, which may further interfere with their academic and social development. For children without speech, other avenues, such as direct behavioral targets or focusing on non-verbal communication may offer the most fruitful avenue for intervention.

#### **412.143 (Poster) Autism Spectrum Disorder and Sotos Syndrome: Which Relation Genotype-Phenotype? a PILOT Study**

**M. Siracusano<sup>1,2</sup>, A. Riccioni<sup>2,3</sup>, C. Dante<sup>2</sup>, L. Arturi<sup>2</sup>, G. Conteduca<sup>4</sup>, M. Grasso<sup>4</sup>, C. Galasso<sup>2,3</sup>, D. Coviello<sup>4</sup> and L. Mazzone<sup>2,3</sup>,** (1)Biomedicine and Prevention, POLICLINICO TOR VERGATA, University of Rome Tor Vergata, Rome, Italy, (2)Child and Adolescence Psychiatry Unit, Policlinico Tor Vergata Hospital, Rome, Italy, (3)Systems Medicine, Division of Child Psychiatry, University of Rome Tor Vergata, Rome, Italy, (4)Laboratorio di Genetica Umana IRCCS Istituto Giannina Gaslini, Genova, Italy

---

**Background:**

The clear definition of the cognitive and behavioral profile of individuals affected by genetic syndromes represents a critical research and clinical issue. Sotos Syndrome (SS) is a congenital overgrowth syndrome caused in the 90% by NSD1 (nuclear receptor binding SET domain protein1) gene mutations, with 5q35 microdeletion representing the most common described. SS is associated with a heterogeneous neuropsychological phenotype, characterized by a variable intellectual functioning and behavioral profile (impulsivity, atypical behavior) not yet well and clearly defined, particularly concerning socio-communicative skills and specifically in relation to the genetic phenotype. To our knowledge, no prior study investigated the presence of autism symptoms using the gold standard measure, Autism Diagnostic Observation Schedule-2nd (ADOS-2).

**Objectives:**

This study has been developed in the context of a project borned from the collaboration with the Italian Association of Sotos Syndrome. Main goal of the project is to evaluate whether the neuropsychological profile differs between SS individuals on the basis of their genotype: presence or absence of 5q35 microdeletion.

## Methods:

Twenty-two children and adolescents clinically and genetically diagnosed with SS were enrolled through the Italian Association of SS. All participants were genetically characterized by Fluorescent in situ hybridization (FISH), arrayCGH or DNA sequencing, and all underwent a standardized neuropsychiatric evaluation of cognitive skills (Leiter International Performance Scale-Revised), autism symptoms (ADOS-2, Social Responsiveness Scale), internalizing and externalizing behaviors (Achenbach Child Behavior Checklist [CBCL]; Conners' Parents).

## Results:

We present preliminary results on 22 participants. From a genetic point of view, 9 individuals presented a 5q35 region microdeletion; whereas 13 individuals did not have the microdeletion but others NSD1 gene specific mutations. The neuropsychological profile of all SS individuals was characterized considering two main subgroups: A) carrying 5q35 microdeletion (7 males, 2 females; age M  $8.2 \pm 2.9$  years); B) NOT carrying 5q35 microdeletion (9 males, 4 females; age M  $10.1 \pm 2.1$ ) (Fig). Statistically significant difference emerged between the two subgroups in regard to cognitive profile (IQ  $p=0.02$   $t=1.4$ ; ABAS-II  $p=0.01$   $t=2.6$ ) and socio-communicative symptoms (ADOS-2 CSS  $p=0.05$   $t=3.1$ ; SRS Total  $p=0.0092$   $t=2.9$ ; ABAS-II Social Adaptive Domain  $p=0.04$   $t=2.1$ ). Specifically, individuals carrying the 5q35 microdeletion - in comparison to participants not carrying the same deletion - showed: lower cognitive functioning in terms of Non Verbal Intellectual Quotient and adaptive skills; higher ASD symptoms at both evaluation of the examiner and parental report. No statistically significant findings emerged concerning behavioral problems (Conners' ADHD index  $p=0.08$   $t=1.8$ ; CBCL  $p=0.3$   $t=1.0$ ).

## Conclusions:

This study contributes to better define the neuropsychological phenotype of individuals with Sotos Syndrome. Preliminary results show that SS individuals carrying the 5q35 microdeletion are characterized by a worse neuropsychological profile in terms of cognitive skills, adaptive functioning and socio-communicative symptoms. In particular, ASD symptoms and attention deficit difficulties, emerged as a promising behavioral area to be longitudinally investigated within this clinical population. A clear definition of the cognitive and behavioral profile of SS children, even in relation to the genetic profile, could lead to a better take in charge and delineation of early intervention.

**412.144 (Poster)** Cognitive and Language Abilities Associated with Protein Levels Differentially in Males and Females with Fragile X Syndrome  
A. Jones<sup>1</sup>, A. Dapore<sup>1</sup>, A. Boggs<sup>1</sup>, C. Gross<sup>1</sup>, S. Schroeder<sup>2</sup>, A. Sterling<sup>3</sup>, C. A. Erickson<sup>3</sup> and L. M. Schmitt<sup>4</sup>, (1)Cincinnati Children's Hospital Medical Center, Cincinnati, OH, (2)University of Wisconsin-Madison, Madison, WI, (3)Psychiatry, Cincinnati Children's Hospital Medical Center, Cincinnati, OH, (4)Developmental and Behavioral Pediatrics, Cincinnati Children's Hospital Medical Center, Cincinnati, OH

**Background:** Fragile X Syndrome (FXS) is an X-linked neurodevelopmental disorder caused by triplet repeat expansion and resultant methylation of Fragile X mental retardation 1 (FMR1) gene resulting in deficient production of fragile X protein (FXP). FXS is the most common form of inherited intellectual disability and single gene cause of autism. Several studies have established a link between peripheral blood FXP levels and general intellectual functioning in individuals with FXS. However, studies exploring the relationship between FXP levels and other key aspects of cognition are limited.

**Objectives:** The purpose of this study was to investigate the relationship between blood FXP levels and cognitive and language functioning in FXS to better understand the pathophysiological basis of these deficits.

**Methods:** Twenty-three male and ten female (17-40 years old) age-matched individuals with FXS were included. Blood samples were obtained from participants to confirm FXS status and obtain FXP levels, using an optimized Luminex-based blood spot assay that allowed us to detect very low concentration levels of FXP. All participants completed a neuropsychological battery including tests of working memory, auditory attention, and expressive language. We compared sexes on neuropsychological measures and examined relationships between these measures and FXP levels.

**Results:** Verbal working memory of single words was significantly reduced in males with FXS compared to females, but memory of complex sentences were only marginally reduced in males compared to their female counterparts; however, this difference became significant after removing males with mosaicism. We found males and females with FXS did not show a significant difference in auditory attention even when removing males with mosaicism. Mean length of utterances, or syntactic complexity, was significantly reduced in males with FXS compared to females.

In males and females with FXS, higher FXP levels were related to increased syntactic complexity. Among all males with FXS, lower FXP levels was associated with increased talkativeness. Males with mosaicism demonstrated a relationship between higher FXP and increased lexical diversity, or the number of different words used. In females with FXS, higher FXP levels were related to improved verbal working memory of single words and sentences as well as to improved auditory attention.

**Conclusions:** Consistent with prior reports, females with FXS have higher verbal working memory and expressive language abilities when compared to males with FXS. On the other hand, auditory processing abilities may be more similar in males and females with FXS. One possible explanation for this is the relationship found between lower FXP levels and lower auditory processing skills in females with FXS. This suggests that auditory attention may be more closely tied to underlying FXS pathology in females, and less susceptible to suspected compensatory patterns typically arising from X-inactivation. Moreover, our findings indicate that FXP levels are associated with cognitive and language abilities differentially based on sex and mosaicism status, suggesting FXP alone may not play causal role of these key features of FXS. Together, our findings provide important new insights into underlying pathophysiological mechanisms and treatment planning.

**412.145 (Poster)** Contributive Role of C12orf57 Mutations in Autism Spectrum Disorder and Intellectual Disability

**R. Taha<sup>1</sup>**, S. Salloum-Asfar<sup>2</sup> and S. A. Abdulla<sup>2</sup>, (1)Neurological Disorders Research Center, Qatar Biomedical Research Institute (QBRI), Hamad Bin Khalifa University (HBKU), Education City, Qatar Foundation (QF), Doha, Qatar, (2)Qatar Biomedical Research Institute (QBRI), HBKU, Qatar Foundation, Doha, Qatar

---

**Background:** Genetic factors are responsible for a wide variety of intellectual disorders. C12orf57 (Chromosome 12 Open Reading Frame 57) is a gene coding protein responsible for the development of the human corpus callosum. Homozygous and heterozygous mutations in C12orf57 have been associated to multiple congenital anomalies, and further proven to be fundamental in the outcome of various forms of intellectual disabilities (ID) and neurological diseases.

**Objectives:** This study aims to highlight the importance of screening for C12orf57 mutations in families with autism spectrum disorder (ASD) to further clarify the link between C12orf57 variants and ASD.

**Methods:** Our team recruited an ASD cohort that was diagnosed and assessed clinically and further confirmed utilizing ADOS-2, ADI, and IQ test scores. Through the use of Nanopore sequencing technology, we analyzed the C12orf57 gene in 70 autistic children and their parents.

**Results:** Out of the 70 children assessed, five individuals showed novel heterozygous variants in the C12orf57 gene that have not been previously associated with ASD. They were further validated using Sanger sequencing.

**Conclusions:** Our findings sheds light on the importance of the C12orf57 gene in the development of ID and ASD.

**412.146 (Poster)** Epigenetic Aging at Birth and Risk of Autism Spectrum Disorder

**A. Y. Song<sup>1</sup>**, M. D. Fallin<sup>2</sup>, L. A. Croen<sup>3</sup>, I. Hertz-Picciotto<sup>4</sup>, R. J. Schmidt<sup>5</sup>, X. Hong<sup>6</sup>, B. Zhang<sup>7</sup>, X. Wang<sup>8</sup>, C. J. Newschaffer<sup>8</sup>, H. E. Volk<sup>2</sup> and C. Ladd-Acosta<sup>2</sup>, (1)Mental Health, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (2)Wendy Klag Center for Autism and Developmental Disabilities, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (3)Division of Research, Kaiser Permanente Division of Research, Oakland, CA, (4)University of California at Davis, Davis, CA, (5)Public Health Sciences, University of California Davis, Davis, CA, (6)The Center on the Early Life Origins of Disease, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (7)John Hopkins Bloomberg School of Public Health, Baltimore, MD, Baltimore, MD, (8)College of Health and Human Development, Pennsylvania State University, University Park, PA

---

**Background:** Evidence supports an epigenetic involvement in autism spectrum disorder (ASD). Epigenomic-wide association studies have linked DNA methylation (DNAm) changes to ASD in multiple tissues. In recent years, “epigenetic clocks” or DNAm based age estimators have been developed to accurately predict biologic age across tissues. Epigenetic age acceleration has been associated with a wide range of adverse child health conditions. Currently, little is known about epigenetic aging at birth and ASD.

**Objectives:** To examine the association between epigenetic age acceleration assessed using DNAm collected at birth and risk of ASD in three prospective cohort studies: the Early Autism Risk Longitudinal Investigation (EARLI), the Markers of Autism Risk in Babies-Learning Early Signs (MARBLES), and the Boston Birth Cohort (BBC).

**Methods:** Epigenetic age was estimated using two existing epigenetic clock algorithms (Knight and Bohlin) for cord blood DNAm data. Cell-intrinsic epigenetic age acceleration/deceleration was defined as the residual of regressing chronologic gestational age on DNAm age accounting for cell type proportions. Diagnoses of ASD were made by psychologists based on clinical evaluations at 36 months of age in two cohorts (EARLI and MARBLES) or were extracted from medical records at any age for the third cohort (BBC). Children were classified as having ASD (N=160), nontypical development (non-TD, N=634), or neuro-typical development (TD, N=547). Multinomial logistic regression models were completed in three cohorts separately to examine the association of epigenetic age acceleration/deceleration at birth with ASD diagnosis adjusted for child sex, maternal race/ethnicity, study site, and maternal education.

**Results:** The two DNAm based estimates of epigenetic age, in three cohorts, all showed significant high overall correlations with chronologic gestational age (correlation ranging from 0.50 – 0.75). For Knight and Bohlin epigenetic age estimates, we computed accelerated/decelerated epigenetic (biologic) age in each study and tested for associations with ASD diagnosis. No significant associations were observed between accelerated/decelerated aging at birth and ASD risk; however, effect estimates for the 2 clocks in all 3 studies suggest decreased ASD risk with accelerated biologic aging. For example, nonsignificant decreases in odds of ASD were observed for 1-week increase in biologic age relative to gestational age at birth (aOR=0.85, 95% CI = 0.67, 1.07) using the Bolin clock in one cohort. In secondary analyses comparing non-TD to TD separately in three cohorts, we did not find evidence for associations with epigenetic age at birth.

**Conclusions:** Overall, we did not observe significant associations of cell-intrinsic epigenetic aging at birth with clinical ASD diagnosis. Future research is needed to further investigate cell-extrinsic aging, a measure of immune system aging that incorporates cell counts, and its impact on child neurodevelopment. We did show that DNAm based estimates of epigenetic age accurately predicts gestational age at birth using 2 clock algorithms in all 3 birth cohorts with diverse race/ethnicity, which offers a valuable molecular tool for assessing gestational age in a range of life course research.

**412.147 (Poster)** Gender Effect on the Severity of Developmental Phenotype in Children with Rare Autosomal Genetic Mutations

**A. Chezana<sup>1</sup>**, O. Leon Attia<sup>2</sup>, M. Shaham<sup>3</sup> and **L. V. Gabi<sup>4,5</sup>**, (1)medicine, Ben Gurion University, Beer Sheva, Israel, (2)Child development Center, Sheba Medical Center, Tel Hashomer, Israel, (3)Statistics, Haifa University, Haifa, Israel, (4)Pediatrics, Maccabi health services, Rehovot, Israel, (5)Maccabi Healthcare, Tel Aviv, Israel

---

**Background:** Since more whole exome sequencing is performed during the workup for autism and intellectual disability, more rare genetic disorders are discovered as etiology.

**Objectives:** To examine gender differences in the presenting symptoms and severity of autism spectrum and developmental disability among children with rare autosomal genetic mutations, specifically language, gross and fine motor delay, age of acquiring independent walking ability, age of diagnosis of Autism Spectrum Disorder (ASD) and severity, and age at the first concerns and referral to a medical profession. We assumed that we will find differences, even though the examined mutations are autosomal and not sex-linked.

**Methods:** We will compare developmental domains in 32 children with a rare genetic mutation characterized by a developmental disability, evaluated between 2012- 2021 at Keshet Center. 11 girls with autism related disorder due to a rare genetic mutation as compared to 21 boys with autosomal mutations and we assessed developmental trajectories and risk factors.

**Results:** An initial analysis of the results showed that the paternal mean age at the birth of the child was 37.2 while the mothers' mean age was 33.5. The heredity was de novo in 53% of cases, in 6.3% maternal inheritance, the same percentage as a paternal inheritance. In 34.4% of cases, the heredity was recessive, inherited from both parents, or unknown. At the first point of time examined, only 31.2% of the children were diagnosed initially with autism spectrum disorder. At the second time point 71.9% received an ASD diagnosis. Only one girl was not diagnosed initially with autism in our research, compared with eight boys (9.1% vs. 38.1% respectively) but the age at first diagnosis was higher in girls.

**Conclusions:** This study is in progress, however initial results show older paternal age linked to autosomal rare mutations and to accumulation of ASD signs and symptoms with age. Although the mutations are not gender related, male gender is predominant, pointing to a delayed diagnosis in females or to a milder phenotype due to epigenetic influences.

**412.148 (Poster)** Identifying Shared and Divergent Transcriptional Dysregulation across Brain Regions in Adult *Chd8* Haploinsufficient Mice  
**C. P. Canales<sup>1</sup>, K. Cichewicz<sup>1</sup>, A. A. Wade<sup>1</sup>, R. Ortiz<sup>1</sup>, E. Smith<sup>1</sup>, C. Ardekani<sup>1</sup>, S. Lozano<sup>1</sup>, J. Zhu<sup>1</sup>, P. Beauregard<sup>1</sup> and A. S. Nord<sup>2</sup>,** (1)Center for Neuroscience, University of California Davis, Davis, CA, (2)Center for Neuroscience, Department of Neurobiology, Physiology, & Behavior, University of California, Davis, Davis, CA

---

**Background:** De novo mutations in the chromatin-remodeling factor *CHD8* (Chromodomain-Helicase DNA-binding protein 8) are strongly associated with autism spectrum disorder (ASD) and more generally with neurodevelopmental disorders (NDDs). Mice with heterozygous germline loss-of-function mutations in *Chd8* exhibit genomic, neuroanatomical, and behavioral pathology. While recent efforts have focused on investigating how *Chd8* haploinsufficiency impairs early brain development, less is known about the impacts of *Chd8* mutations and its cellular role in the postnatal brain.

**Objectives:** Using mice harboring a heterozygous *Chd8* mutation that present behavioral deficits relevant to ASD and ID, we aimed to map and compare the transcriptomic landscape across three brain regions from *Chd8* mutants and wild type mice. Our goal is to identify the molecular consequences of *Chd8* haploinsufficiency in the postnatal brain, leading to better understanding of ASD etiology.

**Methods:** We used RNA-sequencing in cerebral cortex, hippocampus, and cerebellum from *Chd8* adult gender-balanced cohorts of heterozygous mutants and wild-type littermates. Using differential expression and weighted gene co-expression network analysis (WGCNA), we tested for genes and modules that are dysregulated and. Western Blot and histology were applied to validate findings.

**Results:** We identified differentially-expressed genes (DEGs) that were altered across all three brain regions, as well as region-specific signatures. We detected perturbation to neuroinflammatory, metabolic, and synaptic pathways. Our findings reveal a small set of genes that are consistently perturbed across brain regions here and also identified across a number of independent studies. We also identified a module of sex-specific DEGs that may be relevant to reports of differences between male and female mutation carriers.

**Conclusions:** Our findings show that decreased *Chd8* dosage alters gene expression in adult brain both via shared pathways, and in region-specific and sex-specific manners. In ongoing work, we aim to resolve specific cell types and functional consequences of these effects. Our results present a systems-level characterization of molecular and cellular pathways that are disrupted in adult *Chd8* mutant brain and reveals new insights to the molecular and cellular underpinnings of severe NDDs.

**412.149 (Poster)** Immune-Phenotyping and Transcriptomic Profiling of Peripheral Blood Mononuclear Cells Based on Severity from Children with Autism Spectrum Disorders  
**S. Salloum-Asfar<sup>1</sup>, R. Taha<sup>2</sup> and S. A. Abdulla<sup>1</sup>,** (1)Qatar Biomedical Research Institute (QBRI), HBKU, Qatar Foundation, Doha, Qatar, (2)Neurological Disorders Research Center, Qatar Biomedical Research Institute (QBRI), Hamad Bin Khalifa University (HBKU), Education City, Qatar Foundation (QF), Doha, Qatar

---

**Background:** Transcriptomic profiling using total RNA-sequencing has been one of the most utilized approaches to link protein levels and genetic information at the molecular level. The transcriptome apprehends a molecular genomic complexity that the DNA sequence solely does not. Some mutations alter a gene's DNA sequence but do not necessarily change expression and/or protein function. Recent studies using transcriptome profiling of peripheral blood mononuclear cells (PBMCs) from individuals with autism spectrum disorder (ASD) revealed several differentially expressed transcripts compared to controls. Moreover, changes in gene expression in individuals with ASD were simultaneously differentially expressed in the different tissues, brain, intestinal biopsy samples, and PBMCs. This enhances detection specificity in different types of samples, and thus blood transcriptome-wide signature could be used to understand ASD transcriptome. To date, reliable biomarkers to diagnose ASD or molecular

mechanisms to define its severity do not exist. A transcriptomic map of the PBM network could identify relationships between genes with enriched expression in ASD based on different symptomatology.

**Objectives:** To define a transcriptomic map based on ASD severity and use it to investigate relationships between genes with enriched expression in ASD.

**Methods:** EDTA whole blood samples were collected from 38 children with ASD, and 8 age- and gender-matched controls and PBMCs were extracted using Ficoll density gradient. The 38 ASD subjects were divided into 20 children, who expressed more symptoms of ASD (severe) and 18 who expressed fewer symptoms of ASD (mild). Whole transcriptome sequencing of PBMCs was performed using TruSeq total RNA Ribo-Zero Library preparation kit. To discover DEGs at the biologically functional level the Ingenuity Pathway Analysis IPA was used. To identify functional pathways influenced by the combinatorial effects of the long noncoding RNAs analysis, the LncPath package in R was used.

**Results:** An average of 97.75% of reads from each sample was uniquely mapped to the human genome. From 47,314 genes, 19,939 protein-coding genes and 27,375 non-coding genes were identified in the children with ASD and healthy controls. We defined the genes expressed in PBMCs isolated from different ASD children identified with different symptomatology (severe and mild) vs. controls. We further defined a PBMC transcriptome signature, a profile of genes with enriched expression in PBMCs, and discovered novel genes and molecular programmes that control regulation of cytokine production and neuroinflammation. Moreover, a functional enrichment analysis demonstrated that differentially expressed genes were significantly enriched in inflammation/immune response, mitochondrion-related function, and oxidative phosphorylation. The biological processes associated with these genes are involved in cytokine stimulation and signaling, immune system development, cell communication, and regulation of cellular response. PBMC transcriptome signature genes are shown to be (i) highly enriched for genes that cause severe symptoms and (ii) significantly over-represented with susceptibility miRNAs identified previously by our group. Furthermore, lncRNAs that were previously identified as key regulators of the inflammatory response were found to be increased in individuals with severe symptoms of ASD.

**Conclusions:** This study provides a new insight of understanding the etiology of ASD neuroinflammation and the possibilities of developing interventions based on severity

**412.150 (Poster) Leveraging Family Structure to Parse the Genetic Architecture of Autism Spectrum Disorder Endophenotypes**

**N. T. Stockham<sup>1</sup>, K. M. Paskov<sup>1</sup>, J. Y. Jung<sup>1</sup>, B. Chrisman<sup>2</sup> and D. P. Wall<sup>2</sup>, (1)Stanford University, Palo Alto, CA, (2)Stanford University, Stanford, CA**

**Background:** The genetic architecture of Autism Spectrum Disorder (ASD) is multifaceted and unresolved, with few common variants reliably associated with the diagnosis status despite consistently high estimates of heritability. A posited hypothesis for this lack of discovery is that there are several etiologically distinct forms of ASD and grouping these distinct forms under one diagnosis status obscures the genomic elements relevant to each etiology.

**Objectives:** The purpose of this work is to estimate the degree of genetic influence on the endophenotype of the subdomains described by Autism Diagnosis Interview-Revised (ADIR) and the closely related Social Communication Questionnaire (SCQ) in the two largest family-based ASD cohorts; the Autism Genetic Research Exchange (AGRE) collection and the Simons Foundation SPARK (SPARK).

**Methods:** We modeled the subdomains with differential causal exposures for the distinct sibling pair types of monozygotic twins, dizygotic twins, full siblings, and half siblings. Additionally we regressed the subdomain scores against the degree of genetic material shared between siblings (Identity-by-Descent) to confirm genetic influence on a subdomain and localize the relevant genomic regions.

**Results:** In the AGRE cohort only the Reciprocal Social Interaction (RSI) subdomain was consistent with exclusively genetic influence, whereas the Restricted Repetitive and Stereotyped Behavior (RRSB) subdomain was consistent with exclusively environmental influence, and the Communication (COM) subdomain was consistent with both genetic and environmental influences. For the SPARK cohort the RSI subdomain of the SCQ was again the subdomain under strongest genetic influence, but the RRSB subdomain also showed significant genetic influence.

**Conclusions:** Different subdomains of the ADIR and SCQ are under different degrees of genetic influence. By regressing on the subdomain severity scores we recovered sufficient statistical power to localize chromosomal regions with a direct and specific effect on the subdomain of RSI in AGRE, and RSI and RRSB in SPARK. While the primacy of genetic influence on the RSI subdomain was replicated in both cohorts, the divergent results for RRSB suggest that the SPARK cohort contains a broader array of ASD subtypes than AGRE.

**412.151 (Poster) Maternal Cortisol Predicts Child Cortisol in Autism Spectrum Disorder and Fragile X Syndrome**

**R. Hantman<sup>1</sup>, E. A. Will<sup>2</sup> and J. Roberts<sup>1</sup>, (1)Department of Psychology, University of South Carolina, Columbia, SC, (2)Psychology, University of South Carolina, Columbia, SC**

**Background:** The hypothalamic-pituitary-adrenal (HPA) axis is a biological pathway implicated in stress regulation and anxiety, wherein cortisol is released during stress. Relative to typically developing (TD) peers, children with Autism Spectrum Disorder (ASD) and Fragile X Syndrome (FXS) have abnormal salivary cortisol responses (Hessl et al., 2002; Scherr et al., 2016; Taylor & Corbett, 2014). Children with ASD and FXS also experience increased anxiety (Cordeiro et al., 2011; White et al., 2009), and their mothers report elevated stress and anxiety (Bailey Jr et al., 2008; Baker-Ericzen et al., 2005). Further, HPA axis regulation is heritable (Federenko et al., 2004), and parental stress is epigenetically linked to child stress responses (Bowers & Yehuda, 2016). Although parental cortisol is associated with TD child cortisol through physiological attunement (Hibel

et al., 2015; Spratt et al., 2016), little is known how parent-child cortisol associations differ in ASD or FXS, despite maternal and child high vulnerability to stress.

**Objectives:** To determine if maternal cortisol predicted ASD, FXS, and TD child cortisol.

**Methods:** Salivary cortisol was collected from 97 mother-child dyads before and after assessments measuring temperament, developmental skills, and ASD. Thirty-five children had ASD ( $\bar{x}$  = 44.64,  $s$  = 6.11 months), 28 had FXS ( $\bar{x}$  = 44.22,  $s$  = 6.29 months), and 34 were TD ( $\bar{x}$  = 44.22,  $s$  = 34 months). Salivary cortisol was collected via salivettes at approximately the same time of day. Cortisol values were natural log transformed and outliers  $>2$  SD were removed (Adam & Kumari, 2009; Hanrahan et al., 2006). Three regression models assessed the relation between maternal and child cortisol. Models included interactions between child diagnosis and maternal cortisol, controlling for nonverbal IQ and saliva collection time. Three models examined child cortisol levels pre-assessment (T1), post-assessment (T2), and cortisol regulation (T2-T1), using the corresponding maternal cortisol levels as predictors.

**Results:** Maternal cortisol significantly predicted child cortisol across groups ( $b$  = 0.594,  $p$  = 0.010; figure 1A) at pre-assessment but not at post-assessment ( $b$  = 0.139,  $p$  = 0.516; figure 1B). Across all groups, maternal cortisol regulation significantly predicted child cortisol regulation ( $b$  = 0.721,  $p$  = 0.001), and there were two significant group effects. Relative to the TD group, a 10% increase in maternal cortisol regulation predicted a 7.19% decrease in child cortisol regulation for the ASD group ( $b$  = -0.719,  $p$  = 0.007). Likewise, relative to the TD group, a 10% increase in maternal cortisol regulation predicted a 7.37% decrease in child cortisol regulation for the FXS group ( $b$  = -0.737,  $p$  = 0.016; figure 1C).

**Conclusions:** Initially, maternal cortisol predicted child cortisol across groups, suggesting that children were attuned to their mothers' cortisol levels. However, this relation ceased for children with ASD and FXS, as they showed a similar lack of cortisol regulation attunement, suggesting that while TD children took cues from their mothers regarding stress, children with ASD and FXS struggled to do so. This finding expands the HPA axis dysregulation literature in children with ASD and FXS from individualistic to dyadic via parent-child cortisol misattunement.

**Background:** Neurodevelopmental disorders (NDD) are a broad group of conditions which includes Autism Spectrum Disorders (ASD), intellectual disability (ID), language delay, and epilepsy. NDDs are genetically heterogeneous, with all possible inheritance patterns involved. Paralleling the genetic heterogeneity, there is a huge clinical diversity that is a major confounding factor when analyzing whole exome sequencing (WES) data

**Objectives:** To improve WES diagnoses in NDD cases exploiting a detailed clinical characterization, X-chromosome inactivation (XCI) profiles, epigenetic signatures and cellular models

**Methods:** We collected and deeply phenotyped 212 pediatric NDD cases from Macedonia (NeuroWes-Macedonia) affected by ASD/ID (82/212; 39%), complex syndromes (74/212; 35%), and isolated ASD (55/212; 26%) and performed trio-WES within the international network of Autism Sequencing Consortium (ASC). We performed XCI using an in-house protocol. Epigenetic signatures will be tested in blood, in collaboration with the EpiSign consortium (Ontario, Canada). We are using stem cells from deciduous teeth (SHED) as an *in vitro* cellular model, and a yeast strain lacking *AARS1* orthologue

**Results:**

Currently, we analyzed 151 NDD trios. We found pathogenic/likely pathogenic variants in 39 (26%), with the highest diagnostic rate among syndromic cases (21/44; 47%), and the lowest in isolated ASD/ID cases (3/31; 9%).

To increase the diagnostic yield, we tested XCI skewing in unsolved affected females and mothers of affected males. In a three boys (3/15; 33%), whose mothers were 100% skewed, we found variants in strong novel gene candidates, previously overlooked by trio-WES analysis, such as *ZMYM3*:R441Q, *PDZD4*:K730N, and *AMOT*:G343R. We used a combination of cDNA/minigene analyses to verify the effect of several splicing variants on transcripts, such as *WDFY3*: c.8098-1G>C, which led to activation of cryptic splice site, and *KIAA1109*: c.9283-8T>G which caused an exon skipping; notably this latter variant did not change splicing scores, and was evaluated only because of the strong phenotypic association with the *KIAA1109* gene.

In cases (9/46; 19%), where causative or variants of uncertain significance are in genes encoding proteins of chromatin-remodeling pathways, we planned to test their "epigenetic signature" in blood. We aim at confirming the functional role of variants in exceedingly rare disease-associated genes such as *HIST1H1E*, *EZH2*, *HDAC8*, and *PHF6*.

Notably, we found two cases with a dual multilocus molecular diagnosis, and one family with two different *de novo* variants, as *TRIP12*:L1044Ffs\*3, and the recurrent *FBN*:A1728V in two similarly affected brothers.

Beyond known genes, we have also found strong novel candidate genes: *PHLPP1* (\*609396), encoding a phosphatase inhibiting the AKT-mTOR pathway. Using patient derived SHED, we initially proved a functional alteration of the AKT-mTOR pathway. A second candidate was *AARSD1* (\*613212), encoding an alanyl-tRNA editing activity protein, highly related to brain myelinations processes. A yeast model proved a growth impairment associated with the missense variant found in our patient

Conclusions: Trio-WES analyses are greatly improved by a deep phenotyping which can reveal overlooked pathogenic variants, dual molecular diagnoses, and novel NDD-associated genes. Our experience also suggests that the use of XCI, blood episinature and cellular models is a key strategy to solve undiagnosed NDD cases and overcome clinical complexity

#### **412.153 (Poster)** Obesity and Genetic Predisposition in Individuals with Complex Neurodevelopmental Phenotypes

**E. Smith<sup>1</sup>, I. Gutierrez<sup>2</sup> and J. A. Martinez-Agosto<sup>3</sup>**, (1)Human Genetics, UCLA, Los Angeles, CA, (2)Univ California Los Angeles, Los Angeles, CA, (3)Departments of Human Genetics, Pediatrics and Psychiatry, Univ California Los Angeles, Los Angeles, CA

---

Background: Obesity remains a growing public health concern and research continues to demonstrate the interplay between genetic and environmental contributions to its etiology. Higher rates of obesity are reported in populations with autism spectrum disorders (ASD)<sup>1</sup>. While several well-established monogenic causes of obesity are also linked to autism, a knowledge gap remains on genetic determinants of obesity in neurodevelopmental phenotypes.

Objectives: Identify genetic predispositions in individuals with complex neurodevelopmental phenotypes associated with obesity.

Methods: A cohort of individuals that underwent a genetic evaluation between 2000-2018 with a peak age distribution between 1-5 years presenting with developmental delay/ID and/or autism were assessed. In the total sample, the proportion of males was 69% compared to 31% females. We identified 25% of individuals with a body mass index (BMI) or weight percentiles greater than 95%. Of these cases, those with genetic variants on testing (Fragile X, chromosomal microarray (CMA), clinical exome sequencing (CES), single gene/panel) were analyzed for novel and established genetic predisposition to obesity phenotypes.

Results: Within the total cohort, the completed testing breakdown was: 42% CMA, 24% Fragile X, 14% karyotype/FISH, 10% CES, and 10% single gene testing. The proportion of rare variants varied across testing modality for Fragile X (0%), CMA (30%), CES (56%) and other testing (26%). The genetic variants identified included well-established genetic predispositions associated with obesity, including uniparental disomy and microdeletion of 15q11.2 (Prader-Willi syndrome), 17p11.2 deletion (Smith-Magenis syndrome), 7q11.23 duplication, 22q11.2 deletion, XYY, and variants in *ATRX*, *LRP2*, and *TUBA1A*. In addition, we identified rare variants not previously associated with obesity. These include single variants within *KCND3*, *LMTK2*, *GNB1*, *DYNC1H1*, *NLGN1*, *TCF12*, *PTEN*, and *IDH2* and CNVs (Xp22.33 duplication, 8p11.21p11.1 duplication, 10q23.31 deletion, 14q11.2 microdeletion, 20p12.3 deletion, 2q13 deletion, 15q13.1q13.2 deletion, 8q23.1 duplication, 2q24.3 deletion, partial tetrasomy in chromosome 21) not previously associated with obesity.

Conclusions: We confirmed previous associations between genetic variants and obesity in individuals with ASD and/or developmental delay and reduced the knowledge gap of novel rare genetic variants associated with obesity. We demonstrate the utility of elevated BMI as a phenotypic marker for identifying individuals with neurodevelopmental differences and likelihood of a genetic etiology. While barriers in access to genetics care are evident, our findings present opportunities for providing personalized care interventions that promote the physical health of individuals with neurodevelopmental phenotypes and obesity through inclusion of a genetic evaluation.

#### **412.154 (Poster)** Pupillary Light Reflex As an Objective Biomarker in Children with Phelan-Mcdermid Syndrome and Autism Spectrum Disorder

**J. Trayvick<sup>1</sup>, S. Barkley<sup>2</sup>, B. Lerman<sup>2</sup>, L. Massa<sup>3</sup>, K. Keller<sup>2</sup>, H. E. Grosman<sup>2</sup>, C. McLaughlin<sup>2</sup>, T. Levy<sup>2</sup>, P. M. Siper<sup>2</sup>, S. B. Guillory<sup>2</sup>, J. D. Buxbaum<sup>4</sup>, A. Kolevzon<sup>2</sup> and J. H. Foss-Feig<sup>2</sup>**, (1)Seaver Autism Center at the Icahn School of Medicine at Mount Sinai, New York, NY, (2)Seaver Autism Center for Research and Treatment, Department of Psychiatry, Icahn School of Medicine at Mount Sinai Hospital, New York, NY, (3)Seaver Autism Center, Department of Psychiatry, Icahn School of Medicine at Mount Sinai Hospital, New York, NY, (4)Psychiatry, Icahn School of Medicine at Mount Sinai, New York, NY

---

Background: Phelan-McDermid syndrome (PMS) is a neurodevelopmental disorder caused by terminal deletion or sequence variation affecting chromosome 22q, resulting in haploinsufficiency of the *SHANK3* gene. Individuals with PMS are at high risk for developing autism spectrum disorder (ASD); the *SHANK3* pathway, which codes for a protein found in the postsynaptic density of excitatory synapses, may be relevant to other forms of ASD (Costales & Kolevzon, 2015). Both individuals with idiopathic ASD and individuals with PMS show signs of sensory reactivity abnormalities. Pupillary Light Reflex (PLR) is an acetylcholine-mediated response that has been studied as a possible metric for the cholinergic

system, which plays a role in excitatory-inhibitory (E/I) balance (Nyström et al., 2018). Previous research has found evidence of differences in PLR in infants at risk for ASD and children with ASD (Nyström et al., 2015; Daluwatte et al., 2015).

**Objectives:** This study used an eye-tracking paradigm to explore PLR as a potential measure of E/I imbalance and sensory abnormalities in PMS and ASD. Based on previous research implicating E/I imbalance in PMS and ASD, we hypothesized that PLR would be different in individuals with ASD and PMS relative to typically developing controls.

**Methods:** Forty-four children participated, including 17 children with ASD ( $M_{age}=7.29$  years; 3 Female), 14 with PMS ( $M=8.07$ ; 10 F), and 13 typically-developing (TD) controls ( $M=9.06$ ; 9 F). The task used an Eyelink 1000-Plus eye tracker and measured pupil response to a brief (100ms) flash of light across 16 trials. Peak pupil contraction and latency of reflex onset were the primary measures.

**Results:** Peak pupil contraction was significantly smaller in PMS ( $M=-3.01$ ,  $SD=22$ ) relative to TD controls ( $M=-3.13$ ,  $SD=.10$ ;  $p=.03$ ). Peak contraction in ASD was not significantly different than in TD controls ( $p>.1$ ), but it did trend toward being smaller (Cohen's  $d=.46$ ). Peak contraction in PMS trended toward being smaller than in ASD ( $M=-3.08$ ,  $SD=.11$ ; Cohen's  $d=.47$ ) although this difference did not reach statistical significance ( $p>.1$ ). No significant differences were found in latency of reflex between any groups ( $p>.1$ ).

**Conclusions:** These results support prior findings of E/I dysregulation in individuals with PMS and suggest that PLR may be a useful metric in measuring these imbalances in PMS and similar disorders affecting the glutamatergic systems. Smaller peak contraction might indicate that sensory abnormalities in PMS and ASD are associated with decreased cholinergic modulation. The lack of significant results in ASD may indicate changes in PLR from infancy to childhood and suggests that more research is needed to fully understand the reflex in this population. Given that eye-tracking is non-invasive, measures of PLR may have the potential to be a biomarker used to study treatment of PMS, genetic disorders with high susceptibility to ASD, and other neurodevelopmental disorders.

#### **412.155 (Poster) Stochastic Epigenetic Mutation Burden in Autism Spectrum Disorders**

*D. Gentilini<sup>1,2</sup>, M. Olivola<sup>1</sup>, M. Nola<sup>1</sup>, C. Guior<sup>1</sup>, L. Calza<sup>1</sup>, R. Cavagnola<sup>1</sup>, P. Politi<sup>1</sup> and N. Brondino<sup>1</sup>, (1)Department of Brain and Behavioral Sciences, University of Pavia, Pavia, Italy, (2)Istituto Auxologico, Cusano Milanino, Italy*

---

**Background:** Despite the relative abundance of genomic data in autism spectrum disorders, little is known about the impact of epigenetic modification. Most studies focused on general differences in methylation levels in specific genes expressed in the brain and encoding protein that interacts with those involved with the development of ASD. To the best of our knowledge, there is no data on stochastic epigenetic mutations, that are extreme differences in DNA methylation levels that are not shared among subjects.

**Objectives:** The present study aims to evaluate epigenetic drift and stochastic epigenetic mutation (SEM) burden in ASD.

**Methods:** We selected epigenome-wide association studies (EWAS) data available in the literature from samples originated from different human tissues (blood and buccal tissues). The distribution and variability of methylation levels in the studied data samples were studied using Box-and-whiskers plots in order to identify SEMs. For each probe, whenever the methylation level of one subject extremely differed from the rest of the population, we considered the outlier sample as epimutated for that locus. Thus, for each locus epimutated subjects were identified as the extreme outliers with methylation level exceeding three times interquartile ranges  $Q1-(3 \times IQR)$  and  $Q3+(3 \times IQR)$ . SEMs were calculated on 96 individual buccal tissues and on 102 blood samples.

**Results:** The burden SEMs was divided into hypo or hypermethylated groups and compared between ASD subjects and controls. The ASD group showed a significant higher number of total SEMs and of hypomethylated SEMs compared to controls both in the mouth tissue and in blood. This finding was still significant after correction for age and gender.

**Conclusions:** ASD subjects presented a higher number of epimutations compared to controls. This could represent a marker of early aging in this group.

#### **412.156 (Poster) Investigation of Genetic Factors Contributing to the ASD Subphenotype Disproportionate Megalencephaly**

*S. S. Nishizaki<sup>1</sup>, C. W. Nordahl<sup>2</sup>, D. G. Amaral<sup>3</sup> and M. Y. Dennis<sup>4</sup>, (1)Psychiatry and Behavioral Services, UC Davis MIND Institute, Sacramento, CA, (2)Department of Psychiatry and Behavioral Sciences, UC Davis, Sacramento, CA, (3)Department of Psychiatry and Behavioral Sciences, The Medical Investigation of Neurodevelopmental Disorders (MIND) Institute, UC Davis School of Medicine, University of California Davis, Sacramento, CA, (4)Biochemistry & Molecular Medicine, MIND Institute, Genome Center, University of California Davis, Davis, CA*

---

**Background:** Among autistic individuals, a subphenotype with brain enlargement disproportionate to height (autism with disproportionate megalencephaly – ASD-DM) seen at 3 years of age is associated with co-occurring intellectual disability and poorer prognoses later in life. However, little is known about the genetic factors contributing to ASD-DM.

**Objectives:** In this study we aim to identify additional ASD-DM associated genes to better define the genetic etiology of this subphenotype of autism.

**Methods:** We identified *de novo* variants potentially contributing to ASD-DM using trio and quad whole genome sequencing data including 11 families from the MIND Institute's Autism Phenome Project (APP) and 89 families from the Simon's Simplex Collection (SSC) cohorts. We validated a subset of proband-identified loss-of-function variants on head-size phenotypes by generating knockout zebrafish using CRISPR gene-editing technology and automated morphometric imaging and analysis enabled by the VAST Bioimaging System.

Results: Through this analysis we have identified multiple genes previously associated with ASD-DM including CHD8, PTEN, and KMT2E. Identified loss-of-function variants include 16 SNVs and 1 duplication, overlapping a total of 18 genes. These genes are enriched for GO biological processes known to be disrupted in ASD, including cell cycle processes and histone proteins. To date, we have tested six putative ASD-DM genes using this pipeline, including *PAX5*, *SCP2*, *RPS6KA*, *YTHDF2*, *HEPACAM2*, and *FAM91A1*. Through screening thousands of larvae, we found two out of six putative ASD-DM genes tested show a head-size phenotype in our model system. This includes the gene *YTHDF2*, which we identified as partially duplicated in an ASD-DM proband, and inversely found that a deletion of this gene in a zebrafish knockout model leads to microcephaly.

Conclusions: The genes identified in this study represent promising putative candidate genes, enabling further advancement in the identification of relevant disease pathways, potential genetic therapy targets, and early detection markers in ASD-DM.

## VIRTUAL POSTER SESSION — GENETICS

### 512 - Genetics --- (V)

**512.099** (*Virtual Poster*) Association between Imputed Gene Expression for Selected Brain Tissues and IQ in Individuals with Autism Spectrum Disorder

**C. Humphreys<sup>1</sup>**, **S. Good<sup>2</sup>** and **X. Q. Liu<sup>1</sup>**, (1)Pharmacy, University of Manitoba, Winnipeg, MB, Canada, (2)Biology, University of Winnipeg, Winnipeg, MB, Canada, (3)Obstetrics, Gynecology, and Reproductive Sciences, University of Manitoba, Winnipeg, MB, Canada

Background: To date, gene expression studies for autism spectrum disorder (ASD) have identified major gene pathways, including synaptic function and WNT signalling, involved in ASD mechanisms (Quesnel-Vallières et al. 2019). However, there are major barriers in ASD research using the gene expression approach: one is the small sample size of available gene expression data, and the other is the difficulty in obtaining gene expression data from brain tissues.

Objectives: The purpose of this study is to explore the relationships between the imputed gene expression levels for five selected brain tissues and IQ using ASD individuals. General cognitive ability, as measured by IQ, is one of the ASD-related phenotypes because many ASD patients also have intellectual disability. The genes for IQ scores may overlap with the genes that affect the severity of ASD.

Methods: This preliminary study used ~35,086 genetic markers from chromosome 9 (generated using the Illumina Human 1M-single Infinium BeadChip or Human 1M-duo BeadChip) and three IQ measures (verbal, performance and full scale IQ scores based on the Wechsler Intelligence Scale for Children-III) in 1,157 cases with European descent from the Autism Genome Project (AGP) Consortium.

Genotype imputation was conducted using the Sanger Imputation Service with the Haplotype Reference Consortium data as the reference panel. The imputed and original genetic markers were then matched with the expression quantitative trait loci (eQTL) from the Genotype-Tissue Expression Database (GTEx v8). Five brain tissues, caudate (basal ganglia), cerebellum, cortex, frontal cortex, and hypothalamus, from GTEx were selected. The expression levels of genes for our AGP data were predicted using the overlapping GTEx eQTL weights and the program PrediXcan ((predict.py). The predicted gene expression levels were associated with IQ using PrediXcanAssociation.py.

Results: Of the 1,157 ASD cases, 85% are male with mean IQ scores of 82-86 (range 23-155 for 481-711 individuals) for the three different IQ measures. After genotype imputation and quality control, 292,852 genetic markers with minor allele frequency >1% were used to match with the GTEx eQTLs.

For the five brain tissues, we were able to match 52-54% of the eQTLs and obtained the imputed gene expression levels for 359 to 395 genes. After correction for multiple testing, one long intergenic non-protein coding RNA (LINC01235) which was expressed in the cerebellum was significantly associated with verbal IQ ( $p=0.00001$ ). For this gene, as the expression of LINC01235 in the cerebellum increased, the verbal IQ score decreased.

Conclusions: LINC01235 was previously associated with tumour progression and worse prognosis in gastric and breast cancer. The role of LINC01235 in ASD or intellectual disability is unknown. The results from this study show that LINC01235 could be a new gene for IQ in ASD individuals. Further investigation is needed to validate the relationship between LINC01235 and IQ and between LINC01235 and ASD using an independent dataset.

**512.100** (*Virtual Poster*) Autism Symptoms in Children and Adolescents with Fragile X, Angelman Syndrome, Tuberous Sclerosis Complex and Neurofibromatosis Type 1: A Cross-Syndrome Comparison

**K. Lubbers<sup>1,2</sup>**, **G. C. Dieleman<sup>1,2</sup>**, **E. M. Stijl<sup>1,2</sup>**, **D. A. Hagenaar<sup>1,2</sup>**, **L. W. ten Hoopen<sup>1,2</sup>**, **J. S. Legerstee<sup>1,2</sup>**, **P. F. de Nijs<sup>1,2</sup>**, **A. B. Rietman<sup>1,2</sup>**, **K. Greaves-Lord<sup>1</sup>**, **M. H. J. Hillegers<sup>1</sup>**, **B. Dierckx<sup>1,2</sup>** and **S. E. Mous<sup>1,2</sup>**, (1)Child and Adolescent Psychiatry/Psychology, Erasmus MC-Sophia Children's Hospital, Rotterdam, Netherlands, (2)ENCORE expertise center, Erasmus MC-Sophia Children's Hospital, Rotterdam, Netherlands

Background: Autism spectrum disorder (ASD) is a common comorbid disorder in various genetic syndromes. The etiology of ASD remains unclear, due to its heterogenic genetic origin and the heterogeneity in symptoms across individuals.

Objectives: This study aims to compare ASD symptomatology in syndromes with a known genetic origin, in order to reveal syndrome specific vulnerabilities that may serve as targets for early intervention and provide insight into the genetic pathways that underlie ASD.

**Methods:** We assessed ASD symptom severity in four groups of children/adolescents (aged 2-26 years) with syndromes that have high ASD comorbidity: Fragile X Syndrome (FXS, n=53), Angelman Syndrome (AS, n=74), Neurofibromatosis Type 1 (NF1, n=254) and Tuberous Sclerosis Complex (TSC, n=97), using the Autism Diagnostic Observation Schedule (ADOS) and the Social Responsiveness Scale (SRS). Assessments were part of routine clinical care and performed in all children seen at the ENCORE expertise center in Rotterdam, the Netherlands. We compared the syndrome groups to an idiopathic ASD group on total severity scores and subscale scores using a MANCOVA.

**Results:** Total scores and the percentage ADOS and SRS ASD classifications were highest for the FXS-group and lowest for the NF1-group. When including individuals with an ASD classification only, overall ASD severity was higher in the FXS and TSC groups than in the AS-group. Syndrome specific strengths and weaknesses included a relative weakness in AS for the creativity/play subscale (highest of all groups) and the reciprocal social interaction subscale (higher than NF1). Contrarily, the AS group showed a relative strength in the Social cognition, communication and motivation domains of the SRS compared to the FXS and TSC groups. NF1 showed a relative strength on the restricted interests and repetitive behavior scale (lowest of all groups).

**Conclusions:** Comparing the groups at subscale level revealed syndrome-specific strengths and weaknesses that would have gone unnoticed by looking solely at classifications or summary calibrated severity scores. Our findings underline the relevance of comparing ASD symptoms across syndromes and highlight the need for syndrome-specific ASD interventions.

#### **512.101 (Virtual Poster) Evaluation of Polygenic Risk Score Performance for ASD in High Risk Sibling Cohorts**

#### **Background:**

Longitudinal High Risk Sibling cohorts for Autism Spectrum Disorder (ASD) capture etiologically relevant developmental periods, and are likely to result in an enhanced number of observed cases, boosting statistical power. Incorporation of polygenic risk scores for ASD (ASD-PRS) in high-risk cohort studies can improve etiologic insights and prediction. Yet, ASD-PRS, derived from well-powered ASD GWAS results, have only been applied in the general population. Performance in high familial risk cohorts has yet to be investigated.

#### **Objectives:**

We derived ASD-PRS across three enriched-risk cohorts: the Early Autism Risk Longitudinal Investigation (EARLI) study, the Infant Brain Imaging Study (IBIS) and the Markers of Autism Risk in Babies Learning Early Signs (MARBLES) Study. All three are part of the Baby Siblings Research Consortium (BSRC). We use a pruning and threshold approach, and pooled studies to evaluate performance with ASD. We also associated ASD-PRS with the Mullen Scale or Early Learning (MSEL), a measure of childhood learning and IQ, and total score on the Social Responsiveness Scale (SRS), a measure of social ability in the general population.

#### **Methods:**

Genotyping was performed on 5M Illumina arrays for EARLI and IBIS, and the Mega Illumina array for MARBLES. After QC procedures, we imputed via the UMichigan server to the 1000G v5 reference panel. ASD-PRS was derived using PGC\_iPSYCH discovery results,<sup>1</sup> scored in PLINK for a range of discovery p-value thresholds, and standardized within each cohort. Associations with ASD status were assessed by logistic regression, accounting for sex, genetic ancestry, maternal education, maternal age at birth, and cohort membership. For MSEL and SRS, we combined ASD and typically developing siblings to perform linear regression, adjusting for the same covariates and including a term for ASD status.

#### **Results:**

Pooling data for high familial risk siblings across the three enriched-risk cohorts (71 ASD and 375 unaffected siblings), we find a suggestive association for ASD-PRS (discovery p-value threshold=0.10) with ASD. Contrasting the highest quintile for ASD-PRS with the bottom four quintiles, the increased odds for ASD is 1.7 (95%CI: 1.3,2.2; p=0.076). Combining the ASD and unaffected sibs while adjusting for ASD status, we also found a significant association of ASD-PRS at this same discovery threshold level with total score on the Mullen Scales of Early Learning (MSEL), such that an increase of one standard deviation unit in the ASD-PRS results in an average decrease of 2.1 points on the MSEL (95%CI: -3.6, -0.47; p=0.0114). No significant or suggestive results were found for SRS.

#### **Conclusions:**

We harmonize an ASD-PRS in three enriched-risk cohorts and show that it behaves intuitively as a tool for predicting ASD risk in this context, though we are underpowered due to sample size. Future efforts will expand our sample to include ASD probands and additional high familial risk siblings from other BSRC sites. Our increased sample size will also allow us to explore non-typically developing siblings and we plan to consider other ASD related traits, including behavioral and cognitive measures.

**512.102 (Virtual Poster)** Examining Quantitative Behavioral Phenotypes and Likelihood of Neurodevelopmental Conditions in Individuals with and without NRXN1 Gene Variants

Brodtkin**<sup>1</sup>, (1)Department of Psychiatry, Perelman School of Medicine University of Pennsylvania, Philadelphia, PA, (2)Department of Genetics, Perelman School of Medicine University of Pennsylvania, Philadelphia, PA, (3)Neuroscience Graduate Group, University of Pennsylvania, Philadelphia, PA, (4)Department of Psychiatry, UPENN, Philadelphia, PA, (5)Lifespan Brain Institute, Children's Hospital of Philadelphia, Philadelphia, PA, (6)Department of Biomedical and Health Informatics, Children's Hospital of Philadelphia, Philadelphia, PA

---

**Background:** Neurexins are presynaptic membrane proteins that are important to synaptic organization and function in the brain. Of the three neurexin genes in humans, *NRXN1* has been associated with several neuropsychiatric and neurodevelopmental disorders, including autism spectrum disorder (ASD) (Cuttler et al., 2021). Previous studies of human *NRXN1* variants have focused on categorical phenotypes (presence or absence of a diagnosis or behavior) (Bena et al., 2013; Dabell et al., 2013; Shehhi et al., 2019). Variability in *NRXN1*-associated phenotypes may be better captured using quantitative (dimensional) behavioral measures, in addition to categorical diagnoses.

**Objectives:** We aimed to characterize the phenotypes of individuals with *NRXN1* variants in a preliminary sample across several ASD-related behavioral dimensions as well as with likelihood for several common neurodevelopmental conditions.

**Methods:** Through the Autism Spectrum Program of Excellence, we have recruited individuals with *NRXN1* variants and their family members without *NRXN1* variants. In this preliminary sample, we identified 106 individuals with *NRXN1* variants based on either external genetic reports or by whole genome sequencing in our study. For family members (n = 22), their membership in the *NRXN1* variant / non-variant group was confirmed by internal whole genome sequencing only. All participants completed a battery of questionnaires covering multiple ASD-related dimensions, including overall ASD traits, social anxiety, executive functioning, the broad autism phenotype, and self-reported medical conditions and psychiatric diagnoses. Quantitative phenotypes for those with *NRXN1* variants and their family members without *NRXN1* variants were compared using the non-parametric Wilcoxon signed rank test. The impact of *NRXN1* variants on risk for selected psychiatric diagnoses (ASD, speech delay, motor delay, and epilepsy) was evaluated using chi-squared tests.

**Results:** While individuals with and without *NRXN1* variants (including intronic deletions, exonic deletions, and single nucleotide variants) appear to differ in quantitative phenotypes (Figure 1), none of these differences were significant in our preliminary sample. However, the difference in neurodevelopmental diagnoses was clear. Those with a *NRXN1* variant were more likely to have ASD ( $\chi^2(1, N = 120) = 11.28, p < 0.001$ ), speech delay ( $\chi^2(1, N = 120) = 16.12, p < 0.001$ ), and motor delay ( $\chi^2(1, N = 120) = 10.82, p < 0.01$ ). They were not more likely to have epilepsy ( $\chi^2(1, N = 120) = 2.18, p > 0.05$ ) than their family members without a *NRXN1* variant.

**Conclusions:** In our preliminary sample, categorical differences in psychiatric diagnoses based on *NRXN1* variants were clear, but quantitative differences in ASD-related phenotypes were not yet significant. Recruitment and data collection are still ongoing, and our goal is to balance the sample sizes to have greater power to identify quantitative phenotype differences. This ongoing study promises to provide further insight into aspects of the ASD phenotype that are associated with *NRXN1* variants.

**512.103 (Virtual Poster)** Inheritance Matters: Comparing Risk of Familial and De Novo CNVs for ASD

**J. Wolstencroft**<sup>1</sup>, **R. Srinivasan**<sup>2</sup>, **I. D. Imagine**<sup>1</sup>, **D. H. Skuse**<sup>3</sup> and **L. Raymond**<sup>4</sup>, (1)UCL GOS Institute of Child Health, London, United Kingdom, (2)UCL GOS ICH, London, United Kingdom of Great Britain and Northern Ireland, (3)Institute of Child Health, London, United Kingdom, (4)University of Cambridge, Cambridge, United Kingdom of Great Britain and Northern Ireland

---

**Background:**

Intellectual disability (ID) is characterised by significant limitations in cognitive functioning and adaptive behaviour and is often associated with behavioural and mental health problems at all life stages. Copy number variants (small structural chromosome changes; CNV) account for 14% of ID and some are associated with increased risk of psychiatric illness. CNVs can be newly occurring (*de novo*) or inherited (familial). ASD is associated both with ID and with genetic anomalies such as CNV.

**Objectives:**

This study compares the behavioural phenotype of children with ASD, recruited in a national UK study of ID of genetic aetiology, by genetic variant inheritance (*de novo*/familial).

**Methods:**

IMAGINE-ID is a national UK study of children with ID of known genetic origin that aims to identify genotype-phenotype risk. Our focus here is on those children (4-19 years) whose condition is due to a pathogenic Copy Number Variant (CNV). Children and young people (5 -19 years) were

ascertained from NHS Regional Genetics Centres, to which they had been referred for microarray testing because of early developmental delay. The Development and Wellbeing Assessment (DAWBA), the Strengths and Difficulties Questionnaire (SDQ) and the Adaptive Behaviour Assessment System (ABAS-3) were administered to caregivers. The DAWBA is a comprehensive diagnostic interview, which has been used in several national studies of children's mental health in the UK. The reliability of diagnostic decision making was established in collaboration with the national study team.

#### Results:

1,634 IMAGINE-ID children with a CNV participated in this analysis. 30.1% variants were *de novo*, 32.4% variants were familial and 37.5% variants were of unknown inheritance. For those where inheritance could be determined (n=1021) 58% were male and the mean age at ascertainment was 8.8 years (SD 3.8).

The proportion of children meeting diagnostic criteria for an ASD was substantially higher among those with a familial CNV (45.7%) compared to those with a *de novo* CNV (28.7%; RR 1.6;  $p<.0001$ ). We compared these subgroups in terms of their physical health, adaptive function, behavioural difficulties and co-occurring neuropsychiatric disorders. Measures of physical disability and adaptive function were similar in the two groups of children, but those whose ASD was associated with a familial CNV had significantly more behavioural/emotional difficulties (SDQ total scores) than those with a *de novo* variant ( $p<.0001$ ). Children with a familial variant were also more likely to have a conduct disorder than those with a *de novo* variant ( $p=.02$ ). No difference in the co-occurrence of emotional disorders or hyperactivity disorders by inheritance was observed.

#### Conclusions:

Familial CNVs that cause intellectual disability are significantly more likely to be associated with ASD than *de novo* CNVs. ASD associated with a familial variant has greater comorbidity in terms of behavioural difficulties and conduct disorders. The aetiology of this increased risk is not known, but the observation has important implications for management and genetic counselling.

#### **512.104** (Virtual Poster) Molecular Functions of ID/ASD-Associated MYT1L in CNS Development

**C. Jiayang**<sup>1,2</sup>, H. Gabel<sup>3</sup>, B. Clark<sup>4</sup>, S. Maloney<sup>2</sup> and J. Dougherty<sup>1,2</sup>, (1)Genetics, Washington University School of Medicine, St. Louis, MO, (2)Psychiatry, Washington University School of Medicine, St. Louis, MO, (3)Neuroscience, Washington University School of Medicine, St. Louis, MO, (4)Ophthalmology and Visual Sciences, Washington University School of Medicine, St. Louis, MO

---

**Background:** Human genetic studies have identified heterozygous mutations on Myelin Transcriptional Factor Like 1 (MYT1L) as the cause for ID/ASD-related MYT1L Syndrome. MYT1L is a pro-neuronal transcriptional factor whose overexpression along with BRN2 and ASCL1 can directly reprogram fibroblasts into neurons. Although many *in vitro* studies suggest that MYT1L mainly suppresses non-neuronal gene expression and cell proliferation to facilitate neuronal differentiation, recent *in vivo* studies utilizing the MYT1L knockout mouse model propose an opposite role for MYT1L as primarily an activator. Given that most MYT1L DNA binding studies have been performed in the overexpression system and limited data were generated *in vivo*, MYT1L's targets and how it regulates these target genes' expression under physiological conditions are largely unknown. Furthermore, MYT1L's molecular functions across different developmental time points and the mechanisms underlying MYT1L Syndrome etiology have not been well established.

**Objectives:** This study aims to identify ID/ASD-associated MYT1L targets *in vivo* and explore how MYT1L regulates the expression of target genes in different developmental time points and brain regions. Meanwhile, utilizing the MYT1L knockout mouse, the study tries to understand how MYT1L loss of function (LoF) contributes to disease pathogenesis.

**Methods:** We adapted Cleavage Under Targets and Release Using Nuclease (CUT & RUN) technique to map MYT1L DNA binding sites in mouse embryonic cortex, adult prefrontal cortex, and adult hypothalamus. Then, we compared MYT1L targets with published or newly generated RNA-seq and ATAC-seq on MYT1L knockout mouse datasets from corresponding time points and brain regions. This comparison allows us to dissect MYT1L's direct and indirect impacts on gene expression and shed light on mechanisms underlying disease phenotypes.

**Results:** We identified highly confident MYT1L DNA binding targets in the mouse embryonic cortex, adult prefrontal cortex, and adult hypothalamus. Although MYT1L appears to have many distinct targets at different developmental time points and brain regions, it shares some common ones related to neurodevelopment. Utilizing the MYT1L knockout mouse line, we also found MYT1L LoF alters its targets chromatin accessibility and corresponding genes expression. We further demonstrated such dysregulation affects cellular and circuit functions potentially associated with many disease phenotypes.

**Conclusions:** Our study revealed ID/ASD-associated MYT1L's molecular functions across development and brain regions in terms of DNA binding, chromatin accessibility, and transcriptional regulation *in vivo*. Meanwhile, we provided insights into the mechanisms by which MYT1L LoF leads to various phenotypes related to human MYT1L Syndrome.

#### **512.105** (Virtual Poster) Visual and Ocular Phenotypes in Neurodevelopmental Genetic Syndromes Associated with Autism Using Electronic Health Records

**A. DiCriscio**<sup>1</sup>, J. A. Little<sup>2</sup>, B. Harry<sup>3</sup> and V. Troiani<sup>1</sup>, (1)Geisinger Autism & Developmental Medicine Institute, Lewisburg, PA, (2)Ulster University, Coleraine, United Kingdom, (3)Geisinger, Danville, PA

---

**Background:** Atypical visual perception, such as ‘seeing the trees instead of the forest’, has been frequently documented in autism spectrum disorder (ASD) and is generally attributed to atypical brain function. However, relatively little research has characterized optometric anomalies in ASD, which may indicate atypical morphology or function of the eye, rather than the brain. Increased prevalence of refractive errors and optic nerve abnormalities in ASD have been found in a few studies with small sample sizes. One study used medical claims and electronic health record (EHR) data in a large sample and reported increased prevalence of ocular abnormalities in ASD patients. However, this one previous study determined ASD diagnoses from the EHR, rather than confirming ASD diagnoses with a clinical team with expertise in ASD diagnosis.

**Objectives:** In the current study, we establish visual and ocular phenotypes in patients with diagnoses conferred at an autism and neurodevelopmental clinic that is housed within an integrated health system. An integrated health system promotes coordinated care, facilitated by a shared EHR, and allows patients to receive general and specialty care within one system. We leverage these comprehensive patient EHRs to assess visual anomalies using existing optometry and ophthalmology records in a cohort of patients with confirmed ASD diagnoses, including clinical genetic screening results.

**Methods:** We evaluated the presence of atypical ocular features via manual chart review of EHR data in 563 patients (ages 3-21) across 3 groups: n=210 neurodevelopmental probands with a genetic syndrome associated with ASD (ND-ASD; e.g. 16p11.2 deletion, 15q11.2-q13.1 duplication and 22q11.21 duplication), n=156 with ASD diagnoses with no known genetic cause, and n=197 age and sex matched healthy controls (HC). We characterized ocular symptoms using a rubric based on the presence/absence of ocular features including including visual acuity, near visual function, refractive errors, atypical accommodation, stereopsis/oculomotor function, retinal function/structure, and photosensitivity/pupil response.

**Results:** Associations between ocular features and diagnostic group was assessed via Chi-squared with appropriate follow-up tests for group comparisons. See results reported in Figure 2. We find increased documentation of ocular features in ND-ASD probands as compared to both ASD and HC, including amblyopia, astigmatism and features of atypical accommodation ( $p$ 's<0.0140); strabismus ( $p$ 's<0.0008); and esotropia ( $p$ 's<0.0032). Additional analyses will focus on exploring whether individual differences in ocular impairment are associated with quantitative differences in ASD behaviors across diagnostic groups and describing ocular phenotypes within genetic syndromes in our patient cohort.

**Conclusions:** Results indicate that ocular and ophthalmologic anomalies are more frequently present in children with known genetic causes of ASD and neurodevelopmental features, with increased prevalence of specific ocular concerns of refractive errors and atypical oculomotor function. These results emphasize the importance of vision assessment in children with ASD, specifically in those pediatric patients with neurodevelopmental genetic syndromes. Our curation and description of specific ocular phenotypes in neurodevelopmental genetic syndromes may also lay the groundwork for linking brain-gene-behavior relationships and identification of ASD subtypes. Further, our results highlight the feasibility of retrospective chart review and the use of EHR data for discovering novel phenotypes associated with ASD.

#### **512.106 (Virtual Poster) Whole Exome Sequencing of Indian Autism Spectrum Disorder Simplex Families Identifies Increased Burden of Inherited Variations**

**A. SNM<sup>1</sup>, S. V.P.<sup>2</sup>, S. Durbagula<sup>1</sup>, A. Korlimarla<sup>1</sup> and A. Mysore<sup>1</sup>, (1)Centre for Advanced Research and Excellence in Autism and Developmental Disorders, St Johns Research Institute, Bengaluru, India, (2)Molecular medicine, St Johns Research Institute, Bangalore, India, (3)Centre for Advanced Research and Excellence in Autism and Developmental Disorders, St Johns Research Institute, Bangalore, India, (4)Center for Advanced Research and Excellence in Autism and Developmental Disorders (CARE-ADD), St. John's Medical College Hospital, St John's Medical College Hospital, Bangalore, India**

**Background:** Prevalence of Autism Spectrum Disorder (ASD) among Indian children below 10 years is varyingly estimated to be 1 in 88 to 1 in 400. ASD research in India has been limited to screening of few single nucleotide polymorphisms (SNPs). Globally, >10,000 ASD families have been sequenced contributing to the current knowledge on >1000 ASD associated genes. Despite displaying high inheritance, sequencing studies have emphasized *de novo* mutations (DNMs) as causal factors of sporadic ASDs. Studies addressing inheritance were conducted on concordant variants identified in multiplex families

**Objectives:** We hypothesized that subtle ASD traits in parents may accumulate overtime and cumulatively produce effects on probands. Thus, we performed the first trio Whole Exome Sequencing (WES) of 15 Indian simplex families of male ASD probands on Illumina HiSeq-platform with 100X coverage.

**Methods:** Data was processed in BWA, GATK and VarScan. Variants called were classified as DNMs or inherited/transmitted variants and annotated using VEP. To narrow-down on neuro-functional genes we devised a novel two-phased filtering strategy at the level of: (i) ‘variants’ to retain only truncating and splice variants, additionally non-synonymous SNPs predicted as damaging by more than 60% of the 25 SNP-effect prediction tools use; (ii) ‘genes’ to prioritize them based on their evolutionary and mutational sensitivity using a weighted scoring method involving Essential gene classification, Haploinsufficiency scores, Residual Variation Intolerance Score and Loss-of-Function scoring. Subsequently, functional enrichment, semantic similarity with high-confidence autism genes, protein-protein interaction and brain tissue expression analysis was performed to identify neuronally relevant genes.

**Results:** A total 17 DNMs across 17 genes were identified in 9 probands including previously known ASD genes- *TSC2*, *DEAF1*, *BRSK2* and *KCNK1*. Our custom weighted scoring picked novel strong-candidate DNM genes-*DOPEY1*, *ADCY1*, *RRS1* and *INO80* with neuronal functions. A total of 754 inherited genes were prioritized including 589 neuronal and behavioural genes, averaging 61 damaging genes per individual- although parents having passed Autism Quotient test. Probands carried an average of 6 strong-evidence ASD genes. Genes *USP45*, *HKDC1*, *CRAT* and *LRP2* carried variations in four subjects, 78 genes were recurrently mutated in more than two probands. Prominent PPI hubs were identified within gene-sets. Our robust genotype to phenotype correlation analysis has identified prominent behaviour genes- *CNTNAP2*, *WFS1*, *ANK3*, *CHD7*, *MYO7A*, *GABRB3* and *SPAST*. Sensory and motor function genes were frequently affected and were commonly inherited paternally. Brain tissue expression

analysis identified cluster of 95 prenatally up regulated genes enriched with neurodevelopmental roles such as axonogenesis, neurogenesis, neuron projection morphogenesis, synapse assembly etc., whereas post-natally over expressed genes were predominantly involved in neurotransmission, synaptic signaling, neurotransmitter receptor localization to postsynaptic specialization membrane etc.

Conclusions: Indian ASD families are heavily burdened by inherited variants than DNMs warranting further genetic studies in larger cohorts and investigation into broad autism phenotypes in ASD parents.

#### **512.107 (Virtual Poster)** 1M Genome Arrays May Not Provide High Quality Coverage for Some Top ASD Hits

#### Background:

Genome-wide association (GWA) for ASD, in the Danish iPSYCH+PGC samples<sup>1</sup>, has identified 5 genome-wide significant loci among 88 top ranked sites that were carried forward for replication. Several smaller studies in populations of European ancestry have used these findings to derive a polygenic risk score (PRS) for ASD (ASD-PRS) and associate with ASD and related traits. However, information about top hits and genome-wide discovery variant representation are not provided, making interpretation difficult.

#### Objectives:

We determine coverage for the top 88 ASD hits from the iPSYCH+PGC GWA results among three enriched-risk cohorts of European and mixed ancestry samples: the Early Autism Risk Longitudinal Investigation (EARLI) study, the Infant Brain Imaging Study (IBIS) and the Markers of Autism Risk in Babies Learning Early Signs (MARBLES) Study. We report pooled single variant associations and information loss genome-wide for the ASD-PRS in these cohorts, based on 1000 genomes European data.

#### Methods:

The Mega (MARBLES) and 5M Illumina (EARLI, IBIS) SNP arrays were used for genotyping. After standard QC procedures, we imputed via the UMichigan server to the 1000g v5 reference panel. Coordinates and names for the 88 top discovery variants were pulled from Grove et al.<sup>1</sup> supplementary material. We used Ensembl to search for proxy SNPs ( $LD\ r^2 \geq 0.80$ ) and assessed for overlap with the clean array and imputed (filtered for  $r^2 > 0.80$ ) data for each study. The top discovery variant or proxy association with ASD was then tested in each cohort using logistic regression, adjusted for genetic ancestry, sex, maternal age and maternal education.

To determine potential loss of information in the ASD-PRS from unrepresented variants across the genome, we created a score in the 1000g samples using the full variant panel, and then created a cohort-specific score, again in the 1000g samples, but instead using only the variants surviving each cohort's post-imputation QC. We report correlations between the full and cohort-specific scores.

#### Results:

Coverage for 5M arrays (see Table 1) is about 60% and improves to 100% with imputation. The Mega array showed only 32% coverage, which improved to 93% with imputed data, leaving 6 of the 88 loci unrepresented. We successfully replicated rs78298487 (logodds=-1.05; pval=0.023) and rs4750990 (logodds=-0.50; pval=0.017); the latter SNP was also identified in a SPARK+iPSYCH meta-analysis.<sup>2</sup> Generally, limiting to samples of European ancestry improved power. The correlations between the full and cohort-specific scores range from 0.87 to 0.90.

#### Conclusions:

We show that coverage of top ASD variants is moderate on measured genotype arrays, but can be recouped for dense 5M chips; however, some loci remain unrepresented with smaller 1M chips, even with imputation. Two of the top ASD variants were successfully replicated in all cohorts. We also provide a metric to represent coverage for a genome-wide ASD-PRS, and show that coverage is high across 1M and 5M arrays, though there is some information loss due to lack of representation of discovery variants even with the imputed data. Current work examining PRS coverage for iPSYCH, GDA and GSA arrays will also be presented.

#### **512.108 (Virtual Poster)** Children with Sexual Chromosome Trisomies: Linguistic or Socio-Communication Impairment?

**Background:** Sex Chromosome Trisomies (SCTs) are genetic syndromes characterized by an additional sex chromosome. Individuals with SCT present a variable physical and neuropsychological phenotype with a high frequency of language delays or impairments. There is mixed evidence of increased rates of social-communication difficulties akin to the core symptoms of Autism Spectrum Disorder (ASD). However existing data are limited to self-report and parent-report measures in individuals over 4 years of age often recruited from clinical samples and therefore potentially prone to referral bias.

**Objectives:** The study examined autistic traits in SCTs, employing for the first time a direct observational measure of social-communication difficulties in toddlers with a prenatal diagnosis to minimise bias.

**Methods:** Participants were 15 children with prenatal diagnosis of SCT (4 males with Klinefelter syndrome, 5 males with XYY syndrome and 6 females with Triple X syndrome) and 15 typically developing (TD) children (9 males and 6 females) assessed at 18 and 24 months. A free play caregiver-child interaction with a standard toy kit suitable for a range of developmental play levels was videorecorded and ten consecutive minutes were rated with the Brief Observation of Social Communication Change (BOSCC). To check agreement, 22% of the corpus was independently rated by a second observer. The inter-rater reliability on the double-coded videos was good on the Total score (intraclass correlation coefficients, ICC = .71). Expressive language and developmental quotient (DQ) were assessed respectively with the MacArthur-Bates Communicative Development Inventory (MCDI) and the Griffiths Mental Development Scales (GMDS).

**Results:** Children with SCT did not differ from TD children for levels of autism symptoms on the BOSCC Total Score at 18 ( $p=.567$ ) or 24 months ( $p=.056$ ), but had significantly lower expressive vocabulary skills on the MCDI both at 18 ( $p=.035$ ) and 24 months ( $p=.008$ ) and a significantly lower DQ on the GMDS both at 18 ( $p=.003$ ) and 24 months ( $p=.001$ ). Table 1.

**Conclusions:** Our findings of lower linguistic and global developmental skills in children with SCT than in TD children are consistent with previous evidence. However, in our study children with SCT did not show a higher prevalence of autistic traits, when compared with TD children. The inclusion criteria (age and prenatal diagnosis of SCT) which should have reduced the referral bias and the use of a direct observation measure arguably explain our findings, which are in contrast with previous evidence of increased rates of ASD-like symptoms in this population. The results must be interpreted cautiously due to the small sample size. In conclusion, while evaluating the skills of children with SCT, possible social communication difficulties should be distinguished from linguistic impairments.

#### 512.109 (Virtual Poster) Kbg Syndrome: Prospective Videoconferencing and Use of AI-Driven Facial Phenotyping

G. J. Lyon<sup>1</sup>, L. Guo<sup>2</sup>, E. Yi<sup>2</sup>, J. Park<sup>2</sup> and E. Marchi<sup>2</sup>, (1)the Institute for Basic Research in Developmental Disabilities, Staten Island, NY, (2)Institute for Basic Research in Developmental Disabilities, STATEN ISLAND, NY

---

#### Background:

KBG syndrome is a rare condition affecting approximately 200 individuals to date, with potentially several others remaining undiagnosed due to its nonspecific and rare nature. Patients have genetic variants in the Ankyrin Repeat Domain 11 (ANKRD11) gene and present with skeletal abnormalities including short stature, intellectual disability, and various cardiac, neurological, and endocrine abnormalities. While those with KBG syndrome share similar facial phenotypic traits, the overall features are non-distinct, and the recent development of artificial intelligence facial recognition software can be considered as an adjunct to diagnosis.

#### Objectives:

We expand on a cohort of 25 individuals from 22 families with molecular diagnoses of KBG syndrome (20 truncating mutations and five with missense mutations). We present eight additional individuals, all with truncating mutations of the ANKRD11 gene. The focus is on quantifying the presence of disease phenotypes in each individual, ranging from neurological abnormalities (i.e., seizures) to abdominal migraines, with the goal of providing better recommendations to families and improving detection and treatment of KBG syndrome.

#### Methods:

All 33 participants gave IRB approved consent and were prospectively interviewed by a single physician over the course of eight months via videoconferencing. All interview videos and clinical charts provided by the families were analyzed for human phenotype ontology terms that were input into an open-source database, Human Disease Gene website. Face2Gene (F2G) and GestaltMatcher, two leading genetic facial recognition algorithms, were used to analyze the facial features of all 33 participants for evidence of KBG syndrome.

#### Results:

A vast majority presented with skeletal (94%), neurologic (94%), and gastrointestinal (85%) abnormalities, typical of KBG syndrome. In our cohort, 20% had diagnoses of autism spectrum disorder (ASD) as well; however, the presentation appears to be mild or atypical since several were interactive, social and maintained good eye contact during videoconference. Other notable findings included three of seven with a cardiac murmur or

arrhythmia and an additional individual reporting pain insensitivity. Overall, six of 33 (18%) report impaired pain and tactile sensation. Another case of absence seizure was reported (32% total), along with two additional reports of EEG abnormalities (19% total). Lastly, half of the patients had a triangular face with a broad forehead and pointed chin, common to the disorder, and two additional individuals reported microcephaly – an uncommon finding, increasing the total in our cohort to 9%. When facial photos were analyzed by F2G, KBG syndrome was ranked amongst the top three most likely disorders in six of eight cases, and all had KBG in the top six.

## Conclusions:

Characterizing and quantifying phenotypes is imperative to the process of developing guidelines for management and treatment of KBG syndrome. Treatment plans can be complicated by the presence of additional diagnoses, such as ASD. Several unique findings were elucidated within our cohort, including the presence of microcephaly, abdominal migraines, presence of concurrent infections and hearing loss, and an increased prevalence of seizures. Future work will focus on retrospectively and prospectively analyzing the impact of seizures on later development in order to guide screening practices.

**512.110 (Virtual Poster)** Microdeletion of Chromosome 2 at q33.1 to q33.3 with Co-Occurring Autism Spectrum Disorder in a 14 Year Old Female **J. Hangauer<sup>1</sup>** and **T. Driscoll<sup>2</sup>**, (1)Psychology, Johns Hopkins All Children's Hospital, St Petersburg, FL, (2)Institute for Brain Protection Sciences, Johns Hopkins All Children's Hospital, St Petersburg, FL

**Background:** Microdeletion of chromosome 2 at q33.1 to q33.3 is an extremely rare chromosomal anomaly syndrome affecting an unknown number of individuals worldwide. Current case reports detail 20 confirmed cases in the literature and unique characteristics of affected individuals is still emerging in the literature including the intersection of the microdeletion and neurodevelopmental disorders including autism spectrum disorder and intellectual disability. A wide variety of abnormalities with physical features (e.g., hand and feet abnormalities; craniofacial disfigurement) as well as learning difficulties (e.g., learning disabilities, intellectual disability) have been found depending on the specific deletion extent. To date, the vast majority of empirical studies and case reports focus on medical complications such as craniofacial patterning rather than developmental and neuropsychological functioning. This case report details the unique characteristics of a 14-year-old female patient with confirmed microdeletion of chromosome 2 at q33.1 via chromosomal microarray (array-CGH) and co-occurring autism spectrum disorder (ASD) requiring substantial support with moderate intellectual disability and co-occurring attention-deficit/hyperactivity disorder. The patient has a history of behavioral challenges, cleft palate, seizure disorder, and apraxia. The patient is non-verbal and communicates using an augmentative communication device. The patient experiences longstanding sleep disturbance. Additionally, significant hyperactive and impulsive behaviors have been present with increasing behavioral challenges.

**Objectives:** To contribute to the growing body of literature on the 2q33.1 to q33.3 microdeletion phenotype as small interstitial deletions are not widely reported in the extant literature and co-occurring disorders (e.g., autism spectrum disorder in females and attention-deficit/hyperactivity disorder) identified through comprehensive psychological or neuropsychological evaluation even less so.

**Methods:** Parent consent was obtained. Patient assent was unable to be obtained secondary to functioning level. Patient completed a comprehensive psychological evaluation consisting of the ADHD-5, ADOS-2, BASC-2, BRIEF-2, Leiter-3, SCARED, SCQ, SRS-2, and Vineland-3. All measures were administered and interpreted by a licensed psychologist with significant experience assessing for autism spectrum disorder and intellectual disabilities. Prior chromosomal microarray analysis (4x180K G3 CGH+SNP) was completed by a physician board certified in clinical genetics confirming presence of microdeletion at 2q33.1 to q33.3 deletion.

**Results:** Patient met DSM-5 diagnostic criteria for autism spectrum disorder requiring substantial support with accompanying intellectual disability, moderate severity and language disorder. Additionally, DSM-5 criteria for attention-deficit/hyperactivity disorder was met. The results of the evaluation provided additional information for the patient's caregivers informing transition planning, additional therapies, and additional supports.

**Conclusions:** The results of the present case study correlate with extant results of previous findings related to microdeletion of the 2q33.1 to 2q33.3 emerging phenotype detailing the wide variation in symptomology that may be present. This case study provides further information to assist in gaining a more clear understanding of the effects of microdeletions on overall functioning from a neuropsychological standpoint and contributes to the literature on autism spectrum disorder in females and co-occurring rare genetic disorders for which there is a paucity of information while informing treatment recommendations.

## International and Cross-Cultural Perspectives

### PANEL — INTERNATIONAL AND CROSS-CULTURAL PERSPECTIVES

#### 206 - Identifying Interdisciplinary and International Approaches to Address Inequities in Criminal Justice System Contact Among Autistic Individuals

**Panel Chair: Lindsay Shea, A.J. Drexel Autism Institute, Philadelphia, PA**

**206.001 (Panel)** Global Criminal Justice Survey: Initial Scale Development and Validation

V. Gibbs<sup>1</sup>, A. M. Love<sup>2</sup>, T. W. Benevides<sup>3</sup>, M. C. Mogavero<sup>4</sup>, K. Hooven<sup>5</sup> and I. Basketbill<sup>6</sup>, (1)Aspect Research Centre for Autism Practice, Autism Spectrum Australia, Sydney, NSW, Australia, (2)Aspect Research Centre for Autism Practice, Autism Spectrum Australia (Aspect), Melbourne, VIC, Australia, (3)Occupational Therapy, Augusta University, Augusta, GA, (4)Department of Criminal Justice, Anthropology, Sociology & Human Rights, Georgian Court University, Lakewood, NJ, (5)Autism, Services, Education, Resources, & Training Collaborative (ASERT), Philadelphia, PA, (6)Philadelphia Autism Project, Philadelphia, PA

---

#### Background:

Core features of autism can place autistic individuals at increased risk for interactions with the criminal justice system and may also place them at a disadvantage at each step of the criminal justice process (Shea et al., 2021). Several studies have found that Autistic adults are largely dissatisfied with their treatment by police and report ongoing feelings of fear and distrust of police (Crane et al., 2016; Gibbs & Haas, 2020; Salerno & Schuller, 2019). Similarly, autistic people who have been involved in legal proceedings report communication and sensory challenges in the court environment along with difficulties navigating the court process (Helverschou et al., 2018; Maras, 2017). Criminal justice professionals, including police, legal personnel and corrections officers have been found to lack knowledge and confidence when interacting with autistic people (Crane, 2016; George et al., 2018), but little is known about criminal justice interactions on a global scale.

#### Objectives:

We aimed to evaluate international perceptions and experiences of criminal justice interactions between criminal justice professionals, autistic people, and parent/carers of autistic people. This presentation will describe the collaborative development process of a comprehensive international stakeholder survey and the results of the initial psychometric analyses.

#### Methods:

We used a clear and standardized scale development process to support the intended use of the multidimensional survey (AERA, APA, & NCME, 2014). Different aspects of reliability and validity including evidence for test content and internal structure were gathered using expert reviews, cognitive interviewing, a survey workgroup, pilot data collection ( $n = 48$ ), and a final data collection effort ( $n = 1661$ ). Experts who participated in the development process included 25 researchers, six criminal justice professionals, and people from the autistic community (six autistics, three carers). Experts were from ten countries to ensure diverse perspectives were considered during development. The survey was translated into 15 languages and forward- and backward-translation occurred to ensure scale reliability across countries.

#### Results:

This study produced initial psychometric evidence for the Global Criminal Justice Survey (GCJ). The GCJ is a dynamic survey with item totals responsive to the individual experiences of the survey respondent. The GCJ includes items for caregivers (GCJ-CG), criminal justice professionals (GCJ-P), and Autistic adults (GCJ-A). The survey measures four primary constructs: 1) perceived autism knowledge and 2) autism knowledge (for criminal justice professional respondents) and 3) perceived procedural justice and 4) police legitimacy (for autistic adults and parent/carers respondents). Results of this study will include a summary of contributions from stakeholders during the development phases and internal structure and reliability for each of the four constructs following data collection.

#### Conclusions:

This study demonstrates a process of collaborative scale development that can be replicated by other researchers provides reliability and validity evidence for the newly designed survey. Knowing more about the perceptions and experiences of interactions between criminal justice professionals, autistic people and parent/carers of autistic people will assist in developing comprehensive policy recommendations aimed at improving interactions between autistic people and the criminal justice system.

#### **206.002 (Panel) Autism in Courtrooms: A Scoping Review of Court Opinions in Criminal Cases Involving Autism**

D. Cooper<sup>1</sup>, E. B. Zimmerman<sup>2</sup>, J. Hyatt<sup>3</sup> and L. Shea<sup>4</sup>, (1)AJ Drexel Autism Institute, A.J. Drexel Autism Institute, Philadelphia, PA, (2)Drexel University Thomas R. Kline School of Law, Philadelphia, PA, (3)Department of Criminology and Justice Studies, Drexel University, Philadelphia, PA, (4)A.J. Drexel Autism Institute, Philadelphia, PA

---

#### Background:

Research demonstrates that autistic individuals interact with the justice system at relatively high rates (Rava et al., 2017; Tint et al., 2017), and are at increased risk of victimization (Weiss and Fardella, 2018). However, questions remain regarding the experiences of autistic individuals and outcomes that take place within courtrooms. Studies have shown that that autistic individuals find courtrooms to be challenging and lack opportunities for meaningful participation (Helverschou et al., 2018). In order to identify interventional opportunities for autistic individuals within courtroom settings, a thorough understanding of their experiences is needed. For example, little is known about charges that result in autistic individuals being present in courtrooms and if autism influences the circumstances of their outcomes. Examining court opinions in criminal cases that mention autism reveals common trajectories into the justice system, foundational information on how judges and court personnel perceive and respond to autistic individuals, and an accounting of how autism shapes court proceedings and decisions.

#### Objectives:

The purpose of this study was to systematically review court opinions in criminal cases involving autism in the United States to identify common charges, courtroom encounters, experiences, and outcomes.

#### Methods:

This review was conducted by systematically searching Westlaw and LexisNexis databases for court opinions in criminal cases that mentioned autism, Asperger's, or autism spectrum disorder at least five times between June 23, 2017, and June 25, 2020. This number was chosen after piloting the search strategy and reasoning that in cases where autism was raised fewer than five times, autism was quickly dismissed and likely had no substantive impact on the case. A data management toolkit was developed to collect key opinion information including, but not limited to, the context in which autism was raised, demographic information of the autistic individual, criminal charges, and the decision and sentencing from the court. At least two independent reviewers double-coded information from each included opinion and data was organized into a single spreadsheet for analysis. Descriptive data were employed to explore key factors in court opinions in criminal cases involving autism.

#### Results:

The search strategy identified 70 eligible opinions that took place during the study period. A majority (n=50) were at the state level and occurred across 24 states. Ohio had the highest number of opinions (n=11). Analysis of the included opinions is ongoing and will be completed by the INSAR 2022 annual meeting.

#### Conclusions:

Autistic individuals engage in courtroom proceedings in a multitude of ways, including as criminal defendants, complaining witnesses, and witnesses. These results will provide a much-needed perspective on this landscape. Findings will reveal how autism is raised in courtrooms and the ensuing responses by judges and court personnel, which can pinpoint opportunities for accommodations that yield more meaningful participation for autistic individuals in courtrooms and appropriate dispositions of criminal cases. Further, results will highlight areas for targeted interventions prior to entering a courtroom, including potential opportunities for diversion, by identifying commonly alleged charges and specific victimization experiences against autistic individuals.

**206.003** (*Panel*) Accommodating Persons with Complex Communication Needs in South African Courts

**D. Msipa and J. Bornman**, *Centre for Human Rights, University of Pretoria, Pretoria, South Africa*

---

#### Background:

Persons with disabilities are at higher risk of experiencing various forms of violence and abuse compared to non-disabled persons (World Report on Disability., 2011). The prevalence of such violence and abuse is even higher for persons with complex communication needs that make it difficult for them to report this violence and abuse (Saxton et al., 2001). Communication needs may result from various types of disabilities such as autism, intellectual disabilities, physical disabilities, or sensory disabilities (McConnell and Talbot., 2013). Irrespective of the cause, all persons with complex communication needs may find it difficult to access justice on an equal basis with others when they have been violated and abused.

In South Africa, witnesses typically give oral testimony in open court (Bekker., 1994). Persons with complex communication needs may, however, find it difficult to participate effectively in court because they have challenges with verbal communication. Consequently, few cases involving persons with complex communication needs are taken to court due to this communication barrier. However, with the right communication accommodations, persons with complex communication needs can participate effectively in court.

#### Objectives:

To describe and rank the ten most important communication accommodations needed to enable persons with complex communication needs to testify in court as perceived by legal practitioners in South Africa.

#### Methods:

The nominal group technique (NGT) will be used. NGT provides an opportunity for group brainstorming in a time-efficient manner whilst promoting input from all members, and preventing individual participants from taking over the discussion (Manera et al., 2019). Five to seven legal practitioners from Pretoria, South Africa, will be recruited to participate in the study. Prior to participation in the study, participants will be required to complete a consent form, a biographical questionnaire, and read the proposed court accommodation guidelines as background reading (White, 2021). Participants will first be asked to generate as many communication accommodations as possible. Thereafter, the complete list of accommodations will be reviewed, duplicates removed and similar accommodations grouped together. Subsequently, participants will be asked to rank these accommodations using group consensus.

#### Results:

During the preparatory phase, an extensive list of all court accommodations was compiled (White., 2021). This document will constitute background reading for the participants. It is therefore expected that the participants will be able to generate some accommodations and provide an opinion about which ones they deem to be the most important. Data for the main study will be collected in early 2022.

#### Conclusions:

A large number of persons with complex communication needs are abused and have a need to testify in court, yet very few of these cases go to court. One of the reasons for this is the fact that there is insufficient knowledge about how to accommodate persons with complex communication needs in court. This study will create awareness and open up possibilities for this to happen in future. It will also empower legal practitioners to accommodate these individuals in court.

#### **206.004 (Panel) Investigative Interviewing with Autistic People: Moving Towards Best Practice**

**R. Bagnall and K. L. Maras, Psychology, Centre for Applied Autism Research, University of Bath, Bath, United Kingdom**

---

#### Background:

Investigative interviews are a crucial evidence-gathering stage within the criminal justice system (CJS), yet they are also socially and cognitively demanding for interviewees. Social and cognitive differences experienced by autistic people mean that investigative interviews are especially challenging for this population. For example, understanding others' mental states, interpreting social contexts, recalling personally experienced events from memory, and engaging in reciprocal social communication are all often difficult for autistic people. These characteristics constitute significant barriers to autistic adults providing credible, accurate and reliable interview statements during criminal investigations unless a more enabling environment is provided.

In this presentation, we will discuss the key issues faced by autistic adults and CJS professionals during investigative interviews; and introduce our emerging research findings with autistic witnesses and suspects.

#### Objectives:

Our ongoing series of studies are separated into two distinct research strands:

(1) Investigative interviewing with autistic witnesses; (2) Investigative interviewing with autistic suspects

Across these two research strands, we aim to better understand:

1. How communication and cognition in autism impacts ability to provide accurate and reliable information during investigative interviews
2. How autistic adults' truthful and deceptive verbal behaviour during investigative interviews may be perceived
3. How autistic people and police interviewers experience and describe the challenges of investigative interviewing
4. How interviewing practice can be adapted to support social cognitive characteristics of autism

#### Methods:

Across research strands a, b, and d our primary research methods are robust experimental studies with age- and IQ-matched autistic and non-autistic interviewees. Here, autistic and non-autistic adults undertake (witness and suspect-relevant) tasks upon which they are subsequently interviewed using either standard interviewing practice or adapted methods, tailored to the social cognitive needs of autistic adults. We also employed qualitative methods to examine the challenges of investigative interviewing with autistic adults (c). Qualitative analyses of real-life police suspect interview transcripts with autistic adults alongside large-scale online surveys examined the investigative interview experiences of autistic adults and police interviewers.

#### Results:

Our current and emerging findings indicate that, when questioned using current (unmodified) witness and suspect interviewing practice, autistic people can have greater difficulty providing crime-relevant information that is accurate, detailed, and specific. Our findings also indicate that, even when providing truthful accounts, autistic interviewees can display verbal cues associated with deception. Further, autistic adults and police interviewers describe significant social and cognitive challenges in their experiences of investigative interviewing. However, the use of investigative interviewing models that are adapted to the needs of autistic adults can help to improve interview performance.

#### Conclusions:

The pathway through the CJS for autistic victims, witnesses and suspects provides numerous challenges and barriers to inclusivity and justice. The investigative interviewing stage is no exception. Our research demonstrates an urgent need for investigative interviewing models that are responsive to the social cognitive needs of autistic victims, witnesses, and suspects. Our findings describe directions for future research, and crucially provide clear recommendations to support the move towards best practice investigative interviewing with autistic people.

## PANEL — INTERNATIONAL AND CROSS-CULTURAL PERSPECTIVES

### 224 - Understanding and Addressing Family Needs in Very Low-Income Contexts: Perspectives from Sub-Saharan Africa

**Panel Chair: Rosa Hoekstra**, *Department of Psychology, King's College London, London, United Kingdom*

**224.001 (Panel)** Empowerment of Caregivers Raising Children with Autism and Other Neurodevelopmental Conditions in Ethiopia  
**Z. Szlamka<sup>1</sup>, I. Ahmed<sup>2</sup>, B. Gebru<sup>1</sup>, M. Kinfe<sup>3</sup>, C. Hanlon<sup>4</sup> and R. A. Hoekstra<sup>5</sup>**, (1)King's College London, London, United Kingdom, (2)Addis Ababa University, Addis Ababa, Ethiopia, (3)Department of Psychiatry, School of Medicine, College of Health Sciences, Addis Ababa University, Addis Ababa, Ethiopia, (4)Addis Ababa University and King's College London, Addis Ababa, Ethiopia, (5)Department of Psychology, King's College London, London, United Kingdom

#### Background:

The global burden of neurodevelopmental disorders (NDDs), including autism spectrum disorder affects low-and middle-income countries disproportionately: access to support programmes is largely unequal, usually favouring families from educated, urban-dwelling backgrounds and higher socio-economic status. Given the relative powerlessness of families raising a child with a NDD, their empowerment has long been in focus in global health service development.

#### Objectives:

We explored ways in which service development can include empowerment approaches for families raising a child with a NDD and their communities in Ethiopia. We did so by looking at perceptions, experiences and expected outcomes of empowerment.

#### Methods:

We conducted a qualitative, phenomenological study to explore the variety of views of stakeholders. Sixty-three semi-structured qualitative interviews were conducted in Amharic (n=19) or English (n=44) with: 1) caregivers of children with NDDs (n=15); 2) community health workers (n=5); 3) representatives of non-governmental organisations (NGOs) working with families and children with NDDs (n= 17); 4) school leaders and teachers (n=7); 5) clinicians (n=11); and 6) representatives of local health, education, and social care authorities (n= 8). Interview guides were developed iteratively and separately for each participant group. Interviews were conducted in capital Addis Ababa, and rural towns Butajira and Bahir Dar. All interviews were transcribed and those in Amharic were translated to English. Data were analysed thematically using NVivo 12.

#### Results:

Overall, four main themes were developed: The impact of poverty on the quality of life of families with NDDs; Caregiving from a gendered perspective; The experiences of single mothers; and Experiencing violence, abuse or discrimination based on gender.

All caregivers discussed how difficult they find it to make ends meet: many cannot work as they are the ones taking care of the child with an NDD. When talking about caregiving, most participants agreed that in Ethiopia it is generally considered a women's task. Clinicians mentioned that it is typically the mother who brings the child to the hospital, while the father considers key family-related decisions. Professional participants mentioned that they frequently come across mothers who are single as their partner left, often because of having a child with an NDD, or because the pregnancy was unplanned. For some mothers separating from their husband was a choice to avoid abuse and improve their children's life conditions. Several mother participants disclosed they faced domestic violence and described how this affected their everyday life. Some thought that they could not ask for help from the community as speaking negatively about their husband would be discouraged; some mothers thought their husband's abusive behaviour may be the cause of their child's NDD.

#### Conclusions:

Mothers and especially single mothers face unique challenges when raising children with NDDs in Ethiopia. Service development and empowerment approaches should include addressing poverty, potential domestic abuse, and gender-based discrimination and violence to support the quality of life of families.

**224.002 (Panel)** Service Provider and Caregiver Expectations for Children with Autism or Intellectual Disabilities in Ghana  
**M. Washington-Nortey<sup>1,2</sup>, Z. Serpell<sup>1</sup> and A. Anum<sup>3</sup>**, (1)Psychology, King's College London, London, United Kingdom, (2)Department of Psychology, Virginia Commonwealth University, Richmond, VA, (3)Department of Psychology, University of Ghana, Accra, Ghana

**Background:** It is well known that teacher expectations for children with autism spectrum disorders (ASD) or intellectual disabilities (ID) can inform their instructional goals and teaching strategies (Padeliadu et al., 1998). Recent studies from the African continent also indicate that, even after receiving specialized training in developmental disabilities, health officers in Ethiopia have low expectations for children with ASD (Tilahun et al., 2019). However, few studies have critically explored the service providers' expectations for children with autism or other developmental disabilities

on the African continent or compared these expectations to caregiver expectations. An investigation into service provider expectations is necessary to inform strategies to improve quality of life outcomes among children with ASD or ID, especially in low-resource African settings.

Objectives:

- (1) To investigate service providers' (i.e., teachers and health officers) expectations for children with ASD or ID in Ghana.
- (2) To examine differences between service providers' and caregivers' expectations of Ghanaian children with ASD or ID.

Methods: To assess service provider expectations, we used a mixed-methods exploratory sequential design (Creswell & Plano Clark, 2011) that included qualitative concept mapping (Kane & Trochim, 2007) followed by quantitative survey data collection. In the concept mapping phase, teachers and health officers ( $n=9$ ) shared their expectations for children with ASD or ID. Subsequently, a larger group of teachers ( $n=39$ ), health officers ( $n=38$ ), and caregivers ( $n=51$ ) of children with ASD or ID rated these shared expectations on two criteria: the importance of the expectation and the likelihood of occurrence. We analysed the data using hierarchical clustering procedures and Multivariate Analysis of Variance (MANOVA).

Results: Concept mapping results evidenced unique culture-specific expectation clusters and other more universal expectation clusters for children with ASD or ID. The expectation clusters were labelled independence, *love and acceptance*, *equal social rights and opportunities*, *vocational rights and protections*, *educational rights and opportunities*, *educational policy and practice*, *government policy and involvement*, *involvement of religious institutions*, and *professional and caregiver training* (see Figure 1). MANOVA results from the quantitative follow-up showed there were significant differences between parents, teachers, and health officers in their perceptions of the importance (Wilks'  $\Lambda=.528$ ,  $F_{(18,124)}=2.60$ ,  $p=.001$ , partial  $\eta^2=.274$ ) and likelihood (Wilks'  $\Lambda=.608$ ,  $F_{(18,150)}=2.351$ ,  $p=.003$ , partial  $\eta^2=.220$ ) of a child with ASD or ID attaining these expectations. Post-hoc analysis revealed significant differences between parents and service providers on the likelihood criterion of almost all expectation clusters and a few significant differences on the importance criterion (see Table 1). However, there were no significant differences between service providers on any cluster's importance or likelihood criteria.

Conclusions: Findings show that whereas expectations reported in extant Western literature focuses only the child (e.g., Ivey, 2001), Ghanaian service providers conceptualize child expectations within a broader ecology. The differences between stakeholder groups highlight the importance of open conversations when planning interventions for specific children. Additionally, clusters like *professional and caregiver training* represent calls for action and denote areas of need, consistent with gaps identified in prior Ghanaian-based studies (Wireko-Gyebi & Ashiagbor, 2018).

**224.003 (Panel)** Findings of a Brief Caregiver Well-Being Programme for Caregivers of Children with Developmental Disabilities in South Africa **L. Schlebusch<sup>1</sup>, N. Chambers<sup>2</sup> and P. J. de Vries<sup>3</sup>**, (1)Centre for Autism Research in Africa, Division of Child and Adolescent Psychiatry, University of Cape Town, Cape Town, South Africa, (2)Centre for Autism Research in Africa, Division for Child and Adolescent Psychiatry, University of Cape Town, Cape Town, South Africa, (3)Centre for Autism Research in Africa, Division of Child & Adolescent Psychiatry, University of Cape Town, Cape Town, South Africa

Background: The complexities of disability, limited psycho-social support, poverty, and stigma can negatively impact caregivers - leaving them distressed, isolated, and fatigued. Caring for caregivers' well-being and mental health is a first step in supporting their capacity to provide nurturing care for their children. Interventions in this area are lacking, especially in low-resource settings. The World Health Organization developed a caregiver skills training programme (WHO CST programme) for families of children with developmental delays, disorders and/or disabilities (DD) to be suitable for use in low-resourced settings. Included in the WHO CST package is an optional 3-session caregiver well-being programme. The programme is based on Acceptance and Commitment Therapy – a mindfulness-based behavioural therapy that can help caregivers of children with a range of psychological and physical difficulties to accept what is out of their control and commit instead to values-driven actions that enrich their lives.

Objectives: Our study investigated whether this ultra-brief, 3-session programme was feasible when delivered to caregivers of children with DD in a rural South African town.

Methods: First, we adapted the WHO CST intervention to the South African context. The programme was then delivered by trained facilitators who met once a week for three weeks with a group of caregivers. The two-hour sessions included stories, exercises and group discussions to convey key messages and skills. We used mixed methods, including several measures and multiple informants (caregivers, facilitators, and independent observers) to assess the programme's feasibility and acceptability.

Results: **Caregivers:** Eleven Black South African caregivers (ten mothers and one grandmother) participated in the study. Just over half the caregivers were single parents, just under half had no university education, and only two had full-time employment.

**Children:** The WHO does not require a diagnosis for a DD to participate in their programme, and in this sample, eight children were reported to have a confirmed diagnosis, which included intellectual disability, autism spectrum disorder, communication disorder, ADHD, cerebral palsy, epilepsy and tuberous sclerosis.

**Feasibility:** The overall acceptability and feasibility impressions of participants were overwhelmingly positive as reflected in the sessional feedback forms completed by facilitators, observers and caregivers, as well as individual interviews with all caregivers following the programme. The programme shows promise of being successful with the intended population. Before the programme, caregivers reported high levels of psychological distress, depression and anxiety. After the programme, caregivers showed positive improvements in the expected directions on all quantitative measures. We noted statistically significant changes on the Generalized Anxiety Disorder Scale ( $t=-1.54$ ,  $p<.036$ ,  $d=.73$ ), Multidimensional Scale of Perceived Social Support ( $t=0.65$ ,  $p<.037$ ,  $d=.72$ ), and Family Impact of Childhood Disability Scale ( $t=5.54$ ,  $p<.021$ ,  $d=.83$ ). This indicates that

caregivers reported less anxiety, and noticed improved social support from others, and more positive impacts about their child with a disability following the programme.

**Conclusions:** Our study found that the WHO Caregiver Well-being programme shows promise as a feasible and acceptable intervention for improving caregiver mental health and well-being in South Africa, with the potential for rapid dissemination and scale-up.

**224.004 (Panel) Acceptability and Feasibility of the World Health Organization 's Caregiver Skills Training Programme for Developmental Disabilities Delivered By Non-Specialists in Rural Ethiopia**

**T. Z. Kebede<sup>1</sup>, B. T. Tekola Gebru<sup>2</sup>, M. Kinf<sup>3</sup>, K. N. Koly<sup>4</sup>, R. Abdulrahman<sup>5</sup>, F. Girma<sup>3</sup>, C. Hanlon<sup>6</sup>, P. J. de Vries<sup>7</sup> and R. A. Hoekstra<sup>2</sup>,**  
(1)Department of Psychiatry, University of Cape Town, Addis Ababa, South Africa, (2)Department of Psychology, King's College London, London, United Kingdom, (3)Department of Psychiatry, School of Medicine, College of Health Sciences, Addis Ababa University, Addis Ababa, Ethiopia, (4)Health System and Population Studies Division, International Centre for Diarrhoeal Disease Research, Bangladesh (icddr,b), Dhaka, Bangladesh, (5)Department of Psychiatry, Yekatit 12 Hospital Medical College, Addis Ababa, Ethiopia, (6)Addis Ababa University and King's College London, Addis Ababa, Ethiopia, (7)Centre for Autism Research in Africa, Division of Child & Adolescent Psychiatry, University of Cape Town, Cape Town, South Africa

**Background:** Autism and other developmental disabilities are common in low- and middle-income countries (LMIC). However, services to address the needs of this group in LMIC are almost non-existent. The World Health Organization (WHO) developed a Caregiver Skills Training (CST) programme that can be delivered in global contexts. The WHO-CST programme was previously adapted for Ethiopia and pre-tested in an urban Ethiopian clinical setting, facilitated by specialists, indicating good acceptability and feasibility. Given the lack of specialists and Ethiopia's largely rural population, delivery by non-specialist providers and in rural settings is an important next topic of investigation.

**Objectives:** To explore the acceptability and feasibility of delivery of the WHO-CST by non-specialists in rural Ethiopia.

**Methods:** A qualitative study design was used. In-depth interviews were conducted with caregivers of a child with a developmental disability who participated in two rural pilots of the WHO-CST programme (n=19). Additionally, four focus group interviews were conducted with non-specialists (n=9) who facilitated these pilots. Seven facilitators were interviewed twice, once after the first and once after the second pilot. Topic guide questions centred around informants' positive and negative experiences with the programme and included questions relating to programme content and delivery structure. Data were analysed using framework analysis.

**Results:** Four themes were developed, mapping onto the framework created for this analysis. 1) Programme content: All participants found the adapted programme content acceptable and relevant to their contexts. Facilitators identified that some illustrations from the participant booklet were contextually incompatible with the rural setting and not all toys suggested in the booklet were available to families. Facilitators indicated that some concepts and techniques were challenging and required extra practice and time to explain to caregivers. An additional challenge for facilitators was tailoring content to meet the participants' different literacy levels. 2) Programme facilitation: Caregivers found programme facilitation by non-specialists acceptable, and using local non-specialists was essential to ensure caregivers who were more comfortable speaking local languages could participate. 3) Training Modalities: Participants indicated that the training modalities, including home visits, group training and ongoing supervision, were acceptable and feasible. Caregivers raised long travel distances and lack of childcare as barriers to attending sessions. Facilitators also spoke of challenges travelling to families' homes. Caregivers were hesitant to engage in role-plays during the training. Practising homework between sessions was difficult for caregivers. 4) Overall programme perceptions: Participants uniformly indicated the programme addressed a need and showed interest in future use of the programme. Participants recommended follow-up training for the sustainability of benefits. Caregivers emphasised how the programme helped them understand their child's problems and improve their skills to support their child. Facilitators highlighted having acquired new knowledge and skills relating to developmental disabilities. The absence of educational provision for children with developmental disabilities in rural Ethiopia remains an important unmet need.

**Conclusions:** The WHO-CST programme delivered by non-specialists is acceptable and feasible in rural Ethiopia, with the inclusion of some modifications and simplification of the programme content. These findings may have relevance to low-resource contexts worldwide.

**PANEL — INTERNATIONAL AND CROSS-CULTURAL PERSPECTIVES**

**225 - The Impact of the COVID-19 Pandemic on Families with Children with ASD Around the World**

**Panel Chair: Linda Dekker,** Department of Psychology, Education & Child Studies, Erasmus University Rotterdam, Rotterdam, Netherlands, Rotterdam Autism Consortium (R.A.C.), Rotterdam, Netherlands, Department of Psychology, Education & Child Studies, Erasmus University Rotterdam, Rotterdam, Netherlands, Rotterdam Autism Consortium (R.A.C.), Rotterdam, Netherlands

**225.001 (Panel) Psychiatric Outcomes and Models of Care in the United States for Children with Autism Spectrum Disorder during the COVID-19 Pandemic**

**R. A. Vasa,** Kennedy Krieger Institute, Baltimore, MD

**Background:** Children with autism spectrum disorder (ASD) are at elevated risk for psychiatric problems in response to the COVID-19 pandemic. Factor contributing to this risk include high rates of pre-pandemic psychiatric comorbidities and difficulties accessing psychiatric care, as well as the pandemic's disruption to routines and access to necessary psychiatric, educational and developmental services.

**Objectives:** The goals of this talk are to: 1) understand the psychiatric and behavioral outcomes of children and adolescents with ASD in the United States during the pandemic and how this may vary based on sociodemographic factors; 2) describe adaptations to clinical service models developed in the United States to address the mental health needs of children and adolescents with ASD during the pandemic.

**Methods:** The presenter will provide an evidence-based review of the current research on psychiatric and behavioral outcomes, which will include both strengths and limitations of current studies, and a comparison with other studies across the globe. The presenter will also describe innovative and adapted clinical mental health models that serve children and adolescents with varying levels of ASD severity who present with a wide variety of psychiatric and behavioral presentations. This will include a discussion on how to effectively conduct telepsychiatry visits, diagnose and treat common psychiatric disorders, and prevent and address mental health crisis. The presenter, who is the director of a psychiatric program of a major university-affiliated ASD center and has extensive experience working with this population, will also infuse the presentation with clinical and program building experiences. Clinical and administrative challenges of implementing these models will be discussed. Case examples will be included.

**Results:** Attendees will gain knowledge about the current literature on psychiatric outcomes of children with ASD during the COVID-19 pandemic in the United States. They will also be able to identify opportunities to improve their current models of psychiatric care for the ASD population, with the goal of delivering coordinated and collaborative psychiatric care for this population both now during these difficult times and in the future.

**Conclusions:** Children and adolescents with ASD are vulnerable to the effects of the COVID-19 pandemic. It is critical that every clinician working with children with ASD population is attuned to the psychiatric impact of the pandemic on the ASD population, and that psychiatric programs continuously strive to deliver best-practice care.

**225.002 (Panel) The Impact of the COVID-19 Pandemic on Emotional Well-Being and Educational Well-Being in Autistic Children**

**R. Plak<sup>1</sup>, R. Rippe<sup>1</sup>, H. Swaab<sup>1</sup> and S. Begeer<sup>2</sup>, (1)Leiden University, Leiden, Netherlands, (2)VU University Amsterdam, Amsterdam, Netherlands**

---

**Background:** The extent to which a child with autism spectrum disorder experiences problems in daily life depends on a combination of child characteristics and environmental factors. Pre Covid-19, little was known about the role of the environment on autism. No child with autism is the same and will react the same to their environment. Due to the radical change in the world, we were able to determine the level of emotional well-being as well as their educational well-being of children with autism before and during the COVID-19 pandemic. In addition, we draw attention to subgroups of autistic children.

**Objectives:** We addressed the question whether emotional well-being and educational well-being in autistic children in the Netherlands changed over time, pre-COVID-19 (T0) during COVID-19 wave I (T1) and COVID-19 wave II (T2). In addition, we aimed to determine effects of sociodemographic, psychosocial and parenting predictors on well-being. Finally, we aimed to define subgroups of autistic children that show positive changes in well-being during the COVID-19 pandemic.

**Methods:** Pre COVID-19 data from the Netherlands Autism Register (NAR)- a longitudinal register- is combined with data from adult participants (caregivers of children with ASD) who completed questionnaires about their child regarding the COVID-19 context of their family, emotional problems in their autistic child during the COVID-19 pandemic that may have occurred, child's fear of contracting COVID-19, how the COVID-19 measures are experienced, educational well-being, how education during COVID-19 is experienced and parental stress during the pandemic.

**Results:** Over time, a significant decrease in total experienced difficulties was found, which remained significant after adjustment for sociodemographic characteristics such as age and gender. Significant additional factors were psychosocial problems, social contacts satisfaction and worry about getting a COVID contamination. This was reproduced only in subdomains of hyperactivity, problems with peers and prosocial behavior.

The change in total amount of experienced difficulties, as well as in emotional problems could best be described by six different response patterns. Three patterns showed a decrease of reported difficulties since and during COVID, albeit at a different rate or at different base level. Other patterns showed either no change or increase. Changes in hyperactivity, peer problems and prosocial behavior were best represented by respectively eight, four and five distinct response patterns, with similar interpretations as for the total difficulty score.

Educational wellbeing and parental stress showed no change during COVID. In either wave it could not be significantly predicted by household size, working status, being in a crucial profession nor by parental efficacy to aid in the child's (home) education.

**Conclusions:** The COVID-19 pandemic has revealed differential reactions in autistic children in the Netherlands. Children showed on average a positive response to the pandemic situation through lower reported difficulties, both at aggregated and at subdomain level. Some children were however seemingly unaffected or negatively affected. Factors uniquely associated with changes in wellbeing were psychosocial problems, social contact satisfaction and worrying about COVID contamination. Parental stress was high and showed no change nor predictive household or professional factors during the pandemic home situation.

**225.003 (Panel) Coping with COVID: Autistic Traits and Mental Health Symptoms of Autistic Youth Early in the Pandemic**

**C. McMorris<sup>1</sup>, K. Turner<sup>2</sup>, J. A. Weiss<sup>3</sup>, S. J. Howe<sup>2</sup>, H. D. Sanguino<sup>2</sup>, C. M. Kerns<sup>4</sup> and M. Ames<sup>5</sup>, (1)Department of Paediatrics, University of Calgary, Calgary, AB, Canada, (2)University of Calgary, Calgary, AB, Canada, (3)Psychology, York University, Toronto, ON, Canada, (4)University of British Columbia, Vancouver, BC, Canada, (5)Department of Psychology, University of Victoria, Victoria, BC, Canada**

---

**Background:** Autistic youth are at heightened risk for experiencing mental health issues, and pandemic-related stressors pose a threat to their wellbeing. Indeed, autistic youth are experiencing worsening sleep related problems and decreased emotional and social wellbeing during the pandemic. Similarly, caregivers have reported significant disruptions to services that have severely impacted their youth and family, with autistic youth showing more prominent autistic traits and their families experiencing moderate distress during the pandemic. Despite early reports and anecdotal evidence outlining that autistic youth may be especially vulnerable to reduced wellbeing during the pandemic; no study has examined what factors may contribute to increased symptomology and poorer overall mental health

**Objectives:** This study investigated how autistic youth are coping by 1) describing caregiver-reported youth mental health prior to and during the pandemic; and 2) using the developmental-ecological framework to explore individual, caregiver, and environmental factors associated with autistic traits, social-emotional symptoms, and overall mental health.

**Methods:** 582 caregivers ( $M_{AGE} = 36.9$  years,  $SD = 6.4$ ) of autistic children ( $M_{AGE} = 8.4$  years,  $SD = 3.3$ ) completed an online survey between June and July 2020. Caregivers provided information on demographics, retrospective reports of their child's pre-COVID and current mental health, and their child's autistic traits and social-emotional symptoms, along with their own perceived stress. Caregivers also rated the degree of COVID-related household and service disruption.

**Results:** Descriptive statistics were calculated to summarize demographic information about caregivers and youth, as well as a series of hierarchical linear regressions for each of the primary outcomes of interest (i.e., autistic traits, social-emotional symptoms, caregiver-reported youth overall mental health). For each regression, the following variables were included in each step: 1) demographics (i.e., child age and gender, household financial status); 2) child variables (i.e., pre-existing mental health condition, autism trait severity); 3) caregiver perceived stress; and 4) environmental variables (i.e., household and service disruption due to COVID-19).

Respondents reported their youth experienced increased autistic traits (51.7% - 54.3%), behaviour problems (49.8%), anxiety (50.5%), and low mood (49.7%) during the pandemic. Caregivers also reported that autistic youth demonstrated poorer overall mental health during the pandemic. Increases in autistic traits were associated with older youth age, experiencing household financial difficulty, higher caregiver perceived stress, and greater household and service disruption. These same variables, plus being female and the youth having a pre-existing mental health condition, were associated with increased social-emotional symptoms. Lastly, less household financial difficulty, youth having no pre-existing mental health condition and less severe autism, lower caregiver stress, and less service disruption was associated with better overall youth mental health.

**Conclusions:** More than half of autistic youth in this study experienced increased autistic traits, behaviour problems, anxiety, and low mood. Poorer overall youth pandemic mental health was also reported. We found several developmental-ecological factors associated with increased symptomology and poorer pandemic mental health, which could be leveraged to target support services to those autistic youth who are most vulnerable to poorer mental health. Strategies to support the autistic community during unprecedented crisis should be developed and implemented.

#### **225.004 (Panel) Care and Informational Needs of Parents of Children with ASD during the COVID-19 Pandemic**

*F. Truijens<sup>1,2</sup>, S. Van Rijen<sup>1,2</sup>, L. Hooijman<sup>1,2</sup>, S. Louwerse<sup>2,3</sup>, K. Visser<sup>2,4</sup>, D. Bastiaansen<sup>2,5</sup>, W. A. Ester<sup>2,6,7,8</sup>, L. W. ten Hoopen<sup>2,9</sup>, P. F. de Nijs<sup>2,9</sup>, R. Van der Hallen<sup>1,2</sup> and L. P. Dekker<sup>1,2</sup>, (1)Department of Psychology, Education & Child Studies, Erasmus University Rotterdam, Rotterdam, Netherlands, (2)Rotterdam Autism Consortium (R.A.C.), Rotterdam, Netherlands, (3)Erasmus MC - Sophia, Rotterdam, Netherlands, (4)Youz, Rotterdam, Netherlands, (5)Yulius, Barendrecht, Netherlands, (6)Department of Child and Adolescent Psychiatry, Curium-LUMC, Leiden University Medical Center, Oegstgeest, Netherlands, (7)Sarr Expert Centre for Autism, Lucertis Child- & Adolescent Psychiatry, Rotterdam, Netherlands, Rotterdam, Netherlands, (8)Parhamia Psychiatric Institute, The Hague, Netherlands, (9)Child and Adolescent Psychiatry/Psychology, Erasmus MC-Sophia Children's Hospital, Rotterdam, Netherlands*

**Background:** The COVID-19 pandemic is challenging for everyone. Parents, especially in case they care for children with special needs like autism, may find themselves particularly challenged. Next to organizing their own life, their job and managing their own emotions and worries, parents are also responsible for the wellbeing of their children. With most parents of children with ASD carefully constructing routines and coping strategies for everyday life, the sudden and all-encompassing turmoil created by the COVID-19 pandemic challenged the parents and families. Never before was there such large-scale life event in which we were able to identify care and informational needs that families may have when dealing with life-events. Information regarding the care and informational needs of caregivers of individuals with ASD may inform policy and facilitate protocols as well as aid professionals in how to best care for and support families with children with ASD.

**Objectives:** The aim of the current study was to examine the care and informational needs of the caregivers of children with ASD during the COVID-19 pandemic by means of in-depth semi-structured interviews.

**Methods:** In collaboration with three mental healthcare institutions specialized in autism in the region of Rotterdam all families who received care in the year prior to the pandemic were invited to partake in the current study (n=200). At T1 (2<sup>nd</sup> lockdown, 01/2021-05/2021) 27 parents/caregivers of children and adolescents with ASD took part in an in-depth interview. T2 (lenient/less restrictive period; 09/2021-12/2021) interviews are currently being conducted to assess long-term impact and deepen knowledge as gathered at T1.

**Results:** Final data collection is currently ongoing. Preliminary results indicate that parents would have appreciated a more conservative approach in policy, the children seem to prefer face-to-face mental health care over online, parents would appreciate more information available for children/lower IQ and parents prefer being informed proactively by schools etc. about the impact of policy changes. Full results are expected by early 2022.

Conclusions: Although many parents understand the special circumstances the pandemic has caused, and understand the difficult position many institutions (e.g., schools and mental health care facilities) are in, they have some specific suggestions for how we may improve care and information transfer. Qualitative research adds valuable information and allows for a deeper understanding as parents can freely discuss the most pressing issues they encounter.

## ORAL SESSION - 6B — INTERNATIONAL AND CROSS-CULTURAL PERSPECTIVES

### 312 - Autism across Communities: Screening and Intervention

#### 312.001 (Oral) First-Generation South Asian Immigrants and Navigating Their Child's Autism

**M. Mahjoob<sup>1</sup>** and **P. Perepa<sup>2</sup>**, (1)University of Toronto & Bloorview Research Institute, Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (2)University of Northampton, Northampton, United Kingdom of Great Britain and Northern Ireland

**Background:** Parents are the primary support network for a child with autism. Research on parental experiences of having a child with autism have emphasized appreciation and personal growth. In addition to these positive factors, parents can experience difficulties in navigating their child's challenging behaviour, feel a lack of social support, and have frustration accessing health services. These caregiving challenges have largely been understood from a Western perspective which fails to account for cultural factors and perceptions of disability.

Furthermore, immigrants face unique stressors such as language barriers, cultural differences, inadequate access to health care, social isolation, and socio-economic challenges. A particularly fast growing immigrant population in Canada and the United Kingdom is the South Asian community. Literature on South Asian immigrant experiences in navigating their child's autism is scarce. A deeper insight on the experience of South Asian immigrant parents of children with autism is critical for support services, clinicians, and health policymakers to best support the South Asian immigrant community.

**Objectives:** The goal of this study was to explore the experience of first generation South Asian parents of children with autism. Specially, we were examining (1) perceptions of autism, (2) stressors, and (3) coping methods.

**Methods:** This study involved: (1) a systematic review to explore the current literature on South Asian experiences of children with autism and (2) a qualitative interview with first-generation South Asian parents of children with autism in the UK. For the systematic review, key search terms were autism, Asperger's, pervasive developmental, South Asia, India, Sri Lanka, Nepal, Afghanistan, Pakistan, Bhutan, or Maldives. We employed a broad search strategy due to the limited research available. Our search revealed 113 studies. Of which, 60 duplicates were removed and 53 studies underwent abstract and title screening according to the inclusion and exclusion criteria. From 53 studies, 11 studies were deemed irrelevant. A full text review was conducted for 42 studies, to which 24 were deemed relevant. A narrative analysis of common themes was conducted for the 24 studies, with a special focus on the distinct experience of first-generation immigrants. For the qualitative part of this study, we recruited first-generation South Asian parents of a child with autism in the UK for semi-structured interviews exploring perceptions of autism, stressors, and coping methods.

**Results:** Common perceptions of autism for first-generation South Asian immigrants included: their child being a gift from god and that the experience of parenting their child was test from a higher power. Common stressors included dissatisfaction with the treatment their child receives in their current country. Coping methods primarily included religious practices.

**Conclusions:** The results of this study suggest first-generation South Asian immigrants face unique experiences in navigating their child's autism. Future research in large sample sizes is required to better understand perceptions, stressors, and coping strategies this community faces. This information can inform the personalized design of healthcare programs and support services to best support the South Asian immigrant community.

#### 312.002 (Oral) Parental Perceptions of Autism in New Delhi, India

**G. Lockwood Estrin<sup>1</sup>**, **S. Bhavnani<sup>2</sup>**, **R. Arora<sup>3</sup>** and **S. Gulati<sup>3</sup>**, (1)Centre for Brain and Cognitive Development, Birkbeck University of London, London, United Kingdom, (2)Child Development Group, Sangath, New Delhi, India, (3)Centre of Excellence and Advanced Research for Childhood Neurodevelopmental Disorders, Child Neurology Division, Department of Pediatrics, All India Institute of Medical Sciences, New Delhi, India

Background:

Our understanding of Autism Spectrum Disorder (ASD) is currently based on research conducted in Western high-income settings. However, we know that differing socio-cultural norms impact the process of identifying symptoms and healthcare seeking around the globe.<sup>1,2,4</sup> There is need for greater diversity and a global perspective in autism research.<sup>1,2,4</sup> Specifically, we need a better understanding of the perspectives of autism from different settings, to explore how help-seeking pathways are impacted by these perceptions, and how a diagnosis impacts families. By comparing perspectives between parents in two groups (mothers with a child diagnosed with ASD, compared to Intellectual Disability (ID)), and also to those from mothers of typically developing (TD) children in New Delhi, India, we take a step towards closing this gap in our understanding.

Objectives:

We aim to investigate: 1) how cultural norms, awareness and competing priorities impact parental recognition of symptoms between ASD and ID groups; 2) how the interpretation of symptoms differ between groups of parents; and 3) how a diagnosis of a developmental disorder impacts the family.

## Methods:

Thirteen semi-structured interviews with mothers of children in three groups: mothers of a child diagnosed with ASD, mothers of a child diagnosed with ID, and mothers of a child meeting developmental milestones. This was a nested qualitative study within a larger case-control study conducted in community and healthcare settings in New Delhi. Thematic analysis was conducted on the transcribed and translated (Hindi to English) interviews.

## Results:

Thematic analysis identified five key themes: Recognition, Interpretation, Reporting of symptoms, Impact of a diagnosis, Social Support. Differences were found between groups in the perceived recognition, interpretation of symptoms and reporting of symptoms. In the ASD group, the perceived barriers to reporting symptoms included stigma, disbelief that symptoms were autism, and a maternal lack of agency, e.g., *“It seemed to me that there was some problem. But no one in the society listens to us ladies, no matters how much educated we are.”* In comparison, the ID and TD group perceived barriers were logistical or financial. The impact of an ASD diagnosis on the mother was highlighted, with perceived stigma, disempowerment and lack of social support being prominent: *“Society isolates you. No one wants to talk to you.”* These were not observed in the ID or TD groups. The mothers in the ASD group also highlighted the importance of being able to talk to others, and the support they received from their child.

## Conclusions:

This study found distinct differences in the perception of autism, and the perceived impact of a diagnosis between groups. This work highlights the social isolation and stigma experienced by mothers of a child diagnosed with ASD, and the lack of support being received by wider family and communities. We emphasize the need for increased awareness of autism in community settings, and improved diagnostic pathways for parents that include greater family support post-diagnosis.

### **312.003 (Oral)** Towards Naturalistic Developmental Behavioural Interventions for Autism in Africa: Content and Contexts of Caregiver-Child Dyadic Interactions in Low-Resource South African Environments

**M. Ndlovu<sup>1</sup>, Z. Dawood<sup>2</sup>, N. Seris<sup>1</sup>, N. Shabalala<sup>1</sup>, M. Harty<sup>3</sup>, M. Viljoen<sup>1</sup>, L. Franz<sup>4</sup> and P. J. de Vries<sup>1</sup>,** (1)Centre for Autism Research in Africa, Division of Child & Adolescent Psychiatry, University of Cape Town, Cape Town, South Africa, (2)Division of Communication Sciences and Disorders, University of Cape Town, Cape Town, South Africa, (3)Department of Health & Rehab Sciences, University of Cape Town, Observatory, Cape Town, South Africa, (4)Duke Center for Autism and Brain Development, Department of Psychiatry and Behavioral Sciences, Duke University, Durham, NC

**Background:** Caregivers can be taught to use Naturalistic Developmental Behavioural Intervention (NDBI) strategies during interactions with their young child with autism spectrum disorder (ASD). However, NDBI research predominantly comes from high-income countries. The evidence-base for NDBI in low/middle-income countries (LMIC) and across cultures is lacking. To understand the ‘fit’ of an NDBI approach in LMIC, it is crucial to quantify the strategies and behaviours of caregivers and autistic children during caregiver-child interactions, and to identify daily routines in which caregiver-child interactions occur.

**Objectives:** To describe the caregiver-child interactions and daily routines of young children with ASD living in low-resource South African environments.

**Methods:** Children with ASD (18-72 months old) and their ≥18-year-old caregivers were recruited under a larger project. Interactions of 21 caregiver-child dyads were video-recorded at baseline using two standardized 6-minute free-play sessions (Part 1: child explores the room and available toys while the caregiver remains seated. Part 2: caregiver leaves their chair and interacts with their child as they would at home). Videos were rated by research-reliable raters, using 16 items from the Joint Engagement Rating Inventory (JERI), a 7-point Likert scale behavioural coding system. Descriptive statistical analyses were conducted. To explore common daily routines, structured interviews were conducted with caregivers (n=10) using the Parent Survey of Home and Family Experiences, adapted for the South African context. Frequency and content analyses were performed.

**Results:** For caregiver-child interactions, observer agreement for 11 of 16 items was reasonable, with weighted Kappas (within 1 scale point) of 0.66–1 and estimated accuracy 88–99%. There was a range of ratings for all items across parts 1 and 2, without ceiling effects. Two items in part 1 and four in part 2 showed floor effects. Caregiver item ratings were all at the midpoint of the scale (*Mdn*=4), suggesting moderate ability of caregivers to support child performance and communication during interactions prior to intervention. Changes in the range of ratings for three items (object engaged, expressive language, attention to caregiver) between part 1 and part 2 (with and without caregivers during play) showed the utility of JERI codes as potential markers of change. Regarding daily routines most children participated in routine activities (e.g., bathing, washing hands, family meals) and play activities (e.g., playing with toys, water, cell phone games) on a daily basis with mothers as the main partners. Most children in the sample never participated in spiritual activities, community activities, and chores.

**Conclusions:** Results suggest the JERI may be applicable to quantify caregiver-child interactions of families with a young autistic child in low-resource South African environments. Caregivers already use some strategies targeted by NDBI coaching to support their young autistic child during interactions, suggesting a degree of ‘fit’ between NDBI approaches and the South African context. Changes in attention to caregiver between parts 1 and 2 suggest caregiver presence supports attentional shifts in children. The common daily routines identified here provide contextual data of activities into which NDBI strategies could be embedded to support child generalization of skills in South Africa.

**312.004 (Oral)** Is Forward-Back Translation Sufficient? Comparing Two Translation Methods for a Parent-Report Autism Screening Tool  
**M. DuBay<sup>1</sup>, J. Sideris<sup>2</sup> and E. Rouch<sup>3</sup>,** (1)School of Education and Human Development, University of Virginia, Chapel Hill, VA, (2)Mrs. T. H. Chan Division of Occupational Science and Occupational Therapy, University of Southern California - T.H. Chan Division of Occupational Science and Occupational Ther, Los Angeles, CA, (3)University of Virginia, Charlottesville, VA

Background:

Health disparities experienced by many of the world’s populations cause substantial differences in ASD diagnostic rates, age of diagnosis, and access to ASD-specific services (Mandell et al., 2009), especially among non-English speaking populations (Baio et al., 2018; Chamak et al., 2011; Morales-Hidalgo et al., 2018).

Currently, the most feasible way to identify children with ASD symptoms at a young age is to screen children universally for common early ASD behavioral markers, typically in a parent-report format (Thabtah & Peebles, 2019). Many ASD screening tools are being translated into other languages. Most frequently, the translation “forward-back” (FB) approach is used, where a single forward translation is followed by a back-translation and same-language review (El-Behadli et al., 2015). However, the FB approach may not be sufficient to retain psychometric properties between the original screener and the translated version (Ben-Sasson & Carter, 2012; Guthrie et al., 2019; Pomés et al., 2016).

An alternative rigorous translation with cultural adaptation (TCA) approach involves a forward translation by a team of trained translators from a range of backgrounds, systematic examination of the forward translation quality, collaborative revisions, and pretesting with target population members (Acquadro et al., 2008; Hagell et al., 2010). After completion, the final version is administered to a large community sample to determine population-specific norms and psychometric properties (Beaton et al., 2000; DuBay & Watson, 2019).

Objectives:

We aim to directly examine the impact of translation methodology on psychometric properties by administering two translations of the *First Years Inventory version 3.1* (FYI; Baranek et al., 2013), a parent-report ASD screening tool for 8-16 month-old children. One version will be translated using the traditional FB approach, and the other using the TCA approach (DuBay et al., 2021).

Methods:

Approximately 450 US-based Spanish-speaking caregivers of children 8-16 months of age will complete a Spanish FYI. Participants will be randomly assigned to complete one of the two translations. Patterns of responses from each translation will be compared using a measurement invariance approach.

Results:

Thus far, 330 US-based Spanish-speaking caregivers have completed the FYI. Those born outside the US, having lived in the US for 9 years on average (range 1-39 years), immigrated from 15 countries spanning North, Central, and South America and the Caribbean. Preliminary analyses indicate that compared to participants who received the TCA version, participants who received the FB version are more frequently responding to the scale using only three response options rather than choosing from all five response options ( $p < .000$ ), reducing the variability in the data for the FB version and possibly negatively impacting validity. Further, 23% of items showed significant differences in mean responses between groups ( $p < .05$ ), which could indicate differential item interpretations across translations. Measurement invariance will be analyzed when all data collection is complete.

Conclusions:

Examining the impact of translation methodology on the validity and reliability of an ASD screening tool will help to inform future translations across languages and screening tools, improving early identification of a range of developmental conditions for numerous cultures and populations.

## POSTER SESSION — INTERNATIONAL AND CROSS-CULTURAL PERSPECTIVES

### 425 - International and Cross-Cultural Perspectives

**425.077 (Poster)** Adaption and Evaluation of the Program Parents Taking Action (PTA) for Parents of Pre/Adolescents with Autism Spectrum Disorder in Colombia  
**M. Garcia, UIC, Chicago, IL**

## Background:

The prevalence of autism spectrum disorder (ASD) has increased in recent decades around the world. In Colombia, there is not a clear statistic about the prevalence of ASD, but it is estimated that 16% of the population under 15 years old has some type of developmental disability (National Administrative Department of Statistics-DANE, 2015). Unfortunately, the lack of research and information about supports for people with ASD and their families limits the services and supports available for this population. While there are emerging supports for families of young children with ASD in Colombia, there is a need to support families of youth with ASD, particularly around topics of puberty, sexuality, and adolescence development.

**Objectives:** The aim of this study was to evaluate the efficacy of the program Parents Taking Action for parents of preadolescents with ASD in Bogota, Colombia using a quasi-experimental design with a control group.

## Methods:

We recruited 38 Colombian parents of pre/adolescent youth with ASD between the ages of 10 – 17 in Bogota, Colombia through community-based organizations. Three groups were selected based on parents' availability to participate (two different times were offered). One of these groups served as a delayed control group. Knowledge, Self-efficacy, empowerment, and Use of Strategies were assessed before and after the intervention, as well as a follow-up interview and goal setting.

## Results:

Intervention participants significantly improved in Knowledge ( $t=4.37$ ,  $p<.001$ ), Self-Efficacy ( $t=7.15$ ,  $p<.001$ ), Use of Strategies ( $t=4.29$ ,  $p<.001$ ), and Family Empowerment ( $t=3.82$ ,  $p<.005$ ) between baseline and post-test. When comparing to control group, differences were significant as the control group did not improve on any of the outcome measures. Interviews supported these findings by showing that parents continued to use the information and strategies after the program finished. Also, parents met their goals as expected.

## Conclusions:

The youth version of *PTA* demonstrated efficacy in the outcomes measured using a quasi-experimental design in Colombia. Parents of preadolescents with ASD in the intervention group increased knowledge, use of strategies, self-efficacy, and empowerment with respect to the topics related to puberty, adolescence and sexuality compared to the control group. The program has potential for high impact as information is scarce and parents do not have resources related to the complicated developmental stages of pre/adolescence. The program shows promise as an efficacious tool for community organizations and health providers to provide extra support to families of youth with ASD.

## **425.078 (Poster)** Barriers to Access Health and Educational Services for Venezuelan Autistic Children. Caregivers Priorities in a Humanitarian Crisis

A. Cosino Chavarria<sup>1</sup>, A. Rattazzi<sup>2</sup>, S. H. Cukier<sup>3</sup>, D. Valdez<sup>3</sup>, R. A. Garcia<sup>4</sup>, A. Rosol<sup>5</sup>, G. Garrido<sup>6</sup>, C. S. Paula<sup>7</sup> and C. Montiel-Nava<sup>8</sup>, (1)University of Texas Rio Grande Valley, Edinburg, TX, (2)PANAACEA, Buenos Aires, Argentina, (3)Facultad Latinoamericana de Ciencias Sociales sede Argentina, Buenos Aires, Argentina, (4)Clínica Las Condes, Santiago, Chile., Santiago, CHILE, (5)Projects, Organizacion Estados Iberoamericanos, Santo Domingo, Dominican Republic, (6)Universidad de la República, Montevideo, Uruguay, (7)Developmental Disorder Program, Universidade Presbiteriana Mackenzie, São Paulo, Brazil, (8)Psychological Science, University of Texas Rio Grande Valley, Edinburg, TX

**Background:** Autistic children might have a higher level of service needs than other individuals with developmental disabilities. Such services are usually costly and need the coordination of caregivers, family schedules, and budgets. Caregivers **worry about finding health and educational services** for their children, adding to the stress. Parenting an autistic child is a challenging experience in many areas and at different levels. These experiences become even more challenging in countries with a lack of infrastructure, trained professionals, and general awareness of ASD. **In** Venezuela, as in many other Low- and Middle-Income Countries (LAMIC), the mental health expenditure per person and the number of mental health professionals is below standard. Despite having universal health coverage, the Venezuelan public health system is administered in overbooked facilities with few trained professionals and long waiting lists.

**Objectives:** This study aims to identify caregivers' perceptions regarding (a) access to health and educational services for their children, (b) impact on family daily life, and (c) challenges and priorities of caregivers of autistic children

**Methods:** A total of 114 Venezuelan caregivers of autistic children completed the Caregivers Needs Survey. The questionnaire comprises four sections: (1) Sociodemographic characteristics of the family, (2) Characteristics of the person with ASD, (3) Use of services and treatments, (4) Perception of parents/caregivers about barriers to access, challenges, priorities, and impact on the family. This study is part of a larger multisite study comprising samples from six countries of the Latin American Network for Autism (REAL): Argentina, Brazil, Chile, Uruguay, Venezuela, and the Dominican Republic.

**Results:** At the time of the study, speech therapy was the most commonly used service (70.27%), followed by occupational therapy (65.77%) and behavioral therapy (45.95%). In terms of educational services, 70.18% of the sample were without school support services. The impact of having a child with autism was evident in 47.37% of caregivers that reported financial problems, and 55.26% cut work hours to care for the autistic child. Communication (50.71) and social interaction difficulties (45.43%) were the main challenges endorsed by caregivers. In addition, having access to good educational services (90.64%) and health services (59.67%) were their most frequent priorities.

**Conclusions:** This study highlights the barriers experienced by caregivers of autistic children in Venezuela. The most commonly endorsed services (ST and OT) are not specific to ASD and have low-to-moderate evidence of effectiveness but are widely available in public and private institutions, usually in outpatient mental health contexts. Parents looking for health or educational services encountered overbooked facilities, waiting lists, and a scarcity of trained professionals. In addition, caregivers indicated limited resources to pay for services and financial difficulties. Venezuela is experiencing a sustained sociopolitical conflict, extreme poverty, and humanitarian crises that have affected every facet of everyday life, adding strain to the availability and accessibility of services for ASD. Our findings emphasize the need for programs that target underserved groups and children living in Third-World countries and their families.

**425.079 (Poster)** Behavioral and Psychological Changes Experienced By Autistic Individuals during Covid-19 Pandemic in Latin America  
**M. Montenegro<sup>1</sup>, D. Valdez<sup>2</sup>, A. Rosoli<sup>3</sup>, G. Garrido<sup>4</sup>, S. H. Cukier<sup>5</sup>, C. S. Paula<sup>6</sup>, R. A. Garcia<sup>7</sup>, A. Rattazzi<sup>8</sup> and C. Montiel-Nava<sup>9</sup>**, (1)University of Texas Rio Grande Valley, Edinburg, TX, (2)Facultad Latinoamericana de Ciencias Sociales sede Argentina, Buenos Aires, Argentina, (3)Projects, Organizacion Estados Iberoamericanos, Santo Domingo, Dominican Republic, (4)Universidad de la República, Montevideo, Uruguay, (5)PANAACEA, Buenos Aires, Argentina, (6)Developmental Disorder Program, Universidade Presbiteriana Mackenzie, São Paulo, Brazil, (7)Clínica Las Condes, Santiago, Chile., Santiago, CHILE, (8)Psychological Science, University of Texas Rio Grande Valley, Edinburg, TX

---

**Background:** Covid-19 pandemic brought an increased incidence of concern in the world at large. For those in regions with large economic disadvantages and wide systematic issues (e.g., Latin American countries) the pandemic hit with an added force. Due to autism spectrum disorder core features, autistic individuals might have experienced increased difficulty adapting and preparing to environmental changes and thus making them a particular vulnerable population. Because of these challenges, autistic individuals are expected to experience a variety of behavioral challenges.

**Objectives:** The present study assesses demographic characteristics and contextual factors' impact on dysregulated behaviors, preoccupation with getting sick, and overall setbacks experienced among autistic individuals during the COVID-19 pandemic in 7 Latin American countries as perceived by their caregivers.

**Methods:** The present study conducted a series of linear regressions and a Kruskal-Wallis test to determine contextual factors' (e.g., country of residence, coexistence, crowded conditions) and individuals' characteristics (e.g., gender, and age of individual) effect on dysregulated behaviors, preoccupation with getting sick, and overall setbacks of autistic individuals as reported by caregivers.

**Results:** The Kruskal-Wallis H test, run to determine differences in scores assessing preoccupation with getting sick, overall setbacks, and internalizing behaviors between countries. Country of residence had a small effect on preoccupation with getting sick,  $X^2(6)=23.23, p=0.001$ ,  $\epsilon^2=0.013$ , on dysregulated internalizing behaviors,  $X^2(6)=49.61, p=0.000$ ,  $\epsilon^2=0.029$ , and on overall setback,  $X^2(6)=75.21, p=0.000$ ,  $\epsilon^2=0.044$ . Pairwise comparisons revealed statistically significant differences in preoccupation with getting sick scores with Brazil and Chile showing increased preoccupation with getting sick compared to remaining countries. Concerning dysregulated internalizing behaviors, Dominican Republic had statistically significant lower scores. Overall setback was lowest in the Dominican Republic. Linear regression established that size of house ( $F(4, 1742)=4.24, p<0.05$ ) and type of coexistence ( $F(4, 1703)=3.67, p<0.05$ ) significantly predicted preoccupation with getting sick, with those residing in a larger house leading to a .296 to .305 decrease in preoccupation with getting sick, whereas better coexistence led to a .212-.426 decrease. Moreover, coexistence but not house size predicted changes in overt behaviors in children  $F(1,97)=38.98, p<0.005$ . Additionally, those that indicated a better coexistence showed a .791-1.193 decrease in dysregulated internalizing behaviors in autistic children. For overall setback, house size and type of coexistence predicted overall setbacks ( $F(1,97)=16.87, p<0.005$ ).

**Conclusions:** For caregivers that had been able to create a comforting routine for autistic individuals who have difficulty adapting to change, the initial stages of the pandemic were especially difficult. During this period many autistic individuals and their families indicated feeling ignored since many protocols aimed at protecting them did not come until later and were limited in usefulness. The present study presents a cross-cultural understanding to predictors in dysregulated behaviors increments, setbacks and preoccupation with getting sick. This information is relevant to inform policies aimed at protecting vulnerable populations when confronted with environmental changes of large magnitude.

**Keywords:** ASD, Latin America, Caregivers, COVID-19, Pandemic, Behaviors, Preoccupation.

**425.080 (Poster)** Changes in the Perception of Age of Diagnosis and Access to Services in Caregivers of Autistic Individuals in Argentina.  
**E. Garza<sup>1</sup>, M. Montenegro<sup>1</sup>, S. H. Cukier<sup>2</sup>, D. Valdez<sup>3</sup>, A. Rattazzi<sup>4</sup>, G. Garrido<sup>5</sup>, C. S. Paula<sup>6</sup>, R. A. Garcia<sup>7</sup>, A. Rosoli<sup>8</sup>, A. Karpur<sup>9</sup>, A. Shih<sup>9</sup> and C. Montiel-Nava<sup>10</sup>**, (1)University of Texas Rio Grande Valley, Edinburg, TX, (2)PANAACEA, Buenos Aires, Argentina, (3)Facultad Latinoamericana de Ciencias Sociales sede Argentina, Buenos Aires, Argentina, (4)Universidad de la República, Montevideo, Uruguay, (5)Developmental Disorder Program, Universidade Presbiteriana Mackenzie, São Paulo, Brazil, (6)Clínica Las Condes, Santiago, Chile., Santiago, CHILE, (7)Projects, Organizacion Estados Iberoamericanos, Santo Domingo, Dominican Republic, (8)Autism Speaks, Princeton, NJ, (9)Autism Speaks, New York, NY, (10)Psychological Science, University of Texas Rio Grande Valley, Edinburg, TX

---

## **Background:**

In the last years, Argentina has developed public health initiatives to protect those with disabilities and developmental concerns. However, as in many Low and Middle-Income countries, the needs of autistic individuals in Argentina are still short of being fulfilled. In specific, there is no universal access to diagnostic and treatment services, or school supports, among others.

## **Objectives:**

To evaluate changes across two different points in time in terms of ASD diagnosis (e.g., type and age), first developmental concerns (e.g., age of first concern and person noticing concern), services barriers and accessibility, and priorities as perceived by caregivers of autistic individuals.

## Methods:

Two independent samples of caregivers of autistic individuals were surveyed by the Red Espectro Autista Latinoamerica (REAL)(n=763) and the World Health Organization (WHO) (n=422) at two different time points (2015 and 2020, respectively). Similar items in both surveys were compared through descriptive, inferential analysis, and chi-square tests of independence.

## Results:

For the 2020 sample, caregivers reported both an earlier age of first concerns observed by caregivers and an earlier professional diagnosis. 22.7% more caregivers noticed developmental concerns by 18 months of age compared to the 2015 sample, while 10.8% more had a professional diagnosis before three years of age. For both samples, there was an association between the person first noticing a developmental concern and the age of diagnosis, with family members predicting an earlier age of diagnosis when compared to teachers and doctors. When family members noticed the first concern, their children were more likely to be diagnosed at 0-3 years old. On the contrary, if teachers noticed the first developmental concern, autistic individuals were more likely to be diagnosed at 4-8 years of age. For the 2020 sample, caregivers reported fewer service barriers (e.g., limited availability, waitlist, costs, etc.) and decreased priorities for receiving social support and better health services. However, rates of caregivers indicating a need for more rights for autistic individuals and greater protection of existing rights increased. Additionally, there was no change in the reported rate of family members who stopped working to care for the autistic individual.

## Conclusions:

The five years that separate both samples show a decrease in the age of diagnosis and improvement in several areas of services such as community awareness, type of diagnosis being provided, and fewer barriers to access services. These results suggest that the changes in public policies and awareness campaigns have impacted access to services. Nonetheless, a similar proportion of family members reported ceasing working to care for autistic individuals and perceived that the fundamental rights of their autistic children needed to be protected. Taken together, such results suggest that despite better care pathways in Argentina, there are still gaps to meet the needs of autistic individuals and their families.

### **425.081** (Poster) Culture, Tortuous Pathways, and the Case for Ameliorating Autism Burden in Nigeria and South Africa

**O. A. Kehinde<sup>1</sup>, O. J. Lindly<sup>2</sup>, B. Ntombela<sup>3</sup> and C. Hermann<sup>4</sup>**, (1)English, University of Zululand, KwaDlangezwa, South Africa, (2)Health Sciences, Northern Arizona University, Flagstaff, AZ, (3)Department of English, University of Zululand, KwaDlangezwa, 3886, South Africa, (4)Psychology, University of Zululand, KwaDlangezwa, 3886, South Africa

---

**Background:** The aetiological basis of Autism Spectrum Disorder (ASD) is still being explained by supernatural causes in some parts of Africa (especially among the low and middle-income countries) due to poor education and awareness about the disorder, and sometimes to avoid stigma and elevated stress. In a bid to seek healing or lessen burden for autistic individuals, some parents embark on tortuous pathways such as seeking help from diviners, spiritualists, or traditional clinical practitioners. Such decisions may stem from the cultural beliefs and practices of many people that surround autistic individuals. Many parents possess beliefs regarding divination, spiritual and/or traditional power in their society, and they might have in one time or the other sought solution to their personal problem using such pathways. Because of this, they may hold the same belief that ASD can be cured using these pathways.

**Objectives:** This study aimed to examine the role that cultural beliefs and practices play in how parents seek help and other interventions to cure or reduce burden for autistic children in Abeokuta and Ibadan, Nigeria, as well as those in Empangeni and Durban, South Africa.

**Methods:** The study adopted a qualitative approach, and data was collected using semi-structured interviews. Using purposive sampling, 5 parents were recruited from different areas in Abeokuta, and 9 in Ibadan. In Empangeni, 3 parents were recruited, and 7 parents were recruited in Durban. The data was analysed using thematic content analysis, and the study strictly adhered to ethical considerations.

**Results:** Most parents (n=17) had visited the orthodox clinicians/traditional healers, spiritualists, or diviners to seek help about the possibility of curing their child with ASD. Many parents (n=19) mentioned the strong influence that their cultural beliefs and practices such as ability of the gods, and the spiritual world to heal and wade off one's problem exerted on being willing to pursue such interventions. It was found that parents were eager to see improvement in their child's functioning, which had the potential to reduce their stress, and stigma in some cases.

**Conclusions:** Culture exerts greater influence on what parents and caregivers believe, practise, and other actions they take to reduce the burden their children with ASD experience, as well reduce their own stress. Government and stakeholders need to create more awareness targeted at parents and other caregivers about what help is needed, and where to obtain it after an individual has been diagnosed with ASD. Parents should refrain from taking self-sought solutions, review their cultural beliefs and stick to those that can genuinely help their children with ASD improve.

### **425.082** (Poster) Early Screening of ASD with the RITA-T in a Culturally Diverse Community

**R. Choueiri<sup>1</sup>, V. Tokatlî<sup>2</sup>, E. Prashad<sup>3</sup> and W. Garrison<sup>3</sup>**, (1)University of Massachusetts Memorial Children's Medical Center, North Worcester, MA, (2)University of Massachusetts Chan Medical School, Worcester, MA, (3)Pediatrics, Developmental and Behavioral Pediatrics, University of Massachusetts Medical School, Worcester, MA

---

## Background:

Early recognition of autism spectrum disorder (ASD) is pivotal to start intensive treatment but continues to be delayed especially in diverse and underserved communities. We have published already on a pilot model using the Rapid Interactive Screening Test for Autism in Toddlers (RITA-T) with an Early Intervention (EI) program in a culturally diverse community to improve early access and identification of ASD. Approximately 35% of families in Worcester speak a language other than English, and close to 40% are non-White, with a range of Immigrants and refugees from South America, Nepal, Vietnam, Ghana, Nigeria, and Iraq. We continued the partnership with more EI programs and primary care providers after the initial pilot and integrated this into clinical practice.

## Objectives:

Study the generalization of a pilot model that included two-level screening with the RITA-T into clinical model and partnerships with Early Intervention and Primary Care in a culturally diverse community to improve early access, screening, and identification of ASD

## Methods:

Over the last 3 years (2018-2021), we trained university based and community based Primary Care Providers, pediatric residents and 4 more Early Intervention (EI) programs in central MA on the RITA-T. The RITA-T training is, on average, three hours long to establish reliability, and its administration and scoring is approximately 10 minutes. The RITA-T does not rely on language. When a child is suspected to have ASD, they administer the RITA-T, discuss concerns with families, and refer them to the evaluation. Evaluation includes then: review of signs and symptoms of ASD; observation of play and administration of the ADOS-2 or the CARS-2, and application of DSM-5 criteria.

This is a retrospective review of referrals and evaluations of children younger than 3 years for evaluation for ASD to our center. We compared: wait time between those referred without a RITA-T screening vs. those referred through this model. We also looked at the correlation of the RITA-T with final diagnosis.

## Results:

Although numbers of referrals of those younger than 3 years remained stable over the last 3 years, referrals through RITA-T model increased gradually and reached a total of 304 toddlers. Ages varied between 18 and 36 months and close to 50% identified as non-white. Wait time varied between 1-4 months for the RITA-T model (average 2 months) vs. 3-7 months for those without RITA-T (average 5 months). RITA-T correlated strongly with final diagnosis: score > 16 for ASD and score < 12 for non ASD. In addition, visits from the RITA-T model were 1 hour shorter than visits for those referred without RITA-T.

## Conclusions:

Generalization of the RITA-T model in clinical care is feasible in this culturally diverse community. This model has reduced the overall wait time for those at risk for ASD in addition to strengthening the network with EI and Primary Care providers.

### **425.083 (Poster)** Employment for Individuals with ASD in Russia – Experience, Opportunities, and Obstacles

*S. Dovbnya<sup>1</sup>, T. Morozova<sup>2</sup>, O. Shamayko<sup>2</sup>, I. Monova<sup>2</sup> and A. Zalogina<sup>2</sup>, (1)NHF Russian Federation, St-Petersburg, Russian Federation, (2)NHF Russia, Moscow, Russian Federation*

**Background:** People with ASD and/or Intellectual Disabilities (ID) can and want to work, this is important for mental and physical health, their family's wellbeing and can bring significant benefits to business and whole society. At the same time, they are often discriminated and socially stigmatized. Also, the number of adults with officially established ASD diagnosis in Russia is generally negligible, although in large cities this number is slowly increasing but remains very low. Successful and stable employment requires support programs and services. There is rich international supported employment (SE) experience but in Russia, however, such initiatives are still rare.

**Objectives:** This study will expand on the limited knowledge on situation with SE for people with ASD or/and ID in Russia and provide more information on job seekers, their families, and employers SE knowledge and experience.

**Methods:** Study Design: 23 in-depth interviews with parents/caregivers of the adults with ASD and ID and 4 interview with self-advocates in Moscow, St-Petersburg, and Nizhny Novgorod. 144 questionnaires completed online by parents/caregivers of adults with ASD or/and ID from across Russia. 10 semi-structured interviews with state and non-governmental service providers; 5 focus groups with employing organizations representatives. Focus groups and interviews were carried out within our guidelines by "O+K Research". Participants: Parents/caregivers of the adults with ASD and/or ID (18 to 40 yo). 4 self-advocates with ASD. There is a need to stress that majority of respondents didn't have officially established ASD diagnosis, so we used self-definition of young adults or their family's opinions which of course limited this study. 95 respondents had a label in their social-rehabilitation plan "severe disability"; 49 had "moderate disability".

**Results:** Majority of respondents didn't consider employment opportunities as real. At the same time only 25% of "severe disability" group believe that members of their family are incapable of any kind of work. Among the parents of "moderate disability" group, a similar opinion was expressed by 1 person out of 49. "Severe disability" group participants have almost no previous work experience. About 30% of "moderate disability" group are employed, another 18% have previous work experience, but only third work full-time, two-thirds have a shorter working day or week. Majority of the

employed respondents work at charitable sheltered workshops, 20% work in the private sector. Their jobs are most likely associated either with art-shops (decoration, drawing), or with simple operations (packaging, cargo works). About half of young adults who defined themselves as “high functioning” have employment experience. For about 40% of them, this experience can hardly be called positive, job placements weren’t sustainable, didn’t match educational level, and income didn’t meet expectations. More than half of all respondents with work experience did not receive any support and didn’t know where to apply for it.

Conclusions: Study results confirmed that for people with ASD and/or ID in Russia employment opportunities are extremely limited and SE projects at open market are extremely rare. Jobseekers, family members and employers have very limited information about SE good practices examples, possible adaptations, legal aspects, etc.

**425.084 (Poster)** Examining the Psychometric Properties of an Implicit Association Test Used to Identify Potential Implicit Biases in Autism Identification

**G. Thomas<sup>1</sup>, A. J. Harrison<sup>1</sup> and J. Bisson<sup>2</sup>**, (1)Educational Psychology, University of Georgia, Athens, GA, (2)Clemson University, Clemson, SC

---

Background: Despite evidence to suggest the prevalence of ASD does not differ as a function of race-ethnicity (Fombonne, 2003), misdiagnoses and delays in diagnoses are most commonly documented among minoritized racial-ethnic groups (Begeer et al., 2013). One hypothesis for these racial disparities is clinician bias (Begeer et al., 2009). To investigate this, Obeid & colleagues (2020) developed a “Disability Valence” Implicit Association Test (IAT) to assess implicit stigma and racial bias related to ASD. Guided by evidence that ASD elicits less stigma than more “disruptive” disorders (Feldman & Crandall, 2007), participants were asked to sort phrases associated with ASD and Conduct Disorder (CD) with positive and/or negative attributes. Using the IAT, this study confirmed that participants demonstrated a heightened stigma for CD as compared to ASD. In this study, an additional IAT evaluating racial association of ASD and CD revealed participants who identified as White implicitly associated images of White children with ASD and the Black children with CD. However, a limitation of this study was that given CD is partially defined by aggression and deviations from the law (American Psychiatric Association, 2013), the characteristics included in the original valence IAT are likely more overtly stigmatizing than ASD and thus, may not be an ideal comparison. A validated IAT that utilizes a less stigmatizing externalizing disorder, such as Oppositional Defiant Disorder (ODD), will allow for more nuanced examination of these racial biases.

Objectives: The purpose of the current study was to develop and validate a different disability valence IAT to examine participants’ implicit stigma toward ASD as compared to ODD, an externalizing disorder that has less overtly stigmatizing diagnostic criteria than CD.

Methods: To identify targets for the ODD category, we created 32 three-word phrases representing symptoms of ODD using diagnostic criteria. Phrases for the ASD category were derived from the original study (Obeid et al., 2020). To ensure construct validity of the phrases, fifty participants rated each phrase on “readability” and the degree to which each statement characterized ODD. To examine the resulting ODD Disability Valence IAT (Figure 1),  $n = 156$  participants were tasked with sorting phrases associated with ASD and ODD with positive and/or negative attributes.

Results: Using the validation data collected, we identified five phrases that had high mean ratings on Likert scales assessing i) readability, ii) representation of ODD and iii) low means for characterizing ASD. We used these phrases as the target items for the ODD category. As hypothesized and in support of the task validity, on the Disability Valence IAT, participants were more likely to implicitly associate good words with ASD and bad words with ODD;  $t(156)=13.96, p<.001$ .

Conclusions: The observed heightened negative associations toward ODD contributes to the existing evidence that externalizing disorders are more stigmatizing than ASD. Future research should use this new disability valence IAT and replicate the racial IAT to quantify if a racial association exists for ASD and ODD. Similar findings may suggest that the implicit biases which contribute to diagnostic disparities are even more subtle.

**425.085 (Poster)** Extension for Community Healthcare Outcomes (ECHO) Autism: Protectea, Argentina: Promoting Best Practices in Detecting and Managing Autism Spectrum Disorders

**V. Nanclares-Nogues<sup>1</sup>, N. E. Granana<sup>2</sup>, A. Richaudeau<sup>3</sup>, V. Maggio<sup>4</sup>, A. James<sup>5</sup>, M. Mahurin<sup>5</sup> and K. Sohl<sup>6</sup>**, (1)ECHO Autism Communities, University of Missouri, Columbia, MO, (2)Servicio de Neurología Infantil, Hospital Durand, CABA, Argentina, (3)Hospital Universitario Austral, Buenos Aires, Argentina, (4)University of Missouri-Columbia School of Medicine, 65212, MO, (5)Department of Child Health, University of Missouri, School of Medicine, Columbia, MO, (6)ECHO Autism Communities, Child Health, Columbia, MO

---

Background: It is estimated that approximately 6 million individuals with autism spectrum disorder (ASD) live in Latin America. Researchers identified issues faced by families affected by ASD throughout Latin American countries, including Argentina, where long wait lists were identified as one of the most prevalent concerns (Paula et.al, 2020). The current pilot project was developed to test a new model for training primary care clinicians in best-practice care for ASD using the Extension for Community Healthcare Outcomes (ECHO) Autism framework. The ECHO Autism PROTECTEA (Program for Early Detection and Conscientization on Development and Autism Spectrum Disorders) project consisted of clinics focused on screening and identification of ASD and developmental differences and management of co-occurring conditions.

Objectives: To share the experience of the ECHO Autism PROTECTEA program in the first 8-month cycle of implementation and determine the feasibility of a telementoring program to reduce barriers for diagnosis and follow-up of individuals with ASD.

Methods: ECHO Autism is an innovative approach that leverages videoconferencing technology to amplify scarce specialist knowledge to mentor generalist clinicians to deliver best-practice care. ECHO Autism PROTECTEA sessions occurred once per month for 90 minutes, where community clinicians presented de-identified cases to the ECHO Autism expert hub team for feedback and guidance. A brief didactic presentation was also provided to address specific knowledge gaps. All participating clinicians completed pre- and post-teleECHO surveys regarding knowledge of ASD,

knowledge of best-practice guidelines in screening and assessment, satisfaction with content provided, and overall information regarding practice patterns. The current project contains analysis of ECHO Autism PROTECTEA clinic data from March 2020 through October 2020.

Results: 8 cases were presented; median age of 7 years (ranging from 2-12) and 1 adult; 5 were male, 3 were female. An average of 115 clinicians attended each ECHO Autism session from centers across the country. Using SPSS, data were analyzed to investigate if there was a change from pre-intervention, when participants reported using non-standardized clinical observation, to post-intervention, with a goal of increasing either standardized screening or formal testing after participation in ECHO Autism PROTECTEA. Across all domains measured, including assessment for overall development and autism, there was a significant change from pre- to post-intervention. Clinicians rated different measures on a Likert scale from 1-4, 4 being very good. 92% of participants found the content, 87% the expertise, and 83% the timing of the ECHO Autism program to be very good, with high applicability to their work (with 69% in the very good range and 27% in the average range). This was also reflected in the consistent attendance and engagement of clinicians. In addition, participants emphasized the opportunity to be able to develop strong multidisciplinary networks and collaborative partnerships across sites.

Conclusions: ECHO Autism PROTECTEA in Argentina demonstrated it is an effective model to deliver prompt access to assessment and best practice care. This model shows great promise as a means to reduce diagnostic waitlists in specialty centers and expand access for families in remote or underserved areas.

#### **425.086 (Poster) Journey Towards a Diagnosis: Studying the Experiences of Latinx Parents of Children with ASD**

**A. I. Mendez<sup>1</sup>, A. Klin<sup>2</sup> and K. Pickard<sup>3</sup>,** (1)Emory University, Marcus Autism Center, Atlanta, GA, (2)Marcus Autism Center, Children's Healthcare of Atlanta and Emory University School of Medicine, Atlanta, GA, (3)Emory University School of Medicine, Marcus Autism Center, Atlanta, GA

---

#### **Background:**

Early identification is a necessary precursor for optimal outcomes for children with autism spectrum disorder (ASD). However, even though gold-standard diagnostic assessments can reliably diagnose ASD as early as 18 months, the median age of diagnosis remains at 4-5 years and lags another 1.5 years for lower-income, minority families. This delay has measureable adverse outcomes: Spanish-speaking Latinx children display an elevated burden of ID and are ascertained at lower rates than their English-speaking, non-Latinx counterparts. Reliably documenting the process by which families obtain an ASD diagnosis will help to clarify the reason for delays in early identification, thus, allowing for more targeted and equitable efforts to lower the age of diagnosis in these populations. Although the qualitative experiences of families from underserved Latinx communities has been documented before, their experiences have not yet been studied systematically. The Diagnostic Odyssey Interview was developed to address this gap. This semi-structured interview was first used on a sample of African American families of toddlers with ASD to document the added barriers and difficulties they face (Constantino et al., 2020). Here, we deploy this interview for the first time in a sample of Spanish-speaking Latinx families of children with ASD and investigate these families' journey towards an ASD diagnosis. In doing so, we will elucidate how this underserved community in research and clinic experienced this process and aim to identify areas of improvement.

#### **Objectives:**

- (1) To evaluate the feasibility of using the Diagnostic Odyssey to document Spanish-speaking Latinx families' journey towards an ASD diagnosis.
- (2) To document barriers to accessing diagnostic services and identify characteristics that may predict more delays to diagnosis.

#### **Methods:**

The recruitment sample was gathered through a retrospective chart review of children evaluated at an ASD-specific clinic. All families had received a diagnosis of ASD for their child and had used a Spanish-language interpreter during their evaluation. Families were contacted via phone to enroll in the study and participate in the phone interview.

Feasibility outcomes were measured as recruitment success and parents' perceptions of participating in the Diagnostic Odyssey interview. Caregivers' experience obtaining a diagnosis will be measured through the interview itself. Data regarding the child's evaluation will be used for exploratory analyses.

#### **Results:**

Data collection is ongoing and is scheduled to be completed by December 2021. The current recruitment sample is composed of 96 families. All families received a diagnosis of ASD for their child and made use of a Spanish-language interpreter during their evaluation.

So far, 82% of parents that have been contacted have expressed willingness to participate in the study.

#### **Conclusions:**

Spanish-speaking, Latinx families comprise a community that has been historically underrepresented in research. Similar to limited prior research, we've begun to show that Spanish-speaking, Latinx families are willing to participate in research when they are approached with the opportunity. More specifically, these results begin to show that the Diagnostic Odyssey Interview is acceptable to families. The complete results of this study will further demonstrate feasibility and elucidate barriers to accessing services.

**425.087 (Poster)** Pilot Study of Citas: Communication Interaction Training on Autism for Spanish-Speaking Caregivers

**L. Morgan<sup>1</sup>**, K. Guerra<sup>2</sup>, S. Gillespie<sup>3</sup>, J. L. Stapel-Wax<sup>3</sup> and K. Pickard<sup>4</sup>, (1)Emory University-Marcus Autism Center, Atlanta, GA, (2)Marcus Autism Center, Atlanta, GA, (3)Pediatrics, Emory University School of Medicine, Atlanta, GA, (4)Emory University School of Medicine, Marcus Autism Center, Atlanta, GA

---

**Background:**

Children with ASD from Latinx families experience significant delays in accessing intervention and, when they do, access a lower dosage and lower-quality intervention compared to non-Latinx, White families (Angell & Soloman, 2017; Bishop-Fitzpatrick & Kind, 2017; Zuckerman et al., 2017). Magaña, Lopez, & Machalicek, (2017) identified a lack of information in the community as one factor that contributes to lower treatment access for Latinx families of children with ASD. Increasing ASD-related knowledge and provider trust are two strategies for decreasing disparities in the diagnosis and treatment of ASD among Latinxs families in the US (Zuckerman et al., 2017).

**Objectives:** The purpose of this study was to test the feasibility and acceptability of Communication Interaction Training on Autism for Spanish-Speaking Caregivers (CITAS), a 6-month intervention designed for Latinx families delivered within the context of a parent education support group

**Methods:**

Thirteen Latinx mothers of children diagnosed with ASD consented to participate and eleven completed the intervention (two participants dropped out due to transportation and childcare challenges). Participating mothers ranged in age from 30 to 52 years ( $M = 29.1$ ,  $SD = 1.2$ ), and their children were a median age of 54.5 months ( $IQR = 43-74$ ). Participants received CITAS, a manualized group intervention delivered once per month over 6 months aimed at increasing caregiver social support, empowerment, and ASD knowledge in a manner that considers the caregiving experience of Latinx families. Two waves of data collection (pre and post) included caregiver report measures available in Spanish that focused on caregiver empowerment, stress, and well-being. Measures included the Parents' Sense of Competence Scale (PSOC; Johnson & Mash, 1989), the Parenting Stress Index (PSI; Solis & Abidin, 1991), and the World Health Organization Quality of Life Questionnaire (WHOQOL-BREF; Lucas-Carrasco, 2012).

**Results:**

A mixed models analysis revealed no significant treatment effects ( $p$ -values ranging from .32 - .91), however medium effect sizes were detected for the Difficult Child subscale of the PSI ( $d=.37$ ; Solis & Abidin, 1991) and total scores on the PSOC ( $d=.49$ ; Johnson & Mash, 1989). A large effect size was detected for the Social Relationships subscale of the WHOQOL-BREF ( $d=.74$ ). Of the participants who completed the study, eight participated in greater than 80% of sessions. Three participants attended 33-67% of sessions. All participants completed 100% of survey measures. Survey results indicated high levels of satisfaction with CITAS, with 90% of responses indicating 'agree' or 'strongly agree' across ten items. Informal interviews with three participants indicated that caregivers valued learning CITAS content and this knowledge contributed to more positive parent-child interactions. Caregivers emphasized that their overall needs were met by connecting with other caregivers who shared common challenges.

**Conclusions:**

The results of this data provided preliminary evidence regarding the feasibility, acceptability, and potential impact of CITAS, low-intensity group treatment. Specifically, the study demonstrated the potential to significantly improve caregivers' knowledge of child development, sense of parenting competence, and social support for Latinx caregivers of children with ASD. These findings will be presented in terms of clinical implications and future research directions.

**425.088 (Poster)** Validation of the M-CHAT-R/F Illustrated, in Spanish: Preliminary Results

---

**Background:** Although screening for ASD is recommended at 18 and 24 months in the primary pediatric setting, implementation of this public health measure is far from optimal, especially in low- and middle-income countries, where capacity might not be at par with the population's needs. The Modified Checklist for Autism in Toddlers, Revised with Follow-Up (M-CHAT-R/F) is a validated, widely studied screening tool that has been translated to over 50 languages, including Spanish, and has shown good psychometric properties in studies worldwide. A previous version, the M-CHAT, was validated in a case-control Mexican cohort. With cultural adequacy and relevance as the main interest, it focused on item-level analysis rather than the performance of the total screener scores. Additionally, there is preliminary evidence from a Mexican sample showing that the M-CHAT illustrated, in Spanish, can achieve better psychometric properties than the version without pictograms. There is still great need to validate screening and diagnostic tools to detect autism in different languages and populations.

**Objectives:** To validate the M-CHAT-R/F, illustrated, Spanish version, in a sample of toddlers in Nuevo Leon, Mexico.

**Methods:** The sample included 896 toddlers ( $N_{male}=548$ , 61.1%) ages 16-36 months ( $M_{age}=24.23$ ,  $SD=5.71$ ), recruited at primary care centers where parents/caregivers completed the screener online. Screener results were categorized based on initial scores as High Risk (HR;  $>7$  points), Moderate Risk (MR; 3-7 points), or Low Risk (LR;  $<3$  points). Follow-Up items were administered by telephone to the MR participants as needed to re-categorize them into HR (final score of  $\geq 2$ ) or LR (final score 0-1). Families with a HR score were invited to attend a no-cost evaluation that included cognitive and adaptive skills testing (Merrill Palmer-3) and autism diagnostic measures (ADOS-2, Toddler Autism Symptom Interview - TASI).

**Results:** From the 896 screeners collected through the initial 20-item questionnaire, 535 (59.7%) were LR, 177 were MR (19.8%) and 184 scored within HR (20.5%). From the MR group, 37 participants were re-categorized as LR. A total of 260 participants from the HR and MR groups were lost to follow up or declined the evaluation. Diagnostic outcomes of the 64 evaluations conducted to date include 79% ASD, 4.6% GDD, 4.6% Language Disorder, 1.5% hearing impairment, and 9.3% typical development/no diagnosis.

**Conclusions:** Our preliminary results show a higher proportion of positive screens as compared to other reported validation studies. This phenomenon, along with the high percentage of cases lost to follow up, could be related to the atypical circumstances that primary care has experienced during the COVID pandemic. It is encouraging that over 90% of the children who screened at risk with the M-CHAT-R/F and attended the evaluation were identified with a condition that warrants early intervention. However, preliminary results should be interpreted with caution, since the level of parent concern and the pandemic restrictions may have biased attendance that otherwise would have occurred based on screening results. Ongoing data collection, especially including evaluation of systematically randomized negative screen cases will contribute to the current knowledge about M-CHAT-R/F's performance in a Spanish-speaking, Mexican population.

**425.089 (Poster)** ASD Screening in Persian: "What Does 'Bright Lights' Mean? a Lamp, Sunlight, or Light-up Toys?"

A. Tiznobeik<sup>1</sup>, H. Dadgar<sup>1</sup> and M. DuBay<sup>2</sup>, (1)Tehran University of Medical Sciences, Tehran, Iran (Islamic Republic of), (2)Human Services, University of Virginia, Charlottesville, VA

---

## **Background:**

Community-based and epidemiological data on developmental disability status in low- and middle-income countries is limited. Given the concerns in these countries, developmental monitoring and screening are considered essential for early identification. While significant advances have been made in the creation, validation, and implementation of screening tools for use in low-income countries, most tools have been developed in North America or Europe, and tools used in low-income countries often originate from existing tools. Having a culturally appropriate tool with good psychometric properties is a challenge. A review of translation and adaptation studies suggested that more rigorous approaches using multi-step methods lead to higher quality translations (Acquadro, et al. 2008). Numerous studies have documented differences in psychometric properties between different language versions of the same tool, both in the traditional and rigorous translation approaches (Fourie and Feinauer 2005; Granas, et al. 2014).

## **Objectives:**

The purpose of this study is to translate, culturally adapt and examine the face and content validity of the Persian version of the "First Year Inventory 2.0," a parent-report screening tool for autism spectrum disorders (ASD).

## **Methods:**

During a pre-planning phase, the research team examined the full intent of each questionnaire item, documenting words or terminology that would need to be replaced, culturally adapted, or further clarified. After completing linguistic, construct, and technical equivalence training, two native Persian translators (a parent of a child with ASD and an occupational therapist) who were highly proficient in English, independently translated the instructions, items, and response options of the "First Year Inventory" questionnaire (Baranek, et al. 2003).

In the next step, two experts with experience in the field of ASD analyzed the quality of the translations, and finally, the research team members and a coordinator, the two versions of the translation were merged into a single version. The integrated version of the questionnaire will be evaluated by 10 parents through qualitative cognitive interviews to determine face validity. To determine the content validity, at least 10 Iranian experts in the field of ASD will be asked to rate the items of the questionnaire in terms of conceptual relevance through a Likert scale. Finally, the questionnaire will be revised based on the data collected and sent to developers for approval.

## **Results:**

Our preliminary expert quality review and an integrated version of the two forward translations have been completed. The instrument has required replacement, addition, or removal of words in order to maintain linguistic equivalence and to adapt the instrument culturally. For instance, the games, such as patty-cake, are not known in Iran and require adaptation. Other illustrative examples along with qualitative and quantitative data will be presented.

## **Conclusions:**

Using a more rigorous translation and adaptation approach compared to the traditional approach, allows us to review each questionnaire item several times, document expert opinions, and ensure the quality of translations. The information that we will obtain will help to develop other screening and assessment tools across cultures.

**525 - International and Cross-Cultural Perspectives --- (V)**

**525.055** (*Virtual Poster*) Comparison of the Effects of Center-Based Vs. Virtual Training and Supervision of a Parent-Mediated Program Based in Applied Behavior Analysis in Children with Autism Spectrum Disorder in Lima, Peru

**M. C. Askins<sup>1</sup>, L. Joseph<sup>2</sup>, A. Chavez<sup>3</sup> and S. Granados<sup>4</sup>,** (1)Alcanzando Inc, Naples, FL, (2)National Institute of Mental Health, Bethesda, MD, (3)Alcanzando Inc, Coconut Creek, FL, (4)Alcanzando Inc., Lima, Peru

**Background:**

Early intervention based on the principles of applied behavior analysis (ABA) has shown to be effective in improving communication, social, and daily living skills of children with autism spectrum disorders (ASD). Despite the research supporting ABA-based early intervention for children with ASD, many have limited or no access to services due to geographic location, economic reasons, and lack of available trained professionals (Antezana, et al., 2017). In Latin America, results of a recent study indicated that services for individuals with ASD were significantly lacking within educational and health systems (Montiel-Nava et al. 2020).

**Objectives:**

Currently, in Latin America there are 73 professionals certified to practice in the behavior analysis field across 20 countries, compared to over 44,000 in the United States alone. In March 2020, due to COVID-19, a country-wide mandatory quarantine was declared in Peru. All early intervention center-based services were required to stop, making it critical to integrate the use of virtually delivered ABA training to parents/caretakers on the implementation of a parent-mediated program with their young children with ASD. The current study assessed the progress of 5 children diagnosed with ASD, who were participating in a center-based early intervention program based on the principles of ABA in Lima, Peru. It compares their progress during center-based sessions versus during a parent-mediated model.

**Methods:**

Participants (n=5, Mean age 51.6 months  $\pm$  8.5 months) were evaluated at the beginning of center-based services and at the end of parent-mediated sessions using the Assessment of Basic Language and Learning Skills - Revised (ABLLS-R; Partington & Partington Behavior, 2010). During the center-based condition, the instructors delivering intervention were trained psychologists. During the parent-mediated condition, parents/caretakers virtually completed a 5-module training on the principles of ABA, and implemented the intervention under the supervision of qualified clinicians.

**Results:**

Data from this small sample indicated that most (n=3) participants met a larger number of objectives under the parent-mediated program; however some participants (n=2) met fewer goals. For all participants during the center-based condition, the average number of monthly objectives gained ranged between 30 and 37 (M= 33  $\pm$  2.5 objectives). Similarly, during the parent-mediated condition, the average number of objectives gained ranged between 26 and 66 (M= 46  $\pm$  15.9 objectives).

**Conclusions:**

Based on this small sample, our results suggest that gains obtained in a center-based model could be replicated and in some cases be improved in a parent-mediated model in which parents are virtually trained and closely monitored by qualified professionals. Results support that best practices can be established and implemented in Latin America and provide a foundation to improve service delivery and access to effective services to individuals with ASD in this region. Further studies with a larger population and for a longer period of time is highly recommended. Future studies should focus on further analyzing the variables that might make this model more effective for some families over others

**525.056** (*Virtual Poster*) Diet Quality and Dietary Pattern of Children with Autism Spectrum Disorder in China

**L. Cai, S. Pan, X. Wang and J. Jing,** Sun Yat-sen University, Guangzhou, China

**Background:** Food selectivity and the consequent inadequate dietary intake is common in children with autism spectrum disorder (ASD). However, there were limited studies regarding diet quality and dietary patterns among school-aged children with ASD, especially in Asian area.

**Objectives:** To investigate the diet quality and dietary patterns in children with ASD in China.

**Methods:** A total of 107 children with ASD and 209 typically developing (TD) children aged 6-10 years were recruited from an ongoing longitudinal study in Guangzhou, China. The information of food consumption was assessed by a validated parent-reported Food Frequency Questionnaire (FFQ), which contains 20 kinds of food such as cereal, vegetables, fruit, animal food, condiments and so on. Diet quality was evaluated by the Chinese Dietary Balance Index (DBI\_16, including three composite indices: High Bound Score [HBS]; Low Bound Score [LBS]; and Diet Quality Distance [DQD]). Dietary patterns were determined by cluster analysis using the k-means algorithm. Chi-square test and multivariate logistic regression analysis were used to compare the difference in diet quality and dietary patterns between children with ASD and TD children.

**Results:** The average DQD of autistic children was higher, which means the dietary intakes of children with ASD were more unbalanced (ASD, 32.4 vs. TD, 28.9,  $P=0.013$ ). By using the cluster analysis, three dietary patterns were identified: the healthy pattern which was in line with recommendations, the cereal/dairy/soybean pattern, and the salt/oil/sugar pattern. The proportion of three patterns in children with ASD and TD children was 20.6% vs. 22.5%, 44.9% vs. 51.2%, and 34.6% vs. 26.3%, respectively. Children with ASD had a significantly higher proportion of the salt/oil/sugar pattern compared with TD children ( $\chi^2=101.85$ ,  $P<0.001$ ).

**Conclusions:** School-aged children with ASD had lower diet quality and a higher proportion of unhealthy dietary pattern than their typically developing counterparts. Our findings highlight the need for regular monitoring nutrition problems and improvement of eating habits among children with ASD.

**525.057 (Virtual Poster)** Disclosing the Child's Autism Spectrum Disorder: Perspectives of First-Generation Immigrant Korean Mothers  
**H. KIM<sup>1</sup>** and **R. L. Dodds<sup>2</sup>**, (1)Human Development & Psychology, University of California-Los Angeles, Los Angeles, CA, (2)Special Education & Counseling, California State University Los Angeles, Los Angeles, CA

---

**Background:** While immigrant families face common challenges such as culture clashes and language barriers, caring for children with autism spectrum disorder(ASD) leads to many issues that can complicate their adjustment to the host culture. Concerning disability culture within the Korean immigrant community, discomfort, stigma, and discrimination are the prevailing emotions, especially for people with disabilities (Kang-Yi et al., 2018), resulting in Korean immigrant mothers feeling hesitant to disclose their children's disabilities. However, very little is known about the influence of the home culture of the Korean-American community on parents' decision-making related to revealing a child's disability.

**Objectives:** This study aims to examine first-generation immigrant Korean mothers' perceptions and experiences of disclosing their children's ASD diagnoses. Specifically, the study examines: 1) first-generation immigrant Korean mothers' perceptions of an ASD diagnosis, 2) their experiences of disclosing their children's disability to others (i.e., to the community, their family members), and 3) difficulties in disclosing an ASD diagnosis to the public school system.

**Methods:** Eleven first-generation immigrant Korean mothers of children diagnosed with ASD were included in the study. Using snowball sampling, the participants were mainly recruited from a support group for Korean-American mothers who have children with ASD. The qualitative case study method, using semi-structured interviews conducted via Zoom, was employed to explore how their cultural backgrounds influence the disclosure of their children's diagnoses and how the participants reached their conclusions. Thematic analysis was used to identify patterns or themes in the dataset.

**Results:** First, participants' interviews showed that traditional Korean values, such as homogeneity, Confucianism, and collectivism, play a critical role in forming perceptions of and revealing disabilities. Second, the fear of stigma (i.e., the labeling effect, negative stereotypes, and wrong conceptualizations) makes mothers of children with ASD reluctant to disclose their children's diagnoses. Lastly, although all mothers showed a positive attitude toward disclosing their child's disability to public institutions, such as schools and other services providers, the expected stigma and benefits from services largely contributed to the parents' decision-making about disclosing a child's disability to the child's school.

**Conclusions:** Although cultural sensitivity has been emphasized, cultural factors that can create cultural clashes in the field of special education require further explanation. This study examined how native cultural conceptions of disability held by Korean immigrant mothers continue to be an obstacle to disclosing their children's disabilities. In addition, the lack of resources and limited access to services prevent mothers from disclosing their children's disabilities. Considering the paucity of empirical studies on this topic, further research should be carried out in the future.

**525.058 (Virtual Poster)** Diversity Representation in Evidence-Based Practices for Social Communication  
**M. Y. S. Bak<sup>1</sup>**, **A. D. Duenas<sup>2</sup>**, **A. M. Reilly<sup>1</sup>**, **H. Abas<sup>3</sup>** and **Q. Pan<sup>1</sup>**, (1)Educational Psychology, University of Minnesota, Minneapolis, MN, (2)College of Education and Human Services, Lehigh University, Bethlehem, PA, (3)College of Liberal Arts, University of Minnesota, Minneapolis, MN

---

## **Background:**

Although the phenotype of autism spectrum disorder (ASD) is highly heterogeneous, a common difficulty among individuals with ASD is in the area of social communication. For individuals with ASD, social communication impairments can result in limited engagement with peers and development of social relationships, thus many of the evidence-based practices (EBP) identified in the 2021 report from the National Clearinghouse on Autism and Evidence Practice (NCAEP) target social communication skills. In 2016, West and colleagues conducted a review of evidence-based practices identified in the previous EBP report and found that most studies reported participants from White and English-speaking populations with ASD. This is particularly concerning when we consider social communication skills, as social communicative behaviors are constructed by cultural communities. Therefore, it is important to examine the current evidence-base for improving social communication to determine the extent to which it includes individuals with ASD from culturally and linguistically diverse backgrounds.

## **Objectives:**

The current systematic literature review investigated the extent to which social communication intervention studies that were included in the 2021 NCAEP report to support EBPs include diverse participants, settings, and culturally responsive learning objectives.

## **Methods:**

The current systematic literature review investigated studies in the 2021 NCAEP report specifically targeting social communication skills in individuals with ASD. Social communication was defined as the use of social behavior and language in various modalities (e.g., verbal, gestural, physical, textual) that facilitate inter-human interaction and communication (APA, 2013; ASHA.org; Prizant & Wetherby, 2005). We analyzed participant and researcher demographics such as race, ethnicity, nationality, socioeconomic status; setting characteristics such as country, school or clinic; dependent variable characteristics such as verbal language, social interaction outcomes; and intervention effect size.

**Results:** Of 1215 studies in the 2021 NCAEP report, 801 studies were included in the current systematic literature review per inclusion criteria for studies regarding social communication objectives. 24.47% (n = 196) of the studies included reported the race and/or ethnicity of their participants. Only 2.62% (n = 21) of the studies reported the nationality of the participants or the country in which the study was conducted. However, 5.11% (n = 41) of the studies included indicators of participant nationality or the country in which the study was conducted such as the language used (e.g., Korean) or the measurement (e.g., Turkish scales). Results also include researcher demographics and other participant characteristics such as cognitive measures.

## **Conclusions:**

The EBP reports from organizations such as NCAEP are often used to train pre-service practitioners and assist in-service practitioners in selecting and implementing effective, scientific interventions for individuals with ASD. Practitioners are increasingly trying to seek culturally responsive interventions especially in the area of social communication for individuals with ASD (Freeth et al., 2014). Although there have been calls for representation of diversity in participants (West et al., 2016), studies that investigated social communication interventions included in 2021 NCAEP may represent a heterogeneous population. We need increased research in social communication interventions to identify and promote effective and sustainable interventions for diverse individuals with ASD in diverse communities.

### **525.059 (Virtual Poster) How Do Japanese People Perceive the Concept of "Developmental Disorders"?**

**A. Taniguchi<sup>1</sup> and T. Yamane<sup>2</sup>,** (1)Graduate School of Human Development and Environment, Kobe University, Kobe, Japan, (2)Graduate School of Developmental and Environment, Kobe University, Kobe, Japan

**Background:** In Japan, the term "developmental disorders" is widely used and has become an umbrella concept that includes several individual diagnoses, such as autism. The high level of recognition of developmental disorders has meant the concept is actively used in Japanese legislation and public awareness campaigns. However, it is conceivable that Japanese people do not place enough importance on the individual diagnostic labels of the various disorders classified under developmental disorders, and they may be applying a broad framework to their perceptions of the various developmental disorders that individuals experience. Although there have been studies examining images and stereotypes of mental illness (e.g., Angermeyer, & Dietrich, 2006), no study has examined Japan's unique cultural perception of the concept of developmental disorders. It is therefore necessary to examine perceptions of developmental disorders because it is generally recognized that perceptions of disorders lead to attitudes toward people with disorders (e.g., Corrigan et al, 2000).

**Objectives:** This paper conducted an exploratory study to clarify the general perception of developmental disorders in Japan.

**Methods:** Semi-structured interviews were conducted with 22 participants (9 males and 14 females; mean age 34.65 years,  $SD=14$ ) ranging from high school students to those in their 60s. The study participants had no diagnosis among themselves or their families and had no professional experience in learning about disorders. For the analysis, we used M-GTA, which is a method of generating concepts from verbatim interview data, interpreting the relationships among multiple concepts, aggregating them, and then presenting the results as a model. The theme of analysis was set as "What is the perception of developmental disorders at the Japanese". The analysis was conducted in five steps according to age, from which a final conceptual model was generated.

**Results:** As a result of the analysis, 27 concepts were extracted from the narrative content. From these, 10 subcategories were generated, which were finally organized into the three major categories of "Symptoms," "Evaluation," and "Causes". First, "Symptom" was categorized as narratives about specific characteristics and symptoms of developmental disorders. Some of these were thought to be related to the diagnosis of developmental disorders, while others were difficult to determine. Next, for "Evaluation", subcategories related to abilities (e.g. talent) and personality (e.g. kindness) were classified. It was suggested that people with developmental disorders, unlike those with mental illness, may be perceived as possessing special abilities and talents. Additionally, it was inferred that the subcategory [talent] classified in "Evaluation" has a compensatory role in the "state image". Lastly, "Causes" was related to the causes and reasons for developmental disorders, which were broadly classified as congenital and acquired. This suggests that there may be a combination of both accurate and inaccurate/false perceptions regarding causation.

**Conclusions:** The results of this study suggest that although people form their perceptions of developmental disabilities based on some medical knowledge, false perceptions may also contribute, therefore it is necessary to distinguish these from accurate knowledge. In the future, we plan to examine the relationship between perceptions toward developmental disabilities and stigma.

### **525.060 (Virtual Poster) Mapping Socio Economic Factors and Their Relation to Strengths, Difficulties and Autistic Traits in a Large Multinational European Autism Cohort**

**T. Del Bianco<sup>1</sup>, G. Lockwood Estrin<sup>1</sup>, J. Tillmann<sup>2</sup>, A. San Jose Caceres<sup>2,3</sup>, H. L. Hayward<sup>2</sup>, D. V. Crawley<sup>2</sup>, B. Oakley<sup>4</sup>, L. Mason<sup>1</sup>, M. Johnson<sup>5</sup>, T. Charman<sup>2</sup>, E. Loth<sup>4</sup>, D. Murphy<sup>2</sup>, J. K. Buitelaar<sup>4</sup> and E. J. Jones<sup>1</sup>,** (1)Centre for Brain and Cognitive Development, Birkbeck University of London, London, United Kingdom, (2)Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (3)Hospital General Universitario Gregorio Marañón, Madrid, Spain, (4)Forensic and Neurodevelopmental Sciences, Institute of Psychiatry, Psychology, and

**Background:** There has been increased recognition that people from low socio-economic backgrounds do not benefit from equitable inclusion in autism research studies, whose conclusions may not be applicable to autistic people from a broad range of socioeconomic and ethnic backgrounds. The first step to addressing this is understanding the socio-economic backgrounds of participants in existing studies, and developing socio-economic scores (SES) that are reliable and whose profiles across domains are specific to autism, reflecting differences in needs and challenges.

**Objectives:** We aim to examine the structure of SES including both demographic and clinical variables in a large cohort of autistic and non-autistic people from the large dataset of the multisite Longitudinal European Autism Study (LEAP), and to investigate the relation between SES and everyday Strengths and Difficulties.

**Methods:** 453 Autistic - mean age = 16.71(5.83), mean FSIQ = 96.82(19.98), females = 123 -, 311 non Autistic - mean age = 17.17(5.94), mean FSIQ = 103.79(18.86), females = 107 - people participated in LEAP. For generating data-driven SES, socio-economic and clinical variables related to child, parental and family resources were selected (Figure 1B). As the outcome variable, we selected the Strengths and Difficulties Questionnaire (SDQ) total, internalising and externalising sub-scores. We performed parallel analysis and Minimal Residual Factor Analysis and labelled the factors based on variable loadings. To assess differential effects of SES in autistic participants, we used these data-driven SES in interaction with a dimensional measure of autistic traits, the Autistic Quotient (AQ) as predictors of SDQ.

**Results:**

The parallel analysis detected 5 factors (RMSE=0.03, TLI=0.8). Based on loads, we assigned the labels: 1) Child's Characteristics: participants' adaptive and cognitive profile 2) Life Changes: life cycle changes related to growth and living arrangements 3) Family System: size of family 4) Parental Resources: parents' education, occupation and income 5) Material Resources: living environment.

The SDQ total increased with Life Changes (Coef. = 2.72, p-value = 0.04) and AQ (Coef. = 0.14, p-value < 0.01); Life Changes and AQ significantly interacted (Coef. = -0.05, p-value < 0.01). The SDQ Internalising Score was higher with higher child adaptive functions (Coef. = 1.27, p-value = 0.03) and Life Changes (Coef. = 2.73, p-value < 0.01), but less so in people with higher AQ (Child's Characteristics : Coef. = -0.02; Life Changed: -0.03, p-values < 0.01). The SDQ Externalising Score decreased with Material Resources (Coef. = -1.52, p-value = 0.04) and increased with AQ (Coef. = 0.05, p-value < 0.01).

**Conclusions:** The 5 factors jointly covered and untangled cognitive and adaptive functions from environmental variables pertaining to SES. Life Changes and Material Resources related to SDQ, and Life Changes interacted with AQ. Formally diagnosed autistic people may experience less difficulties because of existing links to health services, less shift towards living independently, or less recognition from parent reports. Future research should aim for more diversified sampling, and data collection in domains that influence the strengths and difficulties of autistic people, such as Life Changes and Material Resources.

#### **525.061** (Virtual Poster) Medical Encounters for Individuals with Autism Spectrum Disorder (ASD): Perceptions and Practices of Filipino Physicians

**M. K. P. Alonzo**, Division of Developmental and Behavioral Pediatrics, Philippine General Hospital, Manila, Philippines

---

**Background:** Given the increasing prevalence of Autism Spectrum Disorder (ASD) with the presence of co-morbidities, more patients with ASD will be encountered by different physicians in the clinical setting.

**Objectives:** This research aimed to assess the knowledge, perceptions and attitudes of Filipino physicians and describe their medical encounters with patients with ASD.

**Methods:** It is a mixed-methods cross-sectional study which employed online surveys and interviews.

**Results:** Among 315 physicians, 87% described an ASD encounter. Most of patients encountered were <18 years of age with only 14% having an encounter with an adult with ASD. The top reasons for consult were for general and unspecified, psychological, neurological and respiratory concerns. Although Filipino physicians have adequate knowledge on autism, they gave themselves low self-ratings for confidence and efficacy in their medical encounters. Pediatric providers were significantly more confident and employed more strategies in their encounters. Personal experience was not correlated to increased knowledge, confidence and self-efficacy. Majority believed that there are barriers to the care of patients with ASD citing the need for 1) training 2) preparation 3) resources 4) hospital and clinic accommodations and 5) establishing a referral system.

**Conclusions:**

Training with regards to care for patients with ASD must be skills-based and should take into consideration the specific clinical setting. The development of clinical practice guidelines with regards to best care of patients with ASD is recommended.

**525.062** (Virtual Poster) Social-Demographic Factors and Clinical Diagnoses of Autism Spectrum Disorder Among 16-30 Months Children: A National Cross-Sectional Study

**M. Cao<sup>1</sup>, X. Wang<sup>2</sup>, L. Lin<sup>2</sup> and J. Jing<sup>2</sup>, (1)Maternal and Child Health, Sun Yat-sen University, Guangzhou, China, (2)Sun Yat-sen University, Guangzhou, China**

---

**Background:** For early diagnosis and management of autism spectrum disorders (ASD), high-quality services are essential but socio-economic dependent.

**Objectives:** This study aimed to determine potential inequalities in the early diagnose of children with autism in China, examine the association of socioeconomic status with ASD diagnosis during 16-30 months of age.

**Methods:** A national, cross-sectional, populational-based study was conducted between August 1<sup>st</sup> 2016 to March 30<sup>th</sup> 2017, and a national sample was derived by convenience sampling, including North region (Beijing), West region (Chongqing and Guizhou), South region (Guangdong), Central region (Hubei) and East Region (Zhejiang). Clinical diagnosis of ASD were made by child psychologists, followed the Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition (DSM-5). We collected information including maternal/paternal education, maternal/ paternal occupation, household income, rural residence and minority of ethnic background. The final sample included 6049 children (mean age 22.68 months with standard deviation 4.11 months, 55.6% male), among which 71 of them were diagnosed with ASD.

**Results:** According to maternal education level, the ASD prevalence was 0.9%, 1.6% and 2.4% among children whose mother had educational level 'college or above', 'high school' and 'junior middle school or below' respectively. After adjusting for demographic factors and prenatal/perinatal indicators, the aOR for having the diagnosis ASD (2.46, 95% CI: 1.32-4.59) among children whose mother's level is 'junior middle school or below' was significantly higher than children whose mother's level is 'college or above'.

**Conclusions:** Among children of lower educated mothers there is a higher risk for being diagnosed with ASD at a young age. This may guide ASD early screening, diagnosis and management. We recommend more support for families with a low socio-economic status to early detect, diagnose and manage ASD.

**525.063** (Virtual Poster) Psychometric Properties of the Chinese Version of the Children's Empathy Quotient and Systemizing Quotient

**X. Wang<sup>1</sup>, L. Lin<sup>1</sup>, J. Jing<sup>1</sup> and B. Auyeung<sup>2</sup>, (1)Sun Yat-sen University, Guangzhou, China, (2)University of Edinburgh, Edinburgh, United Kingdom**

---

**Background:** The profiles of empathizing and systemizing can be used to reflect specific characteristics of ASD and describe gender-typical behaviors in general population but no validated Chinese version of the Children's Empathy Quotient (EQ-C) and Systemizing Quotient (SQ-C) are available in Mainland China yet.

**Objectives:** We aimed to validate the Chinese version of the EQ/SQ-C in children aged 4-12 years from both clinical and general population.

**Methods:** A total of 782 typically developing (TD) children, aged 4-12 years was recruited with whose parents completed the Chinese version of EQ/SQ-C. A 23-item three-factor EQ-C and a 22- item four-factor SQ-C was developed which showed good internal consistency and test-retest reliability.

**Results:** Girls scored significantly higher on EQ-C ( $31.4 \pm 7.8$  vs.  $28.2 \pm 7.7$ ) but there were no gender differences in SQ-C scores. When categorizing cognitive styles by considering EQ/SQ-C, TD children showed different cognitive styles (empathizing-dominant for girls with 42.3% identified as Type E; systemizing-dominant for boys with 40.7% identified as Type S). A further sample of 222 children with autism spectrum disorder (ASD) additionally assessed for intelligence and socio-economic status (SES) was recruited. They scored lower on EQ/SQ-C compared to TD children ( $13.2 \pm 5.1$  vs.  $29.7 \pm 7.9$ ;  $12.4 \pm 5.8$  vs.  $23.5 \pm 8.3$ ) and were generally systemizing-dominant (Type S: 46.7% for boys and 44.0% for girls). Autistic children scored higher on the SQ-C in those without intellectual disability and with higher paternal education level and family income ( $14.2 \pm 6.1$  vs.  $10.9 \pm 5.0$ ,  $13.3 \pm 6.2$  vs.  $11.5 \pm 5.1$ ,  $13.7 \pm 5.6$  vs.  $11.9 \pm 5.8$ ), while there were no differences in the EQ-C.

**Conclusions:** This study indicated good reliability and validity of the Chinese 23-item EQ-C and 22-item SQ-C, which can be used in Chinese children with and without ASD.

**525.064** (Virtual Poster) The Validity and Reliability of the Chinese Version of the Social Communication Questionnaire

**L. Lin, S. Liu, X. Wang and J. Jing, Sun Yat-sen University, Guangzhou, China**

---

**Background:** The Social Communication Questionnaire (SCQ) has been used to assess the symptoms of autism spectrum disorder (ASD) worldwide except in Mainland China.

**Objectives:** This study aims to validate the Chinese version of the SCQ in children aged 2~12 years from both general and clinical population.

**Methods:** We recruited 819 Chinese children in this study, including 505 typically developing (TD) children, 202 children with ASD and 112 children with non-ASD neurodevelopmental disorders. All the children's parents completed the Chinese version of the SCQ and all children with ASD were additionally assessed for intelligence and the Childhood Autism Rating Scale (CARS) to confirm their diagnosis.

Results: We have developed a 40-item, 4-factor structure of SCQ with two domains (social communication and social interaction; and restricted, repetitive, and stereotyped patterns of behavior), which showed adequate goodness of fit (comparative fit index [CFI] = 0.981, Tucker Lewis index [TLI] = 0.980, standardized root mean squared residual [SRMR] = 0.116, root mean square error of approximation [RMSEA] = 0.061), with good internal consistency (Cronbach's alpha = 0.923). We have provided different cut-offs to distinguish ASD cases from TD children (10.5 for children under 4 years [sensitivity: 0.963, specificity: 0.952], 11.5 for children 4 years and above [sensitivity: 0.926, specificity: 0.975]) or children with other neurodevelopmental disorders (13.5 [sensitivity: 0.851, specificity: 0.875]).

Conclusions: Through this large sample validation, we confirmed that the Chinese version of the SCQ could be used for children aged 2~12 years with relatively good psychometric properties.

**525.065** (Virtual Poster) Understanding Cultural Sensitivity in Autism Education: A Semi-Structured Interview with Chinese American Parents of Children with Autism

**X. Yang<sup>1</sup>** and **E. T. Crehan<sup>2</sup>**, (1)*Child Study and Human Development, Tufts University, Medford, MA*, (2)*Eliot-Pearson Department of Child Study & Human Development, Tufts University, Medford, MA*

---

Background: The acculturation process has increased the diversity of the autistic population seeking professional services and education in the U.S. As the diagnosis of autism increases within Chinese American immigrant population, there is an increasing need to understand this population and provide appropriate intervention and education for this group. Among all the factors influencing the intervention process, culture remains an essential one that needs extra attention. To our knowledge, no previous studies have evaluated the cultural appropriateness of the education Chinese American autistic children received. The current study explored the cultural sensitivity of the education and intervention autistic students received from the perspectives of their Chinese American parents.

**Objectives:**

The study intended to understand the perception and expectation of Chinese American parents over the cultural sensitivity of intervention strategies and educational materials their autistic children receive in the U.S.

**Methods:**

An online screening questionnaire and a semi-structured interview were conducted with eight Chinese American parents (7 mothers; 1 father; average time in the U.S. 7.5 years ( $SD = 2.71$ ) with children between 4 to 11 years old ( $M = 7.88$ ,  $SD = 2.64$ ; 4 born in China, 4 in U.S.) were recruited. Participants completed the screening questionnaire with basic demographic information of their family and autistic children online first. Eligible participants were interviewed via online meeting in Mandarin (native language). Interview questions were developed to explore participants' perception of cultural sensitivity in educational materials/strategies, their expectation and recommendations of cultural education, and experiences after diagnosis. Thematic analysis approach was used to analyze interviews (Braun and Clarke, 2006).

**Results:**

Analysis of the transcripts focused on four themes: immigration context and family environment, cultural sensitivity perception and expectation, attitudes and experiences with ASD diagnosis and stigma, as well as expectations and suggestions. Chinese American parents' experiences and attitudes towards the cultural-related stigma influenced how they perceived children's autism diagnosis and symptoms as well as their expectations of children's culturally-sensitive education. The education materials and intervention strategies provided to their children with autism were not considered culturally-sensitive. Parents expected more systematic guidance and support from the education institutions and provided suggestions to lower the pressure of the special education system.

**Conclusions:**

Interviews supported the idea that cultural sensitivity is a critical missing piece of education for autistic children with Chinese American parents. Based on Mistry et al.'s integrated conceptual framework (2016), a theoretical model was created to provide culture-centered interpretation of the interconnected relationship between the specific context Chinese American parents' lived in and their parenting domains (Figure 1). It analyzed parents' attitudes towards autistic diagnosis and symptoms, expectations of children's culturally-sensitive education through their understanding of cultural-related stigma. The model highlighted the necessity and importance to construct and reform the distribution of special education resources that are culturally sensitive to Chinese American parents and autistic children. Follow-up research with larger sample size and diverse family type are emphasized to improve and refine the model. Broadening the study sample to include perspectives from individuals outside Chinese American families is also recommended for future work.

**525.066** (Virtual Poster) Brief Report: Parental Stress in Parents of Autistic Children in China and the Netherlands

**F. Liu<sup>1</sup>**, **S. Begeer<sup>2</sup>**, **A. M. Scheeren<sup>3</sup>** and **C. Wang<sup>4</sup>**, (1)*Horstenberg, Vrije University Amsterdam, Amsterdam, Netherlands*, (2)*VU University Amsterdam, Amsterdam, Netherlands*, (3)*Vrije Universiteit, Amsterdam, Netherlands*, (4)*Department of Social Psychology, Nankai University, Tianjin, China*

---

Background: Parents of autistic children experience higher stress levels than parents of non-autistic children. Asian parents with autistic children may experience more stress compared to Western parents (Chung et al., 2012; Nomaguchi & House, 2013), though findings are mixed (Smith et al.,

2021). In addition to culture, fewer autism symptoms, female gender of the autistic child, and high Social Economic Status (SES) have been linked to lower parenting stress. It is unknown whether these factors have a different impact on parenting stress in Asian (China) and Western (The Netherlands) countries.

**Objectives:** In this pre-registered study, we (a) compared parenting stress levels between parents of autistic children from China and the Netherlands, using the abbreviated Parenting Stress Index (PSI), and (b) examined the impact of caregiver factors (age, income, educational level) and child factors (gender) on parenting stress in both countries, and exploring the association with parents' worries about COVID-19.

**Methods:** 95 Chinese parents (76 boys; 19 girls) and 118 Dutch parents of autistic children (93 boys; 25 girls) aged 2 to 16 years ( $M = 9.64$  years,  $SD = 4.24$ ) participated. Most parents (92%) were well educated and had middle to higher-level family income (83%) (see Table 1). A hierarchical multiple regression analysis was used to examine if parenting stress differed between countries, with caregiver factors (age, income, educational level) and child factors (gender) and COVID-19 worries as the predictors (step 1), followed by country (step 2) and the interaction terms between caregiver/child factors and country (step 3).

**Results:** Caregiver factors, child factors and COVID-19 worries explained 15% of the variance in parenting stress. Younger parents and parents with more COVID-19 worries reported more parenting stress. Country explained 15.9% additional variance in parenting stress, indicating that Chinese parents ( $M = 43.36$ ,  $SD = 8.45$ ) reported higher parenting stress than Dutch parents ( $M = 32.92$ ,  $SD = 11.69$ ) (see Table 2).

**Conclusions:** Chinese parents of autistic children reported higher parenting stress levels than Dutch parents, despite fewer COVID-19 worries. Culture could play a role: Chinese culture emphasizes interdependence and parents' responsibility for training a child to behave properly in society. Chinese parents of autistic children may place less value on their own needs and may fear non-conformity of their child, promoting self-sacrificing behaviour and social isolation, which may negatively impact parental mental health and well-being. Moreover, having an autistic child in China may be perceived relatively more as a social devaluation. It may invoke different stressors (e.g., cultural concerns of losing face) that are particularly salient in Chinese parents. Factors influencing parenting stress in different socio-cultural settings is an important issue that requires further study.

**525.067 (Virtual Poster)** Working Towards Inclusive Education for Autistic Children in Algeria: An Analysis of the English As a Foreign Language (EFL) Teacher Preparation Programme

**I. Z. Kassous<sup>1</sup>, D. R. Simmons<sup>2</sup> and I. Alves<sup>1</sup>, (1)School of Education, University of Glasgow, Glasgow, United Kingdom, (2)School of Psychology and Neuroscience, University of Glasgow, Glasgow, United Kingdom**

**Background:**

Since signing the Convention on the Rights of Persons with Disabilities (CRPD) in 2007, Algeria has been striving to improve rights in all domains including education. However, it has been suggested that these laws are merely "words on paper" (Kaci, 2019). One potential example case is inclusive education. To what extent have inclusive education practices been followed in Algeria? We have investigated teachers' knowledge and attitudes with the hope of identifying training needs and barriers to implementation with respect to the educational inclusion of autistic children.

**Objectives:**

The focus of this study was on Ecole Normale Supérieure (ENS) and University students/graduates (prospective teachers) of English as a Foreign Language (EFL). We investigated their knowledge of autism and their attitudes towards inclusive education for autistic children. We also explored the connections between prospective teachers' knowledge/understanding of autism and the EFL teacher training programme.

**Methods:**

These research objectives were addressed qualitatively, using a combination of semi-structured individual interviews and focus group discussions. 13 Individual interviews involved introducing scenarios about autistic children in a general classroom and direct questions about participants' knowledge of autism and attitudes towards inclusive education for autistic children. In each of the two focus groups ( $n=3$  per group) we discussed how participants' teacher training experiences contributed to their knowledge. Critical thematic analysis was used to analyse the data generated.

**Results:**

We identified the following themes: (1) knowledge of the characteristics of autism, (2) personally/socially driven sources of information, (3) fluctuating attitudes and (4) educability of autistic children. Participants' knowledge of autism was highly variable (Theme 1). Whilst some had accurate information, the responses of other participants exhibited stereotypical views about autistic children all being (e.g.) "highly intelligent". The chief characteristics of autism reported were communication difficulties, repetitive behaviours and sensory issues. Regarding their sources of information (Theme 2), some participants mentioned the role of the internet and social media in developing their current understanding of autism. Personal experiences and previous contact with autistic people also influenced a number of participants. It is noteworthy that 3 participants mentioned 'The Good Doctor' TV series and how it contributed to their knowledge and understanding of autism. Participants' attitudes towards teaching autistic children fluctuated between positive, negative and mixed (Theme 3). A number of participants saw autistic children as 'unintended students' (Titchkosky, 2002) who should receive education in special schools or classes (Theme 4). The main argument among those who were hesitant towards including/teaching autistic children was related to lack of knowledge and effective training.

## Conclusions:

Our participants' knowledge of autism was highly variable and mostly obtained from individual experiences and personal efforts rather than any sort of institutional training programme or material. Nonetheless, this situation is unlikely to be unique to Algeria or even developing countries like Algeria.

### **525.068 (Virtual Poster)** Examination of the Impact of the Get SET Early Program on Racial and Ethnic Disparities on the Screen-Evaluation-Treatment Chain in Toddlers with ASD

**C. Pham, E. Bacon, C. Barnes, S. Arias, L. Lopez, E. Courchesne and K. Pierce, Neurosciences, University of California, San Diego, La Jolla, CA**

---

**Background:** Although trends are improving, children from underrepresented minority (URM) backgrounds are often identified with autism spectrum disorder (ASD) less frequently, at older ages, and with reduced access to services than their Caucasian counterparts, which could negatively influence developmental outcomes for these groups. It is not clear if disparities exist at all levels along the screen-evaluation-treatment chain, or if early detection programs such as *Get SET Early* that standardize steps for screening, evaluation, and treatment referral are effective at reducing disparities.

**Objectives:** The aim of the present study was to determine if engagement in the *Get SET Early* program (Pierce et al., 2011; 2021), a universal early screening and detection program, results in equal levels of ethnic and racial participation and performance from the screening level to the treatment level, thus reducing any existing disparities along the screen-evaluate-treat chain. To do so, uptake rates within key metrics of the model were examined stratified by ethnicity and race, including average screen age, screen failure rates, parent concern rates, pediatrician referral rates, average evaluation age, average treatment start age, and average hours of treatment received over the most recent six months of treatment.

**Methods:** Following the *Get SET Early* program training, 97 pediatricians digitally administered 30,554 CSBS-DP-IT Checklist screens at 12, 18, and 24-month well-baby exams, and parents designated presence or absence of concern. Toddlers who failed the screen, or whose pediatrician had an ASD concern, were referred to a clinic that specializes in the infant-toddler period and evaluated by licensed clinical psychologists and referred for treatment the same day as appropriate. Treatment engagement data was retrieved directly from the San Diego Regional Center that administers Part C funding for ASD treatment and was also supplemented by parent report.

**Results:** Children from URM backgrounds were screened at expected rates for San Diego County; however, they were more likely to fail the screener than their Caucasian/Not Hispanic counterparts. Parents of children from URM backgrounds also expressed more concern than Caucasian/Not Hispanic parents. Pediatrician referrals were most influenced by screen failure and parent concern, over ethnic/racial group membership. Overall, there were no group differences between the mean age at first screen (range 16.98 to 17.32 months), evaluation and treatment referral (range 20.50 to 22.93 months), first treatment engagement (range 21 to 27 months) or level of treatment engagement between groups (4.50 hours per week to 9.55 hours per week).

**Conclusions:** Leveraging standardized early detection programs such as *Get SET Early* may help reduce disparities traditionally found along the screen-evaluation-treatment chain. Though there remain gaps within the pipeline that need to be addressed, e.g., applicability of specific screen items to some groups or how to further ensure that families will follow-through with treatment referrals, implementation of systemized programs that are easily accessible among all demographic groups may be key in ameliorating disparities in access to care across communities.

### **525.069 (Virtual Poster)** Examining Cultural Differences in Face Processing: Implications for Assessment and Intervention in Autism Spectrum Disorder (ASD)

**Y. Bean<sup>1</sup> and A. J. Harrison<sup>2</sup>, (1)School Psychology, University of Georgia, Athens, GA, (2)Educational Psychology, University of Georgia, Athens, GA**

---

**Background:** Most autism spectrum disorder (ASD) assessments and treatments evaluate or target “typical” social conventions such as eye contact, joint attention, and social referencing (Lord et al., 2012; Volkmar et al., 2014). Research documenting cultural differences in overt or observable social behaviors, such as eye contact and body language (e.g., Fugita et al., 1974; Archer, 2007), highlights the need to adapt assessment and intervention to align with distinct cultural norms. Recommendations for how to adapt best practices to take into account cultural variability should be informed by research documenting cultural differences in both overt and more covert social behaviors (e.g., face processing and emotion recognition). Preliminary research shows cultural differences in face processing when comparing across countries (e.g., Matsumoto, 1989; Ekman & Friesen et al., 1987); however, a more nuanced examination of sociocultural differences within individuals from different racial-ethnic groups living in the same country can result in more culturally sensitive ASD diagnostic procedures and interventions.

**Objectives:** We examined cultural differences in face processing, due to the role this may play in ASD assessment and treatment planning. Theory suggests that groups of racial-ethnic minoritized individuals, as compared to White participants, may prioritize different facial features. This study examined differences in total dwell (viewing) time to key facial features (eyes, mouth, and nose) across racial-ethnic groups.

**Methods:** Data from 88 participants was analyzed across distinct racial/ethnic groups (Asian, Black, and White). Each participant completed questionnaires to obtain demographic information (race, ethnicity, etc.), individualism versus collectivism identification, and acculturation level. Participants then completed a 20-minute face processing task in which they viewed a series of racially-ethnically diverse facial stimuli depicting a range of emotions for 5 seconds each. Amount of participant eye gaze to facial features was quantified using an eye tracker.

**Results:** Results from a 3 (Racial Group: White, Black, Asian) x 3 (Facial Feature: Eyes, Mouth, Nose) repeated measures ANOVA revealed a significant emotion by group interaction  $F(2, 154) = 2.61, p = .01$ . A post-hoc examination showed that White participants demonstrated significantly different patterns than both Black ( $p = .05$ ) and Asian ( $p = .014$ ) participants. The difference between Asian and Black participants was not significant ( $p = .48$ ). To further examine the nature of the interaction, post hoc tests examined the duration of time spent looking at each facial feature within each racial group. Results revealed that White individuals viewed the mouth more than Asian individuals ( $p = .040$ ) and viewed the eyes more than Black participants ( $p = .002$ ).

**Conclusions:** In alignment with our hypothesis that participants from collectivistic countries may avoid overly expressive features like mouths (Yuki et al., 2007), we found that White participants prioritized mouths more than Asian participants. We also found a novel, meaningful difference in how White and Black participants prioritized facial features. This indicates culture affects more subtle social functioning within racial-ethnic groups and could inform the development of culturally sensitive assessments and treatments for individuals with ASD. Follow-up analyses will also examine the effect of acculturation and worldview on facial viewing times.

**525.070 (Virtual Poster)** Identifying the Best Discriminating Signs of Autism Spectrum Disorder (ASD) in High-Risk Siblings in Singapore  
**C. M. Wong, N. Mohd Zambri, H. H. Fan, L. H. S. Lau, L. M. Daniel and H. C. Koh, Department of Child Development, KK Women's and Children's Hospital, Singapore, Singapore**

---

**Background:** Singapore's population comprises a multiracial demographic of 76% Chinese, 15% Malay, 7.5% Indian, and 1.5% other races. The estimated prevalence of ASD in Singapore is 1%, and although nationwide developmental surveillance is conducted for young children, there is no standardised ASD-specific screening. The Modified Checklist for Autism in Toddlers, Revised with Follow-up (M-CHAT-R/F) is the most commonly used. Koh (2014) previously found that the M-CHAT Critical 6 and Best 7 scoring methods were accurate (sensitivity >0.75) in detecting ASD in 18-30-month-old Singaporean children referred with developmental concerns. However, studies from other Asian countries have reported lower M-CHAT sensitivity (Toh 2018), and that the critical/discriminating items may vary by race/culture (Wong 2018, Kamio 2015, Seung 2015, Wong 2004).

**Objectives:** To determine the accuracy of the M-CHAT-R/F as a Level Two screener in a population of siblings at high risk for ASD in Singapore, and to identify the best discriminating signs of ASD.

**Methods:** Siblings aged 12-30 months of children with confirmed ASD were invited to undergo a structured screening programme which involved parents completing the M-CHAT-R/F at 12, 18 and 30 months old. Only the English version was used as Singaporeans are predominantly English-speaking. Although the M-CHAT-R/F is only validated for children 16 months and older, the 12-month screening was conducted to explore its utility compared to other 12-month screeners. The siblings then underwent an Autism Diagnostic Observation Schedule – Second Edition (ADOS-2) assessment at 36-48 months old to determine if they met the autism spectrum diagnostic algorithm. Sensitivity, specificity, positive predictive and negative predictive values for the M-CHAT-R/F were computed, and Fisher's exact test was used to determine higher-discriminating items. Discriminant Function Analysis will be conducted on more complete data.

**Results:** 185 siblings underwent screening (54.5% male; 64% Chinese, 26% Malay, 5.7% Indian). 18 withdrew and 88 have completed the ADOS-2 to date. 32 met criteria for ASD. 23 of the 88 were screened at 12 months, 49 at 18 months, and 70 at 30 months, with some being screened at more than one time point. Results on the 88 indicated overall low sensitivity but high specificity of the M-CHAT-R/F at all age groups, even with using Critical 6 scoring. Further analyses of the 30-month data indicated that the most discriminatory items were protodeclarative pointing, spontaneous showing, response to name, gaze following, and gaining attention. ADOS-2 assessments are ongoing hence detailed results will be presented at INSAR 2022.

**Conclusions:** The performance of tools developed for low-risk ASD screening should also be examined in higher-risk populations. In a population of Singaporean siblings at high risk of ASD, the M-CHAT-R/F did not perform as well as previously found. This may be due to high-risk siblings having more subtle features of ASD which are missed by screening but picked up on ADOS, or biased parental reporting if their older child had more obvious signs of ASD. Higher-discriminating items appear to be different from those defined in the US population.

**525.071 (Virtual Poster)** South Korea's Perception of Autism and Play, and the Effects on Parents and Educators of Children with ASD  
**S. Kim<sup>1</sup> and A. K. Marcelo<sup>2</sup>, (1)Kindle Behavior Consultants, Burlington, MA, (2)Psychology, Clark University, Worcester, MA**

---

**Background:**

Play has been used as an intervention for children diagnosed with Autism Spectrum Disorder (ASD). Although the relations of play and ASD have been widely studied, there is a dearth in studies in this area of research in more diverse samples, especially in Asian samples. For example, there are a small handful of studies on ASD and effectiveness of play intervention on children with ASD in South Korea. Understanding how specific ethnic-racial groups perceive these constructs, in terms of their form and function, is important in developing more effective and accessible interventions to support families with children diagnosed with ASD across different cultures.

**Objectives:**

This exploratory study aims to examine if and how the effects South Korean cultural attitudes have on Korean children with ASD, their parents, and their educators. Additionally, cultural attitudes towards play, and if Koreans view play as something that could be beneficial for children with autism's development, will be collected.

## Methods:

South Koreans (N=???; data collection ongoing) in Korea completed questionnaires with open ended questions via Qualtrics on their knowledge of ASD, perceptions of children with ASD, and perceptions of play/play intervention. Participants chose if they identified as a parent or an educator of a child with ASD, or part of the public with no personal connection to ASD.

## Results:

Preliminary findings illustrate that common belief from the public is that people with ASD feel isolated, trapped, and have severe developmental and physical disabilities. Much of the public perceived play intervention/education as a positive strategy because play was seen as something easy that would garner interest from children and could teach social/communication skills. Most of the general public's responses reflected a stereotypical view of autism. Many of the written responses stated that play is something children with ASD would benefit from, because play is considered easy, play can teach communication skills, and improve social interaction skills which many noted children with ASD may struggle with.

## Conclusions:

Most of the general population group carried a stereotypical belief of ASD, such as an inability to socialize at all, and that ASD is a severe disability which requires life-long parental care. This belief neglects that autism is on a spectrum, and there is no one diagnosis that fits everybody. If the majority of a population believes that ASD has a certain look, then parents may forgo taking their child to the doctor for a diagnosis if their child does not completely fit the stereotype. Furthermore, this could harm children who do not fully fit into the stereotype as they may be denied intervention services and other forms of care. These misconceptions could contribute to a deeper separation of people with developmental disabilities from neurotypicals in society. Data collection is ongoing, and focusing on recruiting more caregivers and teachers of children with ASD. Gaining an understanding on how South Koreans perceive ASD, people diagnosed with ASD, and play as a potential intervention, will allow us to develop better intervention programs to help children with ASD across different cultures.

## **525.072 (Virtual Poster) The Relationship between Social Camouflage and Mental Health in Japanese Autistic Adults.**

**F. Oshima<sup>1</sup>, T. Takahashi<sup>2</sup>, M. Hongo<sup>3</sup>, L. Hull<sup>4</sup>, W. Mandy<sup>4</sup> and E. Shimizu<sup>1</sup>,** (1)Research Center for Child Mental Development Chiba University, Chiba, Japan, (2)Waseda University, Saitama, Japan, (3)Chiba University, Chiba, Japan, (4)Department of Clinical, Educational and Health Psychology, University College London, London, United Kingdom

---

## Background:

An autism spectrum disorder (ASD) diagnosis is intended to signal the need to support, to improve functioning and quality of life. However, many autistic people are not diagnosed adulthood and therefore miss out on the support and understanding they need. One of these reasons for autistic people being undiagnosed or diagnosed late is potentially related to camouflaging of autistic characteristics (Hull et al., 2017). Social Camouflaging (SC) refers to strategies that mask social difficulties and enable "passing" as though non-autistic in social situations (Hull et al., 2017; Livingston et al., 2020). While appearing to improve external adaptation in social situations, SC has been shown to increase fatigue and anxiety in people with ASD and is associated with worse mental health outcomes (Lai et al., 2017). As cultural differences, including gender, highly influence SC, there is a need to clarify the characteristics of SC in a range of cultural contexts. But most SC research to date has been done in Western countries, especially the UK, and the relationship between mental health and SC in autistic adults in Japan is not clear.

## Objectives:

This study aims to clarify the relationship between SC and mental health in Japanese autistic adults.

## Methods:

A total of 192 men and women aged between 20 and 65 years with a diagnosis of ASD and an IQ in the normal range participated in the study. All gave informed consent to participate in the study, and completed the following self-reported, Japanese-version questionnaires: the Camouflaging Autistic Traits-Questionnaire (CAT-Q), the Broad Autism Phenotype Questionnaire (BAPQ), the Warwick-Edinburgh Mental Well-being Scale, the Patient Health Questionnaire-9 (PHQ-9), the Liebowitz Social Anxiety Scale, and the Generalized Anxiety Disorder-7 (GAD-7).

## Results:

Figure 1 & 2 show the results of the hierarchical multiple regression analysis. In the present study, SC did not predict worse mental health in Japanese autistic adults. Furthermore, non-linear effects of SC were found on the GAD-7 and PHQ-9. Again, there were no gender differences in the relationship between SC and mental health deterioration. Hull et al. (2021) found that the higher the camouflage score, the greater the generalized anxiety, depression, and social anxiety. In our data, on the other hand, depression and generalized anxiety were nonlinearly related to higher camouflage scores. While there were no significant differences between men and women, but non-binary subjects were not studied.

## Conclusions:

In Japan, SC for people with ASD was not simply associated with poorer mental health. It is suggested that the relationship between this outcome and the socio-cultural background needs to be clarified.

## Interventions - Non-pharmacologic - Preschool & Infant

### PANEL — INTERVENTIONS - NON-PHARMACOLOGIC - PRESCHOOL & INFANT

#### 229 - Leveraging Diverse Digital Technologies to Disseminate Evidence-Based Autism Interventions

**Panel Chair:** Ty Vernon, *University of California, Santa Barbara, Santa Barbara, CA*

**Discussant:** Karen Bearss, *Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA*

##### **229.001 (Panel)** Pivotal for Early Autism Intervention: Preliminary Outcomes of a Smartphone App-Based Parent Education Program

**E. F. Ferguson, A. Arias, M. Jimenez Munoz, S. Licon, K. M. Russell, P. Adams, A. Nees and T. W. Vernon, University of California, Santa Barbara, Santa Barbara, CA**

**Background:** Many families experience challenges accessing appropriate interventions to promote language and social development in young children on the autism spectrum (Bishop-Fitzpatrick & Kind, 2017). Online training for caregivers of autistic children may increase access to high-quality treatment methods and jumpstart child development through daily parent-child interactions (Ingersoll et al., 2016). While self-directed parent education programs have generally resulted in inferior outcomes when compared to in-person professional training, video self-monitoring and self-management of one's performance, paired with adaptive app-based feedback based on self-scoring, have the potential to facilitate training outcomes that approximate those obtained by in-person clinical services. Pivotal Response Treatment (PRT) may be an ideal autism intervention to explore in an app-based training program. PRT is a parent-friendly naturalistic developmental behavioral intervention (NDBI, Schreibman et al., 2015) that combines motivational and behavioral principles to develop communication skills in naturalistic settings. Given the substantial evidence supporting the efficacy of PRT (Verschuur et al., 2014), increased access to these treatment techniques has the potential to benefit families nationwide.

**Objectives:** To examine the increase in parent PRT fidelity scores associated with participation in a Department of Defense-funded RCT to evaluate the efficacy, feasibility, and acceptability of using *Pivotal*, a self-directed mobile training app developed by the research team.

**Methods:** Participants include 48 parent-child dyads across the U.S. (24 randomized to a video self-scoring PRT app version and 24 to a standard PRT app without self-scoring functionality). Child participants (1 - 4.5 years) have an existing diagnosis of ASD and parent endorsements of significant language delay. Parents complete intake and follow-up assessments, eight PRT lessons, and record and review parent-child videos in-app after each lesson, which are automatically uploaded to the research team for analysis. In the adaptive condition, parents review and self-score PRT videos with their child and then receive in-app feedback to improve their PRT performance. Researchers masked to treatment condition score all videos for PRT fidelity of implementation (Primary Outcome). Refer to Table 1 for a list of all fidelity components coded as part of PRT fidelity of implementation.

**Results:** Analysis of baseline to initial intervention videos from participating families indicate a significant increase in the use of PRT fidelity components. The widely used passing percentage of 80% was used as the benchmark for meeting PRT fidelity standards. Overall PRT fidelity increased from a mean of 45.13% (SD = 14.34) at baseline to 67.90% (SD = 16.68) after a single week of app-based PRT training (Cohen's  $d = 1.47$ ). The critical PRT fidelity component of contingency increased from a mean of 15.53% (SD = 18.57) at baseline to a mean of 92.60% (SD = 12.82) across families (Cohen's  $d = 4.91$ ).

**Conclusions:** Initial parent training through the Pivotal app was associated with significant improvements in the demonstrated use of PRT intervention strategies captured through analysis of parent-uploaded video recordings. These data provide exciting evidence that this app-based approach may serve as an effective parent training tool to facilitate dissemination of high-impact early intervention techniques.

##### **229.002 (Panel)** Making an Impact: Relative Efficacy of Self-Directed and Therapist-Assisted Telehealth Parent-Mediated Intervention on Parent Learning and Well-Being

**B. R. Ingersoll, Psychology, Michigan State University, East Lansing, MI**

**Background:** Parent-mediated intervention is a cost-effective and ecologically valid approach to increasing access to intervention that leads to increases in parenting self-efficacy and decreases in parenting stress. Although there has been growing interest in extending telehealth interventions to parent-mediated intervention for children with ASD, empirical evaluations of such programs are limited, and little is known regarding the relative benefits of self-directed and therapist-assisted telehealth interventions. A pilot study of ImPACT Online, a telehealth adaptation of a parent-mediated intervention targeting social communication suggested that both self-directed and therapist-assisted intervention led to improvements in parent learning and well-being, although parents in the therapist-assisted group made greater gains in intervention fidelity and positive view of the child (Ingersoll et al., 2016). However, the lack of a control condition and follow-up period limited the conclusions that can be drawn regarding the impact of the intervention on parenting outcomes.

**Objectives:** The objective of this study was to replicate our pilot results on the impact of self- and therapist-assisted ImPACT Online on parenting learning and well-being, using a larger sample, the inclusion of a web-based informational support control condition, and a follow-up period.

**Methods:** Sixty-five families of young children with ASD were age and IQ matched and then randomized to self-directed ImPACT Online (n=24), therapist-assisted ImPACT Online (n=22), or an informational support condition (n=19), and received intervention for 5 months. Outcome assessments occurred at post-intervention and a 3-month follow-up. Preliminary analyses of group differences in parent intervention knowledge, intervention fidelity, positive view of the child, parent self-efficacy, and parenting stress were examined at post-treatment and follow-up using ANCOVA.

**Results:** Consistent with our pilot findings, we observed significant group differences for parent intervention knowledge at post-intervention ( $F(2,45)=3.66, p<.05$ ), parent fidelity at post-intervention ( $F(2,30)=3.88, p<.05$ ) and follow-up ( $F(2,28)=3.83, p<.05$ ), and parent positive perception of child at post-intervention ( $F(2,45)=4.17, p<.05$ ) and follow-up ( $F(2,48)=4.23, p<.05$ ). Post-hoc analyses found a significantly higher scores for the therapist-assisted group than the informational support group on all measures, with the self-directed group falling in between. We did not observe significant group differences in parent self-efficacy or parenting stress and post-intervention or follow-up, suggesting that improvements in parent self-efficacy and parenting stress in our pilot findings may not have been directly attributable to exposure to the intervention.

**Conclusions:** This study provides additional support for the efficacy of therapist-assisted telehealth parent-mediated intervention for teaching parents intervention strategies to support their child's social communication skills and improving their positive perceptions of their child. Additional research on the potential benefit of self-directed telehealth programs as well as the impact of telehealth-based parent-mediated intervention on child outcomes is needed.

**229.003 (Panel) START Connections Online: Outcomes of an Online Social Interaction Skill Group for Adolescents with Autism**

**K. M. Russell<sup>1</sup>, K. Rackham<sup>2</sup>, A. Bhatt<sup>2</sup> and T. W. Vernon<sup>1</sup>, (1)University of California, Santa Barbara, Santa Barbara, CA, (2)University of California Santa Barbara, Santa Barbara, CA**

---

**Background:** The social challenges associated with autism can have life-long impacts on the ability to establish meaningful relationships. Social skill interventions have emerged to target socialization vulnerabilities of autistic adolescents, but there is a critical need for effective dissemination of these programs to overcome barriers to service access. Digital communication platforms offer a promising method for facilitating these trainings, but it is unknown if virtual sessions can yield similar outcomes to in-person. The Social Tools And Rules for Teens (START; Vernon et al. 2016; Vernon et al, 2018; Ko et al, 2018) Program is an intervention for increasing social competencies and motivation while reducing autism-related social communication challenges. This program for adolescents with autism combines a 20-topic social curriculum with immersive experiential learning with peers during unstructured socialization periods to provide a supportive, natural context for social experimentation and skill building.

**Objectives:** The aim of this study was to develop and evaluate START Connections, an online adaptation of the original START model. Specifically, we aimed to assess the preliminary efficacy, feasibility, and acceptability of START Connections when compared to the outcomes of the original START RCT participants. It was hypothesized that teen and parent participants would perceive the START Connections program as acceptable and efficacious. Additionally, we hypothesized that participant's social competence and motivation would increase and be comparable to in-person START outcomes, as measured by parent and teen surveys, real-world social data, coded conversation samples, and social impression ratings.

**Methods:** Participants were 42 adolescents with autism (START Connections: 13, in-person START: 14, waitlist control: 15) aged 12-16 (Mean age=13.67) and their parents. Inclusion criteria included the use of full sentence phrases to communicate, the ability to respond to and ask questions, a verbal IQ  $\geq 70$ , and verification of their autism diagnosis. Participants were diverse across genders (31% female) and racial and ethnic identities (26% Latinx, 57% white, 14% Asian, 3% Other). The bi-weekly START Connections program consisted of an individual therapeutic check-in, group socialization time, group discussion and practice of 20 social skill topics, group activity, and individual checkout via Basecamp and Zoom software programs.

**Results:** Results indicate that socialization measures significantly improved following implementation of START Connections. Analysis of treatment gains in the START Connections participants yielded evidence of medium to large effects on several parent-report and adolescent self-report measures of emotion regulation (EDI;  $d=0.72$ ), autism symptom severity (SRS-2;  $d=0.75$ ), and social motivation and competency (SMCS;  $d=0.36$ ). Additionally, significant improvements in individual target skills (questions asked and comments made) were observed for 75% of participants through observations of naturalistic conversations with unfamiliar peers. Both parents and teens endorsed high levels of program enjoyment (Mean=8.5/10) and improvement of skills (Mean= 6.8/10). Mixed ANOVAs revealed comparable outcomes between START Connections and in-person START groups, with both groups superior to waitlist control outcomes.

**Conclusions:** Results show promise for the online START Connections model in improving social communication in autistic teens. These results warrant a prospective investigation comparing in-person to digital implementations of social skill programming.

**229.004 (Panel) Implementation of Telehealth Services to Deliver Applied Behavior Analysis**

**A. Pomales-Ramos<sup>1</sup> and B. R. Ingersoll<sup>2</sup>, (1)Michigan State University, East Lansing, MI, (2)Psychology, Michigan State University, East Lansing, MI**

---

**Background:** Telehealth implementation of applied behavior analysis (ABA) has resulted in positive outcomes for autistic children and caregivers and reduced service disparities (Ferguson, 2019), but has not been widely adopted until recently. During the COVID-19 pandemic, agencies turned to telehealth to deliver ABA services and prevent service disruption. Understanding providers' experiences and perspectives on telehealth adoption can inform practice considerations that support successful telehealth implementation.

**Objectives:** The current study examines ABA providers' adoption of telehealth services and factors that influence acceptability and intentions for continued use.

**Methods:** We surveyed 479 providers delivering ABA services to autistic children recruited through the Behavior Analyst Certification Board email list. Clinicians reported on telehealth adoption and barriers using a 5-point Likert-scale. Clinicians also completed the Telehealth Usability Questionnaire (TUQ), Implementation Climate Scale (ICS), the Acceptability of Intervention Measure (AIM), and rated their intention to use telehealth in the future on a 5-point scale. Telehealth adoption and barrier items were analyzed using descriptive statistics. A hierarchical regression was conducted to examine predictors of telehealth acceptability (AIM). Provider demographics associated with acceptability were entered in the first step, TUQ subscales were entered in the second step, and ICS subscales were entered in the third step. A correlation was used to examine acceptability as a predictor for intentions for continued telehealth use.

**Results:** Of the sample, 18.9% had provided telehealth services before stay-at-home orders, 58.6% transitioned to providing telehealth services during COVID-19, and 22.5% had never used telehealth. Clinicians who currently or previously provided telehealth services reported using telehealth to deliver direct intervention (84.63%), parent coaching (56.87%), assessment (37.46%). In terms of modality, 86.83% used videoconferencing, 47.73% used a hybrid model, 8.23% asked clients to send video recording. Clinicians more frequently reported difficulty addressing client-level barriers than technological or administrative barriers, with addressing eloping or maladaptive behaviors over telehealth being the most difficult barrier (Table 1).

Telehealth acceptability was significantly predicted by BCBA certification, telehealth perceived usefulness, ease-of-use, and effectiveness, and agencies' openness and selection for telehealth service provision (Table 2). Providers' ratings of telehealth acceptability was significantly correlated with their intention to continue using telehealth in the future [ $r(310) = .618, p < .001$ ].

**Conclusions:** We explored providers' adoption of telehealth services. Direct services and parent coaching were frequently delivered via videoconferencing and hybrid modalities. These modalities facilitate service provision in different settings which may support generalization of new skills across contexts. Providing telehealth services to autistic children who elope or demonstrate maladaptive behaviors presented additional barriers, thus indicating a need for targeted strategies that facilitate telehealth use with these clients.

The study also highlighted factors that influence providers' telehealth acceptability, which significantly predicted intentions for continued use. Agencies that stated importance or prioritized telehealth use fostered acceptability. Strategies that facilitate or simplify telehealth use and enhance interaction quality between client and clinician influence acceptability. These considerations can support telehealth service implementation and continued use, which is a helpful tool to increase access to evidence-based services and reduce service disparities.

## ORAL SESSION - 1A — INTERVENTIONS - NON-PHARMACOLOGIC - PRESCHOOL & INFANT

### 301 - Community Caregiver-mediated Early Intervention

**301.001** (Oral) Feasibility and Acceptability of Parenting Interventions Delivered in Spanish to Caregivers of Children with Autism and Other Developmental Delays: A Mixed-Methods Design

**J. Safer-Lichtenstein<sup>1</sup>, L. L. McIntyre<sup>2</sup>, G. Rodriguez<sup>3</sup>, D. Gomez<sup>4</sup>, S. Puerta<sup>1</sup> and C. L. Neece<sup>4</sup>, (1)University of Oregon, Eugene, OR, (2)Special Education and Clinical Sciences, University of Oregon, Eugene, OR, (3)Loma Linda University, Loma Linda, CA, (4)Psychology, Loma Linda University, Loma Linda, CA**

**Background:** Parents of children with autism spectrum disorder (ASD) or developmental delay (DD) experience increased stress due to raising a child with a disability, particularly if the child has challenging behaviors (Baker et al., 2003). Thus, there is benefit to interventions that: 1) help parents cope with stress, and 2) manage challenging behaviors. This is particularly true for Spanish-speaking Latinx populations, who are often underrepresented in ASD services and research (Zuckerman et al., 2017). Two interventions that have shown promise in reducing caregiver stress are providing psychoeducation (Bitsika & Sharpley, 2000), and teaching Mindfulness-Based Stress Reduction (MBSR) through meditation (Neece et al., 2014). Furthermore, Behavioral Parent Training (BPT) has proven to produce positive outcomes around child challenging behavior (McIntyre, 2013).

**Objectives:** This presentation will discuss pilot testing of these three interventions for Spanish-speaking Latinx caregivers of young children with ASD/DD as part of a larger, randomized-control trial. The primary objective is to investigate the feasibility and acceptability of these interventions for this population.

**Methods:** Sixty Spanish-speaking caregivers of 3-5-year-old children with ASD/DD were enrolled in this cohort. Two cohorts of English-speaking caregivers ( $n = 80$ ) were previously run, resulting in a total sample of 140 caregivers. Participants were randomly assigned to either MBSR plus BPT (BPT-M) or psychoeducation plus BPT (BPT-E). In BPT-M, participants received six weeks of group-based MBSR intervention, followed by 10 weeks of BPT. In BPT-E, participants received six weeks of group-based psychoeducation, then 10 weeks of the same BPT intervention. Of note, BPT for both groups was delivered virtually due to the onset of COVID-19 following the six-week stress reduction component. Attendance was recorded at each session. Participants also completed a Parent Satisfaction Questionnaire. Qualitative data on parent satisfaction was gathered through focus groups and analyzed using Thematic Analysis.

**Results:** Attendance and satisfaction data were analyzed as two separate two-way, between-subjects analyses of covariance, with independent variables of “group” (BPT-E versus BPT-M) and “language” (Spanish versus English). Demographic variables of caregiver ethnicity, income/education, acculturation, stress, and child problem behaviors were controlled. The dependent variable was run first as satisfaction and second as attendance. For satisfaction, neither intervention type nor language was significant on its own after controlling for the covariates. However, the interaction effect of intervention type by language was significant  $F(1, 56) = 7.16, p = .010$ . Participants in Spanish BPT-E reported significantly greater average satisfaction than those in English BPT-E, while the reverse was true for BPT-M. There were no significant differences between groups or languages in attendance. Focus group data revealed seven main themes that further elucidated the crossover effect in satisfaction.

**Conclusions:** This study adds data on the extent to which child behavioral and caregiver mental health services are feasible and acceptable to an often underserved population. Findings suggest that Spanish-speaking caregivers preferred psychoeducation supports over MBSR, in contrast to the preferences of English-speaking caregivers. These data inform how to best adapt these types of interventions to support these families, recognizing that there may be differing needs within this community.

---

**301.002 (Oral)** Stakeholder Perspectives on Family ‘Fit’ for a Parent-Implemented Naturalistic Developmental Behavioral Intervention

**K. M. Frost<sup>1</sup>, D. Duggan<sup>2</sup>, D. Weedmark<sup>2</sup> and B. R. Ingersoll<sup>1</sup>,** (1)*Psychology, Michigan State University, East Lansing, MI, (2)Michigan State University, East Lansing, MI*

---

**Background:** Parent-implemented naturalistic developmental behavioral interventions (NDBIs) are evidence-based practices for supporting social communication development for young children on the autism spectrum. These interventions are increasingly being researched and deployed in community settings. Many factors may influence an intervention’s “fit” (i.e. appropriateness, feasibility) for different families, which in turn may affect client outcomes (e.g. retention; Swift & Callahan, 2009), providers’ decision to offer a treatment (Rye, Friborg & Skre, 2019), and providers’ decision to flexibly adapt treatments to address poor fit (Georgiadis, Peris & Comer, 2020).

**Objectives:** The goal of this study was to examine stakeholder beliefs about family “fit” for a parent-implemented naturalistic developmental behavioral intervention.

**Methods:** Semi-structured interviews were conducted with stakeholders (10 expert trainers, 21 certified providers, and 11 caregivers) about their experiences with Project ImPACT. As part of a longer interview, participants responded to questions about how ImPACT fits for families, based on parenting style, values, cultural background, or other facets of individual difference. We used a codebook-based thematic analysis to identify key themes. Recruitment of additional caregivers is underway and analyses will be updated accordingly.

**Results:** Themes, subthemes, and illustrative quotations can be found in Table 1. Many caregivers spoke about how the intervention felt like a natural extension of their parenting style, while others identified specific aspects they found more challenging based on their personality or usual style of parenting. Providers and experts discussed specific cultural and linguistic factors that decrease fit, including cultural attitudes about play and the challenge of in-vivo coaching when the coach and family do not share a common language. Another prevalent theme pertained to decreased fit for families with little time to devote to practicing the intervention, due to work schedules, multiple children in the home, or other stressors (e.g. parent wellness, financial distress). Providers and experts also discussed the role of motivation or commitment as an essential but malleable contributor to good fit, while acknowledging that not all families want to engage in parent-mediated interventions.

**Conclusions:** Project ImPACT is increasingly being implemented in community settings. In order to successfully implement a high-quality service for diverse families, it is important to identify and remedy potential sources of poor fit. A combination of client-level adaptations (e.g. coaching in daily routines, flexible scheduling, providing case support to connect families with other services), program modifications (e.g. augmenting the manual’s coverage of using the techniques in the presence of several children), organizational (e.g. agency scheduling practices), and systems level factors (e.g. linguistic diversity among practitioners, availability of respite services) may support increased appropriateness and feasibility of parent-mediated NDBIs for diverse families.

---

**301.003 (Oral)** Exploring Coaching and Follow-up Supports in Community Implemented Caregiver-Mediated Jasper Intervention

**S. Y. Shire<sup>1</sup>, W. I. Shih<sup>2</sup>, T. Barriault<sup>3</sup> and C. Kasari<sup>4</sup>,** (1)*Special Education and Clinical Sciences, University of Oregon, Eugene, OR, (2)University of California - Los Angeles, Los Angeles, CA, (3)Roots and Wings Psychology, Sudbury, ON, Canada, (4)University of California, Los Angeles, Los Angeles, CA*

---

**Background:** Although a growing number of caregiver-mediated interventions models for families with children with autism are being examined in efficacy trials, few have been transferred to community implementation. Preliminary data suggest that caregivers make some gains through observation (Shire et al., 2015). However, the role of observation prior to coaching has yet to be explored. Further, little is understood about how to support caregivers following coaching intervention when gains can stagnate. In partnership with a publicly funded intervention agency in Canada this pilot project explored intervention implementation strategies and follow-up supports.

**Objectives:** This study engaged a partnership with a publicly funded intervention agency operating two sites in Northern Ontario, Canada serving small urban centers, large rural areas, and First Nations communities. Applying a Community Based Participatory Research approach (Minkler & Wallerstein, 2003), the project aims were co-constructed with agency leadership: (a) explore fidelity of both clinician-child implementation and caregiver coaching; (b) examine the influence of starting caregiver coaching immediately (Coach) versus four-weeks of observation of the practitioner supporting their child followed by coaching (Observation+Coach) on caregivers’ strategy use and children’s play and social communication skills, and (c) explore families’ adherence to individual versus group follow-up visits.

**Methods:** In this Hybrid Type-I Effectiveness-Implementation (Curran et al., 2012) pilot randomized trial, caregiver-child dyads were randomized at (a) entry to Coach or Observation+Coach and (b) intervention exit to individual or group follow-up. The 12-week caregiver-mediated Joint Attention, Symbolic Play, Engagement and Regulation (JASPER: Kasari et al., 2010) intervention was provided agency staff (three supervisors and nine practitioners) to a diverse community sample of families with young children awaiting or diagnosed with ASD. They served 56 children ( $n=26$  Observation+Coach,  $n=30$  Coach). Children ( $M=2.75$  years) were White (60.7%), Indigenous Canadians (10.7%), Asian (5.6%), and Hispanic (1.8%). Mullen age-equivalent mental age scores were significantly different at entry ( $p=0.024$ ) between Site 1 ( $M=16.93$ ,  $SD=7.66$ ) and Site 2 ( $M=19.78$ ,  $SD=7.89$ ).

Three video recorded measures were delivered by independent staff assessors at entry, exit, and follow-up: (a) Early Social Communication Scales (ESCS: Mundy et al., 2003), (b) Structured Play Assessment (SPA: adapted Ungerer & Sigman, 1981), and (c) Caregiver-Child Interaction (CCX: Kasari et al., 2010). Blinded raters scored children's initiations of joint attention, play actions, joint engagement, and caregivers' strategy implementation.

**Results:** Practitioners implemented the intervention and coaching strategies well ( $M=83\%$ ). Overall, caregivers made significant gains in strategy use ( $F(1,74)=78.33$ ,  $p<0.001$ ) with no significant differences between conditions ( $p=0.797$ ). Children demonstrated overall improvement in child-initiated JE ( $F(1,73)=51.42$ ,  $p<0.001$ ), IJA ( $F(1,55)=27.26$ ,  $p<0.001$ ) and total play diversity ( $F(1,63)=21.88$ ,  $p<0.001$ ) by intervention exit with no significant differences between conditions. Caregivers' strategy use was associated with children's joint engagement ( $F(1,71)=18.14$ ,  $p<0.001$ ) but not IJA or play assessment outcomes. Adherence to follow-up was limited but greater for individual ( $n=12$  completed all sessions) over group ( $n=1$ ).

**Conclusions:** Overall, children and caregivers made gains through public community implemented caregiver-mediated intervention. Similar outcomes across conditions suggest that the agency may offer families different caregiver-mediated intervention approaches. Adherence indicates a preference for individual over group follow-up.

#### **301.004 (Oral) Comparison of Who Caregiver Skills Training Delivered Remotely and in Person**

C. Ferrante<sup>1</sup>, P. Sorgato<sup>1</sup>, S. Ghersi<sup>2</sup>, A. Salandin<sup>2</sup>, S. Rizzo<sup>2</sup>, C. Chiesa<sup>1</sup>, T. W. CST Team<sup>3</sup>, M. L. Scattoni<sup>2</sup>, C. Servili<sup>2</sup> and E. Salomone<sup>1</sup>,

(1)Department of Psychology, University of Milan-Bicocca, Milan, Italy, (2)Fondazione Paideia, Turin, Italy, (3)Department of Mental Health and Substance Abuse, World Health Organization, Geneva, Switzerland, (4)Istituto Superiore di Sanità, Rome, Italy

**Background:** During the pandemic telehealth often represents the only viable option to guarantee continuity of care. However, while remotely-delivered caregiver-mediated interventions show promising acceptability, feasibility and effectiveness, there is scant evidence of their equivalence to in-person delivery.

**Objectives:** We compared feasibility, acceptability and effectiveness data of an adaptation of the WHO Caregiver Skills Training (CST) delivered remotely during lockdown with those of a pilot RCT of CST delivered in person against treatment as usual (TAU), which had shown excellent feasibility, acceptability and favourable treatment effects in public health settings.

**Methods:** In-person-CST was delivered per manual. Online-CST was delivered via adapted activities in virtual Group Sessions and Home Visits via video-conferencing. Participants were caregivers of children with ASD (Table 1). Caregivers and program interventionists completed feasibility and acceptability measures (5-point scales; 'satisfactory'=3, 'good'=4) and took part in focus groups. Observers completed integrity ratings. Pre-post clinical outcomes were measured with the Caregiver Knowledge and Skills Test (including CSQ, self-efficacy, and KSQ, knowledge and skills) and the Autism Parental Stress Index.

**Results:** Online and in-person-CST were delivered with high and similar levels of integrity, attendance and therapeutic alliance, and minimal drop-out rates. Feasibility ratings of standard components were high and similar, but the intervention contents were rated as significantly more complex to deliver in online-CST ( $p=.048$ ). Intensity of caregiver adherence to home practice was not different in the two delivery methods, and caregivers in online-CST reported fewer contextual barriers ('unexpected circumstances'  $p=.007$ ; 'lack of time'  $p=.021$ ). In online-CST, overall facilitator and caregiver acceptability ratings were in the 'good' range, however caregiver-rated comprehensibility, applicability, alignment with values and facilitator-rated caregiver participation were lower than in in-person-CST ( $ps <.001$  to  $.012$ ). For the adapted components (Table 2) facilitator-rated feasibility and acceptability were above satisfactory levels, although issues with technology were reported and feasibility ratings of home visits were in the 'satisfactory' range. Most caregiver ratings were in the 'good' range, however 'unsatisfactory' for perceived realism of the videorecorded modelling of strategies, presence of distractions and representativeness of child behaviour during the home visits. ANCOVAs of change scores controlling for baseline levels showed that in-person- and online-CST improved significantly more than TAU on caregiver knowledge and skills ( $\eta^2=.131$ ) and were not different from each other. There were no statistically significant effects for parental stress or self-efficacy. The thematic analysis of focus groups indicated that online-CST reduced the barriers to participation and delivery, partly at the expense of perceived quality of interpersonal relationships.

**Conclusions:** Online-CST was highly feasible and acceptable to caregivers and facilitators although lower in some dimensions of acceptability and participation than in-person-CST. Despite these barriers, online-CST improved caregiver knowledge and skills as in-person-CST. Due to design features, including lack of a control group during lockdown, deemed unethical, and the reduced sample size, the findings should be interpreted with caution. Despite these limitations, the study shows that online-CST could represent a feasible, albeit partial, clinical response in contexts where in-person delivery is not possible, due to geographical distance, restrictions to travel or personal circumstances.

## 402 - Interventions - Non-pharmacologic - Preschool & Infant

### 402.013 (Poster) Fidelity in Caregiver and Educator-Mediated Intervention Research: A Systematic Review

S. L. Arbuckle<sup>1</sup>, S. Y. Shire<sup>2</sup> and W. Bao<sup>3</sup>, (1)Special Education, University of Oregon, Eugene, OR, (2)Special Education and Clinical Sciences, University of Oregon, Eugene, OR, (3)University of Oregon, Eugene, OR

**Background:** Implementation fidelity is defined as, the degree to which a treatment is carried out as intended by program developers and may also encompass components such as adherence, completeness and dosage, quality of delivery, participant engagement and program differentiation (Dusenbury, Brannigan, Falco, & Hansen, 2003). Accurate assessment of fidelity is critical to the reliability, validity, replicability and scale-up of any intervention research study (Feely, Day, Lanier, Auslander, & Kohl, 2019). Measurement and assessment of fidelity within indirect service delivery models commonly used in early intervention and early childhood special education must be monitored at multiple levels (e.g., coach/trainer, implementer), presenting unique challenges for researchers and practitioners.

**Objectives:** Through a systematic review of the literature, we aimed to (a) identify the degree to which fidelity is monitored and reported across caregiver and educator mediated interventions and (b) explore the frequency with which researchers are examining the relationship between fidelity and child outcomes as well as the results.

**Methods:** Following the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines, we conducted a systematic search and review of the literature on caregiver and educator mediated social communication interventions published between 1994 and 2020.

**Measures:** Data extraction was completed by the first and third authors (SA & WB). A variety of variables including child and adult demographics, intervention components, fidelity measurement and reporting practices, and child and adult outcomes were extracted. To examine fidelity reporting, studies were examined individually and then grouped by intervention and scored using a 6-item scale adapted from Schoenwald et al. (2011) designed to categorize the rigor with which studies assess and report on fidelity. Risk of bias (methodological quality) was assessed for all studies (Gersten et al. 2005; Reichow, 2011).

**Results:** The 82 included studies represented 30 different manualized interventions and 11 non-manualized interventions. Most studies used a group design including randomized controlled trials, quasi-experimental designs and sequential multiple assignment randomized trials (SMART). The remaining studies used single case experimental designs.

**Fidelity:** When assessed using the Schoenwald et al. (2011) scale, no interventions received the highest score which required established measures of fidelity complete with reported psychometrics. The most common scores for caregiver and educator fidelity reporting were 2's (report of quality control methods such as therapist training or specific manual) and 5's (fidelity measure and data reported comprehensively with data on reliability or validity), while fidelity reporting for trainers most commonly scored a 3. It was uncommon that interventions included statistical examination of the relationship between fidelity and outcomes for any participant.

**Conclusions:** Currently, fidelity monitoring and reporting in caregiver and educator mediated intervention research is a developing practice. A lack of rigorous and comprehensive reporting of fidelity in this review limits the field's understanding of how interventions are being delivered and what mechanisms are responsible for changes in outcomes. Moving forward, more attention must be paid to how fidelity is being monitored and reported (at both the trainer and caregiver/educator levels) in research.

### 402.014 (Poster) CST: Caregiver Skills Training, Virtual Modality and COVID-19

D. Suaya Demaria<sup>1</sup>, N. E. Granana<sup>2</sup>, P. C. Consortium<sup>3</sup>, V. Nanclares-Nogues<sup>4</sup> and P. Dixon<sup>5</sup>, (1)Pediatrics, Health Center 11, Buenos Aires, Argentina, (2)Servicio de Neurología Infantil, Hospital Durand, CABA, Argentina, (3)Primary Care Department, Ministry of Health City of Buenos Aires, Buenos Aires, Argentina, (4)Pediatric Developmental Center, Advocate Children's Hospital, Chicago, IL, (5)Wayne State University, Ann Arbor, MI

**Background:**

CST is an intervention program mediated by Caregivers of children developmental delays or disorders, including *autism*, developed by the WHO and Autism Speaks. The program has proven efficacy and has been found to be beneficial in underserved populations, given the difficulties in access to support, lack or modest economic resources, or due to distance. Families with children between 2-7 years of age are included, and no specific diagnosis of autism was required.

**Objectives:**

The intervention aimed at supporting parent-child interactions. It also contributed to the formation of networks and better integration of families into their communities. Our main objectives were to explore the program's feasibility to increase communication, management of disruptive behavior, promoting autonomy, and heighten coping skills from parents.

**Methods:**

24 families of children who attended early childhood daycare centers in vulnerable areas were recruited. Inclusion criteria were deficits in communication and socioindividual areas detected by screening with the Ages and Stages Questionnaire 3rd Version (ASQ-3). We delivered 8 weekly group meetings and 3 individual sessions in a virtual format. In addition, the caregivers received booklets with the essential contents covered and illustrated stories that served as an identification models. The topics were presented and explained during training sessions. Reflective discussions were generated. Videos with role-plays helped to practice new skills.

#### Results:

Ninety percent of families completed the intervention. All these families were currently without any treatment due to the COVID-19 pandemic. The program was adapted to be performed virtually. An evaluation was carried out before and 12 weeks after completing the workshop sessions. Parents reported an increase in their ability to reduce tantrums from 37% in the pretest to 56% in the posttest and to participate in a back and forth games with the child from 8% to 31%. Their children increased autonomy from 20% to 50%. They experienced an improvement in communication to request and to share, and an empowerment in the caregiver's selfcare skills. Caregivers could seek recreational moments at least once a week from 29% to 62.5%. Families reported that training fulfilled their expectations at 87%. They observed that 9 of 10 children improved their behavior. We found out that 94% of parents reported that they could enhance their abilities as caregivers and 87% achieved favorable changes in their everyday life.

#### Conclusions:

CST intervention demonstrated very positive results in overall parent self-efficacy and family functioning. Parents felt empowered and knowledgeable on how to stimulate the development of their children and reported great improvements in their child's communication, interaction and behavior. The virtual modality actually increased adherence to treatment. CST showed continued success as a tool to enhance parent skills. As a team, it was gratifying to observe families move through the process and provide tools to improve their quality of life.

#### **402.015** (Poster) Changes in Maternal Language during a Parent-Mediated Intervention

**A. Bentenuto, G. Bertamini, S. Perzoli, S. De Falco and P. Venuti, Department of Psychology and Cognitive Science, University of Trento, Rovereto, Italy**

---

**Background:** In recent decades, a growing literature has highlighted the fundamental role of parents in therapy (Althoff, 2019;). Starting from the child's own interests the therapist and/or parents try to slowly raise engagement, interaction, communication, affection, and then specific cognitive skills. Parental speech directed to young children is important for many developmental purposes (Herrera et al., 2004). In fact, through language parents can convey both affect and information to children.

**Objectives:** The main purpose of this study was to explore how the maternal speech directed to children with ASD change after a period of 14 months of parent-mediated intervention. Moreover, we aimed to analyse how mothers' language was associated with symptoms severity and cognitive profiles of children.

**Methods:** Participants were 22 mothers in interaction with their children with ASD (Chronological age:  $M = 43.77$  months;  $SD = 13.60$ ; Mental age:  $31.99$  months;  $SD = 12.07$ ). Functional aspects of speech produced by mothers during 10-min of free play interactions have been analyzed pre and post intervention. Mother' speech was verbatim transcribed with ELAN (Version 6.2, 2021, The Language Archive) an annotation tool for audio and video recordings. Maternal speech was then categorized in terms of the primary function of each speech unit, using a coding scheme validated in previous studies (Bornstein et al., 1992; de Falco et al., 2011). These classes are mutually exclusive and exhaustive. The functional analysis was applied by two independent coders.

**Results:** Data analyses showed a significant increase in affective function of maternal speech after the intervention (mean  $T0 = 23.95$ ,  $SD = 12.96$ ; mean  $T1 = 29.55$ ,  $SD = 14.08$ ;  $t(21) = -2.05$ ;  $p = 0.05$ ). After the intervention (mean  $T0 = 5.73$ ,  $SD = 3.64$ ) mothers used significantly more "action descriptions" than at the beginning (mean  $T1 = 9.82$ ,  $SD = 8.81$ ;  $t(21) = -2.35$ ;  $p = 0.03$ ). Correlation analyses show a significant negative association between affective maternal speech and the cognitive functioning of the children ( $r = -0.35$ ;  $p = 0.023$ ), and a positive correlation between the use of question about the child internal states and the social-affective area of the children ( $r = 0.46$ ;  $p = 0.002$ ). Considering linguistic predictors of change, preliminary results showed that the general cognitive functioning of the child is associated with the amount of referents that the caregiver uses referring to the child's internal state ( $\beta = 0.70$ ;  $t(20.04) = 2.32$ ;  $p = 0.03$ ).

**Conclusions:** The direct involvement of mothers during intervention seems to support some specific adjustment regarding the quality of the exchange between mother and child. In particular, these results highlighted that a specific parent-mediated intervention focused on the promotion of the social reciprocity, helped mothers to use more affective language, a crucial element for the quality of the dyadic exchange.

#### **402.016** (Poster) Comparison Groups in Early Childhood Autism Research: A Meta-Analytic Review

**S. Albarran, J. E. Crank, M. Sandbank and M. Canihuate, The University of Texas at Austin, Austin, TX**

---

**Background:** Comparison group characteristics are important to consider when interpreting the results of intervention studies. Comparison conditions may influence the magnitude or direction of intervention effects. Misinterpretations of intervention effects could lead to underutilization of effective strategies to support children on the autism spectrum, or lead to ineffective allocations of available resources that support the learner. Although recent reviews and meta-analyses have summarized the effects of various intervention approaches on various outcomes, none of these reviews systematically described comparison conditions, nor did they examine whether comparison group moderated intervention effects.

**Objectives:** This project will describe the types of comparison conditions tested in studies of autism-focused early childhood interventions, and investigate whether comparison condition type moderates intervention effects.

**Methods:** The data for this project were collected as part of the larger Project AIM meta-analysis. Comparison group categories were coded as either: Business as Usual (BAU), separate intervention, or a modified version of the same intervention being tested. Only comparison conditions that included intervention methods that were different from those used in the intervention condition were coded as 'separate.' Comparison conditions were coded as modified versions of the intervention being tested when they employed similar methods with different parameters (e.g., different implementer, dose frequency). Using robust variance estimation to account for correlated effects, we will test whether intervention effects are significantly moderated by comparison group category. Subgroup summary effects will be calculated for each comparison group category and plotted for comparison. We anticipate that summary effects for interventions tested against BAU conditions will be significantly larger than summary effects for interventions tested against separate or modified interventions.

**Results:** The original investigation summarized treatment effects by intervention approach and outcome domain across 1,615 effect sizes extracted from 150 reports. All original effect sizes will be included in the current investigation. Coding and analyses are in progress and will be completed prior to the presentation to provide a visual representation of findings for discussion.

**Conclusions:** Evidence-based practice guides have largely overlooked a research design characteristic that may significantly influence researcher perception of intervention effectiveness. If comparison conditions significantly influence estimates of intervention effects, such guides must take comparison groups into account in evidence summaries.

**402.017 (Poster) Early Intensive Behavioral Intervention (EIBI): Predicting Outcome and Examining Relations between Treatment Intensity, Treatment Quality and Treatment Acceptability**

**M. Andreassen<sup>1</sup>, S. Eikeseth<sup>2</sup> and R. Lugo<sup>3</sup>, (1)Psychology, Inland Norway University College of Applied Sciences, Lillehammer, Norway, (2)Department of Behavioural Sciences, Oslo Metropolitan University, Oslo, Norway, (3)Norwegian University of Science and Technology, Gjøvik, Norway**

---

**Background:**

Early intensive behavioral intervention (EIBI) is an empirical based intervention which may improve cognitive and adaptive functioning for preschool children with autism spectrum disorders (ASD). However, there is a need to identify characteristics that interact with outcome. Previous research identified age at intake, level of intake adaptive and intellectual functioning, as well as treatment intensity as possible key factors.

**Objectives:**

This study is a prospective study designed to examine different predictors of outcome after 12 months of community-based EIBI in 171 children (142 males; mean age of 49.74 months) with ASD. Predictors included are Age at Intake, Intake Adaptive Behavior (Vineland-II), Treatment Intensity, Treatment Quality and Treatment Acceptability.

**Methods:**

All procedures were in accordance with the ethical standards of the institutional and national research committee. Correlational analysis was used to test the hypothesis. In order to evaluate predictors of outcome, hierarchical multiple regressions (MR) was conducted for each outcome measure. Non-parametric tests ( $\chi^2$ ) were used for variables that did not meet normal distribution.

**Results:**

Higher intake Vineland Adaptive Behavior Composite (ABC) score and higher intake scores of all Vineland Subscales predicted significantly higher outcome scores. Age at Intake predicted Communication at follow-up ( $R^2=.451$ ,  $F=34.16$ ,  $p<.001$ ,  $\beta=-.248$ ,  $t=7.40$ ), indicating that younger age is associated with greater improvements in Communication. Furthermore, Social Skills at intake ( $R^2=.039$ ,  $F=6.02$ ,  $p=.016$ ,  $\beta=-.197$ ,  $t=-2.45$ ) and higher Treatment Quality predicted lower Maladaptive Behaviors ( $\Delta R^2=.019$ ,  $F=50.75$ ,  $p=.074$ ,  $\beta=-.137$ ,  $t=-1.81$ , 1-tailed finding) at follow-up. Treatment Quality assessed 12 months into treatment was significantly higher than Treatment Quality assessed after 6 months of treatment ( $\chi^2=48.05$ ,  $df=2$ ,  $p<.001$ ), and thus Treatment Quality improved over time, although lower Treatment Quality was associated with lower Treatment Quality at follow-up ( $\chi^2=21.78$ ,  $df=4$ ,  $p<.001$ ,  $V=.305$ ). Children receiving higher Treatment Intensity also received better Treatment Quality ( $R^2=.061$ ,  $F=9.07$ ,  $\beta=.247$ ,  $p=.003$ ). Treatment Acceptability was high for both parents and therapists ( $M=5.6$  ( $SD=5.07$ ) and  $M=5.5$  ( $SD=4.30$ ), respectively on a 6-point Likert scale). Treatment Acceptability was not associated with outcome.

**Conclusions:**

For Vineland ABC and all Vineland subscales (Communication, Social Skills, Daily Living Skills, Motor Skills and Maladaptive Behavior), higher intake scores predicted significantly higher outcome scores. Furthermore, younger Intake Age and Higher Treatment Quality was associated with improved outcome. Treatment quality improved over time, but children who received lower treatment quality initially tended to receive overall lower treatment quality. Children who received higher number of treatment hours also tended to receive better treatment quality. Parents and therapists scored Treatment Acceptability as very high, and high Treatment Acceptability score was independent of the children's outcome. Although this study

does not include a control group, findings add to our knowledge of potential predictors of outcome for children receiving EIBI.

**402.018** (Poster) Effects of Therapist Dosage on Child-Therapist Rapport in Toddlers with Autism Spectrum Disorder  
**M. Jiménez**, G. Vivanti and M. Schuler, A.J. Drexel Autism Institute, Drexel University, Philadelphia, PA

---

Background:

Children with Autism Spectrum Disorder (ASD) often receive early intervention from teams involving multiple therapists, including therapists whose involvement is of limited duration (e.g., staff covering in case of sickness of the primary therapist). A plausible yet untested scenario is that the quality of child-therapist rapport might be affected by the number of therapists in the intervention team and the consistency of their involvement in the intervention program.

Objectives:

We examined whether the number of therapists in the treatment team of young children with ASD receiving early intervention, and the consistency of their involvement in intervention delivery contribute to the quality of child-therapist rapport. We hypothesized that child-therapist rapport would be of higher quality in teams with a smaller number of therapists and in response to therapists who are more consistently involved in the intervention program.

Methods:

We examined child-therapist rapport in 22- to 33-month-old children with ASD who received the Early Start Denver Model for 6-months, 6-10 hours per week, with intervention delivered either by a team of 1-2 therapists (Low Therapist Dosage group) or a team of 3+ therapists (High Therapist Dosage group). Preliminary data involving 11 children are presented, with effect sizes examined as a preliminary indication of support to the study predictions, to be substantiated via ongoing analyses involving a larger sample (anticipated  $n=40$ ). For each participant we examined two 10-minute videorecorded intervention sessions within their six months of intervention: one with their primary therapist (i.e., the therapist who administered the majority of sessions during the 6-month intervention period) and one with their secondary therapist (a therapist involved for less than one month in the intervention program). Child-therapist rapport was coded using a novel behavioral coding scheme that included frequency of challenging behavior, compliance, child initiations, and shared affect initiated by the child towards their therapist. Inter-rater reliability for the child-therapist rapport coding scheme was conducted on 20% of the videos using intraclass correlation coefficient.

Results:

Intraclass correlation coefficient for the behavioral coding scheme indicated excellent agreement ( $ICC=88\%$ ). Preliminary findings involving 11 participants, five in the Low Therapist Dosage and six in High Therapist Dosage showed that compared to children in the High Dosage Therapist group, children in the Low Dosage Therapist group had fewer challenging behaviors in response to their primary therapist ( $d=.65$ ) as well as more initiations ( $d=.74$ ) and more compliance ( $d=1.1$ ) in response to their secondary therapists. Additionally, children appeared to show more initiations ( $d=1.0$ ) and more compliance ( $d=.44$ ) in response to their primary therapist compared to their secondary therapist, although this was the case only for the children in the high therapist dosage group.

Conclusions: Our preliminary results, if substantiated by our ongoing analyses with the larger sample, suggest that children receiving intervention from teams composed by a smaller number of therapists might experience better rapport with their therapists, particularly in response to therapists who are more consistently involved in the intervention program.

**402.019** (Poster) Efficacy of the Early Achievements Intervention in Preschools: A Teacher-Implemented Interpersonal Synchrony Curriculum Supplement Increases Motor Imitation, Joint Attention, and Initiations of Peer Engagement in Preschoolers with ASD  
**R. Landa**<sup>1,2</sup>, A. M. Engelstad<sup>3,4</sup> and C. B. Holingue<sup>1,5</sup>, (1)Center for Autism and Related Disorders, Kennedy Krieger Institute, Baltimore, MD, (2)Department of Psychiatry and Behavioral Sciences, Johns Hopkins University School of Medicine, Baltimore, MD, (3)Center for Autism and Related Disorders, Boston Children's Hospital and Harvard University, Baltimore, MD, (4)Harvard University, Cambridge, MA, (5)Department of Mental Health, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD

---

Background: Few evidence-based early interventions for children with autism spectrum disorders (ASD) have demonstrated efficacy in public school settings. Through former research, an interpersonal synchrony intervention designed for toddlers (see Landa et al., 2011) was adapted with input from school professionals into a preschool curriculum supplement (Wilson & Landa, 2019). In a pilot trial, teachers randomized to training in Early Achievements (EA-ASD) learned to implement EA-ASD with high fidelity, and children receiving EA-ASD made greater gains in initiation of joint attention and nonverbal cognition than children receiving Business-As-Usual (BAU) instruction (Engelstad et al., 2020). This randomized controlled trial evaluates the efficacy of EA-ASD in 23 schools spanning 4 states across the US including a racially, geographically, and socioeconomically diverse sample of preschoolers with ASD.

Objectives: The goal of this study was to evaluate the efficacy of the EA-ASD intervention in public preschool classrooms. Objectives were 1) to determine whether teachers receiving EA-ASD professional development attain high levels of fidelity, 2) to examine child growth on proximal social communication measures, and 3) to examine child growth on distal measures of nonverbal cognition, language, and social communication.

**Methods:** 70 classroom teachers and 159 preschoolers with ASD were randomized to EA-ASD or BAU instruction. Teachers in both conditions received five day-long professional development workshops, with content for BAU group not related to EA-ASD. In addition to EA-ASD workshops, teachers randomized to EA-ASD also received 20 job-embedded coaching sessions. Teacher fidelity and child social communication data were blindly coded from monthly videotapes. Pre- and post-intervention assessments measured child growth on distal measures. 3-level hierarchical linear models accounting for clustering at the individual, classroom, and school levels were used to assess growth patterns.

**Results:** Teacher fidelity levels at baseline were not different between groups (mean fidelity for BAU = 32.8%, EA-ASD = 29.6%). EA-ASD teachers demonstrated significantly greater gains in fidelity of implementation than BAU teachers ( $\beta=0.12$ ,  $p<.001$ ). On average, EA-ASD teachers achieved 87.9% fidelity at post-intervention (BAU = 32.2%). Children receiving the EA-ASD intervention showed significantly greater improvements in motor imitation from pre- to post-intervention than children receiving BAU ( $\beta=1.48$ ,  $p<.05$ ). Children's gains in imitation generalized across contexts and communication partners, as demonstrated by growth on the *Motor Imitation Scale* (Stone, 1999), on which children in EA-ASD made significantly greater gains than children in BAU ( $\beta=3.55$ ,  $p<.05$ ). Children in EA-ASD made significantly greater gains on the proximal measures of initiation of and response to joint attention than children in BAU ( $\beta$ 's=1.13 and 3.68, respectively,  $p$ 's<.05). Children in EA-ASD made significantly greater gains in initiation of peer engagement than children in BAU ( $\beta=0.64$ ,  $p<.05$ ). The following school year, six months post intervention, EA-ASD teachers sustained fidelity levels (mean

**Conclusions:** With professional development workshops and coaching, public preschool teachers can learn to implement EA-ASD with high levels of fidelity. EA-ASD instruction is associated with child gains in motor imitation, initiation of and response to joint attention, and peer engagement, with gains in motor imitation generalizing to unfamiliar contexts.

**402.020 (Poster)** Imitation in Autism within Early Intervention: Examining the Roles of Motor Skills and Social Engagement  
*K. D. Kelly, C. Coopersmith and G. Vivanti, A.J. Drexel Autism Institute, Drexel University, Philadelphia, PA*

---

**Background:** Imitation difficulties are commonly reported in young children with autism spectrum disorder (ASD), but there is limited understanding on what drives or mediates them. Motor difficulties are also reported frequently in young children with ASD, yet findings have been inconclusive as to whether such difficulties are related to imitation. Additionally, though challenges in social engagement are a core feature of ASD, their role in imitation is unclear. Within the context of early intervention, increases in social engagement behaviors have been related to therapist strategies such as utilizing child interests and following the child's lead. Therefore, a plausible yet untested scenario is that autistic children may imitate more frequently while participating in highly engaging activities with their therapist compared to in activities that are not. Additionally, atypical motor skill development might further contribute to the variability of imitation performance observed in this population in early intervention.

**Objectives:** This study aimed to evaluate whether motor imitation of actions without objects in children with ASD is modulated by child motor skills and social engagement within the activity.

**Methods:** We examined clips of video-recorded intervention sessions as part of a previous study involving trained therapists delivering a play-based, naturalistic intervention, the Early Start Denver Model (ESDM), to 10 young children (aged 20-41 months) with ASD. One "early in treatment" and one "late in treatment" video clip was chosen for each participant. We created a novel coding scheme to analyze (1) how frequently the child was imitating, and (2) the degree of social engagement with the therapist throughout the activity. A blind coder was trained on the coding scheme and coded all videos, and intraclass correlation analyses were conducted on 35% of randomly selected videos. Motor skills were measured through the motor subscales of the Vineland Adaptive Behavior Scales and the Mullen Scales of Early Learning.

**Results:** Initial results based on 20 videos from 10 participants showed an intraclass correlation for the coding scheme of  $>.7$  across variables. There was not a significant association between imitation and baseline motor skills or child age. Conversely, social engagement and imitation frequency were significantly correlated ( $r=.65$ ,  $p=.002$ ). Social engagement continued to be a significant predictor of imitation in a regression analysis that included "child" as a factor as each child was featured in two videos [ $F(2, 17) = 6.595$ ,  $p=.008$ ,  $R^2=.37$ ]. Analyses designed to test the study predictions on a larger sample ( $n=50$ ) are under way.

**Conclusions:** Initial results suggest that children who are more socially engaged with their therapist during a play activity are more likely to imitate the therapist's actions. Motor skills did not appear to be significantly related to imitation in this preliminary analysis, yet this will be further explored in a larger sample. Imitation in young children with ASD might be enhanced in response to socially engaging activities compared to activities or partners that are less engaging, supporting that social engagement likely has an important role for promoting imitation during naturalistic play routines.

**402.021 (Poster)** Implementing a Community-Based Caregiver Intervention in Low-Resource Contexts: A Focus on Implementation Strategies during the Planning and Preparation Phase

*J. Combrinck<sup>1</sup>, N. Chambers<sup>2</sup>, P. J. de Vries<sup>3</sup> and L. Schlebusch<sup>4</sup>, (1)Faculty of Health Sciences, Psychiatry, University of Cape Town Faculty of Health Sciences, Cape Town, South Africa, (2)Division of Child and Adolescent Psychiatry University of Cape Town, Centre for Autism Research in Africa (CARA), Cape Town, South Africa, (3)Centre for Autism Research in Africa, Division of Child & Adolescent Psychiatry, University of Cape Town, Cape Town, South Africa, (4)Centre for Autism Research in Africa, Division of Child and Adolescent Psychiatry, University of Cape Town, Cape Town, South Africa*

---

**Background:** There are more than 50 million young children with autism and other developmental disabilities (DD) in the world, most of whom live in low- and middle-income countries (LMICs). However, there is a substantial treatment gap in these parts of the world. The World Health Organization (WHO) developed a Caregiver Skills Training Programme (WHO-CST) for families of children with DD, to help address the treatment gap. The WHO-CST includes a range of evidence-informed strategies aimed at empowering caregivers to support their children's communication

and learning, and is designed to be adaptable, appropriate, feasible, and scalable in resource-limited contexts. The Diamond Families Project is a multi-partner project that aimed to implement and evaluate the WHO-CST programme, specifically in South Africa. To promote successful and sustainable implementation, the project included a range of activities in the planning and preparation phases guided by the principles and strategies of Implementation Science.

**Objectives:** The objective of this study was to identify and describe the specific implementation strategies used across all the activities that occurred during the planning and preparation phases of the Diamond Families Project prior to running the 12-session WHO-CST programme in South Africa.

**Methods:** We used three steps to achieve our objective: (1) Data extraction: We analysed the project archives to identify all activities that took place and captured the data in an activity log. (2) Identify: Each activity was then coded into implementation strategies, using a coding manual compiled from three existing implementation strategy coding schemes. A consensus coding approach was used on all data. (3) Describe: Descriptive statistics were used to describe the frequency, duration, actors, and costs of each implementation strategy.

**Results:** One hundred and fifty activities were identified, which represented 34 unique implementation strategies. The most frequently used strategy was “Developing an implementation blueprint” (28%), which focused on how to implement the intervention in low resource communities. The strategy that required the most person-hours was “Promoting adaptability” (627 hours). This included activities such as Setswana translations of the facilitator booklets with help from a community champion and community visits to gain insight into the rural context. The most expensive strategy was “Developing academic partnerships”, which included planning meetings with Africa Autism Treatment Network and discussions with the Service Systems Stakeholder group, to find effective answers to address our local needs and to establish a community-academic partnership.

**Conclusions:**

The results suggest that the successful implementation of this new intervention in South Africa included time devoted to developing the implementation plan, adapting materials to suit the local context, and building partnerships with academic and community stakeholders. Furthermore, the most frequently used strategy was found not to be the most expensive. These findings contribute to an evidence-base of implementation-focused research in South Africa, which can guide the successful implementation of other interventions in similar low resource settings.

#### **402.022 (Poster)** Implementing the Who Caregivers Skills Training Program Via Telehealth in Rural Missouri

**C. Montiel-Nava<sup>1</sup>, M. Tregnago<sup>2</sup>, J. Marshall<sup>3</sup>, K. Sohl<sup>4</sup>, A. Curran<sup>5</sup>, M. Mahurin<sup>6</sup>, M. Warne-Griggs<sup>6</sup>, T. W. CST Team<sup>7</sup> and P. Dixon<sup>8</sup>,**

*(1)Psychological Science, University of Texas Rio Grande Valley, Edinburg, TX, (2)Easterseals Midwest, Columbia, MO, (3)Easterseals Midwest, St. Louis, MO, (4)ECHO Autism Communities, Child Health, Columbia, MO, (5)Department of Child Health, University of Missouri, School of Medicine, Columbia, MO, (6)University of Missouri, Columbia, MO, (7)Department of Mental Health and Substance Abuse, World Health Organization, Geneva, Switzerland, (8)Autism Speaks, Washington D.C., DC*

**Background:** Caregivers of autistic children who reside in low-resource areas- including rural settings- often do not have access to quality parent skills training programs that may improve child outcomes and lead to decreased parent stress and increased parent competency and efficacy. Telehealth strategies that incorporate technology to provide health care services have been explored as a potential solution to the challenges of reaching families in rural settings, resulting in positive caregiver outcomes and satisfaction with services.

**Objectives:**

This is a mixed-methods study with a phenomenological framework to evaluate the feasibility and acceptability of the WHO- Caregivers Skills Training Program. It also used a pretest-posttest design to explore the preliminary efficacy of the program's implementation via telehealth in a rural setting.

**Methods:**

Caregivers of 15 autistic children (3-7 years), residents of rural Missouri, completed the nine group sessions in an online format (conducted through Zoom) and three virtual home visits. This pilot study measured feasibility outcomes using parental attendance to CST sessions, attrition, parental and master trainers' post-session feedback forms, caregiver's knowledge and confidence in skills, and parental and master trainers post-program focus groups. Indicators of preliminary efficacy outcomes were the rate of score reduction in parent-reported ratings of autism-related behaviors, parental stress, family distress, and parental sense of competence.

**Results:**

The attendance rate for the group sessions was 96.8% and 100% for the three home visits, and none of the caregivers dropped out, attaining a 0-attrition rate. Four main themes emerged from the focus groups related to participants' experiences with the program and suggestions for its implementation. For most caregivers' ratings of content's complexity (73%), relevance (66%), and usefulness (60%) were greater than or equal to 4 (somewhat easy) for all nine sessions. Throughout the program, the most liked activity was the demonstration (36%), and the least liked was the practice with other caregivers. From baseline to week 12, there was a statistically significant improvement on the communication subscales of the ATEC ( $d=.78$ ,  $p<0.01$ ) and the AIM, in both frequency ( $d=.68$ ,  $p<0.05$ ) and impact ( $d=1.55$ ,  $p<0.01$ ). AIM impact scores also showed a reduction for atypical behaviors ( $d=.95$ ,  $p<0.01$ ) and the total impact score ( $d=.63$ ,  $p<0.05$ ). For caregivers' outcomes, only confidence in skills ( $d=-.57$ ,  $p<0.05$ ) and the parental sense of confidence ( $d=.62$ ,  $p<0.05$ ) showed a positive change.

## Conclusions:

This adaptation study supports the feasibility of implementing the WHO CST program via telehealth in a US rural setting. In general, participants thought the online format was convenient, with benefits outweighing the disadvantages. The preliminary efficacy of the CST program delivered via telehealth is promising. The significant results aligned with the primary outcomes of the program (increase joint engagement and communication and reduce challenging behaviors). This is the first implementation of a telehealth PMI conducted with non-specialists in a rural US setting; and could be generalizable to similar rural, mainly white settings. Results from this study can impact public policy by offering a scalable and sustainable program to bridge the gap between research and community implementation.

### **402.023** (Poster) Investigating the Extent to Which Consultation Improves Community Providers' Adherence to a Manualized Social Communication Intervention

**D. Straiton<sup>1</sup>, B. R. Ingersoll<sup>1</sup>, J. Grestorex<sup>2</sup> and M. Moeyaert<sup>3</sup>,** (1)Psychology, Michigan State University, East Lansing, MI, (2)Michigan State University, East Lansing, MI, (3)Educational and Counseling Psychology, University at Albany, State University of New York, Albany, NY

---

**Background:** Project ImPACT is a manualized Naturalistic Developmental Behavioral Intervention (NDBI) that increases social communication skills in autistic children. Providers using an evidence-based practice (EBP) such as Project ImPACT for the first time often do not deliver the intervention to fidelity. Consultation is an implementation strategy that is considered a core component of successful implementation programs. This study investigates the extent to which consultation improves adherence to the Project ImPACT manual.

**Objectives:** This preliminary analysis investigates the extent to which consultation improves providers' adherence to the Project ImPACT manual during telehealth intervention sessions with caregivers of Medicaid-enrolled autistic clients. We outline methods for using multilevel modeling within a single-case experimental design (SCED), which extends the typical SCED analysis method of visual analysis (i.e., inspecting graphs of data) by introducing advanced statistical modeling with effect estimates within cases (i.e., effects for individual providers) and across cases (i.e., average effect across providers).

**Methods:** We fit a two-level multilevel model to analyze data from an ongoing trial which had an ABCD single-case experimental design with multiple baselines. Our sample includes 16 behavior analysts from 5 agencies. Agencies were randomized to the baseline period (3-6 weeks) in which providers delivered Project ImPACT without consultation. After the baseline period, providers received 12 weeks of group consultation. Thirty-eight intervention sessions were behaviorally coded by 4 blind undergraduate research assistants. Adherence to the manual was measured using the Project ImPACT Fidelity Coaching Checklist, yielding a percentage for the adherence score. We ran a two-level multilevel model examining the change in average adherence score from the baseline period to the consultation period.

**Results:** Sufficient data was currently available for 4 of the 16 providers.

At the single-case level, there are no statistically significant changes in level of adherence within the 4 cases (i.e., individual providers); however, the trend for one provider is approaching statistical significance ( $p = 0.09$ ), such that the provider's average fidelity score for sessions in the consultation phase were approximately 15% higher than scores in the baseline phase.

The two-level model analyzed the change in adherence scores averaged across the 4 providers. Consultation did not statistically improve adherence scores, though it is changing scores in the expected direction (i.e., improving scores),  $b = 0.97$ ,  $t = 0.12$ ,  $p = 0.91$ . See Table 1 and Figure 1 for effect estimates and regression plots.

**Conclusions:** This preliminary analysis does not show a statistically significant improvement in adherence from baseline to the consultation period. This analysis is likely underpowered to find an effect of consultation, with only 4 providers in the current analysis (the trial is ongoing and not all sessions are coded yet). We expect to have appropriate power to determine an effect when we have additional adherence data from the current providers and from additional providers, with a planned sample of ~25 providers across 6 agencies to be completed by January 2022. Additionally, future analyses will include providers with longer baseline periods that can provide a more stable estimate of adherence during the baseline period.

### **402.024** (Poster) Music-Enhanced Reciprocal Imitation Training in ASD: A Single-Subject Study of a Telehealth Parent Coaching Intervention

**T. Liu<sup>1</sup>, K. Martinez-Torres<sup>2</sup>, O. Boorom<sup>1</sup>, S. Camarata<sup>1</sup> and M. D. Lense<sup>1</sup>,** (1)Vanderbilt University Medical Center, Nashville, TN, (2)1215 21st Avenue South Medical Center East, Vanderbilt University, Nashville, TN, (3)Hearing & Speech Sciences; Psychiatry & Behavioral Sciences, Vanderbilt University Medical Center, Nashville, TN

---

**Background:** Parent-mediated interventions support the social communication and play skills of young children with ASD, but there remains a need for interventions that are accessible for parents and can be delivered via remote, telehealth modalities. Reciprocal Imitation Training (RIT) is one such intervention that has shown promise for both parent-mediated and telehealth formats. As a Naturalistic Developmental Behavioral Intervention (NDBI), RIT coaches parents in using contingent imitation, linguistic mapping, modeling, prompting, and reinforcement to teach object and gesture imitation in a play-based setting. Imitation is a common deficit in children with ASD, and imitation training has corollary effects on joint attention, play skills, and language (Ingersoll & Schreibman, 2006; Ingersoll & Lalonde, 2010). Like other NDBIs, RIT relies on predictability and structure to support children's skill development through routines and repetition. Imitation is also a core component of musical play during early childhood, and the affordances of musical play naturally shape parents' interaction with their children (Lense & Camarata, 2020). Many children with ASD are motivated by music, and music-based interventions may support social communication development. As a natural, reinforcing, and predictable activity, musical interactions may align well with RIT principles to support parents' learning of RIT principles and child imitation behavior.

**Objectives:** Evaluate the feasibility of a music-based, telehealth adaptation of RIT — music-enhanced RIT (tele-meRIT) — as a novel format for coaching parents in NDBI strategies for increasing their child's imitation skills.

**Methods:** This single-subject, multiple baseline design study included 4 male children with ASD (32-53 months old) and their parents. Following baseline parent-child play sessions, parent-child dyads participated in weekly individual tele-meRIT sessions and small group music class sessions for 10-weeks over Zoom. During meRIT sessions, parents learn to incorporate rhythm and song into the RIT strategies through psychoeducation, direct coaching, and weekly homework goals. At each weekly session, and at a one-week and one-month follow-up, parent-child dyads were recorded during a 10-minute free play probe. Probes were coded for parent fidelity of RIT implementation (using a standardized scoring rubric), parent musicality, and frequency of child spontaneous imitation.

**Results:** No parent met fidelity of implementation during the baseline. All parents increased their use of RIT strategies and met fidelity ( $\geq 80\%$ ) by the end of the 10-week treatment period. Parent fidelity was maintained at the follow-up probes. Children exhibited no to minimal spontaneous imitation during baseline sessions, which did not increase during the treatment session probes. Nevertheless, a post-intervention evaluation survey indicated high parent satisfaction with the tele-meRIT program, including perceived benefits to their children's imitation and play skills more broadly.

**Conclusions:** Implementation of a telehealth, parent-mediated version of meRIT is feasible. Results demonstrate that even though meRIT additionally involved instruction and coaching in incorporating rhythmicity and song into their play interactions, parents were able to achieve fidelity in the RIT principles, suggesting one avenue by which music can be integrated within evidence-based parent-mediated NDBIs. Further qualitative and quantitative analyses will demonstrate how parents incorporated music into the RIT strategies such as via sung speech and prosodic changes.

**402.025 (Poster)** Pandemic-Related Interruptions to Early Intervention Services: Impacts on Students Academic and Behavioral Outcomes  
*S. Hurwitz and T. O'Neal, Special Education, Indiana University, Bloomington, IN*

---

## **Pandemic-Related Interruptions to Early Intervention Services: Impacts on Students Academic and Behavioral Outcomes**

### **Abstract**

**Background:** The COVID-19 pandemic disrupted educational systems for young students with disabilities, especially for students with autism. Delayed enrollment into special education, dropped early intervention services, and postponed Kindergarten entry due to COVID closures and precautions caused many students to miss out on the early intervention and early school-aged services to which they were entitled. Additionally, the pandemic did not equitably impact all students. Some families were able to afford private therapies, learning pods, and special teachers while others were unable to access programs and services due to financial constraints, transportation, work conflicts, and connectivity issues. Thus, post-pandemic recovery efforts will be especially relevant for students from minoritized and poor backgrounds that are more likely to have been underserved during the 2020-2021 school year.

**Objectives:** The purpose of this study is to evaluate the academic and behavioral impacts of delays in assessment and interruption of early intervention services on young students with autism.

### **Research Questions:**

- 1) How did the pandemic impact the identification of students with autism and their consequent enrollment into special education?
- 2) Were specific subgroups (e.g., students from minority backgrounds, ELL, financially struggling) disproportionately affected by pandemic-related disruptions to educational services?
- 3) Is there an increase in disruptive behavior (or disciplinary outcomes) as students (re)enter school?

**Methods:** Three years of student-level SIS data from three school corporations in the state of Indiana are being analyzed. This data is collected and de-identified by INsite (Indiana Student Information to Empower), which is a partnership between a University's School of Education and K-12 school districts. INsite uses the Ed-Fi data standard to allow multiple data systems to be inter-operable. Student-level data includes demographic information, race, ethnicity, grade level, disability type, disciplinary data, and NWEA math and reading scores (when applicable). Students are being followed longitudinally.

**Results:** Analyses show that preschool enrollment of students with disabilities dropped by more than 10% between April 2020 and April 2022 and dropped by 12% for students with autism. Additionally, as students returned to school in fall 2021, behavior problems like eloping, physical aggression, and adamant refusal, are being reported at high levels among K-2<sup>nd</sup> graders, and referrals for special education evaluation have spiked. Academic (NWEA) outcomes are being examined.

**Conclusions:** Post-pandemic, students with autism will require substantial support to rebound academically and behaviorally as they (re)enter school. The results of this study focus on issues of equity, suggesting that minoritized and poor children who were underserved during the pandemic will require intensive intervention. Unfortunately, the special education teacher shortage is growing. This widespread dearth of qualified and well-trained specialists jeopardizes recovery.

**402.026 (Poster)** Piloting an Evidence-Based, Parent Mediated Intervention for Spanish Speaking Latinx Families

**K. Guerra<sup>1</sup>, K. Pickard<sup>2</sup> and N. M. Hendrix<sup>3</sup>,** (1)Marcus Autism Center, Atlanta, GA, (2)Emory University School of Medicine, Marcus Autism Center, Atlanta, GA, (3)Marcus Autism Center, Emory University School of Medicine, Atlanta, GA

---

**Background:** Parent-mediated intervention (PMIs) are an evidence-based intervention approach for young children with ASD (Nevill et al., 2018). However, treatment disparities limit access to PMIs for children with ASD from Spanish-speaking, Latinx families (Mangaña et al., 2013; Zuckerman et al., 2017). Addressing issues of equity requires proactively supporting access to PMIs and ensuring that their delivery is guided by frameworks designed for the development and adaptation of psychosocial interventions for Latinx families (i.e., Ecological Validity Model; Bernal & Bodilla, 1995). In the absence of using these frameworks, there is significant risk that PMIs do not reflect the needs, values, and systemic barriers experienced by Spanish-speaking Latinx families. Within the ASD field, interventions developed for Spanish-speaking Latinx families to date have had promising results but utilize a parent education model (Lopez et al., 2019). Although important, there remain gaps in understanding the extent to which existing PMIs can be proactively delivered and tailored.

**Objectives:** (1) Pilot an evidence-based PMI, Project ImPACT (Ingersoll & Dvortcsak, 2019), for Spanish-speaking Latinx families of a young child with ASD; (2) Examine caregiver and child outcomes associated with participation; (3) Assess caregiver perceptions of Project ImPACT and provider adaptations using the Ecological Validity Model.

**Methods:** Caregivers of a child with ASD (12-40 months) were referred to Project ImPACT by their primary care physician or following the receipt of an ASD diagnosis. All caregivers indicated Spanish as their preferred language. After consent and enrollment, participating caregivers received Project ImPACT from a bilingual provider in either an individual or group model. In both formats, Project ImPACT was delivered once each week for one hour over 12 weeks. Prior to and following participation, caregivers completed the following measures validated in Spanish: 1) child social communication skills; 2) parent social support; 3) parenting sense of competence; and 4) parent empowerment. Data were also collected on caregiver attendance, fidelity, overall satisfaction, and perceived acceptability (i.e., exit interview). All adaptations to Project ImPACT were tracked after each session using probes specific to the Ecological Validity Model.

**Results:** Data collection is ongoing. To date, 8 caregivers have enrolled and are between sessions 1 and 10 in the individual model. Caregivers are predominantly mothers and participating children are 80% Male and ranging 23 to 38 months of age. Data collection is anticipated to be complete and include a total of 20 families by May 2022. One-way analysis of variance (ANOVA) will be used to examine changes in caregivers' social support, perceived parenting competence, empowerment, and Project ImPACT fidelity. Thematic analysis will be used to code adaptations and caregiver exit interviews.

**Conclusions:** Results from this study will demonstrate the preliminary child and caregiver outcomes associated with participation in Project ImPACT. Importantly, findings from this study will directly highlight the acceptability of Project ImPACT for Spanish-speaking, Latinx families historically not included within PMI research, and the extent to which Project ImPACT may benefit from cultural adaptations as guided by the Ecological Validity Model.

**402.027 (Poster)** Positive Reinforcement during Naturalistic Developmental Behavioral Interventions: Application of the New Coding Scheme Opris

**S. K. Kleber<sup>1</sup>, J. Kitzerow<sup>2</sup>, S. C. Mueller<sup>3</sup>, Z. Kim<sup>1</sup>, K. Teufel<sup>1</sup> and C. M. Freitag<sup>1</sup>,** (1)Autism Research and Intervention Center of Excellence Frankfurt, Dept. Child and Adolescent Psychiatry, Psychosomatics & Psychotherapy, Goethe-University Frankfurt, Frankfurt, Germany, (2)Autism Research and Intervention Center of Excellence Frankfurt, University Hospital Frankfurt; Department of Child and Adolescent Psychiatry, Frankfurt, Germany, (3)Autism Research and Intervention Center of Excellence, Department of Child and Adolescent Psychiatry, Psychosomatics and Psychotherapy - University Hospital Frankfurt, Goethe University, Frankfurt am Main, Germany, Frankfurt a.M., Germany, (4)Autism Research and Intervention Center of Excellence Frankfurt, Department of Child and Adolescent Psychiatry, Psychosomatics and Psychotherapy, University Hospital Frankfurt, Goethe University, Frankfurt, Germany

---

**Background:** Supporting learning of new skills through positive reinforcement (PR) is one of the basic methods of behavioral therapy and a central component of the natural developmental *Frankfurt Early Intervention Program for Preschool Children with ASD (A-FFIP)*. Although this mechanism of learning has been well established in ASD, PR has not yet been directly investigated in the therapeutic context.

**Objectives:** We describe *OPRIS (Observation of Positive Reinforcement in Intervention Settings)*, a new scheme for coding PR based on video recordings of intervention sessions. In addition, we explore the correlation of child characteristics, such as core ASD symptoms and cognitive abilities, with the type of PR (TPR) observed during the acquaintance phase of A-FFIP.

**Methods:** Cross-sectional data of  $N = 17$  children with ASD, aged  $M = 49.94$  ( $SD = 10.54$ ) months are presented. For each child, one session of the A-FFIP acquaintance phase was coded from video. Two raters logged PR situations throughout the sessions with OPRIS (inter-rater agreement on single item level  $.701 < ICC < .979$ ). Different aspects of each PR situation were specifically classified: I) contextual factors in the form of child intention and target behavior, II) type of reinforcers, and III) child response. Here, the number of reinforcement situations and frequency of TPRs observed with OPRIS are reported. The correlation between different TPRs and the child's cognitive ability (Bayley-III and WPPSI-III), social communication and repetitive behavior symptoms (BOSCC total score, RBS-R) was explored with Spearman's correlation.

**Results:** Therapists provided a reinforcer around 48 times ( $M = 47.7$ ,  $SD = 10.70$ ) per session. On average, the children accepted 56% of these. In 11% of the cases the child's response was unclear, due to ambiguous behavior or insufficient visibility. Natural non-social PR ( $M = 8.47$ ,  $SD = 8.04$ ), natural social PR ( $M = 8.35$ ,  $SD = 6.33$ ), and the combination of both ( $M = 7.12$ ,  $SD = 5.09$ ) occurred most frequently. No single arbitrary non-social

PR was observed. Medium to large correlations were found for the BOSCC total score with social PR ( $r = -.65$ , 95% CI  $[-.88, -.25]$ ) and combined PR ( $r = .53$ , 95% CI  $[.03, .82]$ ). Cognitive abilities correlated positively with social PR ( $r = 0.49$ , 95% CI  $[-.03, .80]$ ).

Conclusions: OPRIS was able to capture different forms of PR. Therapists employed natural non-social and social PR, but no arbitrary non-social stimuli, which reflects the nature of A-FFIP as naturalistic developmental behavioral intervention (NDBI). High interindividual variability regarding the TPR was observed. Correlation analysis with child characteristics indicate that therapist are able to use different TPRs based on the child's core ASD symptoms and cognitive abilities. Since many of these child characteristics have been reported as predictors of intervention outcome in other studies, our findings emphasize the importance to differentiate child characteristics and the mediating effects of diverse TPR in the future.

#### **402.028 (Poster)** Pre-Treatment Developmental Quotient, Age at Treatment Start, and Early Intervention Type Predict Differential Developmental Trajectories in Autism

---

#### Background:

Early detection and intervention are theorized to facilitate better outcomes in autistic children. However, response to early intervention varies considerably between individuals. A number of pre-treatment individualized characteristics as well as intervention-specific factors (e.g., type, intensity) also are theorized to moderate outcomes. These factors are hard to definitively untangle within smaller individual studies but could be examined in larger mega-analyses that pool together datasets and control for differences between datasets.

#### Objectives:

Examine the moderating influence of a variety of treatment-specific as well as individualized pre-treatment factors for predicting early intervention developmental trajectories.

#### Methods:

We pool data from 10 studies on early intervention in autistic toddlers, collected over 9 sites internationally (USA, Switzerland, Israel, Italy, Australia) and comprising  $n=567$  children with autism ( $n=450$  males,  $n=117$  females) ages 12-60 months. Participants received from 6 to 27 months of intervention, with variable levels of intensity, and were enrolled in either Early Start Denver Model (ESDM;  $n=315$ ) or other treatment as usual/community (TAU/COM;  $n=252$ ) interventions. Longitudinal data common to most datasets included Mullen Early Scales of Learning (MSEL), Vineland Adaptive Behavior Scales (VABS), ADOS, and Griffith Mental Development Scales (GMDS). Linear mixed effect models were used to predict MSEL age-equivalent scores or VABS domain standardized scores trajectories from random effects of dataset (random intercepts) and age grouped by subject (random slopes and intercepts) and fixed effects of age, treatment type, intensity, sex, age at treatment start, and pre-treatment developmental quotient. Control for multiple comparisons was achieved using FDR  $q<0.05$ .

#### Results:

For all MSEL subscales, the interaction effect between age and pre-treatment developmental quotient was highly significant ( $p<3.41e-10$ ). Decile splits indicate that this effect is driven by progressively steeper slopes with higher pre-treatment developmental quotient. Age at treatment start was also highly significant for all MSEL subscales, with early starts having better outcomes. MSEL Visual Reception (VR) and Receptive Language (RL) showed a significant treatment type by age interaction, with ESDM having steeper slopes than TAU/COM. All VABS subscales except motor showed a significant main effect of pre-treatment developmental quotient.

#### Conclusions:

This work provides definitive evidence that pre-treatment developmental level and starting intervention early are the most important predictors of verbal, non-verbal cognitive ability, and fine motor skills as measured by MSEL. ESDM also facilitates better outcomes particularly for non-verbal cognitive ability and receptive language. Unlike MSEL, predicting VABS outcomes was more challenging. This work provides an overview for understanding the main ingredients that facilitate positive outcomes in early intervention.

#### **402.029 (Poster)** Prediction and Monitoring of Treatment Response in Early Intervention: Measuring Social Visual Engagement during a Randomized Clinical Trial of the Early Social Interaction Project

**E. Kushner<sup>1</sup>**, K. Pickard<sup>2</sup>, J. L. Stapel-Wax<sup>3</sup>, A. M. Wetherby<sup>4</sup>, A. Klin<sup>5</sup>, W. Jones<sup>5</sup> and L. A. Edwards<sup>6</sup>, (1)Emory University, Marcus Autism Center, Atlanta, GA, (2)Emory University School of Medicine, Marcus Autism Center, Atlanta, GA, (3)Emory University School of Medicine, Atl, GA,

#### Background:

In order to improve the efficacy of interventions for young children with ASD, we must understand the mechanisms of change by which interventions work, as well as accurately measure change during and due to intervention. Eye-tracking is a promising objective and automated method for tracking progress in interventions. It may be a particularly useful measure of progress and/or outcome in naturalistic developmental behavioral intervention (NDBIs), as these interventions emphasize building engagement and social communication skills (Schreibman et al., 2015), constructs already shown to relate to measures of social visual engagement (SVE) in young children with ASD (Jones & Klin, 2013).

#### Objectives:

This project sought to determine 1.) whether eye tracking measures of social visual engagement (SVE) predict response to Early Social Interaction (ESI), a parent-mediated NDBI, and 2.) the extent to which patterns of SVE change in response to participation in ESI.

#### Methods:

Children participating in a longitudinal study from birth to 24 months were screened at 12 months for early signs of ASD. The present study includes all children who screened positive at 12 months and later received diagnoses of ASD ( $n=27$ ). All were invited to participate in ESI from 12-24 months. Seventeen families participated and 10 declined. All parents completed the Communication and Symbolic Behavior Scales (CSBS) and Vineland Adaptive Behavior scale (VABS-II) at 12 and 24 months. Eye-tracking measures of SVE (quantified as percentage of time spent fixated on different facial regions of interest (ROIs)) were collected at 11 timepoints over the course of the study. Linear regressions were used to determine the relationship between SVE to eye regions at 6 months and treatment response, measured by change scores on the CSBS and VABS-II from 12 to 24 months. Functional data analysis was utilized to model longitudinal trajectories of SVE to eye regions for intervention and non-intervention groups.

#### Results:

SVE to eye regions at 6 months significantly positively predicted change scores in the Speech domain of the CSBS and the Communication domain of the VABS-II ( $F(1,15)=5.48, p=0.03$ ;  $F(1,8), p=0.01$ ) for children who participated in ESI. Trajectories of SVE to eye regions for children in the intervention and non-intervention groups are displayed in Figure 1. SVE to eye regions did not differ between intervention and non-intervention groups at 12 months. Between 12 and 24 months, eye-fixation in the ESI group remained relatively stable whereas eye-fixation steadily declined in the non-intervention group. By 24 months the non-intervention group fixated significantly less on eye regions ( $t(23.05)=2.14, p=0.04$ ).

#### Conclusions:

Measures of SVE in infancy predict improvement in communication abilities over the course of ESI intervention; specifically, infants who look more at others' eyes showed greater gains in communication abilities while participating in ESI. Additionally, longitudinal trajectories of SVE to eye regions suggest that these trajectories may differ between infants who participated in ESI intervention and those who did not. These findings provide preliminary evidence that measures of SVE are predictive of and responsive to NDBI effects.

#### **402.030 (Poster)** Predictors of Active Engagement in Inclusive Preschool Classrooms for Children with and without ASD: Teachers' Classroom Supports and Children's Social Visual Attention

**M. Siller<sup>1</sup>, L. Morgan<sup>2</sup>, L. A. Edwards<sup>3</sup>, S. Fuhrmeister<sup>4</sup>, B. Schirmer<sup>5</sup>, A. Rudrabhatla<sup>6</sup>, E. Kushner<sup>6</sup>, Q. O. Wedderburn<sup>7</sup> and E. J. Chatson<sup>7</sup>, (1)Emory University School of Medicine, Atlanta, GA, (2)Emory University-Marcus Autism Center, Atlanta, GA, (3)Marcus Autism Center, Atlanta, GA, (4)Marcus Autism Center, Children's Healthcare of Atlanta, Atlanta, GA, (5)Marcus Autism Center, Children's Healthcare of Atlanta and Emory University School of Medicine, Atlanta, GA, (6)Emory University, Marcus Autism Center, Atlanta, GA, (7)Emory University, Atlanta, GA**

---

**Background:** Learning occurs when children are actively engaged during planned teaching opportunities (NRC, 2001). In classroom-based interventions, where teachers implement intervention strategies or embed learning supports within/across daily routines/activities, measures of active engagement (AE) provide a meaningful metric for quantifying the intensity of children's intervention receipt. By its very nature, AE is a transactional construct, and moments of AE may emerge because of classroom interventions/supports implemented by the teacher, because of generalized behavioral tendencies of the child (e.g., social attention), or both.

**Objectives:** This research uses observations collected across three classrooms of an inclusive laboratory preschool for children with/without ASD to investigate whether observational classroom measures of AE (frequency of children's directed communication) are predicted by (1) observational measures of classroom interventions/supports (teachers' active facilitation and supportive language use), and/or (2) objective generalized measures of children's social visual engagement (eye tracking).

**Methods:** The research sample includes 42 children between 24 and 62 months ( $M = 46.7$ ,  $SD = 11.1$ ; 71% male), including 20 children with a diagnosis of ASD. Day-long classroom videos were recorded once per week, for five weeks. For each child and day-long recording, a 5-minute segment of center time (i.e., indoor free-play) was selected randomly for subsequent coding (i.e., up to five repeated observations per child). Video segments were coded for (1) the frequency of children's directed communication (Classroom Measure of Active Engagement; Morgan et al., 2018),

and (2) qualitative ratings of teachers' active facilitation and supportive language use (Classroom Assessment Scoring System; Pianta et al., 2008). Further, 32 of the 42 children participated in a single eye-tracking session during which participants viewed videos of naturalistic social situations (e.g., children engaged in play). Children's eye movements were recorded and used to quantify children's generalized visual social engagement (% gaze allocation to the faces of the protagonists shown in the videos). Finally, children's parents completed the Social Responsiveness Scale (SRS; Constantino & Gruber, 2005) to provide a continuous, quantitative measure of autistic traits. To accommodate the nested data structure (five repeated classroom observations nested within children), data were analyzed by specifying mixed models for longitudinal data using SAS Proc Mixed.

**Results:** Preliminary results showed that observed frequencies of children's directed communication were not predicted by children's age, diagnostic group (ASD vs. TD), or continuous, quantitative measures of autistic traits ( $p > .40$ ). In contrast, observed frequencies of children's directed communication were significantly predicted by (1) observational measures of classroom interventions/supports (average ratings of teachers' active facilitation and supportive language use scores),  $F(1,65) = 4.3, p < .05$ , and eye-tracking measures of children's generalized social visual engagement (gaze allocation to faces while viewing naturalistic social interactions on video),  $F(1, 54) = 4.9, p < .05$ . Importantly, measures of social visual engagement and classroom interventions/supports were not associated, suggesting that both variables contribute unique information in predicting AE.

**Conclusions:** Results from this research illustrate the transactional nature by which children and teachers collaborate to create moments of AE in inclusive preschool classrooms for children with and without ASD.

**402.031 (Poster)** Preparation for Adaptation of Intensive Early Intervention for Toddlers with ASD: Childcare Providers' Perspectives on Training Approach

**M. Maye<sup>1</sup>, S. R. Edmunds<sup>2</sup>, A. K. Stone MacDonald<sup>3</sup> and A. S. Carter<sup>4</sup>,** (1)Henry Ford Health System, Detroit, MI, (2)Boston Children's Hospital, Boston, MA, (3)University of Massachusetts Boston, Boston, MA, (4)Department of Psychology, University of Massachusetts Boston, Boston, MA

**Background:** Naturalistic developmental behavioral interventions (NDBI) are effective interventions for toddlers with autism spectrum disorder (ASD) that occur in a natural environment, during daily activities and tasks, and at a developmentally appropriate level. An NDBI adaptation for community childcare settings specifically developed to be contextually sustainable and to promote community spread would: 1) increase access to ASD-specific early intervention; 2) support working parents or parents in need of respite care; and 3) possibly reduce parent stress, anxiety, and depression via increased support.

**Objectives:** To explore childcare providers' (providers) knowledge of ASD, confidence and experiences caring for toddlers with ASD and their openness to, and preferred format of, additional training.

**Methods:** Providers completed an online or paper survey regarding their interest in training and experiences with ASD. All providers had provided childcare to a toddler with known or suspected ASD within the last 12 months. Providers were predominantly female (78.9%), lead teachers in their classrooms (49.1%) and ranged widely in their age (20-65 years,  $M = 35.38$  years,  $SD = 12.21$  years) and educational experiences (43.7% BA+). Providers reported working close to full time ( $M = 34.9$  hours/week,  $SD = 9.44$  hours/week), but there was still a wide range in reported classroom hours (Range: 5 to 50 hours/week). Most providers were reporting on professional experiences gained in toddler-specific (76%) or preschool-specific classrooms (18.5%).

**Results:** Most providers were willing to attend/receive at least 1 hour of any type of training format: in-person didactics (98%), online didactics (98%) or in-person coaching (93%). Providers indicated a preference to complete more hours of in-person didactics than any other type of training format (in-person 33%; online 23.7%, live coaching 12.7%). Provider knowledge of ASD did not predict interest in ASD training,  $OR = 1.16, B = 0.15, p = .06$ , nor did provider confidence in working with children with ASD,  $OR = 0.95, B = -0.05, p = .64$ . However, the greater the extent to which a provider perceived ASD symptoms to interfere with children's learning, the more likely providers were to indicate interest in training,  $OR = 2.57, B = 1.27, p = .01$ . Providers who reported working with a toddler with other types of challenging behaviors were also more likely to be interested in training,  $OR = 0.11, B = -2.17, p = .01$ . However, provider perception of interfering child behaviors did not predict quantity of training sessions willing to complete.

**Conclusions:** Providers have clear interest in receiving additional ASD-specialized trainings to support toddlers with ASD in their classrooms – especially when they perceive child behaviors to interfere with learning. Generally, providers interest in type/length of training mirrored current professional development practices but did not align with effective adult learning strategies. These insights demonstrate that an intensive training program, like most NDBI interventions require, may be an unattainable goal for community childcare providers. Childcare adaptations of NDBIs should likely focus on incorporating intervention strategies that are common between NDBIs and existing national early education and care accreditation practices to promote provider engagement and sustainability.

**402.032 (Poster)** Proof-of-Concept Study of a Novel Parent-Mediated Intervention for Infants at Elevated Likelihood of Autism

## Background:

Associations between parent responsiveness and social-communication outcomes in children with autism provide conceptual support for interventions promoting parent responsiveness. Hypothetically, parent responsiveness fosters parent-child dyadic engagement, which mediates children's social-communication outcomes. However, interventions targeting *infants at elevated likelihood for autism* (EL-AU), have generally yielded modest or null effects on infant outcomes. We developed a new intervention, Parents and Infants Engaged (PIE), coaching parents to recognize and respond to infant variables that likely play transactional roles in social-communication development: prelinguistic communication (PC) and sensory reactivity (SR).

## Objectives:

Estimate PIE's effects on: (a) dyadic engagement (primary outcome); (b) parent responsiveness to infant SR and PC cues; and (c) infant intentional communication and broader social-communication.

## Methods:

We enrolled 36 parent-infant dyads. Infants were 14.1 ( $SD=1.7$ ) months; 27/36 male; 25/36 White; 7/36 Latino. Eligibility required First Years Inventory v.3b-Lite screening scores  $\geq$  cutpoint for EL-AU, and observed language delays and extreme patterns of sensory hypo-/hyper-reactivity at Baseline. Participants were randomized to one of two arms differing in PIE domain coaching order – PC Arm was first coached on responding to infants' PC cues and SR Arm on responding to infants' SR cues. Across domains, coaches engaged parents in reflecting on the effectiveness of their responses to infant cues in establishing or maintaining engagement. After 6 weekly coaching sessions in their initial PIE domain, families returned for Posttest1. They then participated in 6 coaching sessions in the 2<sup>nd</sup> PIE domain, followed by Posttest2. Coders blind to Arm and Timepoint coded 20-minute parent-child interaction videos at Baseline, Posttest1 and Posttest2 for dyadic engagement, parent responsiveness, and infant intentional communication. The Brief Observation of Social-Communication Change (BOSCC) was administered at Baseline and Posttest2 by an assessor blind to Arm and scored by coders blind to Arm and Timepoint.

## Results:

Dyadic engagement improved significantly over time,  $F(2, 58) = 7.8, p = .001$ . Parent responsiveness improved from Baseline to Posttest1, to both infant SR,  $t(63) = 2.79, p = .008$ , and PC,  $t(60.7) = 2.28, p = .026$ , with no Arm x Time effects. Infant intentional communication increased significantly over time,  $F(2, 61) = 9.66, p < .001$ ; BOSCC Social Communication domain scores decreased (improved) significantly,  $F(1, 27.5) = 4.9, p = .04$ . All Arm and Arm x Time effects were nonsignificant.

## Conclusions:

In this proof-of-concept study, participants were randomized to coaching domain order, with all receiving the full PIE intervention by Posttest2. Time effects on targeted parent, infant, and dyadic outcomes aligned with our hypotheses. Coaching in *either* PIE domain was associated with increases in parent responsiveness to *both* infant PC and SR cues at Posttest1, failing to support our hypothesis that responsiveness would improve specific to coaching domain. Moderate to strong time effects on targeted dyadic and infant outcomes by Posttest2 support PIE's potential efficacy. Despite nonsignificant Arm x Time effects, relative patterns of change for the two Arms, especially in dyadic engagement, suggest possible benefits of first coaching parents in the SR domain. Further evaluation of PIE in a well-powered randomized controlled trial is planned.

**402.033 (Poster)** Systematic Review of Very Early Life Interventions for Infants at-Risk or Diagnosed with Neuro-Developmental Disorders  
**S. Wunderlich<sup>1</sup>, J. Zeidan<sup>1</sup>, A. Ibrahim<sup>1</sup>, M. Micai<sup>2</sup>, F. Fulceri<sup>3</sup>, C. Servili<sup>4</sup>, P. Dixon<sup>5</sup>, A. Shih<sup>6</sup>, M. L. Scattoni<sup>7</sup> and M. Elsabbagh<sup>7</sup>**, (1)McGill University, Montreal, QC, Canada, (2)Research Coordination and Support Service, Istituto Superiore di Sanità, Rome, Italy, (3)Istituto Superiore di Sanità, Rome, Italy, (4)Department of Mental Health and Substance Abuse, World Health Organization, Geneva, Switzerland, (5)Wayne State University, Ann Arbor, MI, (6)Autism Speaks, New York, NY, (7)Neurology and Neurosurgery, McGill University, Montreal, QC, Canada

---

**Background:** Neuro-developmental disorders (NDDs) involve atypical brain development early in life. Risk factors for developing a NDD often interact overtime with an individual's characteristics resulting in a wide range of heterogeneous outcomes between individuals. Previous reviews targeting Early Intervention (EI) include a broad range of interventions designed to improve different aspects of child development, however, our selected population has yet to have been examined.

**Objectives:** We conducted a systematic review evaluating existing EI literature across individuals who are at-risk or diagnosed with NDD.

**Methods:** We used the PRISMA guidelines for systematic reviews. Literature search was done using e-databases: PsycINFO, Embase, and Medline, from January 2000 until May 2021. The search strategy focused on Population, Intervention, Comparison, and Outcomes (PICO). We included articles if they were (1) a randomized clinical trial; (2) on infants pre-birth and up to 3 years of age diagnosed or at-risk for NDD; (3) and included outcomes relating to infant risk signs and symptoms or developmental outcomes, caregiver well-being, infant-caregiver interaction, and family functioning. We used the Cochrane Tool for Assessing Risk of Bias.

**Results:** We screened 1,417 results for eligibility of which 97 studies met our criteria. 17 studies met the criteria for low risk of bias across all domains, excluding performance bias. Of the 17 studies, most interventions targeted populations at risk of developing a NDD and/or their families (n=12). In the remaining studies, interventions focused on either autism or Down syndrome (n=5). Only three studies involved group level delivery either partly (n=2) or entirely (n=1), however there were four parent-mediated interventions studied. The dosing frequency varied from 4 biweekly sessions to weekly sessions over 36 months. The length of each session varied from 30 minutes to 2-hour session blocks. The delivery of the interventions was mainly conducted by specialized, trained professionals who used manuals (n=13). In nine studies interventionists continued to receive supervision. Although outcome measures varied substantially across studies, improvements were reported in many studies. Of the 17 studies, they reported improvements in infant outcomes across infant risk and diagnostic status (n=3), motor functioning (n=2), cognitive development (n=5), behavior and emotional regulation (n=4), adaptive functioning (n=1), attention (n=2), language (n=3), and functional play (n=1). Eleven studies reported caregiver outcome improvements in mental health (n=5), global and social functioning (n=2), distress and perceived support (n=2), non-directiveness (n=1), and smiling (n=1). One study reported dyadic outcomes which reported improvements in parent-child interactions, including child attentiveness, responsiveness, and joint engagement. One study focused on clinical outcomes such as length of hospital stay (n=1). Only one study reported an implementation outcome: teaching assistants' implementation strategy when using a newly acquired intervention model in a preschool setting.

**Conclusions:** Very EI before three years of age yields improvement across a range of caregiver, infant, and dyadic outcomes. Nevertheless, the limited number of studies that met quality standards and the heterogeneity in outcomes impeded a meta-analysis. Future studies using comparable measures across populations can eventually inform the extent to which intervention mechanisms and outcomes differ.

#### **402.034 (Poster) The Current State of Preemptive Interventions: A Systematic Review and Meta-Analysis**

**L. H. Hampton and E. Rodriguez, The University of Texas at Austin, Austin, TX**

**Background:** Understanding the impact of preemptive interventions on developmental outcomes for those with a high likelihood for autism is a critical step in building a transdiagnostic sequential model of optimized care, given the current autism prevalence rates. Interventions designed to address core symptoms of autism have a strong evidence base and many of these interventions have also been adapted for toddlers with a growing evidence base. However, earlier intervention has yet to demonstrate definitive evidence of long-term outcomes, despite the wide acceptance and face validity of this practice. The purpose is to examine the impact of preemptive interventions on parent outcomes and child developmental outcomes.

**Objectives:** Are preemptive interventions for infant/toddlers with a high likelihood for autism associated with (1) improved parent implementation? (2) improved developmental outcomes? (3) reduced autism symptoms? And (4) What study characteristics moderate the outcomes?

**Methods:** A total of 571 articles were assessed for eligibility using the PRISMA framework for abstracting data and assessing study quality, and a total of 16 individual sources were included, representing 13 studies. The primary outcomes included parent responsiveness and parent implementation of intervention strategies, caregiver stress, and child developmental outcomes included language, communication, motor, social, and adaptive skills. A robust-variance meta-analysis was used to estimate effects across 13 studies.

**Results:** The meta-analysis includes 13 unique studies, 11 of which are randomized trials. These studies include a total of 715 infant/toddlers with a high likelihood for autism. All of the included studies used a parent-mediated intervention based in developmental or developmental-behavioral principles. There was a significant association between the intervention on parent implementation of responsiveness strategies immediately following the intervention ( $G=.544$ ,  $SE=.166$ ,  $p=.01$ ). However, there was no significant association between the intervention and child outcomes ( $G=.104$ ,  $SE=.086$ ,  $p=.257$ ). The systematic review includes 5 studies reporting moderator and/or mediator analyses which point towards a significant and meaningful association between parent implementation and long-term child social communication outcomes.

**Conclusions:** Previous reviews have examined interventions for young children autism on individual outcomes and to date, no study has reviewed preemptive interventions across all developmental outcomes. In particular, the findings identified in the current meta-analysis highlight the urgent need to develop a nuanced intervention approach during a time of ever-changing concern about child development. Early interventionists and clinicians who frequently work with parents of children with a high-likelihood for autism may need greater training in how to discuss early autism signs and early preemptive interventions with families. Additionally, it may be important to refer all infant/toddler siblings with a high likelihood for autism to intervention in light of the findings that those with the fewest symptoms benefited most from the parent-mediated intervention (Yoder et al., 2021a).

#### **402.035 (Poster) The Effect of "Resilience Intervention with Parents of Children with ASD" on Parental Resilience and Well-Being and on Children's Behavior and Emotion Regulation**

**T. Gev<sup>1,2</sup>, O. Karnieli-Miller<sup>3</sup>, N. Gershon<sup>1</sup>, D. Hamiel<sup>1,4</sup>, N. Cohen-Aronson<sup>1</sup>, S. Jaffe<sup>1</sup>, A. Shlomiuk<sup>3</sup> and N. Laor<sup>1,3</sup>, (1)Center for the Treatment and Research of Autism - Association for Children at Risk, Giv'at Shemu'el, Israel, (2)Department of Psychology, Bar-Ilan University, Ramat Gan, Israel, (3)Sackler Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel, (4)Baruch Ivcher School of Psychology, Reichman University (IDC Herzliya), Herzliya, Israel**

**Background:** Parents of children with ASD deal with stressors stemming from their child's course of development and experience increased levels of stress, anxiety and depression compared to parents of children with typical development (Bitsika et al. 2013). These experiences challenge their psychological resilience and well-being. Research on parent-specific interventions aimed at improving psychological resilience and well-being is

scarce (Kuhlthau et al., 2020; Schwartzman et al., 2021). Furthermore, the possible impact of parental improved resilience and well-being on these children's behavior and emotional regulation was rarely studied.

The Resilience Intervention with Parents of Children with ASD (RIPCA) is 17-weeks group-based program, designed to teach parents evidence-based resilience strategies, emotion regulation techniques, and child behavior management strategies. RIPCA was adapted from a parent and teacher-delivered resilience intervention (Wolmer, Hamiel, & Laor, 2011; Wolmer et al., 2011).

Objectives: (1) to examine the effect of RIPCA on parental resilience and well-being; (2) to examine the effect of the RIPCA on child behavior and emotion regulation; (3) to explore parents' perceptions of the program and its impact on them and/or their children.

Methods: A pilot study of mixed methods - quantitative pre-post design and qualitative interviews with parents during and after the program was conducted. Participants included 21 parents of school-age children with ASD (4-8 years old) who completed questionnaires evaluating their resilience and well-being and their child's anxiety, behavior, and emotion regulation pre- and post-intervention. Parents' experiences of the intervention were explored through semi-structured interviews with 17 parents, during and after the intervention. Interviews' analysis employed the Immersion/Crystallization method – reading/re-reading the interviews in an iterative consensus building process.

Results: Following RIPCA, both parental well-being and positive relationships, an indicator of resilience, significantly increased. Parents reported a significant decrease in children's maladaptive behaviors: agitation and crying, social withdrawal and hyperactivity/noncompliance. In addition, improvement in parental resilience and decreased child anxiety, agitation and crying and hyperactive behaviors, exhibited significant positive correlations.

The qualitative interviews identified that parents felt RIPCA enhanced their awareness and understanding of needs and stressors as parents to children with ASD, while balancing their own stress thus improving children's well-being. Sharing experiences among parents decreased feelings of isolation and shame. Their increased awareness of feeling and thinking, allowed them to choose alternative approaches of handling child-related stressful situations, thus decreasing automatic anger reactions toward the child, improving communication of their own and the child's emotions and needs to impart their children some of the acquired strategies.

Conclusions: This pilot study preliminarily supports the effectiveness of RIPCA in (1) improving resilience and well-being among parents of young children with ASD, (2) decreasing children's maladaptive behaviors: agitation and crying, social withdrawal, and hyperactivity/noncompliance. The qualitative findings indicate parents' benefit from both safely sharing their challenges and acquiring strategies to handle challenging day-to-day interactions with their children. Additional research is needed to assess and enhance the impact of resilience interventions both on parents and on their children with ASD.

**402.036 (Poster)** The Impact of Parent Resolution of Diagnosis on Intervention Fidelity in a Parent-Delivered Intervention for Pre-School Children with Autism: A Mixed Methods Study

**C. Dissanayake<sup>1</sup>, P. Grogen<sup>1</sup>, M. Yaari<sup>2</sup>, R. Jellet<sup>1</sup> and K. L. Unwin<sup>1</sup>,** (1)*Olga Tennison Autism Research Centre, La Trobe University, Melbourne, VIC, Australia,* (2)*Department of Psychology, The Hebrew University of Jerusalem, Jerusalem, Israel*

Background: Despite growing interest in parent-delivered interventions (PDI) for autistic children, evidence of their efficacy and effectiveness are variable. Parent treatment fidelity has been associated with child outcomes but little is known about what impacts fidelity in a PDI. One factor not previously examined is parents' resolution to the child's diagnosis which involves adjusting their expectations about the child following diagnosis and sensitively responding to their cues, strengths and needs. Resolution is, therefore, relevant to PDI fidelity where parents are rated on how they interpret and respond to their child's cues. Few studies have examined resolution to diagnosis in the context of autism but there is evidence of an association between resolution and parent wellbeing.

Objectives: The study aims were to examine a) whether there is an association between parent resolution of diagnosis and PDI fidelity; b) whether resolution to diagnosis is associated with parent wellbeing; and c) to describe and compare interview responses of parents who were classified as resolved/unresolved to their child's autism diagnosis.

Methods: Parents of 31 children (90% mothers) diagnosed with autism (58% male; 3-6years) attended 10-12 parent-delivered Early Start Denver Model (P-ESDM) coaching sessions. A mixed-methods approach was adopted to address the study aims, with a thematic analysis undertaken of parent Reaction to Diagnosis Interviews (RDI; Pianta & Marvin, 1993) to identify themes raised by resolved and unresolved parents. The P-ESDM fidelity tool was used to measure parents' adherence to the intervention principles, with mean fidelity scores calculated at each session, and change scores calculated to ascertain the mean change between fidelity scores at their first and final sessions. The Depression, Anxiety and Stress Scale and the Parenting Stress Index Short Form were used to ascertain parental wellbeing. Children were assessed with the Mullen Scales of Early Learning and the Autism Diagnostic Observation Schedule at study intake.

Results: Parents demonstrated a significant improvement in fidelity over time ( $d = 1.32$ ). In relation to the RDI, 48% of parents were classified as resolved and 52% as unresolved. Quantitative analysis revealed that while there was no significant difference on mean fidelity scores between resolved and unresolved parents, parents classified as resolved demonstrated significantly higher fidelity change scores over time ( $d = .6$ ), as well as significantly lower scores on depression and parenting stress than parents classified as unresolved ( $d$ 's ranging from  $.6 - .8$ ). Despite child measures not distinguishing the resolved and unresolved groups, qualitative analysis revealed that parents' perceptions of their child's progress and their hopes for the future distinguished resolved from unresolved parents.

Conclusions: Findings suggest that parent resolution to diagnosis is likely to impact change in PDI fidelity and also their wellbeing, although causality cannot be ascertained in this study. Targeted supports may be required for parents who experience psychological distress to ensure they have the internal resources to successfully deliver parent mediated intervention.

**402.037 (Poster)** The Relationship between Child-Initiated and Caregiver-Initiated Joint Engagement and Joint Attention Following Jasper Treatment in Toddlers at-Risk for ASD.

**M. Tafolla Magana<sup>1</sup>, T. Cohenour<sup>2</sup>, S. Seese<sup>1</sup>, W. I. Shih<sup>1</sup>, A. Gulsrud<sup>1</sup> and C. Kasari<sup>1</sup>,** (1)University of California, Los Angeles, Los Angeles, CA, (2)UCLA, Los Angeles, CA, (3)University of California - Los Angeles, Los Angeles, CA, (4)UCLA Semel Institute for Neuroscience & Human Behavior, Los Angeles, CA

---

Background: Early interventions for children with ASD often target social communication abilities, including joint attention and language. Joint engagement between adults and children can facilitate increased gesture and language use, and evidence has supported this in both TD children (Tomasello & Farrar, 1986) and children with ASD (Adamson et al., 2017; Shih et al., 2021). While past studies have examined the mediating effects of overall time spent in joint engagement (JE; Shih et al., 2021), this study examined the relationships between mean length of child-initiated JE (JE-C) and adult-initiated JE (JE-A) and social communication following a treatment intervention.

Objectives: Investigate the relationship between mean length of child- and adult-initiated joint engagement and initiations of joint attention (IJA) in infants/toddlers at risk for ASD.

Methods: This study used data collected for an autism intervention study for infants showing signs of ASD. Participants ( $N=78$ , 21% female, 50% white) between 12-21 months of age and with elevated scores on the ADOS-T (Luyster et al., 2009) were eligible (Table 1). Participants were randomized to a Baby JASPER (Kasari et al., 2021) or Standard Baby Classroom. Both classrooms were structured around the AEPS curriculum (Bricker, 2002). Baby JASPER classroom activities were tailored to target early emerging areas of weakness in ASD (joint attention, play); the Standard Baby Classroom targeted various developmental domains. Caregivers in the Baby JASPER classroom received weekly hands-on training in caregiver-mediated JASPER; caregiver in the Standard Baby classroom received weekly parent education. JE-A and JE-C were coded from caregiver-child free play interactions. IJA was measured via Early Social Communication Scales (Mundy et al., 2003). Four linear regression models were run predicting IJA: Models 1-2 tested whether mean duration of JE-A and JE-C in seconds predicted concurrent IJA at Entry after controlling for Visual Reception (VR; proxy for nonverbal cognitive ability). Models 3-4 tested whether mean duration of JE-C and JE-A at Exit predicted IJA at exit after controlling for VR, treatment, IJA at entry and total length of caregiver-child interaction video in seconds.

Results: The relationship between child-initiated mean length of joint engagement and IJA at exit differed by treatment group and results neared significance ( $p=.065$ ). There was a small positive relationship between JE at exit and IJA at exit in the JASPER condition and a slightly negative relationship between the two in the control group at exit. See Table 2 for descriptive information. There was no interaction between adult-initiated joint engagement and treatment ( $p=.13$ ) on IJA.

Conclusions: Results suggest that JASPER can impact the relationship between JE and IJA even in the short period of eight weeks. Mean length of joint engagement gives us a more detailed information about engagement periods as opposed to the overall time in a state of JE. Given that social communication is a core challenge for young children with ASD, these findings support interventions that may increase JE periods between two play partners, and thus may increase a child's ability to learn and initiate social skills (IJA) within a play interaction.

**402.038 (Poster)** Young Children with Autism Placed in Special and Inclusive Educational Settings Exhibit Similar Improvements in Core ASD Symptoms over Time

**M. Ilan<sup>1</sup>, M. Faroy<sup>2</sup>, D. A. Zachor<sup>3</sup>, L. Manelis<sup>4</sup>, A. Michaelovski<sup>5</sup>, I. Ayni<sup>6</sup>, I. Menashe<sup>7</sup>, I. Dinstei<sup>8</sup> and G. Meiri<sup>9</sup>,** (1)Psychology Department, Ben-Gurion University of the Negev, Beer Sheva, Israel, (2)Preschool Psychiatric Unit, Soroka University Medical Center, Beer Sheva, Israel, (3)The Autism Center/ALUT, Pediatrics, Tel Aviv University / Shamir (Assaf Harofeh) Medical Center, Zerifin, Israel, (4)Negev Autism Center, Ben Gurion University of the Negev, Beer Sheva, Israel, (5)Zusman Child Development Center, Soroka University Medical Center, Beer Sheva, Israel, (6)Cognitive and Brain Sciences, Ben-Gurion University of the Negev, Beer Sheva, Israel, (7)Public Health Department, Ben-Gurion University of the Negev, Beer Sheva, Israel, (8)Cognitive and Brain Sciences Department, Ben-Gurion University of the Negev, Beer Sheva, Israel, (9)National Autism Research Center of Israel, Ben-Gurion University of the Negev, Beer Sheva, Israel

---

Background: In Israel, children with autism are eligible for placement in either special or inclusive education settings. In special education settings, small groups of up to 8 children with Autism spectrum disorder (ASD) receive treatment from a large professional staff including special education teachers and therapists. In contrast, regular education settings include up to 35 typically developing children and children with ASD are accompanied by a personal assistant with limited professional education. Nevertheless, children placed in inclusive programs have the benefit of exposure to their typically developing peers. Remarkably few studies have compared the developmental outcome of children across the two educational settings.

Objectives: To compare longitudinal changes in autism severity of 2-5-year-old children who were placed in special education versus inclusive education settings.

Methods: We examined longitudinal data from 121 children, who were recruited at the National Autism Research Center of Israel. Children were 11-65 months-old (mean age = 32.6 months) at the time of diagnosis. Autism diagnostic observation schedule 2 (ADOS2) scores were collected during initial diagnosis and again 12-24 months later. T-tests were used to compare longitudinal changes in total ADOS calibrated severity scores (CSS) and separately in the social affect (SA) and restricted and repetitive behaviors (RRB) domains. Chi-Square tests were used to compare the percentage of toddlers who improved in each group. Mann Whitney tests were used to assess differences in longitudinal language production changes, which were estimated using a scale of 0 to 7, (no spontaneous word production to language appropriate for age, respectively) based on item A1 of the ADOS.

Results: Initial characteristics of children placed in special or inclusive education did not differ significantly with respect to age of diagnosis ( $t(119) = 0.95$ ,  $p = 0.34$ ), ADOS CSS ( $t(119) = -1.25$ ,  $p = 0.21$ ), SA CSS ( $t(119) = -1.7$ ,  $p = 0.09$ ), RRB CSS ( $t(119) = -0.11$ ,  $p = 0.9$ ), level of language production ( $U(121) = 1271.5$ ,  $p = 0.105$ ), and parental age (mothers:  $t(115) = 0.53$ ,  $p = 0.59$ ; fathers:  $t(105) = 0.18$ ,  $p = 0.86$ ). However, parental education of children placed in inclusive education was higher (mothers:  $t(103) = 3$ ,  $p = 0.003$ ; fathers:  $t(40.48) = 3$ ,  $p = 0.004$ ).

Similar longitudinal changes were apparent in ADOS CSS in both groups. The percentage of children who improved in ADOS CSS in inclusive education (61%) and special education (52%) settings did not differ significantly ( $\chi^2(121) = 0.68$ ,  $p = 0.41$ ). There was also no significant difference in the magnitude of change in total ADOS CSS across the two groups ( $t(119) = 0.93$ ,  $p = 0.35$ ) nor in SA CSS ( $t(119) = 1.22$ ,  $p = 0.22$ ) or RRB CSS ( $t(119) = 1$ ,  $p = 0.3$ ). Longitudinal changes in spoken language scores also did not differ significantly across children placed in mainstream and special education ( $t(119) = 1.44$ ,  $p = 0.15$ ).

Conclusions: These findings suggest that children placed in either educational setting improve similarly in core ASD symptoms as assessed by the ADOS. This may be surprising given the large difference in structure and cost of the two settings. It is possible that while changes in autism severity are less apparent after short period of intervention, outcomes in cognitive abilities and adaptive behaviors would be different between the two educational settings and should be assessed in future studies.

## VIRTUAL POSTER SESSION — INTERVENTIONS - NON-PHARMACOLOGIC - PRESCHOOL & INFANT

### 502 - Interventions - Non-pharmacologic - Preschool & Infant --- (V)

**502.005** (*Virtual Poster*) Early Intervention Modifications for Autism during Covid19 – an ABAB Design Case Series from a Tertiary Care Center in India

A. Dinesan<sup>1</sup>, S. Lakshmi<sup>1</sup>, S. Santosh<sup>2</sup>, N. Srikanth<sup>1</sup>, S. M. Kaku<sup>1</sup> and A. Mysore<sup>1</sup>, (1)Center for Advanced Research and Excellence in Autism and Developmental Disorders (CARE-ADD), St. John's Medical College Hospital, Bangalore, India, (2)Center for Advanced Research and Excellence in Autism and Developmental Disorders (CARE-ADD), St. John's Medical College Hospital, Bangalore, India

#### Background:

Early Intervention is critical for children with autism. At CAREADD, we follow the Com DEALL Early Intervention program which is a group-based intervention model that uses an interdisciplinary team approach and runs for a period of ten months (Karanth et al 2010). We started the program in January 2020 with 7 children. In April, the pandemic intervened. Initially, during the lock down, we adapted by providing Home Training Programs with regular follow up calls to help parents manage their children. Eventually we adapted the Com DEALL program into an online mode using small-group interventions conducted via Microsoft Teams. Briefly face to face interventions resumed before reverting to online modes during the second wave.

#### Objectives:

This paper is an observational qualitative case series report which aims to study the difference between online and offline modes of interventions in seven children with ASD enrolled in our early intervention program, and the effects of this modified intervention on parental knowledge and stress.

#### Methods:

The ABAB design saw three children undergo 3 months of face-to-face intervention(A), followed by 8 months of online(B), 2 months of face-to-face interventions again (A) and 1 month of online interventions (B). We extended intervention beyond 10 months to sync with the academic year.

Another series had only an ABA design with 3 children, aged below 5 years, of whom 2 were discharged after this program to an inclusive school. One family opted out due to personal reasons.

#### Results:

While face-to-face intervention provided comfort, familiarity, ease of working with children and reduced parental stress, online intervention relied heavily on the parents and depended on their skills and motivation to implement therapists' suggestions. We found that online intervention compelled some parents to understand and manage their child's issues while increasing their awareness and knowledge of the condition. Severity of Autism also played an important role with increase in behavioural and sensory issues in more severe cases. Online intervention seems to be more effective when families have had some face-to-face interactions and sessions with therapists, understand the process of therapy and are motivated.

#### Conclusions:

We have documented interventions and outcomes using ABAB design in a clinical series. Further investigations evaluating long term outcomes online modes of therapy need exploration as it may benefit families staying in remote parts of the country with no access to specialized therapy services in general.

**502.006 (Virtual Poster)** Evaluating Parent Treatment Fidelity and Child Social Communication Outcomes Following Participation in a Parent-Mediated Intervention for Toddlers with Autism Spectrum Disorder

**E. Greenfield<sup>1</sup>, N. M. Hendrix<sup>1</sup>, G. Binion<sup>1</sup>, N. Brane<sup>2</sup>, K. Guerra<sup>2</sup>, K. Ulven<sup>2</sup> and K. Pickard<sup>3</sup>,** (1)Marcus Autism Center, Emory University School of Medicine, Atlanta, GA, (2)Marcus Autism Center, Atlanta, GA, (3)Emory University School of Medicine, Marcus Autism Center, Atlanta, GA

---

**Background:**

Parent-mediated interventions (PMIs) using naturalistic developmental and behavioral intervention strategies capitalize on the role of parents to foster social communication development (Schreibman et al., 2015). These PMIs positively impact parent fidelity (e.g., Stahmer et al., 2020) and child outcomes (e.g., Yoder, 2020). Optimizing methods for monitoring fidelity across treatment is important as parent use of intervention strategies has been shown to mediate improvement in social communication outcomes (Yoder et al., 2021). Yet, trends of biased sampling toward highly educated families poses the question of how socioeconomic status may impact parent strategy use and child outcomes (Hao et al., 2021).

Traditionally, fidelity coding can be a resource-intensive process that may not be feasible for community settings. Briefer measures may serve as an efficient alternative (Suhreheinrich et. al, 2013). The present study examined whether clinician perceptions of parent fidelity using a brief Likert scale (*Fidelity of Intervention Implementation*; Ingersoll & Dvortcsak, 2010) were associated with treatment outcomes for children with ASD participating in an evidence-based PMI (Project ImPACT; Ingersoll & Dvortcsak, 2019). The setting was an outpatient clinic serving primarily Medicaid populations based on family income.

**Objectives:**

This study aimed to investigate the association between clinician ratings of parent fidelity and child social communication outcomes following participation in Project ImPACT.

**Methods:**

Data collection is ongoing. Within the current sample, participants were 36 children and their caregivers at or under the age of 40 months. 69.4% of the families had Medicaid or a Medicaid CMO as their primary insurance. Families participated in 12-14 1-hour treatment sessions in-person (36.1%) or via telehealth (63.9%). Treatment focused on promoting social engagement, communication, imitation, and play skills. Following each session, clinicians rated parent use of strategies on a scale from 1 (i.e., *adult does not implement the strategy*) to 5 (i.e., *adult implements the strategy effectively throughout the session*). Fidelity ratings of 4 or higher were considered the threshold for appropriate delivery. Parents also completed the *Social Communication Checklist (SCC)* pre- and post-treatment. Information was collected regarding progress toward treatment goals collaboratively established with families.

**Results:**

Child participants showed significant improvements in social communication skills from pre-treatment (M=110.76, SD=18.82) to post-treatment (M=134.84, SD= 23.01);  $t(24)=-7.16, p<.001$ . Significant improvements were noted across *Social Engagement* ( $p=.026$ ), *Expressive Language* ( $p<.001$ ), *Receptive Language* ( $p=.001$ ), *Imitation* ( $p<.001$ ), and *Play Skill* domains ( $p=.003$ ). By the end of the program, 66.7% of parents met fidelity of implementation (M= 4.05, SD= 0.58), and 72.2% of participants successfully met all treatment goals. Despite improvements in child social communication skills and parent fidelity, no significant relationship was detected between fidelity and SCC scores.

**Conclusions:**

These results suggest that a brief Likert scale may serve as an efficient method to measure parent treatment fidelity and monitor progress over time. However, additional research is needed to evaluate whether this measure may be associated with improvements in social communication skills and to determine if it will correlate with more traditional, comprehensive measures of treatment fidelity, particularly as rigorous study of PMIs implemented in diverse settings continues.

**502.007 (Virtual Poster)** Feasibility of Early Interventionists Implementing a Parent-Mediated Intervention: A Randomized-Controlled Trial in Autism Treatment

**J. Bender<sup>1</sup>, E. Kaiser<sup>1</sup>, C. Rock<sup>1</sup>, N. Bond<sup>1</sup> and J. L. Stapel-Wax<sup>2</sup>,** (1)Marcus Autism Center, Atlanta, GA, (2)Emory University School of Medicine, Atl, GA

---

**Background:** Early identification and treatment of ASD is crucial during the first three years of life to maximize developmental potential when neuroplasticity is optimal. The Early Social Interaction (ESI) Model is a parent-implemented intervention teaching families how to support their child's active engagement in everyday activities. The effectiveness of the ESI model has been documented in a multisite randomized controlled trial (RCT) that resulted in improved child outcomes on standardized measures of social communication, developmental functioning, and adaptive behavior (Wetherby et al, 2014).

**Objectives:** The purpose of this study is to expand the results of the initial RCT by training Part C Early Intervention Providers (EIPs) to coach families of toddlers with early signs of ASD. EIPs will have access to an autism specific screening tool that can identify children at risk for ASD. Our goal is to identify children under the age of 24 months, recruit and retain 18 EIPs, then provide intervention with the ESI Model. Participants received online training and randomized into two study arms: Business-as-Usual (BAU) or Early Social Interaction (ESI). Providers offer study

participation to families with children demonstrating delays in social-communication and/or red flags for autism. We expect EIPs to work with an average of three toddlers totaling 54 families.

**Methods:** The Early Social Interaction (ESI) Study was implemented in 2019 with funding from the Institute of Education Sciences. Due to the onset of the COVID-19 pandemic, EIPs began having sessions with caregivers via WebEx. New EIPs were oriented virtually. Clinician-blinded developmental evaluations of participants resumed in July 2020, with revisions to administration of some measures. Use of video conferencing platforms, electronic surveys, and online resources allowed us to continue this study in the community despite pandemic restrictions to offer support to families of children with early signs of autism.

**Results:** Thirty-two EIPs were recruited to the study since January 2019. To date, 30 were enrolled in the study (i.e., 20 in ESI arm, 10 in BAU arm). Ten EIPs across groups withdrew from the study (33% attrition). Currently, 20 EIPs have recruited 39 families. Forty-seven screening home observations (HOBs) were completed (85% since COVID-19). Of the 47 screens, 39 enrolled in the study (90% since COVID-19). Intervention sessions transitioned to telehealth, totaling 374 sessions across arms (87.5% since COVID-19). EIP fidelity shows group differences of intervention fidelity scores (i.e., averages: BAU - 30%, ESI - 78%; fidelity is met at 80%). Evaluations restarted in July 2020 totaling 58 (93% since COVID-19).

**Conclusions:** The ESI Model was proposed as an in-home intervention, with EIPs coaching the parents to administer the intervention. The grant continues to see study participation grow despite the restructuring of various study processes. The number of EIPs recruited to the project exceeded the number anticipated and family recruitment continues. Fidelity differences across groups may indicate the telehealth platform is beneficial. The results of developmental progress in this population is to be determined due to the pandemic; however, we demonstrated a modified study continues to recruit and provide services in the community.

**502.008 (Virtual Poster)** Adapting PEERS® for Preschoolers for Telehealth: A Novel Remote Caregiver-Mediated Social Skills Intervention for Young Children with Social Challenges

**R. S. Factor, L. Glass, D. Baertschi and E. A. Laugeson, UCLA Semel Institute for Neuroscience and Human Behavior, Los Angeles, CA**

---

**Background:** By early childhood, social impairments are evident and associated with significant ramifications for children with autism spectrum disorder (ASD) and other developmental disorders. PEERS® for Preschoolers (P4P) was developed as an extension of the evidence-based social skills PEERS® program for children ages 4-6. P4P has had positive outcomes with large effect sizes. Due to COVID-19, there was reduced access to interventions for young children, when treatments moved to online delivery. The importance of providing this service for families prompted the translation of P4P to a caregiver-focused social skills-telehealth group.

**Objectives:** This study aims to investigate the translation, satisfaction, and initial findings of the novel telehealth caregiver-focused version of P4P, with the intention of improving social skills for young children with difficulty making and keeping friends.

**Methods:** Eleven caregivers of children (9 boys, 63.6% Caucasian; May projected  $n=21$ ) between 4-6 years ( $Mage=5.06$ ;  $SD=.701$ ) with social difficulties (81.8% ASD) participated in P4P telehealth groups (16 1.5 hour sessions once/week). Consistent with in-person P4P groups, children were required to have adequate expressive and receptive language. Caregivers were fluent in English and required to have access to telehealth. Children unable to participate in social coaching or playdates were excluded. Measures included a satisfaction survey (questions on a 5-point scale), the Parenting Stress Index, 4<sup>th</sup> Edition, Short Form (PSI-4-SF), the Social Responsiveness Scale, Second Edition (SRS-2), and the Quality of Play Questionnaire (QPQ). Descriptive analyses and pre/post comparisons were conducted. Data collection is ongoing.

**Results:** Almost all caregivers (90%, 9/10) were quite to somewhat satisfied with the group ( $\geq 20\%$  response options). All 10 caregivers found the distinct components (e.g., homework review, social skills, discussion) of the translated P4P to be somewhat to very helpful (100%,  $\geq 20\%$  response options). Additionally, 100% of caregivers reported improvement in confidence to coach their child in social skills as well as navigate social situations with other parents. Parental stress decreased upon completion of P4P (PSI-4-SF). Though the study was not powered to detect significant pre/post results, there were positive trends across almost all measures. On the QPQ there was a trend toward increase in invited playdates at own house  $t(7) = 1.19, p = .28, d=.29$ . Additionally, there was a correlation between invited playdates and total SRS-2 score post-P4P intervention ( $r = .71, p = .05$ ). There was a decrease in conflict scores during playdates  $t(7) = 1.59, p = .155, d=.56$  and decrease in social difficulties on the SRS-2,  $t(7) = .70, p = .59, d=.25$ . Finally, there was a significant correlation between caregiver confidence in their ability to social coach their child and their child's improvement in social skills ( $r = .73, p = .017$ ). Overall, 90% of caregivers reported a positive change in their child's social skills via survey.

**Conclusions:** We aimed to innovatively create and examine a caregiver-focused telehealth version of P4P. These preliminary results support the telehealth translation, especially regarding improving parental confidence. Future work will enable greater understanding and powered analyses for efficacy of the telehealth version and comparison to in-person P4P implementation.

**502.009 (Virtual Poster)** Examining Variability in Naturalistic Developmental Behavioral Intervention (NDBI) Strategy Use in Caregivers  
**H. Brown<sup>1</sup>, D. Swain<sup>2</sup>, C. Kasari<sup>3</sup>, S. J. Rogers<sup>4</sup>, A. M. Estes<sup>5</sup>, A. M. Wetherby<sup>6</sup>, C. Lord<sup>7</sup> and S. H. Kim<sup>1</sup>, (1)Psychiatry, Center for Autism and the Developing Brain, White Plains, NY, (2)Virginia Polytechnic Institute and State University, Blacksburg, VA, (3)University of California, Los Angeles, Los Angeles, CA, (4)Department of Psychiatry and Behavioral Sciences, University of California at Davis, Sacramento, CA, (5)Speech and Hearing Sciences, University of Washington, Seattle, WA, (6)Florida State University Autism Institute, Tallahassee, FL, (7)UCLA Semel Institute for Neuroscience and Human Behavior, Los Angeles, CA**

---

**Background:**

Early NDBIs for ASD are often caregiver-mediated. Although caregivers play a critical role in the intervention process, research focused on caregiver characteristics and response to intervention has been limited. Thus, there is a clear need to examine variability in caregiver skills at intervention entry and the effects of early caregiver-mediated intervention on caregivers.

#### Objectives:

We aim to 1) examine varying profiles of NDBI strategy use in caregivers of young children with ASD at intervention entry based on a clustering analysis; and 2) examine how caregiver NDBI strategy use changes over the course of caregiver-mediated interventions.

#### Methods:

Data were drawn from 191 caregivers ( $M_{\text{age}}=34$  years,  $SD=6.49$ , 89% mothers, 49% with bachelor's degree/above) and their children ( $M_{\text{age}}=29.41$  months,  $SD=12.19$ ,  $n=152$  boys) who participated in randomized controlled trials of three different NDBIs. Caregiver-child play sessions were blindly coded to evaluate changes in child social communication (Brief Observation of Social Communication Change, BOSCC; Grzadzinski et al., 2016) and in caregiver strategy use (Measure of NDBI Strategy Implementation – Caregiver Change; MONSI-CC; Vibert et al., 2019), including subdomains of Environmental Set-up, Child-Guided Interactions, Active Teaching and Learning, Opportunities for Engagement, and Naturally Reinforcing and Scaffolding. Hierarchical clustering analysis with Ward's method was conducted to identify clusters based on z-scores of all MONSI subdomains at intervention entry. Group differences were examined with chi-square tests and ANOVAs, with Tukey HSD post-hoc analyses. Pre-post differences for MONSI-CC total/subdomain scores, and BOSCC Social Communication scores were compared at intervention entry and follow-up time points approximately 3 months after intervention-entry ( $n=155$ ) using paired sample  $t$ -tests. Alpha was set at .01 to account for multiple analyses.

#### Results:

Four caregiver strategy implementation profiles emerged based on scree plot analysis and agglomeration schedule (Fig.1): Limited implementation ( $n=36$ ), Emerging implementation ( $n=91$ ), Inconsistent implementation ( $n=14$ ), Consistent implementation ( $n=50$ ). The clusters did not differ for most caregiver demographics (race, age, education) or child factors (race, IQ, gender); however, there was a trend for caregiver gender with most fathers in the moderate group (80%;  $\chi^2(3) = 9.71$ ,  $p = .021$ ). Children of caregivers in Limited and Emerging implementation groups had less mature language,  $F(3,18)=8.92$ ,  $p<.001$ , social communication skills,  $F(3,187)=16.73$ ,  $p<.001$ , or were younger,  $F(3,187)=5.66$ ,  $p=.001$  than the inconsistent and consistent groups. Caregivers in the Limited  $t(19)=8.17$ ,  $p<.001$ ,  $d=1.83$ , and Emerging implementation  $t(41)=7.20$ ,  $p<.001$ ,  $d=1.11$  groups improved significantly in their overall strategy use across intervention (and in all subdomains). Children of caregivers in the Limited implementation group made significant gains in their social-communication across intervention  $t(19)=3.84$ ,  $p<.001$ ,  $d=.86$ .

#### Conclusions:

Levels of NDBI strategy use prior to intervention vary highly across caregivers, independent of most caregiver characteristics. Caregivers with Limited or Emerging overall strategy use had children who were younger. Children of caregivers in the Limited or Emerging strategy groups had less mature language and social-communication skills. Caregiver use of NDBI strategies improved significantly for those starting with fewer overall skills and their children also showed greatest improvements in social communication.

#### **502.010** (Virtual Poster) Preliminary Evidence for the Feasibility and Acceptability of Group-Based Telehealth Parent Coaching for Sleep Problems in Children with ASD

**R. Finlayson<sup>1</sup>**, **A. M. Estes<sup>2</sup>** and **I. Schwartz<sup>1</sup>**, (1)College of Education, University of Washington, Seattle, WA, (2)Speech and Hearing Sciences, University of Washington, Seattle, WA

**Background:** Sleep problems affect between 45 and 86% of children with ASD and have been associated with impaired social communication, increased affective and behavioral disorders, and increased restricted and repetitive behaviors that may interfere with learning and inclusion. Without effective intervention, these sleep problems can persist throughout childhood and into adolescence and adulthood for individuals with ASD. Accordingly, there is a critical need to identify effective and feasible interventions for sleep disorders in children with ASD. Prior studies have demonstrated improved child sleep using individual and group parent coaching to teach parents to deliver behavioral sleep interventions; however, there have been no studies on group parent coaching for sleep problems delivered via telehealth to date.

**Objectives:** Primary: To determine feasibility and acceptability of a group-based parent coaching intervention delivered via telehealth to improve sleep for children with sleep problems and ASD. Secondary: To evaluate preliminary evidence for improved sleep in children with ASD using actigraphy, sleep diaries, and the Children's Sleep Habits Questionnaire (CSHQ).

**Methods:** 6 families with children with ASD and sleep problems completed a sleep assessment consisting of 10 days of actigraphy and twice-daily sleep diaries, and the CSHQ pre- and post-intervention. Parents were assigned to groups according to child age (2-4 years; 5-8 years) and were coached on targeted behavioral interventions in a small-group format via videoconferencing once per week for 6 weeks. Coaching sessions covered an introduction to sleep, optimal sleep environment, building consistent sleep habits, strategies to address night and early morning wakings, and addressing bedtime resistance. Social validity was assessed post-intervention using a 10-item questionnaire with ratings on a 5-point scale.

**Results:** The intervention was well accepted by parents, with all items rated as agree-strongly agree (see Figure 1). Parents reported increased self-efficacy when dealing with their children's sleep problems, and satisfaction with the group-based telehealth model. Improvement was demonstrated on each family's primary sleep goal and on subscales in the CSHQ for all participants. 2 of 6 participants fell from the clinical to subclinical range for total sleep problems on the CSHQ.

**Conclusions:** This short-term, low-cost intervention package was feasible and highly acceptable to families. This approach shows promise for improving sleep for children with ASD. If future research is consistent with these findings, this model may improve access to effective, acceptable, and contextually appropriate interventions to improve sleep problems in children with ASD.

**502.011 (Virtual Poster)** The Prevalence of Background Noise during Electronic Versus Traditional Toy Play: A Study of Young Children with Autism and Their Parents

M. Sturman<sup>1</sup> and C. E. Venker<sup>2</sup>, (1)CSD, Michigan State University, East Lansing, MI, (2)Communicative Sciences and Disorders, Michigan State University, East Lansing, MI

---

**Background:** Over the past two decades, electronic toys—toys that talk, sing, and/or have flashing lights—have become increasingly prevalent compared to traditional (i.e., non-technologically enhanced) toys. Though electronic toys are commonly marketed as having developmental benefits for infants and young children (including those with autism), a growing body of research indicates that electronic toys decrease the quality of parent-child interactions. For example, parents of children with autism say less and provide less rich language input during electronic than traditional toy play, which may exacerbate the language and communication delays experienced by many young children with autism. Here, we consider another way in which electronic toys may decrease the quality of parent-child interactions: by creating high levels of background noise that interfere with children's ability to comprehend spoken language.

**Objectives:** To determine the extent to which background noise overlaps with parent utterances during traditional and electronic toy play.

**Methods:** Participants were 14 children with autism (2–4 years old) and their parents. Parent-child dyads participated in two, 10-minute play sessions—one with a traditional toy set and one with an electronic toy set (order counterbalanced across participants). Both toys sets included a barn with animals, shape sorter, vehicles, and a puzzle. Play sessions were video-recorded and transcribed using Systematic Analysis of Language Transcripts (SALT) software. Parent utterances were coded as occurring in the presence of background noise if they overlapped with child vocalizations, child speech, or electronic toy noises (speech and non-speech).

**Results:** The mean percentage of parent utterances with background noise was 17% during traditional toy play and 53% during electronic toy play. On average, background noise overlapped with 3 parent utterances per minute in the traditional toy condition (median = 3.36, *SD* = 1.95) and 9 parent utterances per minute in the electronic toy condition (median = 8.03, *SD* = 3.37). A Wilcoxon Signed Rank Test revealed that the number of parent utterances with competing background noise was significantly higher during the electronic condition than the traditional condition (*p* = .001).

**Conclusions:** Though electronic toys are commonly marketed as having developmental benefits, the current findings add to growing evidence that electronic toys decrease the quality of parent-child play interactions. In the current study, over half of the utterances that parents produced during electronic toy play occurred in the presence of background noise, compared to less than 20% during traditional toy play. Based on a large body of experimental research, the high rates of background noise produced during electronic toy play are likely to make it more difficult for children with autism to understand what their parents say. This is concerning because children with autism experience substantial challenges with spoken language comprehension even in the absence of background noise. Traditional toys may be preferable for creating high-quality parent-child interactions that support language development in young children with autism.

**502.012 (Virtual Poster)** Treatment Mechanism of the Who Caregiver Skills Training

E. Salomone<sup>1</sup>, M. Settanni<sup>2</sup>, K. Suma<sup>3</sup>, C. Servili<sup>4</sup>, H. McConachie<sup>5</sup> and L. B. Adamson<sup>1</sup>, (1)Department of Psychology, University of Milan-Bicocca, Milan, Italy, (2)Department of Psychology, University of Turin, Turin, Italy, (3)Psychology, Georgia State University, Atlanta, GA, (4)Department of Mental Health and Substance Abuse, World Health Organization, Geneva, Switzerland, (5)Population Health Sciences Institute, Newcastle University, Newcastle upon Tyne, United Kingdom

---

**Background:** The WHO Caregiver Skills Training (CST) is an open access caregiver-mediated intervention for children with neurodevelopmental disorders and delays. CST, consisting of 9 group sessions and 3 home visits over 3 months, is based on naturalistic-developmental-behavioral methodologies and has shown good feasibility of delivery and acceptability of intervention components to caregivers in several low- and high-income countries. In Italy it was delivered in public health settings with excellent feasibility and acceptability showing favorable effects on the dyadic fluency of the interaction, child non-verbal communication, caregiver skills, self-efficacy and stress.

**Objectives:** The objective of the study was to examine the mechanism of effect of CST. In line with the intervention's theory of change, participation in CST is expected to lead to an improvement in the child and dyad outcomes through an increase in the caregiver's skills supportive of the interaction.

**Methods:** The study was a randomized controlled trial of CST provided by health professionals in child neuropsychiatry services in Italy. 86 parents (77% mothers, age: *M* = 36.7 years, *SD* = 5.53) of children with ASD (78% male, age: *M* = 44.8 months, *SD* = 9.48) were randomized to CST (*n* = 43) or treatment as usual (*n* = 43). The primary outcomes, measured at baseline (T1), immediately at the end of the intervention (T2) and 3 months after the intervention (T3), are derived from coding of parent-child interaction with the Brief Observation of Social-Communication Change

(BOSCC) and the Joint Engagement Rating Inventory (JERI). The JERI yields the following constructs: Flow of interaction, Joint Engagement, Child Availability to Interact and Parent Skills Supportive of Interaction. Codings were performed with high levels of reliability by two raters blind to group allocation and time (JERI items: Cohen's Kappa range: .89–1; BOSCC Total Score: ICC = .92).

**Results:** Serial mediation analyses showed that parent skills (JERI Parent Skills Supportive of Interaction) in the CST group improved significantly more than in the TAU group at T2 and T3, and this in turn led to an overall improvement of all the child and dyad outcomes, as reflected in the significant total indirect effects for all outcomes measured at T3: BOSCC Total Score [-2.58 (SE=1.04)], JERI Flow of interaction [0.63 (SE=0.19)], Joint Engagement [1.15 (SE=0.33)], and Child Availability [1.37 (SE=0.42)]. The direct effect was not significant for any of the outcomes, and therefore the effect of the intervention appears to be fully mediated by changes in parent skills. The total effect of the intervention was, however, not significant for JERI Child Availability to Interact, Joint Engagement and BOSCC Total Score.

**Conclusions:** CST works, as hypothesized, through the improvement of the caregiver's ability to support interaction. The pattern of findings highlights the need to test strategies to improve the effectiveness of CST in public health settings, including identifying additional treatment mediators or moderators and testing whether increasing the intervention dosage or providing more tailored support to caregivers who struggle most with implementing the intervention strategies will lead to detectable changes in child joint engagement and communication.

**502.013 (Virtual Poster)** Longitudinal Predictive Association of Interaction Features and Response Trajectories in Autism Spectrum Disorder (ASD) Early Developmental Intervention.

**G. Bertamini<sup>1</sup>, A. Bentenuto<sup>1</sup>, S. Perzollì<sup>2</sup>, E. Paolizzi<sup>1</sup>, P. Venuti<sup>1</sup> and C. Furlanello<sup>3</sup>, (1)Department of Psychology and Cognitive Science, University of Trento, Rovereto, Italy, (2)University of Trento, Rovereto, Italy, (3)HK3 Lab, Milan, Italy**

Background:

Studying interaction is becoming increasingly important in the context of ASD intervention. Research highlighted the need to understand predictors and process variables to explain the high interindividual variability observed in treatment response (Frost et al., 2020; Wetherby et al., 2018). Further, NDBI models of intervention foster the quality of child-therapist relationship and exchanges, as well as exploiting child motivation, shared pleasure and interpersonal synchrony (Vivanti et al., 2020). However, interaction features are still under-investigated, mainly due to the lack of objective, quantitative and scalable instruments. This translational effort could be important for both research and clinical practice (Dawson et al., 2019).

Objectives:

This study aims at investigating longitudinal predictive relationships between interaction features and treatment response in ASD early developmental intervention.

Methods:

N=26 preschool children (mean age=38.36 months; sd=10.36) with ASD were monitored from diagnosis and after one year of NDBI intervention. GMDS-R (Luiz et al., 2006) and ADOS-2 (Lord et al., 2012) were administered before and after. Learning Rates (LR, Klintwall et al., 2015) were used to measure the developmental trajectory over time. A quantitative observational coding system (Bertamini et al., 2021) was employed to annotate 20-min segments of 4 video-recorded sessions of intervention (1%, 25%, 50%, 99%), as well as the pre- and post- ADOS-2 social routines. A set of interaction descriptors was automatically extracted and a pipeline for model selection and evaluation by means of regularized random forests, repeated-CV, AIC/BIC/BF and LASSO was employed to predict the LR at one year using interaction features at 1% and 25%.

Results:

A preliminary analysis indicated significant changes in interaction dynamics over time. Interactions tended to progressively become more synchronous ( $p<0.001$ ;  $BF>100$ ), more engaging ( $p<0.001$ ;  $BF>100$ ) and last longer ( $p=0.01$ ;  $BF=4.7$ ). In addition, children responded more often to therapists' involving attempts ( $p<0.001$ ;  $BF=87$ ) and interrupted the exchanges less frequently ( $p=0.001$ ;  $BF=24$ ). Longitudinal models pointed out the importance of early interaction features, beyond children's baseline characteristics, for overall treatment response prediction ( $F(2,21)=4.51$ ;  $p=0.023$ ). A decrease in both (1) the latency between synchronous behaviors ( $b=-0.34$ ;  $p=0.076$ ) and (2) the proportion of child's interruptions ( $b=-0.41$ ;  $p=0.025$ ) were significant predictors of the LR, explained a significant proportion of variance ( $\text{adj-}r^2=0.23$ ;  $10\times\text{cv-}r^2=0.45$ ;  $\text{loocv-}r^2=0.14$ ;  $\text{MAE}=0.32$ ) and were associated with better outcomes at one year. The variation in child's withdrawal rate was negatively correlated with the LR ( $r=-0.43$ ;  $p=0.036$ ).

Conclusions:

The dynamics of interaction features in the first part of the intervention seems to be relevant for treatment response. The analysis will be extended to symptom severity. The ADOS-2 pre- and post- annotations will be included, together with the variation between the other mid time points and baseline children's variables in order to improve model accuracy. The results will be discussed in terms of clinical implications.

**502.014 (Virtual Poster)** Parent-Child Intervention Delivered during the COVID-19 Lockdown in Italy

**C. Colombi<sup>1</sup>, C. Blandino<sup>2</sup>, C. Pierotti<sup>3</sup>, G. Santolini<sup>3</sup>, F. Muratori<sup>4</sup> and A. Contaldo<sup>5</sup>, (1)Stella Maris Institute, Pisa, MI, Italy, (2)CETRA, Calambrone (Pisa), Italy, (3)Stella Maris Institute, Pisa, Italy, (4)Department of Clinical and Experimental Medicine, University of Pisa, Pisa, Italy, (5)IRCCS Stella Maris Foundation, Calambrone (Pisa), Italy**

Background: Accessing services for children with ASD was particularly difficult during the lockdown imposed by the COVID-19 health emergency in Italy (Levante et al., 2021). One way of increasing access to intervention was to teach intervention strategies to parents.

Objectives: The first aim of this project was to adapt an existing evidence based intervention, the Parent-Early Start Denver Model (P-ESDM) (Rogers et al, 2012), combining in person and online delivery in order to increase access to treatment during the lockdown within an Italian community context. The second aim was to examine the progress of the children enrolled in the study. The third aim was to evaluate whether parents learned intervention strategies.

Methods: The P-ESDM was delivered to 12 young children with ASD, between 18 and 50 months of age, and their caregivers. Each family participating in the study received two 1-hour session per week of the treatment, delivered once per week in presence and once per week online, for 24 weeks. Social-communication behaviors were measured by the Brief Observation of Social Communication Change (BOSCC) (Lord et al., 2016). Learning of the therapy strategies in the parents was measured by the ESDM Parent Fidelity Measure (Rogers et al., 2012)

Results: Preliminary data indicated gains in social-communication behaviors in children as measured by the BOSCC. After 24 weeks of intervention the children demonstrated a statistically significant decrease in the BOSCC ( $t=2.0$ ;  $p=.02$ ). Parents learned the therapy strategies as demonstrated by improved scores in the fidelity measure at the end of the intervention. Acceptability of the program was very good as indicated by retention of all participants except for one who left the program due to relocation.

Conclusions: Our preliminary results suggest that the P-ESDM delivered in a parent-child context with an online component may be useful to teach intervention skills to parents and to increase social communication in young children with ASD within an Italian community setting.

## Interventions - Non-pharmacologic - School-Age, Adolescent, Adult

### PANEL — INTERVENTIONS - NON-PHARMACOLOGIC - SCHOOL-AGE, ADOLESCENT, ADULT

#### 215 - Comprehensive Transition Programs for Autistic Youth: Efficacy in Targeting Immediate Outcomes and Beyond

**Panel Chair:** Laura Klinger, *TEACCH Autism Program; Psychiatry, UNC TEACCH Autism Program, Chapel Hill, NC*

**Discussant:** Brett Nachman, *North Carolina State University, Raleigh, NC*

**215.001 (Panel)** Self-Determination and Adaptive Behavior Outcomes of an EF Intervention for Transition-Age Autistic Youth  
*C. E. Pugliese<sup>1</sup>, R. Handsman<sup>2</sup>, B. B. Maddox<sup>3</sup>, L. Anthony<sup>4</sup> and L. Kenworthy<sup>1</sup>, (1)Center for Autism Spectrum Disorders, Children's National Hospital, Washington, DC, (2)Center for Autism Spectrum Disorders, Children's National Medical Center, Washington, DC, (3)University of Pennsylvania, Philadelphia, PA, (4)University of Colorado, Denver, Aurora, CO*

Background: Greater self-determination (knowledge, efficacy, and abilities surrounding decision-making, problem-solving, goal-setting, and self-management), adaptive, and executive function (EF) skills have been associated with positive post-secondary outcomes in autistic adolescents. Self-determination, EF, and adaptive skills are essential to independent functioning, but are substantially impacted in autistic youth. This presentation utilizes data from a school-based randomized effectiveness trial of an executive function intervention, Unstuck & On Target: High School (UOT:HS) in improving self-determination, and examines the impact of self-determination on later adaptive skills. UOT:HS targets self-advocacy, flexible problem solving, planning, time management, and independent goal-setting across 25 1-hour lessons.

Objectives: 1) Examine change in self-determination as a result of UOT:HS, 2) Determine the relationship between self-determination skills and later adaptive functioning in autistic adolescents.

Methods:

Participants included 49 adolescent autistic teens (8 female) aged 14-20 ( $M=16.3$ ,  $SD=1.3$ ) with  $FSIQ \geq 80$  ( $M=105.8$ ,  $SD=14.7$ ), who met DSM-5 criteria for autism supported by the Social Communication Questionnaire and/or ADOS. Eight schools were randomized to UOT:HS ( $n=29$  students) or treatment as usual (TAU,  $n=20$  students) using a clustered, parallel clinical trial design masked to outcomes. Teens and parents completed the AIR Self-Determination Scale (AIR-SDS; Wolman et al., 1994), which produces a total score and the following subscales: "Things I Do" (self-determination skills) and opportunities to practice self-determined behaviors at home ("What Happens at Home") and at school ("What Happens at School"). Parents completed the Adaptive Behavior Assessment System Third Edition (ABAS-3). Multiple regressions tested: 1) the impact of UOT:HS on parent/youth AIR-SDS total scores at endpoint controlling for demographics and baseline score, and 2) the influence of baseline parent-reported AIR-SDS subscale scores above and beyond the intervention on later ABAS-3 Conceptual, Social, and Practical scores.

Results: Parent-report of their child's total AIR-SDS score improved more in UOT:HS compared to TAU (Table 1). Specifically, parents in UOT:HS reported greater improvement in opportunities to practice self-determined behavior at home ( $t=3.19$ ,  $p=0.003$ ) than TAU parents ( $F_{4,36}=14.20$ ,  $p<.001$ ). Baseline parent and child self-determination ratings were not correlated in either group, but endpoint informant ratings were significantly

correlated in the UOT:HS group only ( $r=.53^{**}$ ). Higher baseline opportunities for self-determination at home predicted better endpoint ABAS Conceptual and Practical skills (Table 2).

**Conclusions:** UOT:HS led to improvement in parent-reported (but not self-reported) self-determination skills (e.g., opportunities to practice self-determination at home) with parent- and student-report of skills aligning more over time only in the UOT:HS group. Parent-reported opportunities to practice self-determination at baseline were associated with greater adaptive scores at endpoint, above and beyond intervention effects. We will utilize thematic analysis of the open-ended AIR-SDS responses about goal types and progress to better understand differences in parent- and self-report across groups. Self-determination skills have been improved through targeted skill building in youth with broad developmental disability (Wehmeyer et al., 2010), and may offer a novel treatment target for enhancing adaptive skills and independent living in transition-age autistic youth.

**215.002 (Panel)** Supporting the Transition to Adulthood for Autistic Youth: Results of a Community-College Based Randomized Control Efficacy Study

**L. G. Klinger<sup>1</sup>, B. Tomaszewski<sup>2</sup>, N. Bagatell<sup>3</sup>, K. Bowman<sup>4</sup>, E. M. Lamarche<sup>5</sup>, M. L. Cook<sup>1</sup>, C. B. Klein<sup>2</sup>, S. A. Stahl<sup>3</sup> and G. M. Osborne<sup>2</sup>, (1)TEACCH Autism Program; Psychiatry, UNC TEACCH Autism Program, Chapel Hill, NC, (2)TEACCH Autism Program; Psychiatry, University of North Carolina, Chapel Hill, NC, (3)University of North Carolina at Chapel H, Chapel Hill, NC, (4)TEACCH Autism Program; Psychology & Neuroscience, University of North Carolina, Chapel Hill, NC, (5)TEACCH, University of North Carolina at Chapel Hill, Carrboro, NC**

**Background:** Current vocational rehabilitation (VR) services supporting the transition to adulthood for autistic individuals have been minimally effective (Alverson & Yamamoto, 2017). Lack of access to effective evidence-based practices has contributed to the poor quality of life experienced by many autistic adults, including those without co-occurring intellectual disability, evidenced by high rates of unemployment, failure to complete postsecondary education, and mental health comorbidities. The TEACCH School Transition to Employment and Post-secondary Education (T-STEP) program was designed as a VR Pre-Employment Transition Service targeting key skills associated with a successful transition to adulthood, including executive function, emotion regulation, and self-determination.

**Objectives:** Use a randomized control waitlist design to examine the efficacy of the T-STEP intervention in improving (1) executive function; (2) employment readiness; (3) self-determination; (4) adaptive behavior and (5) emotion regulation including depression, anxiety, and coping self-efficacy.

**Methods:** Participants were 92 autistic adolescents and young adults (24 female) aged 16-21 ( $M = 18.61$ ,  $SD = 1.23$ ) with  $FSIQ \geq 80$  ( $M=106.83$ ,  $SD=2.43$ ; range 80-157) served under the diagnostic category of autism through a high school IEP and/or met community college criteria for disability services. The 12-week T-STEP intervention was provided at two community colleges and included 48 hours of intervention: a 24-session twice weekly 1.5 hour class focused on self-determination (goal setting), executive function (organization, time management), social communication (asking for help, professional social skills), and emotion regulation skills (coping with distress, acceptance corrective feedback) and 12 counseling sessions focused on self-advocacy linking students to college supports including disability services, career counseling, and academic advising. Students were randomized to a fall semester T-STEP intervention or to a waitlist control group who received a spring semester intervention. During COVID-19, the T-STEP transitioned from onsite at the community college to a virtual intervention conducted via Zoom. See Table 1 for a list of measures completed at baseline and at the end of the fall semester.

**Results:** Patterns were similar across both onsite and virtual programs and are combined. Controlling for symptom severity, we examined Intervention Condition (T-STEP vs. Waitlist Control) by Time (Pre vs. Post-assessment during the fall semester). Compared to waitlist control students, students participating in the T-STEP demonstrated improvements in caregiver-reported BRIEF executive function abilities ( $F(1,77.2) = 7.47$ ,  $p = .008$ ) and self-determination on the AIR SDS ( $F(1, 79.5) = 5.72$ ,  $p=.02$ ; Figure 1). T-STEP students self-reported significant improvements in self-determination capacity on the AIR-SDS ( $F(1, 81.4) = 4.13$ ,  $p = .04$ , emotion coping skills on the Coping Self Efficacy Scale ( $F(1,76.4) = 6.78$ ,  $p = .01$ ; Figure 1), and decreased anxiety on the STAI ( $F(1,76.1) = 9.02$ ,  $p = .04$ ). No changes were noted in depression, adaptive behavior, or employment readiness.

**Conclusions:** Results support the efficacy of the T-STEP as a transition to adulthood intervention program that improves key areas associated with successful postsecondary outcomes. Specifically, the T-STEP program was associated with improvements in caregiver and student-reported self-determination, executive function, emotion regulation and coping skills, and anxiety. Future research is needed examining long-term adult outcomes including college completion and employment.

**215.003 (Panel)** Distal Outcomes for Autistic Individuals Completing a Community College-Based Intervention

**B. Tomaszewski<sup>1</sup>, K. Bowman<sup>1</sup>, N. Bagatell<sup>2</sup>, E. M. Lamarche<sup>3</sup>, M. L. Cook<sup>1</sup>, C. B. Klein<sup>2</sup>, S. A. Stahl<sup>3</sup>, G. M. Osborne<sup>1</sup> and L. G. Klinger<sup>4</sup>, (1)TEACCH Autism Program; Psychiatry, University of North Carolina, Chapel Hill, NC, (2)University of North Carolina at Chapel H, Chapel Hill, NC, (3)TEACCH Autism Program; Psychology & Neuroscience, University of North Carolina, Chapel Hill, NC, (4)TEACCH, University of North Carolina at Chapel Hill, Carrboro, NC, (5)TEACCH Autism Program; Psychiatry, UNC TEACCH Autism Program, Chapel Hill, NC**

**Background:** There has been an increase in the literature on transition to adulthood programs for autistic adults without co-occurring intellectual disability. While these programs have demonstrated preliminary efficacy in increasing self-determination, executive function, student adjustment to college, and immediate employment outcomes (White et al., 2019; Baker-Erickson et al., 2018), these studies have not examined employment and postsecondary education beyond the immediate post-treatment time point. The current study examined follow-up outcomes 3-months after completing the virtual TEACCH School Transition to Employment and Post-Secondary Education program.

**Objectives:** The objectives of the current study were (1) to describe the employment and college outcomes for autistic adolescents and adults after a 3-month follow-up period from completing the virtual T-STEP intervention program, and (2) examine intervention effects that predict employment and college performance.

**Methods:** 45 autistic adolescents and young adults with average to above-average IQ (Mean = 107.54, SD = 15.12) completed the 12-week T-STEP program and completed 3-month follow-up assessments (Mean Age at start of intervention = 18.40 years, SD = 1.14, Range = 16-21). 61.4% of participants were male, 13.6% were Asian, 20.5% were Black, 4.5% were Hispanic or Latino, and 63.6% were White. At pre- and post-test, caregivers completed measures of workplace readiness using the Becker Workplace Adjustment Profile (BWAP-2), measuring four domains, Work Performance, Interpersonal Relations, Work Habits, and Cognitive Skills, and executive function using the Behavior Rating Inventory of Executive Function- Adult version (BRIEF-A). At the 3-month follow-up visit, autistic adolescents and young adults reported their postsecondary education and employment status. They completed the Student Adjustment to College Questionnaire (SACQ) if they were currently enrolled in postsecondary education (N=26). Descriptive statistics, chi-square analysis, nonparametric tests of correlation, and profile analyses were performed.

**Results:** At 3-month follow-up, 36 students were graduated from high school and 9 students were still enrolled in high school (See Table 1 for the secondary, postsecondary, and employment outcomes of the sample. Of those students who graduated high school, 79% were employed and/or attending college (See Figure 1). Autistic students who reported being in college full-time had the most significant increase in parent-reported BWAP-2 work habits and attitudes (measuring time management, daily living skills, motivation) from pre- to post-test during the T-STEP intervention compared to students in part-time college, students not attending college but graduated high school, and students still in high school. Parent-reported increases in work habits and attitudes during the T-STEP were also associated with higher self-reported college adjustment scores on the SACQ (Spearman's  $\rho = .46, p = .04$ ). Students working and in college had higher Social Adjustment scores on the SACQ (M=122.50, SD=6.95) than students not currently working (M= 111.93 SD=10.76).

**Conclusions:** A majority of students were employed or in postsecondary education 3-months following the end of the T-STEP. Improvements in time management, daily living skills, and motivation during the T-STEP program were predictive of better self-reported college adjustment scores. Focusing on these skills in transition-based interventions may lead to future long-term intervention effects. Research examining even longer-term outcomes (e.g., college graduation) is needed.

#### **215.004 (Panel) The Cross-Cultural Adaptability of Transition Program for Australian Autistic Youth: A Feasibility Study**

**B. Afsharnejad<sup>1</sup>, J. Tang<sup>2</sup>, S. Kasiraman<sup>3</sup>, U. Jonsson<sup>4</sup>, E. A. Lee<sup>5</sup>, S. Bolte<sup>6</sup> and S. J. Girdler<sup>7</sup>,** (1)Autism Research Team, Telethon Kids Institute, Perth, WA, Australia, (2)School of Occupational Therapy and Social Work, Curtin University, Perth, Australia, (3)Curtin University, Bentley, WA, Australia, (4)Karolinska Institutet, Stockholm, Sweden, (5)School of Occupational Therapy, Social Work and Speech Pathology, Curtin University, Perth, WA, Australia, (6)Center of Neurodevelopmental Disorders (KIND), Centre for Psychiatry Research; Department of Women's and Children's Health, Karolinska Institutet, & Stockholm Health Care Services, Region Stockholm, Stockholm, Sweden, (7)School of Allied Health, Curtin University, Bentley, WA, Australia

**Background:** Transitioning to adulthood is a significant developmental milestone for youth, requiring prior planning and preparation. To date, there is a paucity of evidence-based transition programs that are tailored for autistic youth. TRANSITION© is a program developed in Sweden to support youth through this transitional journey. However, the cross-cultural feasibility and efficacy of the program in an Australian context remains unknown.

**Objectives:** This feasibility study investigated the cultural validity and acceptability of the TRANSITION© program in supporting autistic youth to increase their skills, independence, and confidence in navigating their major life areas, including employment, education, finance, health, housing, leisure and relationships

**Methods:** After translating the TRANSITION© manual from Swedish to English, the content was amended and co-produced with an autistic advisory group, improving the language and relevance of the content in the program. The modified program was then delivered to 21 autistic youth aged 16 to 25 years (age = 18.96 years; SD = 2.08; 86% male; IQ>70) over 8 two-hour group sessions and sixteen 30-minute individual sessions with health professionals from a community-based service provider. Due to the global pandemic in 2020, the program was adapted to an online format continuing via an online format after six face-to-face sessions. The cross-cultural feasibility and preliminary efficacy of the TRANSITION© program were evaluated using a mixed methodology design. Changes in participants' adaptive functioning, self-efficacy and mental health were assessed using a pretest-posttest design before and immediately after the program utilising a random-effects regression model (linear mixed model). Focus groups were then conducted with the participants, their parents and group facilitators exploring their opinion about the acceptability of the program.

**Results:** During the pandemic, 10 participants discontinued the study. Findings indicated that TRANSITION© had significantly improved the participants' functioning in the leisure, self-direction, and home living categories of ABAS-III ( $p < 0.05$ ), with the effect size (Cohen's  $d$ ) ranging from 0.7 to 0.71. Autistic youth, their parents and group facilitators all expressed satisfaction with the TRANSITION© program, even if they discontinued it, but suggested ideas to improve the program in relation to the relevance of some topics. Additionally, although appreciating the comprehensiveness of the program, believed they might not need to complete all domains. Also, most participants reported that they preferred the online sessions or had no preference, except two participants reported that they preferred the face-to-face sessions.

**Conclusions:** Findings indicate that TRANSITION© has the potential to improve Australian autistic youths' skills and independence in managing their everyday life areas while transitioning to adult life. The feasibility study finalised the modification of the TRANSITION© program, preparing it for efficacy evaluation via a randomised controlled trial.

## ORAL SESSION - 1B — INTERVENTIONS - NON-PHARMACOLOGIC - SCHOOL-AGE, ADOLESCENT, ADULT

### 307 - Novel Ways of Engaging the ASD Community with Behavioral Interventions for Youth and Adults

**307.001** (Oral) Improving Outcomes in Minority Children with Autism Spectrum Disorder Affected By the COVID-19 Pandemic through the Evaluation of a Telehealth Family-Mediated Intervention

**M. Nava Palma<sup>1</sup>**, J. Trayvick<sup>2</sup>, J. Beltran<sup>3</sup>, S. Barkley<sup>4</sup>, L. Tolentino Espinoza<sup>5</sup>, L. Mayo<sup>5</sup>, H. Morsbach Sweeney<sup>6</sup>, J. H. Foss-Feig<sup>4</sup> and M. P. Trelles<sup>4</sup>, (1)Psychiatry, Seaver Autism Center at the Icahn School of Medicine at Mount Sinai, New York City, NY, (2)Seaver Autism Center at the Icahn School of Medicine at Mount Sinai, New York, NY, (3)Psychiatry, Icahn School of Medicine at Mount Sinai Hospital, New York City, NY, (4)Seaver Autism Center for Research and Treatment, Department of Psychiatry, Icahn School of Medicine at Mount Sinai Hospital, New York, NY, (5)Centro Ann Sullivan Peru (CASP), Lima, Peru, (6)Center Ann Sullivan International - CASI, Lawrence, KS

**Background:** Evidence-based interventions in ASD are successful at improving outcomes, but rely on frequent contact with a multidisciplinary team of professionals. The COVID-19 pandemic and requisite social distancing underscored the inherent limitations of these programs. Caregiver involvement has been recognized as an essential component to ASD treatment; however, models of care have failed to systematize caregiver involvement, with few studies quantifying its impact, leaving parents underprepared to manage challenging behaviors. In the aftermath of the COVID-19 pandemic, it has become essential to evaluate the feasibility of family-centered and caregiver-mediated interventions for individuals with ASD. One such program is the Functional Natural Curriculum (FNC), developed by the Centro Ann Sullivan del Peru (CASP). The FNC provides caregivers with the necessary tools to teach their children essential skills to promote independence, facilitate academic learning, and enable inclusion in all aspects of life.

**Objectives:** This project aimed to evaluate a 16-week virtual program, based on the FNC, developed and delivered by CASP, on child and caregiver outcomes, in a group of Latino children with ASD and their caregivers living in New York.

**Methods:** 13 families with children between the ages of 3 and 17 years were randomly assigned to the control group (n=8, M<sub>age</sub>=10.75, 3 females) or the intervention group (n=5, M<sub>age</sub>=10.6, 2 females). The Aberrant Behavior Checklist (ABC) was used to measure child behaviors along five domains: Irritability, Lethargy, Stereotypy, Hyperactivity, and Inappropriate Speech. The PROMIS Emotional Distress/Depression Scale was used to measure caregiver distress. Absolute difference in scores were calculated between baseline and follow up. Between group T tests were used to examine the difference scores in the intervention group compared to the control group.

**Results:** On the ABC, the intervention group's change scores were significantly greater than those in the control group for the Irritability domain ( $t(12.5)=-2.24, p=0.04$ ) and the Lethargy domain ( $t(13.4)=-3.54, p=0.003$ ). The intervention group trended toward greater change scores in comparison to the control group on the Hyperactivity domain ( $t(10.42)=-1.96, p=0.08$ ) with a large effect size ( $d=0.86$ ). There was no significant difference between control and intervention groups in the Inappropriate Speech and Stereotypy domains. The PROMIS Emotional Distress/Depression scale for caregivers showed a trend towards improvement ( $t(10.02)=-1.56, p=0.15$ ) with a moderate effect size ( $d=0.67$ ), though these results did not reach significance.

**Conclusions:** Our early findings identify promising trends in the improvement of child behavior and caregiver distress levels in the intervention group, suggesting that the CASP virtual program may offer an effective framework for improving outcomes among Latino children with ASD and their caregivers. Furthermore, large and moderate effect sizes speak to the importance of further study in a larger cohort. Together, these results demonstrate the utility of telehealth, family-centered interventions to promote the wellbeing of children with ASD whose services have been affected by the COVID-19 pandemic. The intervention also holds promise for other under-resourced communities with limited access to care on a routine basis.

**307.002** (Oral) A Pilot Feasibility Trial of Telehealth-Delivered Trauma-Focused Cognitive Behavioral Therapy (TF-CBT) for Autistic Youth  
**C. G. McDonnell<sup>1</sup>**, T. M. Andrzejewski<sup>1</sup>, E. A. DeLucia<sup>2</sup> and J. Dike<sup>3</sup>, (1)Department of Psychology, University of Wyoming, Laramie, WY, (2)Department of Psychology, Virginia Polytechnic Institute and State University, Blacksburg, VA, (3)Virginia Tech, Blacksburg, VA

**Background:**

Autistic youth disproportionately experience traumatic events and associated traumatic stress, including symptoms of posttraumatic stress disorder (PTSD) and co-occurring elevations in mood, anxiety, and externalizing behavioral concerns. However, strikingly little research has evaluated the effectiveness of evidence-based interventions for reducing traumatic stress among autistic youth, and unaddressed trauma may contribute to lifelong health disparities for autistic people. Thus, the development of evidence-based treatment approaches for trauma among autistic youth is an urgent research priority. Developing strategies that can be effectively delivered using remote telehealth technology is critical for expanding the reach of these services, in order to (1) ensure service delivery during ongoing COVID-related restrictions, and (2) provide access to youth and their families who experience other barriers to in-person treatment, especially because barriers to service access are common among youth victimized by trauma.

**Objectives:**

The goal of the present study is to determine whether trauma-focused cognitive behavioral therapy (TF-CBT), one of the leading evidence-based interventions for reducing traumatic stress among non-autistic youth, is also effective for autistic youth. In particular, we evaluated (1) whether TF-

CBT was associated with significant reductions in traumatic stress, mood, anxiety, and behavior problems, (2) whether potential reductions were maintained 1-month post treatment completion, and (3) youth and caregiver satisfaction with treatment.

#### Methods:

In this pilot study, 10 autistic youth (ages 10-17, who had also experienced trauma and who were reporting traumatic stress) and their caregivers received 12 weeks of individually-delivered TF-CBT via telehealth. Autism diagnoses were confirmed via remote observation (CARS-2<sup>Obs</sup>) and parent report (Social Communication Questionnaire). Traumatic stress symptoms were assessed via clinical interview (ADIS Parent and Child Versions) and child (self) and parent report on the Child and Adolescent Trauma Screen (CATS). Assessments also included depression (child/parent report on the Short Mood and Feelings Questionnaire), anxiety (child/parent report on the Screen for Anxiety Related Emotional Disorders), and externalizing behavior problems (parent report on the Strengths and Difficulties Questionnaire). Full assessments were re-completed at the end of treatment and again one month later. Youth and their parents reported on multiple domains of treatment satisfaction.

#### Results:

Overall, paired samples t-tests showed significant and large reductions from pre-post treatment in posttraumatic stress symptoms according to both youth and caregiver report. Depression, anxiety, and externalizing concerns also significantly dropped over the course of treatment. Critically, these improvements were maintained at one-month follow-up (see Table 1 for all pre-post analyses). Lastly, youth and their caregivers reported high levels of treatment satisfaction across multiple domains, including satisfaction with the telehealth technology (see Table 2).

#### Conclusions:

Telehealth-delivered TF-CBT is a promising intervention approach for autistic youth. This pilot study shows that TF-CBT is feasible and effective when delivered remotely. Significant reductions were observed from pre-post treatment in youth PTSD symptoms, depression and anxiety, and externalizing behavior concerns. The intervention had high rates of treatment involvement and satisfaction. Clinical considerations and telehealth resources will be discussed. Future directions for more rigorously evaluating TF-CBT for autistic youth will be considered.

### **307.003 (Oral)** A Randomized Controlled Study and Replication of Compass to Improve Individualized Educational Planning for Students on the Autism Spectrum in an Australian Context

**A. M. Love<sup>1,2</sup>, R. Y. Cai<sup>3</sup>, E. Gallagher<sup>4</sup>, J. Stephenson<sup>5</sup> and V. Gibbs<sup>1</sup>,** (1)Aspect Research Centre for Autism Practice, Autism Spectrum Australia (Aspect), Melbourne, VIC, Australia, (2)Aspect Research Centre for Autism Practice, Flemington, VIC, Australia, (3)Aspect Research Centre for Autism Practice, Autism Spectrum Australia, Melbourne, VIC, Australia, (4)Aspect Research Centre for Autism Practice, Autism Spectrum Australia, Sydney, NSW, Australia, (5)Macquarie University, Sydney, NSW, Australia

#### Background:

The Collaborative Model for Promoting Competence and Success (COMPASS; Ruble et al., 2012) is an evidence-based and collaborative framework for improving the quality of services and individualized outcomes for students on the autism spectrum within school contexts. During the last several decades, researchers have identified effective educational procedures for students on the autism spectrum, but minimal evidence exists to support the dissemination and widespread application of those interventions in community-based settings. COMPASS has shown effectiveness in improving individualized student growth and quality of individualized planning (IP) goals, increased teacher and student engagement, and strengthened parent/teacher alliance through three randomized controlled trials in the US; however, we were interested in the application in an educational context outside of the US.

#### Objectives:

The purpose of this study was to replicate COMPASS in an Australian context and to explore the application of COMPASS in a setting exclusively for students on the autism spectrum. The primary research question was: *Do teacher-child pairs who participate in COMPASS have better IP goal attainment for targeted objectives than that of teacher-child dyads who do not participate in COMPASS?*

#### Methods:

We used a randomized-controlled methodology to trial COMPASS with 91 participants. This included two groups (an intervention and control group) and three participant categories: consultants ( $n = 15$ ), teachers ( $n = 36$ ), and students ( $n = 40$ ). Consultants ( $M_{age} = 43.8$  years,  $SD_{age} = 6.2$ ) had been in a consulting role for an average of 6.9 years ( $SD = 4.4$ ). Teachers ( $M_{age} = 41.0$  years,  $SD_{age} = 9.9$ ) had been teaching for a mean of 15.4 years ( $SD = 9.9$ ). Students were formally diagnosed with autism and ranged in age from 5-18 years ( $M = 9.3$ ,  $SD = 3.2$ ). Further demographic data (e.g., autism severity for students, autism training for teachers and consultants, etc.) were collected. Goal attainment scaling was used to analyze progress on IP goals for each student along with a range of fidelity, adherence, satisfaction, and attitude measures. Data was collected during the 2021 school year across four primary time points.

#### Results:

At the time of the submission of this abstract, the final data collection point remained and additional results will be included in the final presentation. Preliminary results demonstrated that the intervention group resulted in significantly more growth on student IP objectives for the domain of communication ( $t(35) = 1.95, p < .001, d = 1.42$ ) and social skills ( $t(36) = 14.46, p < .001, d = 0.86$ ). There was a significant difference in the number of goals and quality of goals, as measured by three different quality indicators.

#### Conclusions:

Preliminary results demonstrated that the replication of COMPASS in an Australian context showed high rates of satisfaction and adherence. Most importantly, student goal attainment scores improved over time for both groups, but the intervention group demonstrated more growth than the control group. The success of this intervention in improving the quality growth of IP goals for students on the autism spectrum demonstrates the need for a standardized intervention that supports teachers in this critical practice.

#### **307.004** (Oral) Public Perceptions of ABA on Facebook: A Preliminary Snapshot

**P. Chaxiong<sup>1</sup>, M. Y. S. Bak<sup>1</sup>, E. Worthley<sup>2</sup> and A. M. Reilly<sup>1</sup>,** (1)Educational Psychology, University of Minnesota, Minneapolis, MN, (2)University of Minnesota, Minneapolis, MN

**Background:** The neurodivergent movement and disagreement on what constitutes evidence of effectiveness between members of the autistic and research community have resulted in two polarized perspectives of applied behavior analysis (ABA). On the one hand, ABA is perceived as the most promising class of interventions available to improve outcomes for individuals with ASD; on the other hand, ABA is perceived as harmful and dehumanizing. As parents of newly diagnosed children often turn to social media platforms like Facebook to inform intervention decisions, understanding what is publicly written about ABA on these platforms is crucial information to the field.

**Objectives:** We conducted a preliminary qualitative study that examines what is said about ABA on public Facebook pages. Such examination may help to indicate how socially valid ABA is. This information is critical for maximizing the reach and effectiveness of ABA while addressing and minimizing its risks.

**Methods:** Four coders analyzed 257 posts about ABA from April 2019, 2020, and 2021 from 18 public Facebook pages on NVivo using the constant comparison method. Facebook as a platform and the pages selected were informed by five interviews with members of the ABA and autistic community (two mothers, one autistic adult, two practicing BCBAs). Posts from April were selected because of heightened activity on pages during Autism Awareness/Acceptance Month. Professional ASD (e.g., Autism Science Foundation) and ABA (e.g., Applied Behavior Analysis International) pages were excluded. Posts that marketed ABA services, training, conferences, and job postings were also excluded.

**Results:** Facebook posts revealed overwhelmingly negative perspectives of ABA. Prominent themes included:

1. Harm (use of harmful tactics [conversion and electric shock therapy, punishment, restraint] and resulting trauma/abuse [PTSD, compliance training, loss of autonomy];
2. Lack of support from both research and the autistic community;
3. Dehumanization (ABA's poor understanding of autistics and behavioral functions, fixing/normalizing autistic individuals as the goal of ABA); and
4. History (ABA's connection to Lovaas and animal studies).

Positive themes highlighted the use of helpful tactics and that ABA was life-changing.

**Conclusions:** Our preliminary examination of ABA posts on Facebook point to the importance of improving ABA public relations to address the field's dark history, association with Lovaas and harmful therapies, and the perception of "fixing" as the goal of treatment. More importantly, results underscore the need to proactively address the ABA experiences of autistic clients. Intentional research to examine experiences of abuse and trauma reported by clients and ongoing collection of social validity data when conducting intervention research are needed.

## POSTER SESSION — INTERVENTIONS - NON-PHARMACOLOGIC - SCHOOL-AGE, ADOLESCENT, ADULT

### 403 - Interventions - Non-pharmacologic - School-Age, Adolescent, Adult

#### **403.040** (Poster) Autism & Gender: A Pilot Study to the Effects of a Peer Support Group for Adolescents with Autism Spectrum Disorder and Gender Dysphoria

**T. Brandsma<sup>1</sup>, K. Visser<sup>1</sup>, L. P. Dekker<sup>2</sup>, J. Volk<sup>1</sup> and A. Balleur- van Rijn<sup>3</sup>,** (1)Youz, Rotterdam, Netherlands, (2)Department of Psychology, Education & Child Studies, Erasmus University Rotterdam, Rotterdam, Netherlands, (3)Youz, Gorinchem, Netherlands

#### Background:

There is a growing interest in the co-occurrence of Autism Spectrum Disorder (ASD) and gender dysphoria (GD). Research has shown that people with ASD show more gender variance than people without ASD. Due to the difficulties associated with ASD (limited social skills, problems in information processing and difficulty with change), regular GD treatment does not seem to be adequately equipped for this specific group.

## Objectives:

In this study we want to gain insight into the clinical needs of adolescents with ASD and GD and their parents in the Netherlands and we conduct a pilot study to the effects of a specific peer support group for adolescents with ASD and GD.

## Methods:

The Autism and Gender support group consists of nine monthly meetings for the adolescents, covering topics such as autism and gender-related needs, psychoeducation on medical interventions, environmental factors, gender expression and practicing gender presentation skills. Several experts by experience guest speakers visit during the meetings. Simultaneously, parents can follow two parent meetings. A pre-post-test design is used. Prior to the start and at the end of the support group, the adolescents fill out a number of short questionnaires, on quality of life, psychiatric problems, self-esteem, degree of autism symptoms, degree of gender dysphoria symptoms. In addition, the adolescents evaluate the support group during each meeting with the ORS and SRS and at the end with an evaluation form.

## Results:

In March 2019 we started a first support group with 12 adolescents with ASD and GD. The second group started in January 2020 with 9 adolescents, the third in September 2020 with 12 adolescents and the fourth (and final in this pilot study) group started March 2021 with 10 adolescents. Currently, baseline data is available for the first three groups (33 adolescents), giving the following results: The average age of the participating adolescents is over 17 years old and 56% was born as a boy and 44% as a girl. The vast majority have a Western background and are not religious. The vast majority (82%) of the adolescents with ASD follow individual treatment in addition to the ASD and Gender group, mostly focussing on comorbid problems, for instance depression and anxiety. About a third also receive Autism specific counselling/coaching in their daily life. Until now, we have a low dropout; only 17.6% dropped out of the peer support group early. We will analyse the rest of the data in the following months.

## Conclusions:

At the start of the pilot study we were unsure whether we were able to find +/- 30 adolescents with ASD and GD to fill up three rounds of the peer support group, but during the study, we received so many applications that we have added a fourth group (and currently have a waiting list). This experience emphasizes the importance of developing specialized treatment options (and additional research) for this target group.

## **403.041 (Poster) Autistic Experiences and Perspectives on Dating and Romantic Relationships: Towards an Inclusive Dating Social Skills Program for Autistic Adults**

**A. Arias and T. W. Vernon, University of California, Santa Barbara, Santa Barbara, CA**

---

**Background:** There is growing evidence that group social skills interventions can be efficacious for teaching social skills and increasing friendships for autistic adolescents and adults (Laugeson et al., 2012; McVey et al., 2016; Vernon et al., 2018). Recently, more attention has been focused on understanding the romantic relationship dating experiences and challenges of autistic individuals, with emerging evidence of less frequent dating/relationships and lower sexual knowledge than their neurotypical counterparts (Dewinter et al., 2017; Weiss et al., 2018). However, only one study has examined a dating-related program adapted for autistic adults to target dating skills and romantic relationship outcomes (Cunningham et al., 2016). Furthermore, no known studies have co-developed their dating curriculum with input from autistic adult community and as a result, existing programs may not address their unique strengths and challenges.

**Objectives:** The present study sought to understand the dating and romantic relationship experiences and challenges of autistic individuals, as well as their interest in topics to be covered in a future group socialization intervention focused on dating and romantic relationships.

**Methods:** Data collection of the sample comprised of 159 autistic adults who completed an online survey. Participants were recruited using a variety of social media posts and listservs. The survey queried participant demographics, previous romantic relationships and experience in those relationships, what participants are seeking in dating/romantic relationships, prior challenges in initiating and maintaining relationships, and what they would like to see in a future social skill program focused on dating. For the present study, we analyzed data from an open-ended item that assessed prior challenges in dating and helpful topics to include in the aforementioned future program, examined the level of knowledge reported on several dating skills, and conducted a descriptive analysis of endorsed qualities desirable of a relationship and of a romantic partner. A thematic content analysis (TCA) of the responses to the open-ended item will be conducted for the open-ended data.

**Results:** Preliminary results of the TCA revealed common themes of security/stability, trust, love, common interests, understanding, and intellectual bonding as characteristics sought in a romantic relationship. When asked about challenges related to initiating and maintaining romantic relationships, dealing with compromise/disagreements, finding common ground, building rapport and trust, using effective communication, and maintaining a relationship beyond initial infatuation emerged as central themes. Finally, common themes endorsed for topics to include in a future dating social skill program included: (a) consent; (b) communication of needs (particularly during time of distress) 3) interpreting social cues and understanding intention ; 4) flirting behaviors; 5) neurodiversity awareness and disclosure while dating.

**Conclusions:** This study provides insight into the unique needs and considerations of autistic adults who are pursuing romantic relationships. Understanding autistic experiences and integrating their input into a future dating skills program ensures that the resulting curriculum aligns with their priorities and relationship expectations .

**Background:** The prevalence of challenging behavior is especially pronounced in children with autism (Maskey et al., 2013). These behaviors are typically associated with increased family isolation, parental stress, and interference with education and interventional programming. Therefore, families with children on the autism spectrum are in desperate need of accessible and affordable, high-quality evidence-based treatments that simultaneously target disruptive behaviors and are congruent with busy family schedules. Parent Child Interaction Therapy (PCIT), one of the most supported evidence-based interventions for defiance (Greco et al., 2001), has shown promising results for families of autistic children (Parlade et al., 2020). Furthermore, recent PCIT adaptations suggest more intensive and time-limited approaches can yield promising gains and address historic barriers to treatment engagement (Graziano et al., 2020).

**Objectives:** To assess the effectiveness and feasibility of an intensive PCIT program delivered remotely to parents of children with autism.

**Methods:** The current study followed a rigorous non-concurrent multiple baseline experimental design across 3 subjects (ages 4:7, 5:0 and 3:6). The selection criteria included (a) a child chronological age of 2 -5, (b) participating caregiver being the primary caregiver (c) a formal diagnosis of autism (d) child disruptive behavior scores as measured by Intensity Scale of the Eyberg Child Behavior Inventory (ECBI) being 131 or above. Participants were randomly assigned to complete 4, 6 or 8 baseline sessions, during which a five-minute video was systematically coded for parents' use of PCIT skills. Participants also completed a series of online assessment batteries, which included parent-reported measures of child disruptive behaviors and adaptive functioning. These batteries were completed at four different time points: intake, mid-treatment, post treatment and 1-month follow-up. All participants received a two-week, 10-session Intensive PCIT treatment course delivered by trained PCIT clinicians through an online video-conferencing platform.

**Results:** Parent's use of PCIT skills remained relatively low during baseline sessions for all 3 participants, with a mean of 3.33 (SD = 2.1) and a range of 0 to 7 observed PCIT skills. During the CDI and PDI phase, positive parenting behavior increased across all three families. At post-treatment, a mean of 32.33 (SD = 9.29) PCIT skills were observed (Cohen's d effect size = 4.30, indicative of a large treatment effect), suggesting a high level of skill use when compared to the proposed proficiency level of 30. These numbers were maintained at the 1-month follow-up, with an average of 29.33 (SD = 9.05) skills observed. ECBI intensity pre-treatment scores fell in the clinical range (>131)(M = 178.66; SD = 6.66). Post-treatment scores fell below the clinical cutoff (M= 124; SD = 22.11, Cohen's d = 3.34) and follow up scores were markedly lower (M= 114.33; SD = 15.95, Cohen's d = 5.26).

**Conclusions:** Results from this study provide support for the functional relationship between exposure to a time-limited and intensive PCIT program and significant improvements in parent PCIT mastery and child behavior challenges. This study highlights a promising intervention approach that could maximize treatment accessibility and retention, while effectively promoting adaptive parenting skills.

**403.043** (Poster) Community-Informed Development and Pilot of the Emotion Awareness and Skills Enhancement Team-Based Program (EASE-Teams)

**K. B. Beck<sup>1</sup>, J. B. Northrup<sup>2</sup>, K. Breitenfeldt<sup>3</sup>, S. A. Porton<sup>2</sup>, T. N. Day<sup>4</sup>, K. T. MacKenzie<sup>5</sup>, C. M. Conner<sup>2</sup> and C. A. Mazefsky<sup>2</sup>,** (1)University of Pittsburgh, Pittsburgh, PA, (2)Department of Psychiatry, University of Pittsburgh School of Medicine, Pittsburgh, PA, (3)Psychiatry, University of Pittsburgh Medical Center (UPMC), Pittsburgh, PA, (4)Florida State University, Tallahassee, FL, (5)University of Pittsburgh School of Social Work, Pittsburgh, PA

---

**Background:**

Emotion dysregulation (ED), difficulty managing the intensity and duration of emotional reactions, is highly prevalent among autistic individuals across the lifespan <sup>1,2</sup>. Research suggests that autistic individuals, with and without intellectual disability, are predisposed to ED and it is a transdiagnostic mechanism that underlies co-occurring psychiatric conditions and suicidality in autism <sup>3-7</sup>. Despite this, psychosocial treatments for ED are lacking for autistic individuals, especially those with limited cognitive and verbal abilities <sup>8</sup>.

Mindfulness-based interventions offer a promising approach to target ED while remaining flexible to the heterogeneous needs across autistic individuals,<sup>9</sup> as meditation practices are easily individualized for varied cognitive and verbal needs.<sup>10</sup> The Emotion Awareness and Skills Enhancement (EASE) program was the first mindfulness-based intervention designed to target ED in autistic adolescents without intellectual disability (ages 12-17). The EASE pilot established feasibility, acceptability, and preliminary efficacy of improving ED ( $d=0.67-2.64$ ).<sup>11</sup>

**Objectives:**

The objective of this study was to adapt EASE for autistic individuals (ages 7-25) with and without co-occurring intellectual disability.

**Methods:**

Over three iterative, adaptation phases, we: 1) elicited stakeholder input to adapt EASE for autistic individuals with intellectual disability; 2) redesigned the adapted manual and expanded the target age range following a small "micro-trial" with a sample of autistic adolescents and adults with intellectual disability (n=6); and 3) demonstrated feasibility and acceptability of a caregiver-client team-based approach (EASE-Teams) in a sample of 10 autistic individuals with and without intellectual disability (ages 7-25) and their caregivers.

## Results:

We learned from conversations with community members and micro-trial participants that ED is a family process, warranting a team-based approach to improve ED where participant and caregiver work together to learn and practice new skills in session and at home (See Figure 1 for treatment details, which will be presented with the stakeholder-informed adaptation process in further detail). Ten pilot participants completed the treatment with 100% adherence. We found a high degree of caregiver involvement ( $M = 3.84$ ;  $SD = 0.41$  on a 1-4 scale) and participant involvement ( $M = 3.57$ ,  $SD = 0.66$ ) in each session. Most caregivers indicated that their child used mindfulness strategies *mostly every day* and they used the strategies *mostly every day*, suggesting excellent engagement in the team-based approach. EASE-Teams was acceptable ( $M = 4.8$ ,  $SD = 0.63$  on a 1-5 scale) and helpful ( $M = 4.5$ ,  $SD = 0.71$  on a 1-5 scale) to families. Statistically significant improvements were noted in participant ED ( $p < .001$ ;  $n = 10$ ), anxiety ( $p = .01$ ) and depression symptoms ( $p = .007$ ), and caregiver stress from their child's dysregulation ( $p = .01$ ). In a semi-structured exit interview, one caregiver emphasized the impact of the treatment in his daughter, stating: "Beforehand she felt 'I don't know what's happening to me' [...] now I feel like she goes 'okay, this is how I am expressing emotions and it's okay.'"

## Conclusions:

Results of this study suggest that this community-informed treatment, EASE-Teams, is acceptable and feasible for a wide range of developmental and cognitive needs. Future research to establish efficacy and refine EASE-Teams for delivery by community-based providers is needed.

### **403.044** (Poster) Effect of Daily Exercise on Body Composition of Adolescents with ASD

**C. L. Hilton<sup>1</sup>**, D. M. Collins<sup>1</sup>, J. Jones<sup>2</sup>, J. Flanagan<sup>3</sup>, C. Habeger<sup>1</sup> and K. Ratcliff<sup>1</sup>, (1)Occupational Therapy, University of Texas Medical Branch, Galveston, TX, (2)Tarnow Center for Self-Management, Houston, TX, (3)Occupational Therapy, Nova Southeastern University, Jacksonville, FL

---

## Background:

The prevalence of obesity in children with ASD is higher than in the general pediatric population and is related to unusual dietary preferences, noncompliant behavior, decreased exercise, social isolation, and medication side effects. Body mass index generally remains stable or worsens as children with ASD get older.

**Objectives:** To examine the effects of a mandatory daily exercise program on body composition of adolescents with ASD.

## Methods:

We conducted a 12-month, repeated-measures intervention study of adolescents with ASD ( $n = 29$ ), examining compliance with exercise participation and changes in BMI. Multiple strategies were used to encourage participation in the exercise program.

## Results:

Compliance with exercise participation was strong and significant improvements were seen in BMI.

## Conclusions:

Findings suggest that mandatory daily physical exercise can be successful in adolescents with ASD and contributes to improvements in body composition.

### **403.045** (Poster) Elaborative Reminiscence: A Feasible and Acceptable Intervention for Autistic Children

**G. Ryan<sup>1</sup>**, M. Cartwright<sup>2</sup>, D. M. Bowler<sup>3</sup>, P. Howlin<sup>4</sup>, E. Strom<sup>5</sup> and S. E. Lind<sup>6</sup>, (1)Autism Research Group, City University of London, London, United Kingdom, (2)City University of London, London, United Kingdom, (3)Autism Research Group, City University, London, United Kingdom, (4)King's College London, London, United Kingdom, (5)Psychology, City, University of London, London, United Kingdom, (6)City, University of London, London, United Kingdom

---

**Background:** A growing body of research with typically developing children has reported significant, beneficial effects of training parents to use an "elaborative reminiscence" (ER) communication technique on a range of cognitive and communicative children's outcomes that are known areas of difficulty in autism (Waters et al. 2019, Salmon & Reese, 2016). These findings have prompted speculation that ER could be a beneficial intervention for autistic children (McDonnell, Valentino & Diehl, 2017). However, no randomised trials have yet evaluated whether ER is a feasible or acceptable intervention for this population.

**Objectives:** This study aimed to assess the feasibility and acceptability of training parents to use an ER intervention with their child. A two-arm, double-blind randomised controlled pilot trial was evaluated for the feasibility of trial procedures, training receipt and enactment, implementation fidelity and intervention acceptability for caregivers.

**Methods:** Thirty-six parents and children were recruited. Children were non-intellectually disabled and aged 7-11 years with a formal diagnosis of autism. Participants were randomly assigned to receive training in either ER or an active control intervention ("present tense talk"; PTT) and

instructed to use the intervention for 20 weeks, 6 out of 7 days each week for 5 minutes. Parents were asked to log their progress. Children were tested pre- and post-intervention for memory (CVLT-C: Delis et al., 1994), self-concept (SDQ-I; Marsh, H. W, 1992) and mental state understanding (Theory of Mind Battery: Peterson & Wellman, 2019; Abell, Happe & Frith, 2000). Trial procedures were evaluated for measure appropriateness, participant recruitment and retention. Parent-child conversations (recorded at baseline, week 1 and week 20) were transcribed and coded for parent conversation style (manual adapted from Reese & Newcombe, 2007) to assess training and intervention adherence. Parent logbooks examined implementation fidelity by comparing participants' actual vs prescribed dosage and frequency of intervention delivery. Intervention acceptability was evaluated by descriptively analysing quantitative data from caregiver surveys (administered at 10 and 20 weeks) and qualitatively analysing post-trial feedback interviews with ER participants using deductive thematic analysis.

**Results:** Preliminary analysis of interviews found most parents reported feeling that intervention benefits outweighed the costs. Preliminary analysis of parent logbooks suggests that 81% of intervention conversations adhered to the recommended dosage of 5 minutes or more. ER parents described 65% of conversations as requiring "almost no effort". Child and parent enjoyment of ER was rated as 4 or 5 (out of 5) for 85% and 75% of conversations, respectively. However, post-trial interviews indicated that dosage and logging procedures were causes of burden and negative attitude.

**Conclusions:** Preliminary analysis suggests that training parents to use ER could be both a feasible and acceptable intervention for parents of autistic children, especially if the dosage and logbook format are amended. We also predict that lowering these burdens would improve the retention rate for a larger-scale study. Even these preliminary findings support the development of a future fully-powered randomised controlled trial into the use of ER as a parenting intervention with autistic children.

#### **403.046 (Poster)** Evaluating Race As a Predictor of Treatment Gains in the UCLA PEERS® for Young Adults Program

**Y. H. Chou<sup>1</sup>, C. Moody<sup>2</sup>, J. E. Lerner<sup>2</sup>, I. Viani<sup>2</sup> and E. A. Laugeson<sup>2</sup>, (1)Psychiatry and Biobehavioral Sciences, UCLA PEERS® Clinic, Los Angeles, CA, (2)UCLA Semel Institute for Neuroscience and Human Behavior, Los Angeles, CA**

---

**Background:** Autistic young adults are more likely than neurotypical adults to experience social difficulties and loneliness (Ee et al., 2019), highlighting a need for effective and accessible social skills treatments for this population. Unfortunately, documented racial disparities indicate that autistic people of color (POC) experience less favorable outcomes in the transition to adulthood and are less likely than their White peers to receive supportive services at this critical developmental juncture (Eilenberg et al., 2019). However, less is known about racial disparities in the effectiveness of interventions for those on the spectrum (Smith et al., 2020). Given adverse outcomes in young adulthood, it is essential to ensure that all autistic individuals, regardless of race, benefit from available interventions. Though one previous study revealed no differences by race in treatment response following the Program for the Education and Enrichment of Relational Skills (PEERS®) for Adolescents intervention (Egbunu et al., 2016), this has yet to be examined in the PEERS® for Young Adults program (Laugeson et al., 2015), one of the few evidence-based social skills interventions for this age group.

**Objectives:** This study explores whether differences in treatment gains following the PEERS® for Young Adults intervention exist between autistic participants of color as compared to autistic White participants. Given null findings for the PEERS® for Adolescents program, we hypothesized no significant group differences in treatment gains between POC and White autistic young adults.

**Methods:** Participants included 87 young adults (81.6% male;  $M_{age}=22.7$ ,  $SD=3.9$ ) with pre-existing autism diagnoses who completed the PEERS® for Young Adults program. Per caregiver-report, 32.2% of participants were POC, while 67.8% were White. Treatment gains were assessed on the Social Skills domain of the Social Skills Improvement System (SSIS-SS; Gresham & Elliott, 2008), Social Responsiveness Scale, Second Edition (SRS-2; Constantino & Gruber, 2012), caregiver- and self-reported Quality of Socialization Questionnaire (QSQ; Adapted from Frankel et al., 2010), and Test of Young Adult Social Skills Knowledge (TYASSK; Laugeson & Frankel, 2010). Independent samples t-tests were utilized to compare the treatment response of POC and White participants on outcomes.

**Results:** On average, young adults significantly improved on all outcomes following PEERS® for Young Adults, with no significant differences between POC and White participants on SSIS-SS,  $t(74)=1.31$ ,  $p>.05$ , or SRS-2 change scores,  $t(76)=-1.63$ ,  $p>.05$ . Similarly, analysis of TYASSK change scores revealed no significant differences between groups,  $t(75)=0.12$ ,  $p>.05$ . Finally, both POC and White young adults increased their number of get-togethers, with no significant differences observed for either caregiver-report,  $t(76)=0.70$ ,  $p>.05$ , or self-report,  $t(69)=1.70$ ,  $p>.05$ .

**Conclusions:** Findings suggest no significant differences in treatment gains between POC and White participants presenting for social skills treatment, as observed across all scales. These results further support that the PEERS® intervention similarly benefits POC and White autistic young adults. Future studies might examine the impact of cultural and socioeconomic factors on treatment efficacy to ensure inclusivity and equity in interventions for autistic adults.

#### **403.047 (Poster)** Evidence-Based Review of the Parent-Implemented Video-Based Intervention to Teach Life Skills to Autistic Children

**G. Yakubova<sup>1</sup> and B. B. Chen<sup>2</sup>, (1)University of Maryland, College Park, MD, (2)University of Maryland College Park, College Park, MD**

---

**Background:** Independent functioning in daily life is an ultimate goal of education for autistic children as they grow into adults. Video-based intervention (VBI) can be used to further increase independent functioning and shift the instruction and prompting from the adult to the child. Prior literature on using a VBI to teach functional and independent living skills to autistic students have been conducted in school settings with the researcher as the interventionist.

**Objectives:** The purpose of this study was to empirically evaluate and synthesize the evidence base for using parent-implemented VBI to teach independent living to autistic children in home settings. We analyzed (1) the components of effective parent-implemented VBI studies, (2) the types and components of parent training methods in a parent-implemented VBI studies, (3) the effects of a parent-implemented VBI on the acquisition of

life skills among autistic children with a culminating aim of determining whether a parent-implemented VBI be classified as an evidence-based practice (EBP) to teach life skills to autistic children in home environments.

**Methods:** A systematic search of the literature yielded nine studies that met the inclusion criteria. These studies were published between 2010 and 2021. We coded and synthesized studies for certain elements of the VBI and parent training methods to create and implement these interventions, types of skills, settings, supplemental support strategies, and child and parent demographics. We then evaluated studies to determine the strength of the evidence base using the Reichow et al. (2008) evaluative method. Finally, we evaluated the studies per What Works Clearinghouse (WWC) design standards. We calculated cumulative effects using the Tau-*U* effect size measure.

**Results:** Parent-implemented VBI can be effective in improving independent living skill acquisition of autistic children in authentic environments. We found that when provided with appropriate training, parents can effectively create and implement VBI with high fidelity. The variation in child and parent characteristics, age ranges and characteristics of autism (2- to 17.1-year-old children), parental age ranges and backgrounds (18–54 years old with varying levels of education and some diversity in racial and ethnic backgrounds), parent training methods, and skill types across studies existed. Within the types of VBI, a variety of models, including parents, researchers, siblings, same-age peers and self-models were used in the form video modeling, video self-modeling, or video prompting. Seven of the nine studies met WWC design standards with or without reservations, six had a 100% success estimate and a strong effect size score per Tau-*U* method ( $d^3$  0.93). Parent-implemented VBI meets the criteria to be considered as a probable EBP.

**Conclusions:** The findings indicate that parent implemented VBI can be effective in improving skill acquisition of autistic children in home environments. Parent-implemented VBI can be classified as a probable EBP to teach life skills to autistic children. Findings also revealed that VBI can be used to create culturally and linguistically appropriate instruction and provide visual modeling using everyday technology, which makes it socially valid and accessible to parents and children from diverse cultural backgrounds as evident from the included studies.

#### **403.048** (Poster) Technology-Based Interventions to Teach STEM Skills to Autistic Students

**G. Yakubova<sup>1</sup>, B. B. Chen<sup>2</sup> and M. Defayette<sup>1</sup>, (1)University of Maryland, College Park, MD, (2)University of Maryland College Park, College Park, MD**

---

**Background:** Technology-based interventions can be effective in teaching a variety of skills to autistic students. When it comes to teaching science, technology, engineering, and mathematics (STEM) skills to autistic students using technology-based interventions, the literature that examines the evidence-base along with features of effective technology-based interventions specifically for autistic students, is lacking. Existing evaluations of evidence are either narrative in nature or focused on students with developmental disabilities.

**Objectives:** The purpose of this evidence-based systematic review was to evaluate the evidence of effectiveness for technology-based interventions to teach STEM content knowledge and skills to K–12 autistic students. Our aims were to (1) analyze (a) the effects and (b) components of technology-based interventions in teaching STEM content knowledge and skills to autistic students, and (2) to evaluate the evidence-base of technology-based interventions.

**Methods:** A systematic search of literature yielded 20 peer-reviewed articles published between 2012 and 2021 that met the inclusion criteria for the study. We coded and synthesized the studies for the types and characteristics of technology-based interventions, STEM content, participant and interventionist characteristics, and design characteristics. We evaluated the included studies per What Works Clearinghouse (WWC) design standards and the Reichow et al. (2008) evaluative method to determine the level of evidence to classify a practice as an evidence-based practice specific to autism research. We also calculated the effect size to analyze the quantitative effects.

**Results:** Fifty-nine autistic participants, ages 5–21, were included across the 20 studies. Studies used a variety of technology-based interventions, including video-based intervention ( $n=10$ ), virtual manipulatives ( $n=7$ ), computer-assisted instruction ( $n=2$ ), and e-texts ( $n=1$ ). Most studies also included behavioral supports such as, self-monitoring checklists, least-to-most prompting, and corrective feedback. Seventeen studies focused on math skills and three studies on science skills. Specific skills included science vocabulary and concept application, single and multi-digit addition and subtraction, number comparison, fractions, word problems, and functional mathematics skills, such as price comparison, recipe adjustment, and tip calculation. Only four studies included an authentic agent as the interventionist (e.g., teacher, therapist, paraprofessional). Seventeen studies met WWC design standards with or without reservations. Using the Reichow et al. (2008) evaluative method, we determined that technology-based interventions for teaching STEM skills to K–12 autistic students can be classified as an established evidence-based practice.

**Conclusions:** Technology-based interventions can be effective in teaching STEM skills to autistic students, however, the majority of studies used technology to teach mathematics skills. Future studies may need to examine the use of technology-based intervention in teaching other aspects of STEM skills. Further examination of training practitioners to implement a variety of technology-based interventions and their effects on student learning is necessary.

#### **403.049** (Poster) Feasibility of Implementing a Virtual Reality Police Safety Intervention Via Teletherapy

**A. S. Russell<sup>1</sup>, A. Zitter<sup>1</sup>, M. Leuzzi<sup>1</sup>, J. Pacheco<sup>2</sup>, K. G. Tena<sup>3</sup>, A. Knox<sup>4</sup>, M. R. Pelella<sup>4</sup>, M. L. Cola<sup>4</sup>, R. Solorzano<sup>4</sup>, S. Turnacioglu<sup>4</sup>, J. S. Miller<sup>4</sup>, V. Ravindran<sup>4</sup>, J. McCleery<sup>4</sup> and J. Parish-Morris<sup>1</sup>, (1)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (2)Saint Joseph's University, Philadelphia, PA, (3)The Children's Hospital of Philadelphia Center for Autism Research, Philadelphia, PA, (4)Floreo, Inc., Washington DC, DC, (5)Psychology, Saint Joseph's University, Philadelphia, PA**

---

**Background:** One fifth of adolescents with ASD will be stopped and questioned by police before their early twenties (Rava et al., 2016). Providing opportunities to practice this kind of encounter is essential because police interactions are challenging, unexpected, include unusual sensory

stimulation, require novel problem solving, and necessitate rapidly processing social situations in real time (Channon et al., 2001; Salerno-Ferraro & Schuller, 2020; Vanmarcke et al., 2016). The COVID-19 pandemic has exacerbated depression and anxiety among autistic people (Oomen et al., 2021) and rendered it near-impossible to safely implement in-person behavioral interventions. In this study, we describe how a virtual reality (VR) intervention was quickly adapted to be administered via video conference, thus providing individuals across the USA an opportunity to practice interacting with police officers in a safe, simulated environment.

**Objectives:** Describe how the Floreo Police Safety VR intervention was implemented via teletherapy and provide preliminary evidence for the feasibility of this approach with autistic adolescents and adults.

**Methods:** Participants completed a telephone screening interview and video-conferenced IQ test, and were then randomly assigned to a treatment-as-usual (TAU) group or intervention group. All participants were mailed a headset to keep, and an iPhone equipped with the Floreo app, which study staff controlled remotely using a paired iPad. Participants in the intervention condition joined three 1-hour teletherapy intervention sessions with study staff (via WebEx), each separated by approximately 1 week. VR lessons consisted of multiple short interactions with virtual police officers, during which participants were simultaneously coached by study staff to practice skills including self-disclosure of an autism diagnosis, eye contact, and following directions. All participants underwent three VR-based assessments of virtual police officer interactions and completed online surveys about their knowledge of and experiences with police at each timepoint. Assessments and the viewfinder inside the VR were recorded. The final sample will consist of 48 participants (24 in each condition), with pre-/post-assessments and a follow-up assessment all evaluating key skills.

**Results:** Implementing a fully virtual VR intervention during a pandemic is logistically challenging, but resulted in a sample with greater geographic diversity than prior in-person iterations (McCleery et al., 2020). To date, 36 autistic individuals from 9 states have participated, with 92% success in data collection. Data loss occurred due to internet connection issues or technological difficulties. In two instances, WebEx glitched and assessment recordings were not correctly exported. In another instance, a participant's internet severely affected recording video quality. Participants contributed valuable feedback on both the intervention and the video-conferenced format.

**Conclusions:** VR holds potential as a comfortable and motivating platform for autistic people to safely practice interacting with police officers. The remote administration of this intervention was successful in reaching a geographically diverse cohort and in collecting usable, rich data on intervention efficacy. Future directions include behaviorally coding teletherapy sessions for a complete sample of 48 participants.

#### **403.050 (Poster)** Generalization of Playground Social Skills Interventions and Identifying Potential Active Ingredients on Social Network Outcomes for School Aged Children with ASD

**W. I. Shih<sup>1</sup>, J. Locke<sup>2</sup> and C. Kasari<sup>3</sup>,** (1)University of California - Los Angeles, Los Angeles, CA, (2)Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA, (3)University of California, Los Angeles, Los Angeles, CA

**Background:** Autistic children are increasingly included in general education classrooms, and parents and teachers highlight the need for school interventions aimed at helping children socially connect to their peers. Several social skills interventions developed for school settings have demonstrated improvements in social outcomes, although the outcomes are often limited and effect sizes small. A goal of many interventions is to increase the connections between children but the mechanism underlying why the intervention succeeds at this outcome is often unexplored.

**Objectives:** This study aims to evaluate the intervention mechanism for increases in peer connectedness as the result of playground situated peer interaction interventions at school.

**Methods:** 140 children with ASD were drawn from two randomized intervention studies (Study 1: n=60; Study 2: n=120). Children were recruited from three school districts, aged 5-12 years old, predominately male (91.7%), ethnically diverse (64% non-white) and grades K-5<sup>th</sup>.

Both studies were delivered in the schools during recess. Each study applied a peer mediated intervention during recess compared to treatment as usual.

#### *Measures:*

The Playground Observation of Peer Engagement is an interval coding system that identifies durations of joint engagement with peers to solitary play (isolated from peers).

The Friendship Survey is a questionnaire used to assess children's friendships and social networks of peer relationships in the general education classroom. The survey yields social network variables of involvement in classroom (social network centrality-SNC: 0=isolated, 1=peripheral, 2=secondary, 3=nuclear), number of friends nominated (i.e. out-degrees), and connectivity (number of significant connections with classmates).

All measures are collected at pre and post intervention (after 6-8 weeks).

#### **Results:**

Regression models (i.e. generalized linear mixed models and linear models) were utilized to evaluate the effect of the intervention on social network outcomes from pre to post intervention and to determine the association between playground engagement with social network outcomes while controlling for study effects.

There were significant intervention effects for SNC ( $F(1,127)=6.82, p=0.01$ ) and out-degrees ( $F(1,127)=5.96, p=0.016$ ) where children who received PSS intervention had increased odds of having higher SNC and greater out-degrees from pre to post intervention compared to children in treatment as usual group. In addition, increased joint engagement on the playground at exit was significantly associated with increased connectivity in the classroom at exit ( $F(1,126)=4.28, p=0.04$ ), but not significantly associated with out-degrees ( $F(1,126)=0.32, p=0.57$ ).

**Conclusions:** These results suggest that increases in peer connections results from improvements of joint engagement with peers on the playground. These findings highlight the need to target joint engagement at school in order to foster stronger connections between children with ASD and their peers.

**403.051 (Poster) Group Selfi: Preliminary Results from an RCT of a Social Media Skills Group Intervention**

A. Osuna<sup>1</sup>, T. W. Vernon<sup>2</sup>, K. Sabini<sup>2</sup>, E. Yamane<sup>2</sup>, J. Flores<sup>2</sup>, J. Lemus-Valle<sup>2</sup>, J. Partida Flores<sup>2</sup>, B. Bas<sup>2</sup>, N. Pierce<sup>2</sup>, G. Goldschmidt<sup>2</sup>, T. Bhatia<sup>2</sup> and A. Nees<sup>2</sup>, (1)University of California Santa Barbara, Santa Barbara, CA, (2)University of California, Santa Barbara, Santa Barbara, CA

**Background:** About 82% of autistic individuals report using social media, a rate similar to neurotypical peers (Ward et al., 2018). Autistic adults that use social media self-report closer friendships and higher friendship quality than those that do not socialize online (van Schalkwyk, 2017). While there are many benefits to having an active social media presence, difficulty adhering to social expectations has been associated with higher rates of cyberbullying and online harassment (Loomes, 2017). Considering that autistic individuals are more likely to engage in inappropriate behavior online (Spain and Blainey, 2015), it is important to understand how to support their online experience. The SELF program was developed to support autistic adults interested in developing and maintaining relationships using social media.

**Objectives:** The objectives of this study were to 1) develop a virtual social media skills group intervention and 2) pilot test the feasibility and acceptability of program materials and procedures.

**Methods:** A total of 68 participants were recruited and screened for eligibility to participate in the Group SELF program. Inclusion criteria included an ASD diagnosis, age 18-40 years, verbal ability score  $\geq 70$  assessed using the KBIT-2 (Kaufman, 2004), an active Facebook account, video chat capability, and a desire to use social media to connect with others. A total of 26 participants met inclusion criteria and were randomly assigned to start the 8-week SELF program immediately or after a 2-month waiting period. SELF program lessons and materials were developed considering participant goals and strategies identified in the literature as being prosocial and improving friendship quality. Intervention strategies included individual goal setting, use of typically developing peer mentors, skill modeling, didactic lessons, in-vivo practice, and self-management. Attendance, attrition, and a feedback survey from participants and peer mentor clinicians were used to gather post-treatment feedback. Recorded sessions (20%) were analyzed for treatment fidelity.

**Results:** Of the 26 eligible participants, two withdrew prior to treatment due to in-person work conflict -- 24 initiated SELF treatment. The active group consisted of 11 participants -- ten completed the program and one dropped due to social anxiety. All participants on the waitlist, except for two that were lost to follow up, completed the program. Total attrition for the 24 participants that initiated treatment was calculated at 12.5%. Total attendance for the 23 participants that completed treatment was 89.3%. Most participants reported satisfaction with the program and agreement in the domains of learning new skills, feeling more confident online, and use of SELF strategies to maintain friendships. Peer mentor clinicians provided feedback related to program procedures. Session fidelity of was rated at 100%.

**Conclusions:** The present study serves as a proof of concept for a virtual social media skills program that specifically targets online social communication. Results will be used for future intervention development. This innovative format has the potential to target a crucial area of social functioning that has not been targeted in autistic individuals. Further research is needed to understand the unique online social experiences and needs of individuals on the spectrum.

**403.052 (Poster) Open Trial of College Success Intervention: Increasing Executive Functioning and Social Skills in College Students with ASD**

M. J. Baker-Ericzen<sup>1,2</sup>, M. Fitch<sup>3</sup> and A. Tran<sup>4</sup>, (1)Administration, Rehabilitation and Post-Secondary Education, San Diego State University, San Diego, CA, (2)Child and Adolescent Services Research Center, San Diego State University, San Diego, CA, (3)Child and Adolescent Services Research Center, San Diego, CA, (4)Child and Adolescent Services Research, University of California, San Diego, San Diego, CA

**Background:**

About 70,000 students on the autism spectrum (AS) exit high school annually. Unfortunately, the outlook for the transition to adulthood is bleak, with over 66% of young autistic adults failing to transition into postsecondary educational (PSE) institutions or employment shortly after leaving high school. For those who do participate in PSE, approximately two thirds do not obtain a degree. As the neurobiological basis of autism is further investigated, new interventions are focusing on remediating the core deficits specific to social and cognitive dysfunction in AS. Impairments in executive functioning are considerable in autistic individuals, and it is likely that these impairments are a leading cause of disability in AS.

**Objectives:**

A new, innovative program was developed, College SUCCESS to teach cognitive executive functioning and social cognitive functioning skills that are often referred to as "soft skills" necessary to succeed in college. This open trial research study investigated college students cognitive and social skills, functional ability and education outcomes as a result of receiving the College SUCCESS curriculum. Feasibility, acceptability and satisfaction data were collected.

## Methods:

A total of 25 autistic students ( $\mu = 22.6$  SD=4.1 yrs; range 18-34yrs) participated. The participants were male (76%), race/ethnically diverse (64%), average IQ ( $\mu = 64.6$  SD=15.6), 72% participated on University and 28% on Community College campuses, 76% receiving Disability Services. 32% received MH counseling and 13% on medication. The College SUCCESS curriculum was delivered 1-2xs totaling 90-180minutes per week (differing for quarter vs semester campuses) via an active group. Skills taught include executive functioning: attention, learning, memory, prospective memory, cognitive flexibility, problem solving, goal oriented thinking and contextual awareness and social cognition: social conversation (giving and receiving compliments, feedback and help), social relationships, initiations, social media, social networking and self-advocacy. Pre and post assessments included a full battery of assessments including 1) cognitive skills: self-, parent-report (BRIEF-A) & observation (Challenge Task-CT); 2) social skills: self-, parent-report (SRS-2), & observation (Social Skills Performance Assessment-SSPA); 3) academic functioning skills and 4) satisfaction. Data was gathered from standardized measures (participant and parent report) and college staff ratings.

## Results:

Two students had perfect attendance; average # of missed groups=3.67. Outcome analyses used paired sample t-tests. Findings reveal significant differences on cognitive ( $ES=.20-.63$ ), social ( $ES=.30-.67$ ) and functioning measures ( $ES=.37-2.05$ ) indicating medium to large effects across informants. (Refer to Tables 1-3). Also, 70-75% students improved academic skills and 100% were observed by the facilitator to use new skills in course. Further, 100% of participants and 100% of parents reported the College SUCCESS program overall was excellent and 92% students reported it helped them and 100% parents reported it helped their young adult.

## Conclusions:

This study demonstrates that a College soft skills intervention positively impacts autistic students. This College program revealed high satisfaction and promise towards improving academic outcomes for adults on the autism spectrum.

**403.053 (Poster)** Parental High Elaborative Reminiscing Predicts Improvement in Autistic Children's Episodic Memory and Theory of Mind  
A. Brien<sup>1</sup> and T. Hutchins<sup>2</sup>, (1)Speech-Language Pathology, California State University San Marcos, San Marcos, CA, (2)University of Vermont, Burlington, VT

---

**Background:** Episodic memory (EM) is memory for past personal experiences and is foundational for the development of a wide range of human-specific, social-cognitive functions. One of these is theory of mind (ToM) which is developmentally and functionally intertwined with EM. Meanwhile, an impressive body of literature has documented that one particular caregiver interaction style (i.e., *elaborative reminiscing*) causally and positively impacts typically developing children's EM, ToM, and socio-cultural learning more generally. Despite its empirical basis and theoretical importance, no formal interventions have been developed to support EM in autism.

**Objectives:** The purpose of this study was to evaluate the effectiveness of a new caregiver-mediated EM intervention that adapts the principles of elaborative reminiscing in ways that align with best practices for supporting social cognition in children with autism. The following hypotheses were evaluated using an uncontrolled pre-post design to evaluate proof of concept and the intervention's potential for therapeutic outcomes: From pre- to post-intervention 1) parents will increase their use of an elaborative reminiscing interaction style, and 2) children will demonstrate improvements in EM and ToM.

**Methods:** Participants were 27 caregivers and their children (20 males; 7 females; ages 6-15 years;  $M = 9.93$ ) with a formal diagnosis of autism. Parent training in elaborative reminiscing (consisting of three modules; total time approximately 3 hours) was modeled after well-established training programs and manualized in a standard operating procedure. Following training, parents implemented the intervention techniques for eight weeks (5 minutes a day/5 times a week). To assess the quality of parental talk at pre-post, structured parent-child interactions were transcribed and coded reliably for the presence of elaborative statements, task support, and mental state terms. Children's EM was assessed using a modified cueing task (to tap EM specificity) and a Remember/Know task (to tap EM accuracy). Children's ToM competence was assessed via parent-report as well as tests of direct performance (alternate forms were used to control for test-practice effects).

**Results:** From pre- to post-intervention, parents increased their use of conversational devices for all indicators of elaborativeness. Children's cueing task scores demonstrated improvement in EM specificity. EM accuracy (i.e., Remember/Know task scores) also improved but only among children with high or age-appropriate language developmental levels. No effect was observed for caregiver-reported ToM (perhaps due to the short retest interval) but scores on direct tests of ToM did improve.

**Conclusions:** Parents of children with autism can be trained to use elaborative reminiscing in a relatively short period of time. Parental high elaborative reminiscing predicts improvement in children's EM and ToM, although the Remember/Know task is likely not appropriate for children with limited language. Our tentative findings suggest that caregiver elaborative reminiscing may be promising for supporting memory and social cognition in children on the autism spectrum. The results justify further study of the therapeutic potential of this novel caregiver-delivered intervention using experimental designs to address threats to internal validity.

**403.054 (Poster)** Qualitative Assessment of Autobiographical Memory in Autism Facilitates Treatment Planning of Parent-Led Interventions  
T. Hutchins<sup>1</sup> and A. Brien<sup>2</sup>, (1)UVM, Burlington, VT, (2)Speech Language Pathology, California State University, San Marcos, San Marcos, CA

---

**Background:** Autobiographical memory (ABM) is memory about the self, including facts about oneself (semantic memory [SM]) and recall for past personal experiences (episodic memory [EM]). SM and EM are integrated in typical ABM development but may diverge in autism; whereas SM appears relatively intact, disruptions in EM are well documented. Several theories have been proposed to explain ABM differences in autism and experimental research has implicated a variety of potential mechanisms and cognitive processes. Still, the most common task paradigms lack ecological validity and are not well suited for understanding how ABM in autism might operate in situations that are personally meaningful and relevant for the individual. This information is interesting from a theoretical orientation but crucial for understanding the heterogeneity and practical impact of ABM in autism and for the development of individualized interventions to support learning and cognition.

**Objectives:** The overarching question of this study was “What are parents’ impressions of their children’s ABM?” Using qualitative analysis, we sought to understand and accurately capture the testimony of parents of children with autism for two aims: 1) to understand each individual child’s ABM strengths and challenges to design family-centered interventions and 2) to identify themes across participants, to apprehend heterogeneity, and identify any new or interesting information that might emerge from the data.

**Methods:** Parents (n=31) of children with a diagnosis of autism (ages 5-13 years) completed the ABM Caregiver Interview (ABMCI) prior to their participation in an ABM parent-training intervention. The ABMCI is a semi-structured interview comprised of 12 open-ended, non-leading questions with standardized prompts. Initial questions are intentionally broad to be as inclusive as possible with regard to the potential variation in responses. Subsequent questions solicit information about specific ABM dimensions (e.g., detail, source, spontaneity) to capture the complex nature of ABM and inform treatment planning. ABMCI responses were analyzed using an inductive, open-coding process. In an initial analysis, ABMCI data were scrutinized by survey item and subthemes were developed to examine each topic across respondents. In a second phase, overarching themes were identified that cut across the data set as a whole.

**Results:** Parents provided information helpful for tailoring the specific recommendations made during parent training and for their subsequent implementation of the intervention. Preliminary analyses revealed the following themes in parents’ responses to the ABMCI: 1) relative strength in SM in the presence of impoverished EM, 2) a facilitative effect of task support, and 3) high degrees of variability in functions theoretically related to ABM (e.g., future thinking, spatial orientation). Some surprising reports also emerged (e.g., difficulty with the concept of time, memory/fantasy confusions).

**Conclusions:** Parents possess a high degree of insight into the nature of their child’s memory and this information is helpful in the development of family-centered interventions to support ABM in children on the spectrum. The themes identified in parent testimony largely corroborated existing research. Still, heterogeneity in the parent’s reports involving the quality of ABM and ABM-related functions was notable and points to directions for future research.

#### **403.055 (Poster) Quality Assessment of Intervention Studies for Transition-Age Autistic Youth**

**K. Bottema-Beutel<sup>1</sup>, S. Crowley<sup>1</sup>, S. Y. Kim<sup>2</sup>, S. Mohiuddin<sup>1</sup>, Q. Yu<sup>1</sup> and P. Postek<sup>1</sup>, (1)Lynch School of Education and Human Development, Boston College, Chestnut Hill, MA, (2)Duksung Women's University, Seoul, Korea, Republic of (South)**

**Background:** Several scoping systematic reviews have attempted to evaluate literature on interventions for transition-age autistic youth, to determine whether specific practices can be identified as ‘evidence based’ (e.g., Steinbrenner, 2020). However, many of these systematic reviews do not examine whether primary studies adhere to quality standards. Meta-analytic work conducted on young children has suggested that study quality is lacking in autism intervention research, and there are too few high quality studies to reliably aggregate effect sizes (Sandbank et al., 2020). Scoping quality assessments of intervention research involving transition-age autistic youth are needed to determine the reliability of evidence supporting commonly used practices for this population.

**Objectives:** The purpose of this systematic review is to evaluate the quality of research focusing on transition-age autistic youth, and to determine if quality indicators have changed over time. We aimed to assess trends related to selection bias (randomization procedures), performance bias (masking participants and procedural fidelity), detection bias (masking of assessors and coders and adequate data collection), and adverse event reporting.

**Methods:** Systematic search procedures were conducted to identify all peer-reviewed studies of non-pharmacological interventions published in English between 1970 and 2020, that included participants with a diagnosis of autism between the ages of 14-22 years. After full-text screening, 191 articles met inclusion criteria, and were coded for study quality indicators. Single-case design studies (SCDs) were evaluated using the assessment tool developed by Reichow and colleagues (2018), and group design studies were evaluated using the assessment tool developed by the Cochrane Collaboration (Higgins et al., 2011). To identify trends regarding study quality by time period, quality indicators were aggregated separately by design type, and for studies published during the first and second half of the represented publication years. Because quality indicators vary as a function of the dependent variable, dependent variables were the unit of analysis.

**Results: (based on coding of 75% of included studies)** Included articles were published between 1984 and 2021, and the majority of studies were SCDs (90%). Study quality indicators are summarized in Figures 1 and 2; Figure 1 shows SCDs published between 1984 and 2002 (there were no group design studies in this time period). Figure 2 shows SCDs (upper panel) and group designs (lower panel) published between 2003 and 2021. Bias risks related to selection, performance, and detection remained high across years. None of the studies published between 1984 and 2002 reported on adverse events, and only 2.5% of studies published between 2003 and 2021 reported on adverse events.

**Conclusions:** Research conducted on transition-age autistic youth is lacking in quality, especially in regards to key indicators such as randomization and masking of assessors, and these issues have persisted over time. Additionally, the reporting of adverse events is nearly absent from this literature. This means that there is very little useful evidence to guide stakeholders in selecting practices that may be beneficial for transition-age autistic youth,

and virtually no basis by which to weigh potential benefits of interventions against potential harms.

**403.056 (Poster)** Remote-Delivered Listening Comprehension Intervention for Children with Autism: Feasibility and Initial Efficacy  
**A. R. Henry<sup>1</sup>, C. Conner<sup>2</sup>, M. C. Zajic<sup>3</sup> and E. J. Solari<sup>2</sup>**, (1)University of Virginia, Charlottesville, VA, (2)University of California at Davis MIND Institute, Davis, CA, (3)Curriculum, Instruction, and Special Education, Curry School of Education University of Virginia, Charlottesville, VA

---

**Background:** One in 54 children are diagnosed with autism spectrum disorder (autism), with 68% exhibiting IQs above 70 (CDC, 2020). Children with autism are often educated mainly in general education settings and frequently exhibit language and reading difficulties (Nation et al., 2006; Whalon et al., 2009), creating an educational imperative for effective practices for learners with autism. The COVID-19 pandemic created numerous disruptions in typical educational practice, revealing an increased need for evidence-based practices to support remote learning. While others have successfully piloted telehealth interventions for children with autism targeting functional skills such as social communication or behavior management (Ellison et al., 2021), there are no remote-delivered intervention studies examining academic-based skills such as reading. To fill this gap, we present data on a pilot study of the remote delivery of a listening comprehension intervention for school-aged children with autism.

**Objectives:** This study examines the feasibility and initial efficacy of remote-delivered intervention aimed at targeting listening comprehension and oral language skills for elementary-aged children with autism.

**Methods:** Fourteen children with autism (mean age 7:11) participated in researcher-led, one-on-one reading intervention sessions 2 days per week, for 11 weeks. All children had adaptive behavior ( $M=77.84$ ;  $SD = 7.75$ ; Vineland-3; Sparrow et al., 2016) and verbal IQ scores ( $M = 90.93$ ;  $SD = 14.05$ ; WASI; Wechsler, 2011) in the average range. All sessions were led over Zoom, a videoconferencing platform. The intervention program used in this study has been efficacious for learners with autism in school-based settings (Henry & Solari, 2020; Solari et al., 2020). Several amendments were made to the intervention to increase engagement online, including visual supports and the use of hand-held props. Each 30-min lesson consisted of a read-aloud (15 min), instruction in story vocabulary (5 min), and a journal activity (10 min).

**Results:** Out of all scheduled sessions, only 4% were no-shows. Procedural integrity was generally high, as instructors were able to adhere to 89.6% of the intended intervention components. All parents reported being “extremely satisfied” or “satisfied” with the implementation of the intervention and 80% reported being “extremely satisfied” or “satisfied” with their child’s progress. Wilcoxon signed-rank tests indicated that participants did not show growth on standardized measures of expressive vocabulary ( $z = -0.87$ ,  $p = 0.39$ ,  $r = -.23$ ) or narrative memory ( $z = -1.15$ ,  $p = 0.25$ ,  $r = -.31$ ). However, they demonstrated statistically significant improvement on listening comprehension,  $z = -2.06$ ,  $p = 0.04$ ,  $r = -.55$ .

**Conclusions:** The results of this study suggest that the listening comprehension intervention is feasible and potentially efficacious for children with autism. This intervention was reliably implemented remotely in short sessions and was ranked high in terms of acceptability and parent satisfaction. Additionally, this intervention targets multiple areas of concern for children with autism including oral language, vocabulary, and listening comprehension. We will discuss future directions in adapting this intervention for remote delivery for children with autism, such as the inclusion of more visual supports and increasing engagement with a virtual reward system.

**403.057 (Poster)** SPARK Research Match: Supporting Clinical Trial Recruitment  
**J. Toroney<sup>1</sup>, J. K. Law<sup>2</sup>, C. W. Lehman<sup>3</sup>, M. Sabiha<sup>3</sup>, P. Feliciano<sup>3</sup>, W. K. Chung<sup>4</sup> and S. Consortium<sup>1</sup>**, (1)Kennedy Krieger Institute, Baltimore, MD, (2)Maryland Center for Developmental Disabilities, Maryland Center for Developmental Disabilities, Kennedy Krieger Institute, Baltimore, MD, (3)Simons Foundation, New York, NY, (4)Department of Pediatrics, Columbia University, New York, NY

---

**Background:** The Simons Foundation Powering Autism Research for Knowledge (SPARK) is an online, longitudinal research study that enrolls individuals with a professional diagnosis of autism and their family members. All participants consent to be contacted about future autism research studies. To date, there are over 260,000 participants enrolled, including more than 100,000 individuals with ASD. Research Match (RM) is a core component of SPARK that facilitates study recruitment for researchers – a major challenge in clinical trials. RM services are available to researchers at no cost. In return, researchers agree to share their study data with SPARK to strengthen its core dataset.

**Objectives:**

- Describe the research match process for clinical trial recruitment
- Report recruitment metrics for clinical trials using RM services

**Methods:** The SPARK cohort is accessible to approved investigators. Applications are submitted online (<https://base.sfari.org/>) and reviewed by the SPARK participant access committee, which includes researchers and community representatives. Studies are approved to recruit for one year with the possibility of renewal. Eligible participants are identified based on study inclusion/exclusion criteria and geographic location. Participants are invited via email and respond whether they are interested in the study. Interested participants provide authorization for SPARK to share contact information with the study team. Investigators must agree to bi-directional data sharing and are required to track participant enrollment. Participant and researcher feedback are captured upon study completion.

**Results:** As of October 2021, SPARK approved 21 applications for interventional studies registered on ClinicalTrials.gov. For 16 recruiting studies (5 completed, 11 active), the number of potentially eligible SPARK participants ranged from 78 to 3,091 (median=481). Participants indicating initial interest in each study ranged from 18 to 654, with per study response rates between 8%-37%. Enrollment of SPARK participants ranged from 0 to 93

individuals, with one study reaching 70% of their overall recruitment goal. Factors associated with increased recruitment, as well as researcher and participant feedback, will be shared.

**Conclusions:** SPARK Research Match is an effective platform for supporting recruitment for autism intervention studies.

**403.058 (Poster)** School-Provided and Private Intervention Service Rates in School-Age Children with Autism with and without Co-Occurring Conditions

M. C. Zajic<sup>1</sup>, A. Manassis<sup>1</sup>, J. Pattamady<sup>1</sup> and J. Gudknecht<sup>2</sup>, (1)Health & Behavior Studies, Teachers College, Columbia University, New York, NY, (2)Human Development, Teachers College, Columbia University, New York, NY

**Background:** Children with autism spectrum disorder (ASD) represent 11% (830,000) of students served by the Individuals with Disabilities Education Act and often receive intervention services to support social, behavioral, and linguistic development in school as part of a special education plan or out-of-school through private intervention services. The intervention needs of children with ASD may differ as well due to the presence of additional co-occurring conditions, including intellectual disability (ID), attention-deficit/hyperactivity disorder (ADHD), or language disability (LD).

**Objectives:** To examine if differences exist among school-age children with ASD with and without ID, ADHD, or LD in terms of receiving school-provided or private intervention services in social skills, speech/language, and behavior services.

**Methods:** This study uses information collected from parents participating in the Simons Foundation Powering Autism Research initiative, a large database of families with verified ASD diagnoses. The current study includes four subgroups of children: 1) ASD ( $n=6,554$ ; 74% male; age=9.13[4.32]); 2) ASD+ID ( $n=491$ ; 78% male; age=9.98[5.15]); 3) ASD+ADHD ( $n=5,642$ ; 81% male; age=11.44[3.47]); 4) ASD+LD ( $n=7,790$ ; 79% male; age=7.43[3.99]). All children received special education services from their school. Parents indicated if their child had received in-school special education services or out-of-school private services related to behavior, speech/language, and/or social skills.

**Results:** 2x2 contingency tables were examined by group for each intervention. All chi-square tests were significant ( $p<.001$ ); effect sizes varied by group and intervention category. Largest effect sizes were found for social skills interventions ( $\Phi=0.52-0.58$ ), followed by speech language interventions ( $\Phi=0.18-0.49$ ) and behavioral interventions ( $\Phi=0.19-0.31$ ). Across groups, the overall trend showed more individuals were observed than expected in having received neither or both interventions for all interventions; in contrast, fewer individuals received a particular intervention in only one context. All four groups showed the largest effect for social skills interventions ( $\Phi=0.52, 0.51, 0.50$ , and  $0.58$  for ASD, ASD+ID, ASD+ADHD, and ASD+LD, respectively). The ASD and ASD+ADHD groups showed larger effects in speech language interventions ( $\Phi=0.42$  and  $0.49$ ) as compared to behavioral interventions ( $\Phi=0.23$  and  $0.19$ ). The ASD+ID and ASD+LD groups showed the opposite effect with a larger effect in behavioral interventions ( $\Phi=0.31$  and  $0.29$ ) compared to speech language interventions ( $\Phi=0.18$  and  $0.17$ ). Within-group findings will be discussed with reference to calculated standardized adjusted residuals.

**Conclusions:** Children with ASD often receive a wide array of interventions provided through school-based services and/or private means. Findings highlight a general trend that children are more likely to receive particular interventions in both settings as opposed to either setting. However, the size of that difference depends on both the intervention type as well as the presence and type of a co-occurring condition. Further applications to intervention services will be discussed to supporting students with ASD with and without co-occurring conditions.

**403.059 (Poster)** Sexuality and Relationship Education for Autistic Adults: A Pilot Program Based on an Evidence-Based Teen Model

E. T. Crehan<sup>1</sup>, J. N. Barstein<sup>2</sup>, L. Stephens<sup>3</sup>, K. Greaves-Lord<sup>4</sup> and L. P. Dekker<sup>5</sup>, (1)Eliot-Pearson Department of Child Study & Human Development, Tufts University, Medford, MA, (2)The Help Group - University of Los Angeles, California, Los Angeles, CA, (3)The Help Group, Sherman Oaks, CA, (4)Child and Adolescent Psychiatry/Psychology, Erasmus MC-Sophia Children's Hospital, Rotterdam, Netherlands, (5)Erasmus MC - Sophia Children's hospital, Rotterdam, Netherlands

**Background:**

Sexuality and relationship education (SRE) programming geared toward autistic adults is limited. Too often, autistic adults report wanting information about topics that are not commonly covered in SRE programs, including gender identity, sexual orientation, and the social aspects of relationships (Brown-Lavoie et al., 2014; Hillier et al., 2020; Strunz et al., 2017). An evidence based SRE program for autistic teens (Tackling Teenage Training; TTT, Visser et al., 2017) was adapted for use with adults.

**Objectives:**

To measure the impact of an SRE program based on an evidence-based adolescent SRE program, for autistic adults

To identify areas of strength and weakness for future iterations of group programming

**Methods:**

First, the TTT curriculum was adapted to meet the learning needs of autistic adults, and to a virtual group format. The number of exercises was reduced, and didactic sections were shortened for some topics (e.g., reproduction, basic puberty information) and more information about gender

identity and sexual orientation was included (e.g., introducing the gender unicorn). Then, 11 autistic adults participated in a 16-week program (10 men, 1 woman). Participants completed a modified Teen Transition Inventory (TTI; Dekker et al., 2017) pre and post program, as well as qualitative ratings each week on the relevance, novelty, and interest in hearing more about each topic.

#### Results:

Five TTI subscales (identified prior to analyses due to relevance to the adult programming) compared pre and post. Three subscales within the Psychosexual socialization domain, Friendship Skills, Perceived romantic competence/romantic ability, and Personal openness about intimacy, all improved compared to the pre-program assessment. A fourth scale within that domain, Social acceptance by peers, got worse over the course of the program. Within the psychosexual selfhood domain, Perceived social competence/Relational confidence also improved post program. Of note, these comparisons are simply trends due to the small sample size for this pilot. Weekly and overall ratings of the program were high. Online dating and Masturbation resulted in the highest relevance ratings, novelty was highest for Online dating and Terms relating to identity/Intersex, and interest in learning more was highest for Masturbation and Gender identity/sexual attraction. Most enjoyed aspects of the training were “role-playing” and “hearing different perspectives/discussions.” Participants identified discussion of peer pressure and emotions in relationships as additional topics they would like to see covered.

#### Conclusions:

TTI results are preliminary but promising; future work should explore whether observed improvements in scores persists in larger groups. For this early stage of this group program adaption, the qualitative results are key to capture stakeholder interest in the program. Highly rated topics were consistent with previous research on what autistic adults want from a sexuality and relationship program (Crehan et al., 2021). This indicates that the teaching materials were of interest and on topics that were important to the adults. Future programming should incorporate areas identified by the participants as currently missing, and should utilize the teaching tools (e.g., role play and discussions) identified as useful by the participants.

**403.060 (Poster)** Systematic Review and Meta-Analysis on Psychotherapeutic Interventions for Co-Occurring Symptoms of Depressive-, Anxiety- and Obsessive-Compulsive Disorders in Autism Spectrum Disorder

*R. H. Wichers, L. C. van der Wouw, M. Brouwer, A. Lok and C. Bockting, Department of Psychiatry, Amsterdam UMC, Amsterdam, Netherlands*

---

#### Background:

The most frequently co-occurring psychiatric disorders in autism spectrum disorder (ASD) include depressive-, anxiety- and obsessive-compulsive disorders (Meng-Chuan et al. 2019). There is evidence from previous meta-analyses that cognitive behavioural therapy (CBT) is an effective treatment for anxiety in children with ASD (Ung et al. 2015; Perihan et al. 2020). However, it is currently unclear whether: 1) other psychotherapeutic interventions are effective, and 2) CBT is effective for adults or for treating other psychiatric problems that affect individuals with ASD.

#### Objectives:

To systematically review any form of psychotherapeutic intervention for co-occurring symptoms of depression, anxiety and OCD in children and adults with ASD.

#### Methods:

Database searches were undertaken until May 2021 using EMBASE, PsycINFO and PubMed. Only randomized controlled trials (RCT) published in peer-reviewed journals were included investigating any form of psychotherapeutic intervention. If 3 or more RCTs were available, a meta-analysis was conducted. Subgroup analyses were performed to compare individual versus group therapy and family-based versus non-family-based therapy.

#### Results:

For CBT 26 RCTs ( $n = 1251$ ), and for social skills interventions 6 RCTs ( $n = 217$ ) met criteria for inclusion. For other psychotherapeutic treatments less than 3 RCTs were available and they were therefore excluded. The pooled effect sizes were moderate for reduction in anxiety symptoms in children ( $g = 0.53$ ), which was most extensively studied (21 RCTs) and small for reduction in depressive symptoms in adults ( $g = 0.43$ ), including 4 RCTs. For OCD symptoms, 3 RCTs were available with mixed age groups, yielding a moderate effect size ( $g = 0.59$ ). There was no difference in overall effect size between individual and group CBT design (both  $g = 0.56$ ). However, combined individual and group sessions resulted in a lower effect size CBT ( $g = 0.23$ ). Pooled effect size of family-based CBT ( $g = 0.90$ ) exceeded non-family-based CBT ( $g = 0.27$ ). For social skills interventions overall effect sizes were small for reduction of anxiety symptoms ( $g = 0.38$ ) and moderate for reduction of depressive symptoms ( $g = 0.62$ ) in children with ASD.

#### Conclusions:

Current available evidence for psychotherapy in individuals with ASD suggests that CBT is an effective treatment for reducing anxiety symptoms in children and to a lesser extent for depressive symptoms in adults. Furthermore, social skills interventions are mildly effective for reducing anxiety symptoms and moderately effective for depressive symptoms in children with ASD. For CBT, it is recommended to apply a family-based approach. As most studies were conducted in children, more future studies should focus on adults with ASD. Also, other psychotherapeutic interventions frequently applied in clinical settings in ASD (e.g. mindfulness based cognitive therapy) should be included in future trials.

**403.061 (Poster)** Systematic Review: Emotion Dysregulation and Challenging Behavior Interventions for Children and Adolescents with Autism with Graded Key Evidence-Based Strategy Recommendations

*H. J. Nuske<sup>1</sup>, A. Young<sup>1</sup>, F. Khan<sup>2</sup>, E. Palermo<sup>1</sup>, B. Ajanaku<sup>1</sup>, M. Pellecchia<sup>1</sup>, G. Vivanti<sup>3</sup>, C. A. Mazefsky<sup>4</sup>, L. Brookman-Frazee<sup>5</sup>, J. McPartland<sup>6</sup>, M. S. Goodwin<sup>7</sup> and D. S. Mandell<sup>1</sup>, (1)Penn Center for Mental Health, University of Pennsylvania, Philadelphia, PA, (2)Sociomedical Sciences Department, Mailman School of Public Health, Columbia University, New York, NY, (3)A.J. Drexel Autism Institute, Drexel University,*

**Background:** Challenging behavior, behavior that is dangerous to the learner or others or interferes with learning or development, such as aggressive or injurious behaviors towards self or others, is common in children and adolescents with autism and can have a devastating impact. Emotion dysregulation is a common feature related to these behaviors. These youth often have difficulty employing proactive emotion regulation and coping strategies. There is a growing body of research in emotion dysregulation in ASD, and several reviews of challenging behavior interventions; however, these reviews have not included group designs or interventions that target emotion dysregulation.

**Objectives:** We systematically reviewed behavioral and psychosocial interventions targeting emotion dysregulation and challenging behavior to determine which evidence-based strategies have the most empirical support in children and adolescents with autism.

**Methods:** We identified 105 eligible studies (84% agreement;  $\kappa = .61$ ), including 28 group designs, 65 single-case designs, and 12 case reports/series on interventions for preschool children to adolescents. We excluded non- psychosocial interventions, interventions tested on adults only, or targeting internalizing symptoms only. We applied a coding system to identify discrete strategies based on well-established autism practice guidelines from the National Clearinghouse on Autism Evidence and Practice (NCAEP), including common strategies among childhood mental disorders. We used an evidence grading system for discrete strategies across studies (Harbour & Miller, 2001) and focused our analysis on strategies from RCTs (rated as 1+ or 1- based on study design rigor).

**Results:** Most studies included preschool (27%) or elementary school (56%) students. Only 11% involved middle school students and 5% high school students. Around one-third of studies report on race/ethnicity and IQ. Those that did documented some diversity (61% white) and variability in IQ (57% included children/adolescents with below-average IQ). Most studies (89%) found a positive effect on behavior or emotion dysregulation outcomes. The five strategies with the most substantial evidence (from 10+ group design studies including multiple RCTs rated 1+ [with low risk of bias]; see Figure 1) were Parent-Implemented Intervention, Emotion Regulation Training, Reinforcement, Visual Supports, and Antecedent Based Interventions. Only 23% of null/negative effect studies performed a Functional Behavioral Assessment (FBA) to inform strategy selection, and only 12% of studies included outcome measures on emotion dysregulation/regulation.

**Conclusions:** Many of the strategies targeting challenging behavior or emotion dysregulation teach replacement skills and techniques to reduce stress indirectly. This review highlights the importance of explicitly teaching emotion-regulation skills to children and adolescents with autism, positively reinforcing replacement or alternative behaviors, providing visual aids, addressing stressors proactively, and involving parents in treatment. It also underlines the importance of conducting an FBA to inform strategy selection and calls for more rigorously designed studies that include emotion dysregulation as an outcome/mediator in future intervention studies.

#### **403.062 (Poster) Facing Your Fears on Campus: Development of a Group-Based Anxiety Intervention for College Autistic Students**

**B. Freedman<sup>1</sup>, J. Monahan<sup>2</sup>, K. L. Baldwin<sup>3</sup>, C. Edmondson<sup>3</sup>, S. Mazza<sup>2</sup> and B. Blumenthal<sup>4</sup>,** (1)Center for Disabilities Studies, University of Delaware, Newark, DE, (2)University of Delaware, Newark, DE, (3)Spectrum Scholars, University of Delaware, Newark, DE, (4)University of Delaware Center for Disabilities Studies, Newark, DE

---

**Background:** Autistic college students often identify mental health support as an unmet need on college campuses (Monahan et al., 2021). While there has been an increase in recent support at colleges and universities specifically designed for autistic people, these often do not include mental health interventions (Cox et al., 2020). Considering the high rates of mental health challenges of college students in general (CCMH, 2021), and the high prevalence rates of mental health challenges among autistic people specifically (Hollocks et al., 2019), the development of evidence-based interventions to support autistic college students represents an urgent need. There are a growing number of evidence-based mental health interventions for children and adolescents on the autism spectrum (e.g., Reaven et al., 2011). While these can be considered for modification for use with college autistic students, this should be done in collaboration with autistic people.

**Objectives:** The purpose of this study was to:

- Adapt an existing mental health intervention (Facing Your Fears) for use with college autistic students.
- Utilize participatory action research strategies to ensure that the adaptations and modifications of the intervention were informed by the end users.
- Examine individual changes of participants following a 15-week pilot of the intervention.

**Methods:** The FRAME system (Stirman et al., 2019) was used to develop adaptations and modifications to Facing Your Fears (Reaven et al., 2011), an evidence-based intervention for autistic youth experiencing anxiety. Once a draft of the full intervention ("Facing Your Fears on Campus") was finalized, a pilot was conducted with three autistic undergraduate students enrolled at the University of Delaware using an iterative, participatory approach. Pre-/Post-assessment included the measurement of mental health challenges using the CCAPS-62 and the Anxiety Scale for Autism-Adults (Locke et al., 2011; Rodgers et al., 2020). Evaluative feedback was collected after each session from the intervention facilitators and participants to promote a feedback system to guide additional modifications. Continuous meetings with an Autistic Advisory Panel also ensured that the intervention was designed to meet the needs of autistic college students. At the completion of the semester (December 2021), we will conduct a focus group with the intervention participants to learn about the benefits and areas for improvement as identified by the students.

**Results:** Preliminary feedback from treatment facilitators and participants, as well as the Autistic Advisory Panel, suggest that the treatment was well-designed in terms of being appropriate for this population. Individual scores on the two mental health measures conducted pre-/post-treatment will be examined upon completion of the pilot (December 2021) and shared in order to consider the intervention's preliminary efficacy.

**Conclusions:** Continued research is needed on the development of mental health interventions that directly target the needs of autistic college students and are informed by autistic people. Additional modifications for Facing Your Fears on Campus, based on the results of this pilot, will be described. Researchers will also share how these modifications were incorporated into future implementation including a Randomized Controlled Trial using a wait-list control group (anticipated Spring 2022).

**403.063 (Poster)** Telehealth Delivery of the Secret Agent Society Group Social Skills Program during COVID-19

**A. Constantine<sup>1</sup>, T. Filstein<sup>1</sup>, C. A. Mootz<sup>1</sup>, A. Lemelman<sup>2</sup>, J. Giordano<sup>3</sup>, J. Winter<sup>2</sup> and R. B. Beaumont<sup>3</sup>,** (1)Weill Cornell Medicine, White Plains, NY, (2)Psychiatry, Center for Autism and the Developing Brain, White Plains, NY, (3)Child and Adolescent Psychiatry, Weill Cornell Medicine, New York Presbyterian Hospital, New York, NY

---

**Background:** Autism Spectrum Disorder (ASD) is characterized by peer socialization difficulties. In-person social skills groups, such as the Secret Agent Society (SAS), are a common evidence-based approach to addressing these challenges in children. However, COVID-19 has severely disrupted these services. The effectiveness of telehealth delivered social skills groups is largely unknown, with published papers lacking autism-specific samples (Gale, Greenberg & Ireland, 2021) or providing no indication of program outcomes (MacEvilly & Brosnan, 2020). This issue requires urgent attention given the potential of COVID-19 to exacerbate the social impairments of children on the spectrum.

**Objectives:** This pilot project aimed to explore advantages, disadvantages, considerations and recommendations for telehealth delivery of a SAS social skills group. It also aimed to examine how the intervention impacted children's re-entry experience after COVID-19 social distancing restrictions were eased.

**Methods:** Five children, 3 boys and 1 girl, with ASD (mean age = 9 years, 1 month; range=8;7-9;11) and their parents participated in SAS via telehealth from October 2020 to March 2021. Eighteen weekly 45-minute online parent- and child-group sessions were run concurrently according to the manualized CBT protocol. Within 3 months of the program ending, participants were asked to complete a qualitative feedback questionnaire about the program, how it impacted their re-entry experience as social distancing restrictions eased, and the pros and cons of the telehealth format.

**Results:** Four of the five children noted that SAS helped them deal with challenges (e.g., bullying) and improved their emotion regulation skills. The fifth child reported that he felt more confident to speak up in SAS group and at school. Two parents also noted improvements in their children's emotion regulation skills, knowledge of coping skills, emotional intelligence, and problem-solving skills. One parent reported that while the transition back to in-person school was challenging, SAS helped their child adapt.

Two children commented that they enjoyed connecting with peers online during a time of limited social contact. Two parents also expressed gratitude for the program's availability when most other social groups were unavailable. Two parents reported that the telehealth format was more accessible and convenient than in-person services. One child also described liking the ability to share favorite objects virtually in-session.

Despite these strengths, two parents and two children expressed a preference for in-person group meetings. Technical difficulties were a telehealth challenge noted by two children, and two parents commented on their children struggling to stay focused virtually. Recommendations for improvement included providing more informal socialization opportunities for children and parents in telehealth sessions and subdividing the child group into smaller break-out rooms to provide more opportunities for active participation.

**Conclusions:** Pending further empirical investigation, telehealth social skills groups hold promise in supporting the social skill development of children with ASD during COVID-19 and beyond. Program engagement and satisfaction may be enhanced by creating in-session opportunities for informal socialization for children and parents, proactively providing tech support for families and incorporating popular multi-player games into child group sessions.

**403.064 (Poster)** The Effect of a Music-Making Program on Student-Teacher Relationships in Adolescents on the Autism Spectrum and with Intellectual Disability.

**M. Kaedbey<sup>1</sup>, C. Sim<sup>1</sup>, H. Dahary<sup>1</sup> and E. M. Quintin<sup>2</sup>,** (1)McGill University, Montreal, QC, Canada, (2)Educational & Counselling Psychology, McGill University, Montreal, QC, Canada

---

**Background:** Research has demonstrated that student-teacher relationships (STRs) are critical for academic and social adjustment within a school setting. STRs are a predictor of concurrent and long-term adjustment, and are important for behavioral, social, and emotional development. STR quality of students on the AS is relatively poor, with decreased closeness and increased levels of conflict when compared to students with typical development (TD) and students with intellectual disability (ID). However, students on the AS who can develop quality relationships with their teachers are more likely to have positive developmental outcomes, such as more social inclusion and less problematic behaviour in the classroom. Preliminary evidence suggests that music programs can foster measurable improvements in student-teacher relations. Given that musical interests and abilities have been shown to be a relative strength for people on the AS, student-teacher relationships of students on the AS may benefit from music programs.

**Objectives:** This study aimed to test whether the joint participation of students and teachers in a school-based 11-week music-making program could yield a change in teacher-perceived student-teacher closeness and conflict, as well as show differences in the proportion of change between students on the AS and with ID.

**Methods:** Thirty-seven adolescent participants with ASD (n= 25) or ID (n= 12) participated in this study implemented in a high school setting. Four classrooms comprised of 6 to 14 students and 3 classroom teachers each followed an 11-week music-making curriculum instructed by a community organization of music teachers who conduct school-based music programs for children and adolescents with developmental disorders. Students and teachers learned to play the djembe primarily as well as other percussion instruments and learned a set of 30 group dependent rhythms. Both the students' classroom and music teachers completed the Student-Teacher Relationship Scale-Short Form (STRS-SF), before and after the music program, to measure potential changes in teacher perceptions of student-teacher closeness and conflict.

**Results:** Paired-sample t-tests revealed improvements in music teacher reports of student-teacher closeness for the AS and ID groups ( $ps < .05$ ) and decreases in student-teacher conflict for the ID group ( $p < .05$ ) as a result of the music-making program. Paired-sample t-tests also showed significant improvements in the classroom teacher reports of student-teacher closeness for the AS group only ( $p < .05$ ).

**Conclusions:** Our finding of improved student–classroom teacher relationships following joint participation in a music program may stem from opportunities for reciprocal and positive interactions between students on the AS and their teachers that is inherent to group music making. Incorporating group music programs in education curricula for students on the AS can foster better student–teacher relationships, which could give rise to better social, cognitive, and academic results.

**403.065 (Poster)** The Implementation and Teaching of Health Practices for Children with Autism Spectrum Disorders during the COVID-19 Pandemic

**B. Aaronson<sup>1,2</sup>, W. McCloud<sup>1</sup>, C. Courshon<sup>1,3</sup>, E. Allen<sup>1</sup>, C. J. Kirk<sup>4</sup> and S. N. Glick<sup>5,6</sup>.** (1)UW Autism Center, University of Washington, Seattle, WA, (2)Pediatrics, University of Washington, Seattle, WA, (3)Educational Psychology, University of Washington, Seattle, WA, (4)Pharmacy, Seattle Children's Hospital, Seattle, WA, (5)Division of Allergy and Infectious Disease – Department of Medicine, University of Washington, Seattle, WA, (6)Public Health – Seattle & King County, Seattle, WA

**Background:** The Summer Treatment Program (STP) is an outpatient treatment setting which includes social skills instruction, behavior modification, and sports practice. It aims to provide a space for children with autism spectrum disorders and attention-deficit/hyperactivity disorder to practice social and behavioral skills within age-appropriate group recreational activities. The University of Washington Autism Center implemented this treatment program during the summer of 2020 in the context of the global COVID-19 pandemic.

**Objectives:** To describe the implementation, teaching, and outcomes of an outpatient summer treatment program for children with autism spectrum disorders during the COVID-19 pandemic.

**Methods:** Children were divided into groups of 7 with at least 3 counselors assigned to each group. Counselors taught and supported health practices using the existing framework of the summer treatment program, including modeling, social reinforcement, and awarding points for following activity rules, which could be used to earn small prizes.

Extensive strategies were used to reduce the risk of COVID-19 transmission. Practices included masking, physical distancing, hand-hygiene, frequent sanitization of materials and surfaces, modification of activities, daily symptom screening, and prioritizing outdoor programming. Parents reported on their satisfaction with specific practices implemented at the day treatment program. They also reported on their child's following of health practices outside of the program.

**Results:** The 2020 sample included 104 children ages 6-12 with a mean (SD) age of 8.9 (1.7) years. There were 94 unique families, and 48 (51%) completed the satisfaction survey.

Parents reported being very satisfied with the following practices implemented at the day program: 47 (96%) with the masking policy, 46 (94%) with physical distancing, 48 (100%) with hand-hygiene, 48 (100%) with frequent sanitization of materials and surfaces, 47 (98%) with modification of activities, 42 (88%) with daily symptom screening, and 48 (100%) with outdoor programming.

Parents reported improvement in the following behaviors at home by the end of the program: 36 (75%) indicated improvement in their child's masking, and 12 (25%) indicated no change. For physical distancing, 27 (56%) indicated improvement, and 20 (42%) indicated no change, and 1 (2%) indicated distancing ability worsened. For hand hygiene, 24 (50%) indicated improvement, and 24 (50%) indicated no change.

**Conclusions:** Additional strategies were necessary to implement a summer treatment program during the global COVID-19 pandemic. Children were required to learn and practice new behaviors and adjust to new norms. Our results indicate parents were overall satisfied with the implementation of health practices, and that some children were able to successfully learn and adopt new practices and generalize them to other settings. Limitations to the generalizability of these findings include a high staff-to-child ratio and a sample of children with ASD who have verbal and conversational language abilities of approximately 6 years or greater, required to meaningfully participate in this standardized summer treatment program.

**403.066 (Poster)** "What Do We Do after We Fail? We Try Again": Autistic Students' Experiences of Project Failures in an Interest-Based Afterschool Maker Program

**Background:** Extant literature encourages the inclusion of engineering concepts as a crucial part of the K-12 educational curriculum. Included in this is the Engineering Design Process (EDP), a cyclical framework that enables engineers to solve design-related challenges. This process enables engineers to identify, plan, brainstorm, collaborate, design, iterate (redesign), and finalize design solutions. As EDP includes iterations (when designs fail) as a core component of its framework, it can be taught to students as a problem-solving strategy that enables them to learn from their failures in a positive manner. We developed inclusive Maker clubs for autistic and non-autistic students with an aim to teach EDP so students can use a strength-based problem-solving approach to succeed in their design challenges.

**Objectives:** We present the experiences of autistic and non-autistic students and teachers about design failures and the use of EDP to rectify and improvise their prototypes within the Maker club context.

**Methods:** Data collection spanned between two school years 2018-2020 and data was collected from nine teachers and 26 students (17 autistic students) between grades 6-8 participating in an inclusive, interest-based Maker extracurricular program in three public middle schools in the Northeast US. Data was collected through student and teacher interviews, detailed teacher logs, researcher observations and photos.

**Results:** Thematic analysis generated four themes. (1) *Developing perseverance in face of challenges:* field observations and teacher interviews suggest that both autistic and non-autistic students demonstrated increased perseverance to work through challenges when activities resonated with their interests. Through this exercise they demonstrated improvement in emotion regulation in face of failure. (2) *Flexibility for problem-solving:* teachers' facilitation of EDP supported students' problem-solving for project failure. Positive reinforcements from teachers and peers also supported students in developing flexibility to solve design problems. Students collaborated and exchanged failure experiences and strategies, through which process they identified alternative solutions to their design problems. (3) *Resourcefulness in problem-solving:* students iteratively tested and refined their prototypes, generating highly effective design solutions that exceeded their initial design problems. Also, students used a variety of materials like cardboard, wooden blocks, design software (TinkerCAD) and 3D printers to develop solutions to their design challenges. This provided them with an array of resources to develop their final projects. Students could also seek support from teachers, makers and engineering experts who guided them through the process using the EDP. Choosing their own materials, design ideas and resources led students to develop autonomy and choice making. (4) *Accepting failure as a normal process:* students learned to accept failure as a normal process in designing and making through their shared experiences of project challenges with peers. Instead of developing a negative identity or internalizing failure, students accepted it as a routine part of the maker club experience.

**Conclusions:** Experiencing failure in design challenges fostered students' determination to overcome design challenges through adaptability and resourcefulness. A mind shift was therefore created where students didn't view failure as a negative part of their identity or lack of skills but rather a normalized routine of the maker club activities.

#### **403.067 (Poster)** Improvements in Social Skills Accompanied By Decreases in Mental Health Symptoms: A Pilot Study with UCLA PEERS Program

**C. I. Parenteau<sup>1</sup>, J. Floyd<sup>2</sup>, T. Glavin<sup>3</sup>, K. Ankenman<sup>4</sup>, E. Lin<sup>5</sup>, J. Charale<sup>6</sup>, W. Ence<sup>2</sup>, Y. S. Kim<sup>3</sup>, S. Bishop<sup>4</sup> and S. Zheng<sup>6</sup>,** (1)University of California, San Francisco, San Francisco, CA, (2)UCSF, San Francisco, CA, (3)STAR Center for ASD and NDDs, University of California San Francisco, San Francisco, CA, (4)University of California San Francisco, San Francisco, CA, (5)Department of Psychiatry and Behavioral Sciences, University of California, San Francisco, San Francisco, CA, (6)Psychiatry, University of California, San Francisco (UCSF), San Francisco, CA

---

**Background:** Social skills training (SST) is a commonly sought-after evidence-based intervention for adolescents with autism, with most improvements reported in social knowledge and skills. Some studies have explored the secondary impact of SST programs on changes in internalizing symptoms, with two studies showing decreased levels of anxiety and depression after participation in UCLA PEERS® for Adolescents social skills training program (Schohl et al., 2014; Yoo et al., 2014). But no study so far has directly explored the associations between changes in social skills and mental health symptoms as a result of SST programs.

**Objectives:** Using pre- and post-treatment data from the PEERS groups, we first examine the treatment effects on adolescents' social knowledge, skills, and mental health symptoms (i.e., anxiety, depression, and loneliness). Then we explored associations between social skills improvements and changes in mental health symptoms.

**Methods:** Thirty-nine adolescents and their caregivers participated in the eight PEERS groups between 2016-2021 (seven in-person groups, one virtual group). The sample consisted of 26 boys and 13 girls aged from 11-18 years old ( $M=14.38$ ,  $SD=1.71$ ), with 26 adolescents having a primary diagnosis of ASD (see Table 1 for sample characteristics). Participants attended 84.88% of the provided sessions on average. Multi-informant measures were completed before and after the groups: adolescents completed the Child Depression Inventory-2 (CDI-2), Loneliness and Social Dissatisfaction Questionnaire (LSDQ), and the Test of Adolescent Social Skills Knowledge (TASSK), while parents completed the Social Skills Improvement Scale (SSiS); both adolescents and parents filled out the Social Anxiety Scale (SAS) and reported numbers of get-togethers hosted.

Descriptive statistics were generated for pre- and post-treatment measures. Paired *t*-tests were conducted to examine the treatment effects on social and mental health outcomes in adolescents with autism, and correlations between change scores in social outcomes and mental health symptoms were generated.

**Results:** Adolescents showed significant positive improvements in parent-report social skills (SSiS- social skills), the number of get-togethers hosted, and self-report social skills knowledge (TASSK total score); and significant decreases in their feelings of loneliness (LSDQ total score; see Table 2 for descriptive statistics and paired t-test results on outcome measures pre- and post-treatment). Even though changes in the depression and social anxiety were not significant in response to the PEERS intervention, decreases in self-reported depression and parent-reported anxiety were associated with increases in parent-report get-togethers hosted ( $r=-0.35$  and  $-0.41$ ).

**Conclusions:** Consistent with previous studies, we observed improvements in social outcomes after participation in PEERS, together with significant decreases in self-reported feelings of loneliness. Moreover, moderate correlations indicated that increases in get-togethers hosted were associated with decreases in depressive symptoms and social anxiety. These findings provide preliminary evidence that improving social engagement with peers may result in decreased mental health symptoms in this population. Given that anxiety and depression are prevalent in adolescents with ASD and are often difficult to treat (especially depression), future studies need to investigate the potential opportunities for improving psychological well-being through increased positive social experiences, as well as associations between improvements in social skills and mental health.

**403.068 (Poster)** Comparing Telehealth and Face-to-Face (F2F) Academic, Seated Play Interventions and Their Assessment for Children with Autism Spectrum Disorder (ASD)

**A. N. Bhat<sup>1</sup>, C. Cleffi<sup>2</sup>, W. C. Su<sup>3</sup>, N. Amonkar<sup>4</sup>, S. Williams<sup>5</sup> and S. Srinivasan<sup>6</sup>,** (1)Department of Physical Therapy, University of Delaware, Newark, DE, (2)Physical therapy, University of Delaware, Newark, DE, (3)Physical Therapy, University of Delaware, Newark, DE, (4)University of Connecticut, Storrs, CT, (5)University of Delaware, Newark, DE, (6)Kinesiology, University of Connecticut, Storrs, CT

**Background:** Children with Autism Spectrum Disorder (ASD) present with significant fine-motor impairments in visuomotor integration and manual dexterity (Kaur et al., 2018). These impairments are associated with core social communication impairments and severity of repetitive behaviors (Bhat, 2021). In an ongoing randomized clinical trial (RCT), we are comparing the effects of creative, whole-body movements (or Play group) to seated play, standard-of-care interventions (or Seated Play, Su et al., 2020; Srinivasan et al., 2021).

**Objectives:** At the onset of the pandemic, the RCT design transformed from a face-to-face (F2F) intervention to offer a virtual/telehealth (TH) format of each intervention type (Play, Seated play, Bhat et al., 2021). At study conclusion, we will have an equal number of children observed in both groups (F2F and TH, N=15 per group). We have obtained feedback from all stakeholders (parents, trainers, testers, and coders) on the benefits and challenges of receiving, providing, and analyzing F2F vs. TH format of intervention delivery.

**Methods:** 30 children with ASD between 6 and 14 years participated over 10 weeks with pretests and posttests conducted during the first and tenth weeks. Children were matched on age, gender, and level of functioning and then randomly assigned to either Play or Seated Play groups. Each child received 8 weeks of training @ 2 sessions/week conducted with an expert trainer and an adult model. The Play group engaged in instrument play promoting imitation/synchrony and bimanual coordination skills. The SP group engaged in tabletop activities such as reading, building, and art-crafts to promote social communication and fine motor skills. Each stakeholder group completed questions based on a 5-point Likert scale to rate the feasibility, acceptability, challenges, and validity of the interventions offered in each format (F2F or TH). Additionally, we will compare percent of socially-directed verbalization, session length, and effect sizes for motor outcomes using Bruininks-Oseretsky Test and task-specific coordination measures.

**Results:** Based on our preliminary analysis of parent and trainer surveys, parents and trainers reported that both formats were feasible and acceptable. Parents felt that they received appropriate training, instructions, and materials to complete the training sessions. For children needing more support, greater parent effort and reduced child engagement was reported for the TH delivery format. We hypothesize that the magnitude of fine-motor intervention effects will not differ between TH and F2F formats as long as a drawing model and parent-led instructions are provided. The TH format of intervention delivery will promote more parent-child interactions whereas the F2F format of intervention delivery promotes more expert-child interactions.

**Conclusions:** The study will add to our past studies (Srinivasan et al., 2015, 2016a, 2016b, Kaur & Bhat, 2021) showing the value of seated play to facilitate social communication and fine motor skills of children with ASD. Moreover, we will add to the evidence on efficacy and feasibility of telehealth-based social communication, academic, and fine-motor interventions. Speech and occupational therapists/special educators may consider conducting certain types of fine-motor/speech assessments via telehealth (natural conversations, manual dexterity and building tests) as an alternative to F2F interventions during future pandemics.

**403.069 (Poster)** Comparing Telehealth and Face-to-Face Creative Movement Interventions and Associated Assessments in Children with Autism Spectrum Disorder

**M. Spearing<sup>1</sup>, W. C. Su<sup>2</sup>, C. Cleffi<sup>3</sup>, N. Amonkar<sup>4</sup>, S. Williams<sup>5</sup>, S. Srinivasan<sup>6</sup> and A. N. Bhat<sup>7</sup>,** (1)University of Delaware, Newark, DE, (2)Physical Therapy, University of Delaware, Newark, DE, (3)Physical therapy, University of Delaware, Newark, DE, (4)University of Connecticut, Storrs, CT, (5)Kinesiology, University of Connecticut, Storrs, CT, (6)Department of Physical Therapy, University of Delaware, Newark, DE

**Background:** Children with Autism Spectrum Disorder (ASD) demonstrate core impairments in social communication as well as comorbid impairments in praxis and imitation/interpersonal synchrony (APA, 2013; Kaur et al., 2018). In an ongoing randomized clinical trial (RCT), we are comparing the effects of a creative movement intervention (CM) and a standard of care, seated play intervention (SP) for children with ASD (Srinivasan et al., 2021, Bhat et al., 2021).

**Objectives:** At the onset of the pandemic, our RCT design was transformed from a face-to-face (F2F) intervention to offer a virtual/telehealth (TH) format for both intervention types (CM, SP). We have about an equal number of children observed in both groups (F2F and TH, N=15 per group) and

have obtained feedback from all stakeholders (parents, trainers, testers, and coders) on the benefits/challenges of receiving, providing, and analyzing F2F vs. TH intervention delivery format for the CM and SP interventions.

**Methods:** 30 children with ASD between 6 and 14 years were matched on age, gender, and level of functioning then randomly assigned to either CM or SP groups. Each child received 2 training sessions per week for 8 weeks. Pre- and post-tests were conducted before and after the training period. The CM group engaged in music, dance, and yoga-based activities promoting imitation/synchrony, bilateral/multilimb coordination, and balance skills; while the SP group engaged in tabletop activities such as reading, building, and art-crafts to promote academic, communication, and fine motor skills. Each stakeholder group completed questions based on a 5-point Likert scale to rate the feasibility, acceptability, challenges, validity, and efficacy of the interventions offered in each delivery format (F2F or TH). Additionally, we assessed session length and effect sizes for praxis/imitation, coordination, and balance performance using standardized Bruininks-Oseretsky Test of Gross Motor Development and Sensory Integration and Praxis Tests as well as task-specific yoga pose imitation and interpersonal synchrony measures.

**Results:** Based on our preliminary results from parent/trainer surveys, both delivery formats are feasible with their own pros and cons. For the TH delivery format, parents reported decreased effort in traveling between sites, and more opportunities for parent-child interactions but more challenges in demonstrating/adjusting their child's movements during imitation tasks, and maintaining synchrony during interpersonal synchrony tasks. We hypothesize that TH intervention will have lower intervention effects on some measures (imitation accuracy and synchrony) but not others (motor coordination, balance, etc.).

**Conclusions:** The study will add to the mounting evidence from our lab (Kaur & Bhat, 2019, 2021; Srinivasan et al., 2015, 2016a, 2016b) on the value of using creative movement in addressing comorbid motor and social impairments in ASD. Moreover, we will add to the pre-pandemic evidence on the efficacy of telehealth-based interventions and their feasibility, acceptability, challenges, and test validity.

**Clinical Relevance:** OTs, PTs, and adaptive physical educators could use creative movement interventions to target a variety of motor and social communication skills in children with ASD. Both TH and F2F are feasible training delivery formats and should be chosen carefully based on the family's preference.

**403.070 (Poster)** Comparing Telehealth and Face-to-Face (F2F) General Movement Interventions & Their Assessment in Children with Autism Spectrum Disorder (ASD)

S. Williams<sup>1</sup>, C. Cleffi<sup>2</sup>, N. Amonkar<sup>3</sup>, W. C. Su<sup>4</sup>, S. Srinivasan<sup>5</sup> and A. N. Bhat<sup>6</sup>, (1)University of Delaware, Newark, DE, (2)Physical therapy, University of Delaware, Newark, DE, (3)University of Connecticut, Storrs, CT, (4)Physical Therapy, University of Delaware, Newark, DE, (5)Kinesiology, University of Connecticut, Storrs, CT, (6)Department of Physical Therapy, University of Delaware, Newark, DE

Background: Children with Autism Spectrum Disorder (ASD) demonstrate significant motor impairments in visuomotor and body coordination, agility, and strength (Srinivasan et al., 2018). These motor impairments are associated with core social communication impairments and severity of repetitive behaviors (Bhat, 2021). In an ongoing randomized clinical trial (RCT), we are comparing the effects of a general movement (or Move Group) intervention and seated play, standard of care interventions for children with ASD (or Seated Play, Cleffi et al., 2021).

Objectives: At the onset of the pandemic, our RCT design was transformed from a face-to-face (F2F) intervention to offer a virtual/telehealth (TH) format for both intervention types (Move, Seated Play, SP). We have an about equal number of children observed in both groups (F2F and TH, N=15 per group, 30 total). We have obtained feedback from all stakeholders (parents, trainers, testers, and coders) on the benefits and challenges of receiving, providing, and analyzing F2F vs. TH format of intervention delivery for the movement and standard of care interventions.

Methods: 30 children with ASD between 6 and 14 years participated over 10 weeks with pretests and posttests conducted during the first and tenth weeks. Children were matched on age, gender, and level of functioning and then randomly assigned to either Move or Seated Play (SP) groups. Each child received 8 weeks of training @ 2 sessions/week conducted with an expert trainer and an adult model. The Move group engaged in strengthening exercises, ball games, and obstacle courses to promote strength, agility, and dual-limb coordination skills. The SP group engaged in tabletop activities such as reading, building, and art-crafts to promote academic, communication, and fine motor skills. Each stakeholder group completed questions based on a 5-point Likert scale to rate the feasibility, acceptability, challenges, and efficacy of the intervention formats (F2F or TH). We will report differences in session length as well as effect sizes for motor outcomes using Bruininks-Oseretsky Test, Test of Gross Motor Development and task-specific strength and coordination measures.

Results: Based on our preliminary analysis of parent and trainer surveys, parents and trainers reported that both formats were feasible and acceptable. Parents felt that they received appropriate training, instructions, and materials to complete the training sessions. For children needing more support, greater parent effort and reduced child engagement was reported for the TH delivery format. We hypothesize that the magnitude of intervention effects will not differ between TH and F2F format. The TH format of intervention delivery will promote more parent-child interactions whereas the F2F format of intervention delivery promotes more expert-child interactions.

Conclusions: This study will build on our past work (Kaur & Bhat, 2019, 2021; Srinivasan et al., 2015, 2016a, 2016b) to support use of general movement interventions in addressing comorbid motor impairments in ASD. Moreover, we will gather evidence on the efficacy of telehealth interventions and their feasibility, acceptability, challenges, and test validity. Gross-motor interventions should be included in the standard-of-care for children with ASD and movement clinicians (OTs/PTs) should be motor advocates for this population.

**403.071 (Poster)** Effects of a Rhythm-Based, Creative Movement Intervention on Gross-Motor Coordination, Locomotor Skills, and Functional Strength of Children with ASD

**Background:** 87% of school-age children with Autism Spectrum Disorder (ASD) are at risk for motor coordination impairments which contribute to increased sedentary behavior time and decreased physical activity (Bhat, 2020). In our past studies, musical or yoga-based interventions led to generalized and task-specific improvements in gross-motor performance (Srinivasan et al., 2015; Kaur & Bhat, 2019). The present study includes another whole-body, Creative Movement (CM) intervention combining music, dance, and yoga, as well as a standard-of-care, Sedentary Play (SP) intervention focused on fine-motor skills and reading.

**Objectives:** We will compare the effects of the CM and SP interventions on the gross-motor coordination, locomotor skills, and functional strength performance of children with ASD. Due to the COVID-19 pandemic, our team provided the CM and SP interventions face-to-face as well as via telehealth and we plan to compare the effects of the different delivery methods on motor skill improvement as well.

**Methods:** The study included 30 children with ASD between 5 and 14 years of age. Each child was seen for 10 weeks with pretests and posttests conducted during the first and tenth weeks. The children were matched on age, gender, and level of functioning and then randomly assigned to either the CM or SP group. Each child received 2, ~1hr training sessions per week over 8 weeks. The CM group engaged in whole-body, music, dance, and yoga-based activities promoting interpersonal synchrony, visuo-motor, bilateral, and multi-limb coordination, as well as postural control and balance skills. The SP group engaged in tabletop activities such as reading, building, and arts and crafts to promote social interactions and develop fine motor skills. The Bruininks-Oseretsky Test of Motor Proficiency, Test of Gross-motor development were administered as a pre- and post-test. We also measured training-specific changes in whole-body coordination and locomotor skills during an early and late training session to assess movement form/modulation.

**Results:** Preliminary data from a subset of 13 children suggests significant generalized training improvements in running speed and agility (CM pretest =13.42(10.63); CM posttest=19.86(13.50),  $p<0.05$ ), bilateral coordination (CM pretest =18.57(5.41); CM posttest=20.86(4.18),  $p<0.01$ ), strength (CM pretest =9.71(5.50); CM posttest=15.57(4.65),  $p<0.05$ ), as well as locomotor (CM pretest =35.71(6.05); CM posttest=42(5.72),  $p<0.001$ ) skills on the BOT & TGMD standardized tests. Whole-body coordination analysis showed that CM group spent maximum time in multilimb coordination during the Moving Game (50.02%) and Yoga (36.98%) compared to other conditions (3-15.5%). 7-8 / 9 children showed improved multilimb coordination during the late session vs. an early session in the warmup (late-early% = 6.4) and yoga (late-early% = 6.9%) conditions.

**Conclusions:** CM interventions can be used to promote gross-motor coordination, locomotor skills, and functional strength in children with ASD. PTs/OTs working with children with ASD can use creative movement approaches to target their clients' motor coordination/locomotor skills. This work will provide the support for inclusion of whole body, rhythmic movement experiences in the standard-of-care for ASD.

#### **403.072 (Poster) Effects of a Whole-Body Exercise Intervention on Gross-Motor Skills and Functional Strength of Children with ASD**

C. Cleffi<sup>1</sup>, N. Amonkar<sup>2</sup>, W. C. Su<sup>3</sup>, S. Srinivasan<sup>4</sup> and A. N. Bhat<sup>5</sup>, (1)Physical therapy, University of Delaware, Newark, DE, (2)University of Connecticut, Storrs, CT, (3)Physical Therapy, University of Delaware, Newark, DE, (4)Kinesiology, University of Connecticut, Storrs, CT, (5)Department of Physical Therapy, University of Delaware, Newark, DE

---

**Background:** 87% of school-age children with Autism Spectrum Disorder (ASD) are at risk for motor coordination impairments which create a significant barrier for adaptive functioning (Bhat, 2020). Postural strength and control are lacking in this population, but are important for broader movement goals, social interactions, and activities of daily living (Bhat et al., 2010). In our past studies, creative and rhythmic whole body interventions led to generalized improvements in gross-motor performance.

**Objectives:** The present study expands on this work by testing a General Movement (GM) intervention combining strength, endurance, and flexibility exercises versus a Sedentary Play (SP) intervention focused on fine motor and academic skill development. We will compare the effects of the GM and SP interventions on the gross-motor coordination and functional strength of children with ASD. Due to the COVID-19 pandemic, our team provided the GM and SP interventions face-to-face as well as via telehealth, so we will also compare the effects of the different delivery methods.

**Methods:** 30 children with ASD between 5 and 14 years were seen for 10 weeks with pretests and posttests conducted during the first and tenth weeks. The children were matched on age, gender, and level of functioning and then randomly assigned to either GM or SP groups. Each child received 2, ~1hr training sessions per week over 8 weeks. The GM group engaged in whole-body obstacle course games, strength exercises, and ball skill activities in a turn-taking format to promote social reciprocity, visuo-motor, bilateral and multi-limb coordination, functional strength and endurance, flexibility, and locomotor and agility skills. The SP group engaged in tabletop activities such as reading, building, and arts and crafts to promote social interactions and develop fine motor skills. The Bruininks-Oseretsky Test of Motor Proficiency Strength Subtest was administered as a pre- and post-test. In addition, upper and lower body strength was assessed at pretest and posttest as well as during training sessions (early, mid, late) using multiple functional exercises. Specifically, we coded for changes in movement modulation, movement quality, and form during these exercises.

**Results:** Preliminary data from a subset of participants in the GM group suggests improvements in the BOT Strength subtest (Mean(SE): Pretest =11.85(3.49); Posttest=16.57(3.33),  $p<0.05$ ). We also found improvements in movement modulation and movement form during performance of upper and lower body strength exercises both within and outside the training context. We hypothesize that the GM group will demonstrate more

gross-motor coordination and functional strength improvements on standardized and training-specific outcomes compared to the SP group who will demonstrate more fine-motor improvements.

**Conclusions:** This study highlights the value of whole-body exercise interventions to promote gross-motor coordination and functional strength in children with ASD. Moreover, we will also assess the effectiveness of delivering GM interventions using telehealth platforms and provide best practice guidelines. This work provides the support for inclusion of whole-body movement interventions in the standard-of-care for ASD. Movement clinicians (OT, PTs) should be motor advocates for their clients with ASD to target gross motor skill impairments.

**403.073 (Poster)** Appropriateness, Acceptability, and Feasibility of a Neurodiversity-Based Self-Determination Program for Autistic Adults  
**T. A. M. McDonald<sup>1</sup>, S. Lalan<sup>2</sup>, I. Chen<sup>3</sup>, C. Cotton<sup>3</sup>, L. Jeradeh Boursoulain<sup>4</sup> and B. A. Malow<sup>1</sup>,** (1)*Sleep Disorders Division, Department of Neurology, Vanderbilt University Medical Center, Nashville, TN, (2)Neurology, Vanderbilt University Medical Center, Nashville, TN, (3)Vanderbilt University Medical Center, Nashville, TN, (4)Department of Pediatrics, Vanderbilt University Medical Center, Nashville, TN*

---

**Background:** Many autistic adults without a co-occurring intellectual disability struggle with transitioning out of high school and face a “services cliff” as they deal with the demands of adulthood, such as employment, education, physical health and wellbeing, living arrangements, transportation, and social relationships. Autistic adults may benefit from self-determination support to address these challenges, since greater self-determination is associated with positive transition outcomes related to employment, socialization, advocacy, positive identity, and stress management. However, previous research on self-determination programs have reported high attrition and low acceptability. Since autistic adults vary greatly in their characteristics, needs, and resources, a one-size-fits-all model for self-determination may be untenable for this population which may require a more person-centered approach.

**Objectives:** To determine the feasibility, acceptability, and appropriateness of a neurodiversity-based self-determination program designed to support autistic adults in the pursuit and attainment of self-determined goals.

**Methods:** We designed a multi-component (goal setting, self-care, self-advocacy, mindfulness-based stress reduction, community engagement, and coaching) self-determination program, grounded in the neurodiversity paradigm, to help autistic adults achieve goals to improve their quality of life. The first phase involved five days of psychoeducation, practice, and social events; the second phase included three months of telecoaching; and the third phase included follow-up. Thirty-four university students coached 31 autistic adults (males, n = 20; females, n = 11) on three evolving goals. During phases 1 and 2, autists identified goals important to them as well as the action steps needed to attain them. During phase 2, autists received telecoaching provided by university students trained on the neurodiversity paradigm. Data were gathered on program feasibility, appropriateness, and acceptability using multiple measures (e.g., daily questionnaires, post-study surveys, weekly goal reports).

**Results:** Participants set goals across a wide range of domains (e.g., recreation/leisure, employment/vocation, social skills/emotion regulation, relationships, health and well-being, daily skills/self-care, finances, and transportation). Most reported improvements in social factors (85%; e.g., confidence and self-advocacy), managing stress (62%), and managing conflicts (54%). On a Likert scale of 1 (“Highly Dissatisfied”) to 5 (“Highly Satisfied”), most participants rated the immersion week (M = 4.58, SD = 0.63) and the coaching sessions (M = 4.42, SD = 0.99) as highly acceptable. Approximately 80% of participants would recommend the program and 19% might recommend the program. Reasons for recommending the program included the program’s impact on goal setting and problem-solving, appropriateness for the autistic community or identity, improvements in life outlook, and an opportunity to engage in social activities with others. Most participants indicated that the amount of coaching time was just right. On average, participants completed one goal per week indicating the program was appropriate for helping autistic adults set and attain self-determined goals. Although the program was feasible, the feasibility of supporting self-determination was impacted by parent involvement, communication challenges, and obstacles with goal setting and attainment.

**Conclusions:** The success of our self-determination program supports that programs and services based on the neurodiversity paradigm may empower autistic and other neurodivergent populations. Future research should examine program efficacy using a randomized control trial.

**403.074 (Poster)** Effects of Creative and Fine-Motor Interventions on Fine Motor Skills and Executive Functioning of Children with ASD  
**W. C. Su<sup>1</sup>, B. Kapinski<sup>2</sup>, N. Islam<sup>1</sup>, C. Cleff<sup>3</sup>, N. Amonkar<sup>4</sup>, S. Srinivasan<sup>5</sup> and A. N. Bhat<sup>6</sup>,** (1)*Physical Therapy, University of Delaware, Newark, DE, (2)University of Delaware, Newark, DE, (3)Physical therapy, University of Delaware, Newark, DE, (4)University of Connecticut, Storrs, CT, (5)Kinesiology, University of Connecticut, Storrs, CT, (6)Department of Physical Therapy, University of Delaware, Newark, DE*

---

**Background:** Children with Autism Spectrum Disorder (ASD) have primary and secondary impairments in social communication skills, fine/gross motor performance, and executive functioning. In the past, our research group reported greater improvements in gross motor skills in children with ASD after receiving rhythmic and yoga-based interventions compared to a fine motor-based (FM), standard of care intervention. In the current ongoing randomized controlled trial (RCT), we compared the effects of creative movement (CM, using music and movement) and seated play, fine motor interventions (FM, using building and art activities, standard of care) on fine motor skills and executive functioning.

**Objectives:** In the current analysis, we will compare the effects of CM and seated play, FM interventions on the fine-motor and executive functioning skills of children with ASD.

**Methods:** Thirty children with ASD between 6 and 14 years were recruited and randomly assigned to the CM or FM groups. Both groups received 16 training sessions (2 sessions/week), over 8 weeks. The CM group engaged in whole-body movements using music, dance, and yoga to promote IPS, imitation, coordination, and balance; whereas the FM group engaged in tabletop activities such as reading, building, and art-craft to promote social interactions and fine-motor skills. Each child completed the following tests before and after the intervention period: a) The fine motor integration,

fine-motor precision, and manual dexterity subtests of Bruininks-Oseretsky Test of Motor Proficiency, edition 2 (BOT-2- FMI, FMP, MD), and b) The Flanker task assessing for inhibitory control (i.e., point accuracy and reaction time during congruent (CONG) and incongruent (INCONG) conditions). We also assessed their task-specific performance during Lego and Playdoh building tasks before and after interventions.

**Results:** Our preliminary data in 24 children with ASD (13 in CM and 11 in FM) suggests positive results after CM and FM training. Both CM and FM groups showed improved BOT-2 FMI and FMP scores ( $ps < 0.05$ ) with no significant changes in the BOT-2 MD scores ( $ps > 0.05$ ). The CM group showed decreased reaction time during CONG and INCONG conditions (RT in sec (Mean $\pm$ SE), Pre = 2.56 $\pm$ 0.69 (CONG), 3.13 $\pm$ 0.79 (IN); Post = 1.36 $\pm$ 0.63 (CONG), 1.71 $\pm$ 0.89 (IN);  $p = 0.03$  and  $0.04$ ); while the FM group showed decreased reaction time during CONG condition only (RT in sec, Pre = 1.63 $\pm$ 0.19 (CON); Post = 1.21 $\pm$ 0.20 (CON);  $p = 0.01$ ). In terms of task-specific performance, 50% children in the FM group (N=10) showed a trend of reduced spatial errors during the Lego task (# of errors, Pre = 4.71 $\pm$ 2.08, Post = 0.29 $\pm$ 0.29;  $p = 0.06$ ) and showed a trend for reduced movement errors during the Playdoh task after intervention (% error, Pre = 45.5 $\pm$ 17.4, Post = 20.0 $\pm$ 14.1;  $p = 0.08$ ).

**Conclusions:** These findings support the use of CM and FM interventions in promoting fine motor skills and inhibitory control in children with ASD, with the CM group showing greater improvements compared to the FM group. ASD clinicians should consider adding creative components (music, synchrony) to their standard of care intervention.

#### **403.075 (Poster)** Implementation Fidelity of T-STEP Program for Transition-Age Autistic Adults

S. A. Stahl<sup>1</sup>, M. L. Cook<sup>2</sup>, Y. C. Syu<sup>3</sup>, B. Tomaszewski<sup>4</sup> and L. G. Klinger<sup>5</sup>, (1)TEACCH, University of North Carolina at Chapel Hill, Carrboro, NC, (2)TEACCH Autism Program; Psychology & Neuroscience, University of North Carolina, Chapel Hill, NC, (3)University of North Carolina - Chapel Hill, Chapel Hill, NC, (4)Frank Porter Graham Child Development Institute, University of North Carolina at Chapel Hill, TEACCH Autism Program, Chapel Hill, NC, (5)TEACCH Autism Program; Psychiatry, UNC TEACCH Autism Program, Chapel Hill, NC

**Background:** There is a critical need for effective vocational rehabilitation services for transition-aged autistic young adults (Alverson & Yamamoto, 2017; Burgess & Cimera, 2014). The TEACCH School Transition to Employment and Post-secondary Education (T-STEP) program includes a comprehensive curriculum (i.e., 24 ninety-minute classes across 12 weeks) that teaches strategies for successfully navigating the challenges with transitioning to adulthood for autistic adults. Though fidelity of intervention implementation is often under-reported in intervention research (Hume et al., 2011), it is critical both for the generalizability of treatment effects and the feasibility of dissemination to other clinicians particularly to the ability for community clinicians to implement an intervention beyond the university environment.

**Objectives:** In evaluating the degree to which the manualized T-STEP intervention was delivered as intended to optimize participant outcomes, we aimed to examine treatment fidelity for outpatient clinicians from the UNC TEACCH Autism Program and community college instructor partners. Specifically, we examined 1) the breadth of content taught during each session, and 2) the types of implementation strategies used by facilitators delivering the intervention.

**Methods:** The T-STEP was conducted for four semesters across two sites with one TEACCH outpatient clinician and one community college instructor serving as interventionist at each site. After attaining a minimum reliability of 80%, research staff were randomly assigned to review video-recorded sessions with 30% double coded for reliability. Interventionists were scored on both the quantity (i.e., amount of content covered) and quality (i.e., number and type of instructional and engagement strategies utilized) of their intervention delivery.

**Results:** Reliability between coders was high ( $> 91\%$ ). Overall, interventionist fidelity across both quantity and quality of intervention delivery was strong. On average, interventionists scored 8.61 out of a maximum score of 9 in the quantity of content items covered across 54 sessions. Average scores in quality were calculated from the number of instructional and engagement strategies utilized; facilitators scored an average of 8.78 out of 9 across all coded sessions. The two instructional strategies that were most frequently used by facilitators were prompting students to use a tool or routine strategy from a previous lesson (e.g., visual reminders) and including or soliciting personal stories or other student examples. The least used instructional strategy was modeling (e.g., live, video) to demonstrate specific skills.

**Conclusions:** Interventionists covered 100% of the content for 50 of the 54 intervention sessions. Across sessions, four different interventionists demonstrated consistently high-quality intervention delivery. Interventionists utilized a variety of evidence-based engagement (e.g., acknowledges or restates student comments) and instructional (e.g., uses visual supports or visual reminders) strategies. Visual reminders were the most common routine strategy prompted by facilitators and have been shown to support planning and organization skills for autistic individuals, with associated increases in both on-task behavior and task completion (Hume & Odom, 2007). Overall, findings support the feasibility of implementing the full T-STEP curriculum to fidelity. Results suggest the T-STEP intervention may be a highly feasible and generalizable treatment approach to meet a critical need for transition-based services for autistic individuals.

### **503 - Interventions - Non-pharmacologic - School-Age, Adolescent, Adult --- (V)**

#### **503.015 (Virtual Poster)** A Realist Evaluation of a Mealtime Service for Autistic Children

A. Chan<sup>1</sup>, C. Li Ern Chong<sup>1</sup>, C. Xin Xuan Ling<sup>1</sup>, Z. M. Goh<sup>1</sup>, M. Davey<sup>2</sup>, R. Tong<sup>1,2</sup> and M. H. Black<sup>1</sup>, (1)School of Allied Health, Curtin University, Perth, WA, Australia, (2)Therapy Focus, Perth, WA, Australia

## Background:

Mealtimes are complex multi-sensory experiences involving various textures, tastes, smells, appearances of food, and auditory input from the environment. Autistic children are more likely to experience feeding and mealtime difficulties compared to their neurotypical peers, with estimates suggesting that over 50% of autistic children experience difficulties at mealtime. Given the complexities of autism and the mealtime difficulties, addressing the needs of autistic children in intervention is difficult, and little is about the active ingredients required for an effective mealtime interventions.

## Objectives:

This study aimed to explore caregiver and therapist perceptions of the contexts, mechanisms, and outcomes of a transdisciplinary mealtime intervention for autistic children.

## Methods:

A qualitative approach guided by the Realist Evaluation framework was used to determine the contexts, mechanisms, and outcomes of a transdisciplinary mealtime program for autistic children. A Realist Evaluation approach is increasingly used to evaluate complex interventions, acknowledging that contextual elements can influence interventions and their outcomes. Based on the Realist Evaluation research design, individual interviews were conducted with caregivers and therapists to explore their perceptions of specialised mealtime management support provided by Therapy Focus' Mealtime Eating Allied Health Liaison Service (MEAHLs) in Western Australia. A total of 10 therapists and 6 caregivers participated, with data analysed thematically using a Realist Evaluation approach framework.

## Results:

Data analysis resulted in 11 context codes, 19 mechanism codes, and three outcome codes which were organised into four context themes, three mechanism themes, and two outcome themes. Contextual factors including child-related factors (interests and mealtime difficulties of the child), family-related factors (caregiver stress and family capacity), therapist factors (case-load and clinical experience) and institutional parameters influenced the caregiver engagement in the mealtime programme and the services that therapists provided. Contexts interacted with programme mechanisms including transdisciplinary collaboration (communication within the team, the role of therapists and contribution of expertise to service delivery), child-centred approach (child's and family's needs and adapting service provision to the child) and managing caregiver expectations (caregiver education and goal setting) to trigger outcomes. Outcomes of the mealtime programme included increased readiness for mealtimes, increased food acceptable, changes in mealtime behaviour and reduced caregiver stress during mealtimes.

## Conclusions:

The realist evaluation applied in this study has demonstrated the complex interaction between the contexts, mechanisms, and outcomes associated with a mealtime programme for autistic children. Taking into account the contextual factors of the child, family and therapist prior to entering into service provisions is required to adapt service provision to effect positive mealtime outcomes. Findings suggest a child-centred transdisciplinary programme that adapts to the unique mealtime needs of autistic children and their caregivers is required to improve mealtime outcomes.

## **503.016** (Virtual Poster) Adaptation of the De-Stress and Progress© Program for Autistic Adolescents: Preliminary Results of Implementation in High Schools

**S. M. Fecteau<sup>1</sup>**, N. Desautniers<sup>2</sup>, K. E. Bapte<sup>3</sup>, J. Sainte-Marie<sup>4</sup>, E. Dubé<sup>3</sup> and G. Sehabî<sup>2</sup>, (1)*Psychoéducation et psychologie, Université du Québec en Outaouais, St-Jérôme, QC, Canada*, (2)*Ottawa University, Ottawa, ON, Canada*, (3)*Université du Québec en Outaouais, Saint-Jérôme, QC, Canada*, (4)*Université du Québec à Chicoutimi, Chicoutimi, QC, Canada*

**Background:** Changes and challenges encountered during adolescence increase the vulnerability to the negative effects of stress and may predispose the onset of mental health disorders. The autistic teenager is no exception. Adolescents with an autism spectrum disorder (ASD) might experience more stress during social interactions than those not on the spectrum, as suggested by high cortisol activity during the interaction. Furthermore, certain characteristics of ASD, such as behavioral deficits related to social skills and emotion regulation, could generate additional vulnerability to various stressors. Compared to children without autism, those on the spectrum may use more frequently avoidance, physical forms of ventilation such as self-stimulation to regulate their internal state and less frequently constructive strategies such as seeking help or comfort. Thus, from a perspective of preventing consequences of stress, it is essential to support adolescents to encourage their optimal adaptation and development. In close collaboration with those working in schools, we have implemented the De-stress for Success® (CESH, Lupien et al., 2013) program within four special education classes in the province of Québec. The program is composed of 5 workshops, offered once a week by a trained school clinician and address the components of stress, the physical signs of stress, emotion and problem focused strategies and social support.

**Objectives:** The overall objective of this study is to explore the potential of the De-Stress for Success® program to support adolescents with ASD, more specifically to estimate the potential effects of this program on adaptive functioning and emotion recognition which are known constructs related to stress.

**Methods:** Before attending the five workshops, one week after the end of the program and five weeks later, 22 students on the autism spectrum ( $M = 14.03$ ,  $SD = 1.15$ ) completed an emotion recognition task with *The Montreal Set of Facial Displays of Emotion* (Beaupé & Hess, 2005), which

includes 54 photographs illustrating shame, joy, fear, disgust, sadness and anger. Their teachers completed the *Behavior Assessment System for Children* (BASC-3; Reynolds et Kamphaus, 2015) at these three time periods.

**Results:** Multivariate analysis of variance on repeated measures support the potential of the program in improving general adaptation and recognition of emotions. The students identified with greater facility facial expression of joy ( $F(21) = 27.48, p < .001$ ) and sadness ( $F(21) = 13.36, p < .001$ ). The teachers noted less behaviors related to atypicality ( $F(18) = 5.41, p < .05$ ) and withdrawal ( $F(18) = 5.27, p < .05$ ). They also observed improvement in adaptive skills ( $F(18) = 22.99, p < .001$ ), precisely social skills ( $F(18) = 5.73; p < .05$ ), leadership ( $F(18) = 6.9, p < .05$ ), functional communication ( $F(18) = 37.23, p < .001$ ) and adaptability ( $F(18) = 15.48; p < .001$ ).

**Conclusions:** These results provide support in favor of a transdiagnostic approach to intervention, by proposing to focus efforts on reducing stress, a common trigger of a multitude of adaptive challenges related to autism (such as self-isolation, difficulties in social skills, functional communication and emotional regulation) instead of intervening separately on these difficulties. Thus, this intervention has an impact beyond the concept of stress.

#### **503.017 (Virtual Poster)** Effects of a Visualizing Intervention on Reading Comprehension in Autistic Children

**K. L. Coburn<sup>1</sup>, J. A. Trapani<sup>2</sup>, S. E. O'Kelley<sup>3</sup> and R. K. Kana<sup>4</sup>,** (1)Department of Psychology, University of Alabama, TUSCALOOSA, AL, (2)University of Alabama at Birmingham, Birmingham, AL, (3)The University of Alabama at Birmingham, Birmingham, AL, (4)Department of Psychology, University of Alabama, Tuscaloosa, AL

#### **Background:**

Previous research has shown that many autistic children and adolescents struggle with reading comprehension, even in the presence of typical decoding abilities (Nation et al., 2006; Norbury & Nation, 2011). This could be due to difficulties integrating multisensory information, such as verbal knowledge and visual imagery (Paivio, 1991). Interventions designed to strengthen the relationship between visualizing skills and verbal comprehension could improve reading comprehension for autistic children. This has widespread implications as improving reading comprehension can lead to improved educational outcomes and establish a foundation for life-long learning (National Reading Panel, 2000).

#### **Objectives:**

This randomized control trial (RCT) aims to assess the outcomes of an intensive reading comprehension intervention, "Visualizing and Verbalizing® for Language Comprehension and Thinking" (V/V; Bell, 1991), in improving comprehension in autistic children.

#### **Methods:**

An experimental group of autistic children (ASD-EXP; target n=50), ages 7-13 years, completed a battery of neuropsychological assessments (pre-test), followed by 10 weeks of intensive V/V intervention (4 hours/day, 5 days/week, for a total of 200 hours) before returning for a repeated assessment battery (post-test). Another group of autistic children were randomly assigned to the waitlist control group (ASD-WLC; target n=50) and completed the same assessments but received the intervention after both pre- and post-test sessions were completed. We hypothesize that the ASD-EXP group will make significant gains in reading comprehension at post-test, as measured by the Gray Oral Reading Test (GORT-5; Wiederholt & Bryant, 2012) Comprehension Score. We further hypothesize that the ASD-EXP group will show significantly greater gains in reading comprehension at post-test than the ASD-WLC group. Data collection for this study is ongoing. Preliminary data from ASD-EXP (n=3) and ASD-WLC (n=5) participants who presented for both pre- and post-test have been analyzed. Pre- and post-test GORT-5 Comprehension raw scores were compared within and between participants using a repeated-measures ANOVA. Percent change on GORT-5 Comprehension score was compared between groups using a two-sample t-test. Percent change was calculated as ((post-test – pre-test)/pre-test)\*100.

#### **Results:**

There was a trend towards a main effect of time on GORT-5 Comprehension raw score, with scores increasing from pre- to post-test for both groups,  $F(1)=3.971, p=.0937$ . There was no significant interaction of time\*group,  $F(1)=.441, p=.531$ . There was no significant effect of group on GORT-5 score at either time point,  $F(1)=.012, p=.915$ . Although pairwise group differences in percent change on GORT-5 raw score were not statistically significant,  $t(6)=1.021, p=.347$ , the ASD-EXP group ( $M=38.33\%$ ) showed greater percent change than the ASD-WLC group ( $M=15.18\%$ ).

#### **Conclusions:**

Trends in this preliminary dataset support the promising utility of the V/V intervention for improving reading comprehension in autistic children. In addition to supporting the use of the V/V intervention specifically, these results may also point to the positive benefit of visualization strategies for autistic children. We plan to do additional analyses with standard scores and anticipate stronger trends and statistically significant differences as more data are collected.

#### **503.018 (Virtual Poster)** Can We Improve Online Education for Autistic Teens through Data-Driven Curricular Revisions? Insights from Educators Who Led Two Game Design Workshops

**A. Riccio<sup>1</sup>, W. Martin<sup>1</sup>, J. Herrell<sup>2</sup>, E. Grossman<sup>3</sup>, E. Pak<sup>4</sup>, C. Ulerio<sup>2</sup>, B. Rosenberg<sup>3</sup>, A. Hurst<sup>6</sup> and K. Gillespie-Lynch<sup>7</sup>,** (1)Education Development Center, New York, NY, (2)Tech Kids Unlimited, Brooklyn, NY, (3)Psychology, CUNY Graduate Center, New York, NY, (4)College of Staten Island,

**Background:** Autistic people are often skilled with computers (DuPaul et al., 2011) and drawn to STEM fields (Wei et al., 2013) yet encounter difficulties obtaining employment (Shattuck et al., 2012). Therefore, evidence-based strategies to help neurodivergent youth engage with STEM curricula as empowered learners are sorely needed.

Our research was designed with an informal educational non-profit where neurodivergent youth learn authorial technology skills. Staff facilitated two game design workshops for autistic adolescents. Workshop 1 (July 2021) combined game design principles, workforce readiness, and social justice issues. Workshop 2 (August 2021) focused on the same concepts after curricular revisions based on Workshop 1. We present staff reflections on the successes and challenges of these workshops.

**Objectives:**

1. Assess staff perceptions of whether students in each workshop achieved four learning goals (LGs).
2. Understand how changes after Workshop 1 impacted staff perspectives.
3. Examine the degree to which educator and student engagement ratings aligned.

**Methods:** Seven staff members (one teacher, assistant teacher, social worker, and occupational therapist and three counselors) were surveyed (Table 1) on the final day of two, ten-day virtual game design workshops for two cohorts of autistic adolescents ( $n=20$ ;  $n=19$ ).

Students and staff completed engagement probes following targeted activities (Riccio et al., 2021). After Workshop 1, staff collaboratively implemented changes including increased differentiation, daily “staff spotlights” about different careers, agendas, and more time to share students’ interests. Staff were given “diversity profiles” to help them provide individualized support based on student’s strengths, interests, and challenges.

**Results:** Staff reported that most students achieved each LG across both workshops (Table 2). Staff were more likely to report that students attained LG2 (social justice) following Workshop 2 ( $p=.029$ ) describing increased effectiveness of teaching methods LG2 ( $p=.031$ ).

Staff reported being more prepared to teach game design concepts than social emotional or social justice themes and being more prepared following Workshop 2 than 1. However, differences were not significant ( $ps >.11$ ).

Staff reported that familiarity with the curriculum and additional teaching strategies improved Workshop 2. Staff felt that opportunities for students to playtest each other’s games contributed to their achieving LG1. Staff reported wanting to provide more 1-on-1 support, but found the virtual format and time constraints challenging.

Despite evidence of improvements across workshops from educators’ perspectives, educator ratings of student engagement were often not well-aligned with students’ ratings of their own engagement; it was rare for more than one educator to achieve a moderate positive correlation between their engagement ratings and students’ own engagement ratings for each activity assessed.

**Conclusions:** Results highlight the importance of data-driven iterations when developing supports for autistic learners. Increased focus on individualization and interaction led educators to have more confidence in student learning following Workshop 2. Additional training may have helped staff engage in meaningful social justice discussions during Workshop 2. Despite benefits of online workshops, educators struggle to accurately assess student engagement online. Results suggest that program evaluation and iteration improve staff readiness to facilitate online educational programming but student feedback is essential for understanding (and thus promoting) engagement.

**503.019 (Virtual Poster)** Does Participation in Social Skills Intervention Improve Quality of Life for Teens with ASD? a Preliminary Investigation  
**L. Hodge<sup>1</sup>, E. Veytsman<sup>2</sup>, E. Baker<sup>3</sup>, T. Choy<sup>4</sup> and K. K. Stavropoulos<sup>4</sup>,** (1)University of California, Riverside, Riverside, CA, (2)Graduate School of Education, University of California Riverside, Riverside, CA, (3)UC Riverside, Riverside, CA, (4)School of Education, University of California Riverside, Riverside, CA

---

**Background:** The Program for the Education and Enrichment of Relational Skills (PEERS®) is an intervention shown to improve social skills in autistic (ASD) adolescents (Laugeson, 2011). However, intervention programs are criticized by some autistic self-advocates claiming that these strategies are neuro-typical centric and encourage behavior akin to social “masking” (Roberts, 2021), which refers to consciously and unconsciously mimicking neuro-typical behavior and suppressing ASD traits, and is related to poor mental health (Cage, 2019).

**Objectives:** (1) Examine how participation in PEERS® is related to quality of life measures such as happiness, social anxiety, and loneliness. (2) Examine how quality of life measures are related to caregiver-reported social skills and ASD severity, as these measures are often used to indicate intervention efficacy.

**Methods:** Participants included ASD adolescents ( $n=13$ ,  $M=14.7$ ) and their caregivers. Measures were collected before (Time 1; T1) and after PEERS® (Time 2; T2). Caregivers completed the Social Responsiveness Scale Second Edition (SRS-2; Constantino, 2012) and Social Skills Improvement System (SSIS; Gresham and Elliott, 2008). Adolescents completed the Loneliness and Social Dissatisfaction Scale (LSD; Asher &

Wheeler, 1985), Social Interaction Anxiety Scale (SIAS; Mattick & Clarke, 1988), and Happiness subscale of the Piers-Harris Self-Concept Scale Second Edition (PH2; Piers & Herzberg, 2002).

Results: Repeated measures ANOVAs did not indicate differences in either social satisfaction/loneliness (LSD) or happiness (PH2) ( $p$ 's > .2) over time. A marginal decrease in social anxiety (SIAS) was observed ( $p=.062$ ). SRS-2 scores decreased ( $p=.002$ ), and SSIS scores increased ( $p=.022$ ). Social satisfaction/loneliness at T1 was negatively correlated with SRS-2 score at T2, ( $p=.022$ ). Social Anxiety at T1 was positively correlated with SRS-2 score at T2 ( $p=.002$ ). SSIS score at T1 was positively correlated with change in SIAS scores between T1 and T2 ( $p=.046$ ). SSIS score at T1 was negatively correlated with change in happiness from T1 to T2 ( $p=.004$ ).

Conclusions: Consistent with previous studies, social skills improved after participation in PEERS®. No significant changes were observed in loneliness/social satisfaction or happiness between the two time points; however, marginal improvements to social anxiety were observed. Teens with higher social satisfaction at the beginning of the program had better caregiver-reported social skills after PEERS®. This suggests that teens who were more satisfied with their social experiences at the beginning of the program were more likely to be perceived as socially skilled by their caregivers at the end of the program. Participants with higher starting social anxiety had lower ending caregiver-reported social skills. It is possible that the participants' social anxiety prevented them from actively participating in the program as much as other participants. Participants who had better initial caregiver-reported social skills had less robust improvements to both social anxiety and happiness. It is possible that less-affected teens had less room to improve in these categories. Overall, results indicate that although significant changes were not observed in happiness or loneliness/social satisfaction after PEERS®, individual characteristics may clarify the relationship between quality of life measures and caregiver-reported social skills. Future research should investigate how participation in intervention affects quality of life in individuals with ASD.

**503.020 (Virtual Poster)** Effectiveness of Improving Joint Attention in Low-Functioning Chinese-Speaking Children with Autism: Comparison of Robot-Based Intervention to Human-Based Intervention

*W. So, Educational Psychology, The Chinese University of Hong Kong, Hong Kong, Hong Kong*

---

Background: Children with Autism Spectrum Disorder (ASD), especially those with low cognitive functioning, have response to joint attention (RJA) and initiation of joint attention (IJA) impairments. Existing interventions rely heavily on human therapists, who are greatly involved in the intervention procedures and provision of feedback and reinforcement. However, human-based intervention incurs high costs to families with children with ASD. Besides, individuals with ASD show deficits in orienting themselves toward social stimuli, engaging with humans, and maintaining social relations. The dynamic facial features and expressions of human beings may induce intensive sensory processing in individuals with ASD, possibly resulting in sensory and emotional overstimulation and distraction. As a result, it is necessary to develop effective, affordable, and timely intervention for children with ASD through the application of technology (such as social robots). Previous research found positive learning outcomes of robot dramas but did not include human-based intervention for comparison of learning effectiveness (So et al., 2020; online). In contrast, Zheng et al. (2020) and Srinivasan et al. (2016a, 2016b) did not find significant positive learning outcomes of robot-based intervention, but their results should be interpreted with caution as their designs of their robotic intervention either might not arouse children's motivation or might not be comparable to human-based intervention.

Objectives: The present study aimed to address the limitations of research design of the previous studies and compare the learning effectiveness of robot-based intervention to human-based in RJA and IJA.

Methods: A total of 38 Chinese-speaking speaking children aged 6-9 were randomly assigned to the robot-based intervention and human-based intervention. They were confirmed with having autism (mean ADOS-2=8), severe social impairments (mean SRS>100), and moderate intellectual disabilities (mean IQ=40). Before and immediately and one month after intervention, they were administered with the Early Social-Communication Scales (ESCS; Mundy et al., 1996). Each child received six training sessions, with each session lasting for 30 minutes, over three weeks. He/she watched one or two dramas in each training session depending on his/her attention span. There were totally six dramas. In the robot-based intervention, two robots demonstrated RJA and IJA in the form of dramas. The intervention procedures in the human-based condition were the same except that human acted in the dramas. Caregivers of the participating children completed the social validity questionnaire after the intervention.

Results: See Figure 1. There was significant interaction effect,  $F(2,68)=3.38, p<.04, \eta^2=.12$ . After taking six drama lessons, children in the robot-based intervention produced more RJA behaviors in the delayed post-test than in the pre-test. They were also found to have an increase in IJA behaviors in the immediate post-test than in the pre-test, and more promising, their increase was maintained in the delayed post-test. However, those improvements were not evident in the children taking human-based drama lessons. These findings were in line with parents' ratings of both kinds of intervention. Parents of the children receiving the robot-based intervention rated the program more positively than those of the children taking the human-based intervention.

Conclusions: Robot-based intervention may be more effective than human-based intervention in promoting RJA and IJA.

**503.021 (Virtual Poster)** Effects of Creative Movement Interventions on Rhythmic Praxis and Drumming Performance of Children with Autism Spectrum Disorder

*P. Mathur<sup>a</sup>, W. C. Su<sup>a</sup>, J. Dolan<sup>a</sup>, C. Cleffi<sup>a</sup>, N. Amonkar<sup>a</sup>, A. N. Bhat<sup>a</sup> and S. Srinivasan<sup>a</sup>, (1)University of Connecticut, Storrs, CT, (2)Physical Therapy, University of Delaware, Newark, DE, (3)University of Delaware, Newark, DE, (4)Physical therapy, University of Delaware, Newark, DE, (5)Kinesiology, University of Connecticut, Storrs, CT, (6)Department of Physical Therapy, University of Delaware, Newark, DE*

---

**Background:** Over 85% children with Autism Spectrum Disorder (ASD) are at risk for motor coordination impairments. Children frequently have impaired balance, bimanual coordination, imitation, interpersonal synchrony, and praxis skills. Praxis is the ability to plan and execute multi-step actions/gestures. For instance, children with ASD have difficulties with spatial and temporal aspects of movement execution when asked to perform skilled hand gestures to imitation and verbal command.

**Objectives:** This study will assess the effects of a creative movement intervention compared to a seated play intervention on the rhythmic praxis and bimanual coordination skills of children with ASD.

**Methods:** 30 children with ASD between 6 and 14 years were recruited. The study lasted for 10 weeks with pretests and posttests conducted in the first and tenth weeks. Children were matched on age, gender, and functioning level and then randomly assigned to one of two groups: Creative Movement (CM) or Seated Play (SP). Each child received 8 weeks of training @ 2 sessions/week. The CM group engaged in rhythmic movements to music while imitating partners during drumming and whole-body movements with a focus on bimanual coordination. The SP group engaged in tabletop activities such as reading, building, and art-craft. Outcome measures included a drumming test that required children to copy incrementally challenging, sequential motor patterns performed by a tester. We coded both spatial (movement precision, modulation, and symmetry/reciprocity) and temporal aspects (movement rhythmicity and pace) of imitation accuracy during the drumming test. The Bilateral Motor Coordination Subtest of the standardized, Sensory Integration and Praxis Tests (SIPT-BMC) was also administered at pretest and posttest.

**Results:** Preliminary data from 9 children in the CM group suggest that 77% of the children showed a reduction in spatial errors during drumming in the posttest (Mean(SE): 10.7(7.11)) vs. pretest (5.3(5.8)). Specifically, 66% children improved their ability to precisely copy multi-step drumming patterns (Pretest:4.7(1.6), Posttest:2.3(0.8)) and 55% of the coded sample improved their ability to appropriately modulate (Pretest:4.6(1.5), Posttest:2.2(0.7)) drumming actions. In terms of temporal errors, 55% of the children improved their ability to replicate the demonstrated rhythms in the posttest (1.7(0.6)) vs pretest (3(0.3)). We did not find any improvements in other temporal error categories during the drumming test. During SIPT-BMC, children in the CM group showed improvements in temporal performance posttest (6.3(1.7)) vs. pretest (11.9(3.4)). We hypothesize that the CM group will show greater improvements in rhythmic praxis and drumming performance compared to the SP groups.

**Conclusions:** Creative movement interventions that provide children opportunities for instrument play and rhythmic movement to music are excellent ways to promote rhythmic praxis, imitation, motor planning, and complex bimanual coordination in children with ASD. Our ongoing work serves as preliminary evidence to advocate for rhythmic movement opportunities within therapy contexts for children with ASD.

**503.022 (Virtual Poster)** Effects of a Rhythm-Based, Creative Movement Intervention on Social Communication, Behavior, and Affect in Children with ASD

A. Khade<sup>1</sup>, M. Shuguli<sup>1</sup>, W. C. Su<sup>2</sup>, C. Cleffi<sup>3</sup>, M. Spearing<sup>4</sup>, N. Amonkar<sup>5</sup>, A. N. Bhat<sup>6</sup> and S. Srinivasan<sup>1</sup>, (1)University of Connecticut, Storrs, CT, (2)Physical Therapy, University of Delaware, Newark, DE, (3)Physical therapy, University of Delaware, Newark, DE, (4)University of Delaware, Newark, DE, (5)Kinesiology, University of Connecticut, Storrs, CT, (6)Department of Physical Therapy, University of Delaware, Newark, DE

**Background:** Children with Autism Spectrum Disorder (ASD) demonstrate social communication impairments and engage in restricted and repetitive behaviors. Our past work has demonstrated the positive effects of whole-body rhythm- and yoga-based interventions on social communication, affect, and repetitive behaviors in school-age children with ASD.

**Objectives:** Our ongoing clinical trial builds on this work by comparing the effects of a rhythm-based creative Movement (CM) intervention to a standard-of-care, Seated Play (SP) intervention on social communication and behavioral-affective skills in children with ASD. In light of COVID-19, a subset of children in both groups were seen online using video-conferencing platforms allowing comparisons between face-to-face versus telehealth-based intervention delivery.

**Methods:** 30 children with ASD between 6 and 14 years were seen over 10 weeks with pretests and posttests conducted during the first and tenth weeks. Children were matched on age, gender, and level of functioning and then randomly assigned to CM or SP groups. Each child received 8 weeks of training @ 2 sessions/week conducted with an expert trainer and an adult model. The CM group engaged in music, dance, and yoga-based activities promoting interpersonal synchrony, imitation, bilateral coordination, and balance skills. The SP group engaged in tabletop reading, building, and art-craft activities to promote academic and fine motor skills. The standardized Joint Attention Test (JTAT), administered at pretest and posttest was used to assess changes in responsive joint attention. We also coded the % duration of verbalization and positive affect as well as rates of repetitive behaviors across an early, mid, and late training session.

**Results:** Preliminary data from the CM group suggest that 9 out of 13 children showed improved responses to the verbal bids on the JTAT from pretest to posttest. From an early to a late session, 77% reduced self-directed verbalization and instead engaged in socially directed verbalization towards the trainers. Moreover, CM interventions promoted greater spontaneous speech initiations (Mean(SE): 11.3(1.4)) compared to responsive verbalization (Mean(SE): 2.1(0.3)) in all children across sessions. 55% of children showed a reduction in total frequencies of repetitive and maladaptive behaviors from an early to a late session. Specifically, children reduced the frequencies of sensory behaviors with objects (Early: 9.9(1.8), Late: 5.9(1.6)) and negative behaviors (Early: 9.1(3.1), Late: 6(2.4)) following training. Our preliminary data suggest that children seen face-to-face and via telehealth demonstrate similar trends in terms of training-related improvements. We hypothesize that the CM group, irrespective of mode of intervention delivery, will demonstrate greater improvements in measured outcomes compared to the SP group.

**Conclusions:** These findings build on past evidence from this research team on the value of socially-embedded CM therapies in addressing core impairments in ASD. Moreover, our preliminary data suggest that telehealth-based intervention delivery is a viable option to access therapies for at

least some children with ASD. Our work supports the inclusion of whole body, rhythmic movement experiences in the standard-of-care in ASD and emphasizes the role of physical therapists as motor advocates for children with ASD.

**503.023 (Virtual Poster)** Effects of the “Transition to Kobe University Program” on High School Students with High-Functioning Autism Spectrum Disorder

**M. Torii<sup>1</sup>**, A. Nishi<sup>2</sup> and Y. Muranaka<sup>3</sup>, (1)Graduate School of Human Development and Environment, Kansai University of International Studies, Kobe, Japan, (2)Graduate School of Human Development and Environment, Kobe University, Kobe-shi, Japan, (3)Support Center for Campuslife, Kobe University, Kobe, Japan

---

**Background:**

Many students with high-functioning autism spectrum disorder (HFASD) exhibit high performance in academic skills. However, some university students with HFASD exhibit difficulties in social and advocacy skills, which results in them dropping out of university. Since these students exhibit problems related to their academic, social, daily living, and advocacy skills at a high school age (Adreon & Durocher, 2007), we developed the Transition to Kobe University Program (TKUP) for high school students with HFASD in 2019. In 2020, the COVID-19 pandemic forced individuals to change their lifestyles and maintain physical distancing. Thus, we modified our TKUP method from a face-to-face (FFTKUP) to an online (OLTKUP) one using the Zoom video conferencing platform. In this presentation, we present the effects of both FFTKUP and OLTKUP on high school students with HFASD.

**Objectives:**

To investigate the effects of both FFTKUP and OLTKUP on high school students with HFASD.

**Methods:**

**Participants:** The participants comprised high school students with HFASD. Two boys and one girl participated in the OLTKUP, while five boys and one girl participated in the FFTKUP. One boy was excluded from the FFTKUP as his score in the Social Responsiveness Scale Second Edition (SRS-2) was below 60 (see Table 1).

**Materials:** The TKUP framework consists of academic, social, and advocacy skills, as well as knowledge about life in the university; for the OLTKUP, we also employed the Zoom platform.

**Procedure:** All sessions were conducted on Friday night after school. For the FFTKUP, we had seven sessions, conducted once a month from June to February 2019, except August.. For the OLTKUP, nine bi-monthly sessions were held, from September 2020 to February 2021. Before and after each session, students answered a questionnaire comprising six items rated on a 10-point Likert scale ranging from “I have no idea” (1) to “I understand” (10).

**Results:**

A comparison of the six items before and after the sessions shows that students with HFASD could understand the transition to university regardless of the programs (see Table 2). Scores of the items were as follows: “difference from high school learning” ( $t(6) = -6.30, P < .01$ ); “campus life” ( $t(7) = -3.47, P < .05$ ); “importance of self-determination” ( $t(7) = -3.42, P < .05$ ); “how to make a report” ( $t(7) = -2.89, P < .05$ ); “schedule management” ( $t(7) = -4.12, P < .01$ ); and “protect privacy” ( $t(7) = -2.20, n.s.$ ).

**Conclusions:**

All high school students with HFASD reported the TKUPs (both FFTKUP and OLTKUP) to be beneficial. Our findings also indicated the OLTKUP to be as effective as the FFTKUP. However, due to the small sample size, the study has certain limitations.

**503.024 (Virtual Poster)** Exploring the Acceptability of a Community-Based Cognitive Behaviour Therapy Program for Autistic Children: A Mixed-Methods Approach

**N. Vashi<sup>1</sup>**, V. Lee<sup>2</sup>, T. Sellitto<sup>3</sup>, F. H. Roudbarani<sup>1</sup>, A. Pouyandeh<sup>1</sup>, S. Ameis<sup>4</sup>, A. Elkader<sup>4</sup>, K. Gray<sup>5</sup>, C. M. Kerns<sup>6</sup>, J. Lake<sup>7</sup>, M. Legree<sup>8</sup>, K. M. Thomson<sup>9</sup> and J. A. Weiss<sup>1</sup>, (1)Psychology, York University, Toronto, ON, Canada, (2)Psychology, Carleton University, Ottawa, ON, Canada, (3)The Margaret and Wallace McCain Centre for Child, Youth, & Family Mental Health, Campbell Family Mental Health Research Institute, Centre for Addiction and Mental Health, Toronto, ON, Canada, (4)Kinark Child and Family Services, Markham, ON, Canada, (5)Centre for Educational Development, Appraisal and Research, University of Warwick, Coventry, United Kingdom, (6)University of British Columbia, Vancouver, BC, Canada, (7)Psychiatry, University of Toronto, Toronto, ON, Canada, (8)Lake Ridge Community Support Services, Whitby, ON, Canada, (9)Applied Disability Studies, Brock University, St. Catharines, ON, Canada

---

**Background:** Autistic children often experience high levels of socioemotional difficulties and can be supported using cognitive behaviour therapy (CBT; Perihan et al., 2020; Weston et al., 2016). Emerging research has evaluated aspects of the clinical utility of these interventions, such as generalizability and feasibility (Goodheart et al., 2006). Another aspect of clinical utility is multi-faceted acceptability, which includes seven

domains: affective attitude, perception of burden, ethicality, intervention coherence, opportunity costs, perceived effectiveness, and self-efficacy (Sekhon et al., 2017). Research is needed to understand the acceptability of CBT interventions when provided to autistic youth.

**Objectives:** A mixed-methods approach was used to investigate caregiver-reported acceptability of a virtual 10-week, group-based CBT intervention for autistic children, Secret Agent Society (Beaumont, 2015), which focuses on social and emotion regulation skills, as delivered by seven community-based autism service agencies in Canada.

**Methods:** 77 caregivers (94% females;  $M = 42.5$  years,  $SD = 5.7$  years) and their children (79% males;  $M = 9.9$  years,  $SD = 1.3$  years) completed the intervention. All children had a confirmed autism diagnosis from a regulated health care professional. On average, caregivers participated in 90% of the caregiver-related sessions ( $SD = 20\%$ , Range: 0-100%) and children completed 95% ( $SD = 10\%$ , Range: 33-100%) of their sessions. Caregivers completed post-intervention surveys including a novel acceptability measure, based on the Theoretical Framework of Acceptability (Sekhon et al., 2017): The Implementation Acceptability Scale (7 items, 5-point Likert scale from “Strongly Disagree” to “Strongly Agree”). Semi-structured focus groups and interviews were conducted with 64 caregivers.

**Results:** Levels of acceptability across domains were variable. Caregivers reported feeling positively about the program (75%), that it aligned with their values (95%), and that they understood how it worked (87%). Some caregivers felt that the program required an unacceptable amount of effort (39%), felt they had to give up resources or opportunities to participate in the program (23%), felt that it was not effective in achieving its goals (38%), and did not feel confident in the skills they had learned (23%). Qualitative analysis revealed that therapist knowledge and rapport-building skills contributed to overall program acceptability. Many caregivers had positive attitudes towards the program, stating benefits in their children’s sense of connectedness with other children and caregivers due to the group-based format, despite the program being provided online during the pandemic. Some caregivers noted high opportunity costs related to the additional time and effort spent maintaining children’s engagement with the online format. However, the online format reduced other opportunity costs (e.g., travel, scheduling). Many caregivers felt that the program was effective in achieving its goals, but there were limitations to applying strategies outside of sessions. The fast-paced sessions and high volume of content were linked to lower feelings of caregiver self-efficacy.

**Conclusions:** Understanding the acceptability of autism-based interventions may provide insight into the factors that influence adherence and uptake of the clinical benefits of interventions in the community. Future research is needed to examine how contextual factors (e.g., pandemic) influence other aspects of the clinical utility of these interventions.

#### **503.025 (Virtual Poster)** Is It Possible to Foster Social Competence Via Telehealth? Examining Effects of PEERS® for Adolescents Telehealth for Autistic Adolescents

**E. J. Adler<sup>1</sup>, H. K. Schiltz<sup>2</sup>, D. M. Glad<sup>3</sup>, S. A. Lehman<sup>1</sup>, S. K. Pardej<sup>3</sup>, R. E. Stanley<sup>3</sup> and A. V. Van Hecke<sup>1</sup>,** (1)Psychology, Marquette University, Milwaukee, WI, (2)University of Wisconsin-Milwaukee, Milwaukee, WI, (3)Marquette University, Milwaukee, WI

Background: Emerging evidence indicates that telehealth services may be effective for autistic individuals (Ellison et al., 2021), yet research on telehealth administration of social skills interventions is still limited. It is important to continue examining the effectiveness of specific telehealth services for autistic youth to further expand access to care during and post-pandemic. The PEERS® intervention (Laugeson & Frankel, 2010), delivered in-person, has been found to increase social knowledge, social responsiveness, social skills, and get-togethers (Laugeson et al., 2009, 2012; Schohl et al., 2014). The telehealth administration of PEERS® offers many benefits (e.g., adherence to health guidelines, increased accessibility, etc.), and may also pose challenges (e.g., potentially fewer informal interactions between participants, unknown implications of virtual social activities). Thus, it is essential to determine whether the telehealth version of PEERS® is equivalent to in-person intervention, outside of the site of development.

**Objectives:** This study explores the effects of the PEERS® for Adolescents Telehealth intervention on core social domains including autistic features, get-togethers, and social knowledge.

**Methods:** 12 families with adolescents aged 11-16 ( $M=13.3$ ;  $SD=1.36$ ; 91% male) were enrolled in the current study based on 1) documentation of an autism diagnosis, 2)  $IQ \geq 70$ , and 3) access to reliable Wi-Fi with at least two devices. Families completed pre- and post-adolescent self-report forms (QSQ-A-R; TASSK) and pre- and post-caregiver-report forms (QSQ-P-R; SRS). Participants completed PEERS® in 16 weeks via Zoom and Microsoft Teams. Paired sample t-tests SPSS 27.0 examined change pre- to post- intervention. Due to the small sample, a combination of null-hypothesis significance testing and effects sizes was used to interpret results.

**Results:** Analyses confirmed decreases in core autistic symptoms as measured by the SRS (Total score),  $t(11) = 3.744$ ,  $p = .003$ ,  $M_{pre} = 103.08$ ,  $SD_{pre} = 24.24$ ,  $M_{post} = 84.92$ ,  $SD_{post} = 26.53$  with a large effect size (Cohen’s  $D = 1.08$ ). Significant change was reported by caregivers regarding total invited and hosted get-togethers, as measured by the QSQ-P-R,  $t(10) = -3.148$ ,  $p = .010$ ,  $M_{pre} = 0.64$ ,  $SD_{pre} = 1.29$ ,  $M_{post} = 6.36$ ,  $SD_{post} = 5.26$  with a large effect size (Cohen’s  $D = .95$ ). Adolescents also reported a significant increase in total invited and hosted get-togethers on the QSQ-A-R,  $t(10) = -4.73$ ,  $p = .001$ ,  $M_{pre} = 0.64$ ,  $SD_{pre} = 1.21$ ,  $M_{post} = 4.09$ ,  $SD_{post} = 2.21$  with a large effect size (Cohen’s  $D = 1.43$ ). Adolescents significantly improved in knowledge of PEERS® concepts and friendship skills as measured by the TASSK,  $t(10) = -4.662$ ,  $p = .001$ ,  $M_{pre} = 13.55$ ,  $SD_{pre} = 1.25$ ,  $M_{post} = 21.27$ ,  $SD_{post} = 4.08$ , and demonstrated a large effect size (Cohen’s  $D = 1.41$ ).

**Conclusions:** These findings indicate that telehealth version of PEERS® yielded similar improvements as those observed in the in-person format. Preliminary findings indicate that PEERS® for Adolescents Telehealth significantly decreases core autistic symptoms, increased knowledge of social skills, and increased number of get-togethers in autistic adolescents. Our findings showcase effects of an evidence-based intervention that can be accessed via telehealth by the autistic community.

**Background:** Self-regulation, which includes emotion regulation (ER) and executive functioning (EF), especially inhibition, plays a crucial role on children's development and life outcome (Diamond, 2013; Moffitt et al., 2011). Challenges in self-regulation are common in children with Autism Spectrum Disorder (ASD) (Kenworthy et al., 2009), and have been shown to be predictive of symptom severity, functioning and treatment outcomes (Gardiner & Iarocci, 2018). Programs and interventions aimed at improving ER and EF in children with ASD have been exponentially increasing. With these new programs comes the responsibility of thoroughly examining the empirical evidence supporting them.

**Objectives:** The current systematic review aims to gather and synthesize information regarding existing interventions that target ER and inhibition in children with ASD, and to examine the evidence supporting these programs, while identifying core components.

**Methods:** The study was preregistered with PROSPERO (CRD42021243700) and procedures and reporting were performed following the Preferred Reporting Items for Systematic review and Meta-Analyses (PRISMA) guidelines. Five databases were used to locate articles: Medline, EMBASE, ProQuest, PsycINFO, and ERIC. Searches were conducted in June 2021 and were limited to peer-reviewed articles published in English or French between 1987 and 2021. The search terms used fell under four general categories: a) ASD, b) children (age 0 to 17), c) training target/outcome (inhibition, EF, and ER), and d) intervention/program. Data extraction was performed using Covidence, and the Evaluative Method for Determining Evidence-Based Practice in Autism (Reichow et al., 2008) and OCEBM were utilized to rate the quality and level of evidence of each study.

**Results:** The database search resulted in 4368 studies, of which 30 met the inclusion criteria involving 884 participants (age range: 3-17 years). Approximately half of the studies included were conducted between 2005-2018, while the remaining half were investigated from 2019-2021. 16 studies targeted inhibition, eight targeted ER and six targeted self-regulation more broadly. 16 studies were group interventions and 14 were delivered on an individual basis. 13 of the studies included were randomized controlled trials (RCT), 11 were non-randomized controlled trials and 6 were case studies, demonstrating mixed evidence for different programs. Studies who received the highest quality rating and support, were mostly programs that targeted school aged children, included a caregiver component allowing for high transferability of skills, and which utilized components of CBT and/or mindfulness, aligning with the current research on evidence-based treatments for ASD. Only one intervention met criteria for a well-established intervention: The Secret Agent Society/Junior detective (Beaumont & Sofronoff, 2008), which targets ER.

**Conclusions:** To our knowledge, this is the first systematic review that investigates inhibition and ER programs for children with ASD. The review highlights key components of interventions that can be utilized to develop a successful program that targets inhibition and ER in children on the spectrum. While most interventions showed promising results, many scored low ratings on quality indicators. Further studies are warranted, particularly RCT studies to bring forth more empirical evidence.

**503.027** (Virtual Poster) Picture Memory in Autistic Children Following a Reading Comprehension Intervention

G. N. Miller<sup>1</sup>, M. E. Beckerson<sup>2</sup>, J. A. Trapani<sup>3</sup>, S. E. O'Kelley<sup>4</sup> and R. K. Kana<sup>2</sup>, (1)University of Alabama, Tuscaloosa, AL, (2)Department of Psychology, University of Alabama, Tuscaloosa, AL, (3)University of Alabama at Birmingham, Birmingham, AL, (4)The University of Alabama at Birmingham, Birmingham, AL

---

**Background:** Often, autistic children's reading comprehension lies significantly below their decoding skills (Huebner & Mann, 2010), requiring an intervention that does not merely focus on improving reading ability. Visualizing and Verbalizing<sup>®</sup> for Language Comprehension and Thinking (V/V, Bell, 1991) is a reading intervention which improves reading comprehension by teaching children to use visual imagery during reading. The V/V intervention is based on the Dual-Coding Theory, which posits two subsystems involved in cognition, a non-verbal (imagery) subsystem and a verbal subsystem for non-linguistic and linguistic information respectively (Pavio, 2007). Prior research has linked facets of these two subsystems, including visual (Lynn et al., 2005) and verbal (Cain, 2006) memory, to reading.

**Objectives:** This study aims to investigate the role of visual and verbal memory in facilitating and improving reading comprehension in autistic children.

**Methods:** In this randomized control trial, children between the ages of 7 and 13 years completed the V/V intervention and presented for pre- and post-testing sessions to track response to treatment. While data collection is ongoing, preliminary data from two autistic groups, an experimental group (EXP; n=6) and a waitlist control group (WLC; n=5), were analyzed. The EXP group completed the V/V intervention between pre- and post-testing sessions, while the WLC group received intervention after completion of both testing sessions. Scaled scores from the following WRAML-2 subtests were utilized: Story Memory (SM), Design Memory (DM), Verbal Learning (VL), and Picture Memory (PM). Mann-Whitney nonparametric statistical analyses were used to assess within-group differences in scaled scores between pre- and post-test and between-group differences in percent change in scores from pre- to post-test.

**Results:** WRAML-2 subtest scaled scores did not significantly differ for either group from pre- to post-testing ( $p=n.s.$ ). Between groups, the difference in the percent change for PM from pre- to post-test was significant ( $U=2.5$ ,  $z=-2.287$ ,  $p=0.017$ ). The mean percent change for PM was 124.76% for the EXP group and -13.52% for the WLC group. Percent change was not significantly different between the groups for SM ( $U=6$ ,  $z=-1.686$ ,  $p=.126$ ), DM ( $U=10$ ,  $z=-.934$ ,  $p=.429$ ), or VL ( $U=10.5$ ,  $z=-.823$ ,  $p=.429$ ). However, for all three of these subtests, mean percent change was higher in the EXP group (SM=150%, DM=34.5%, VL=58.09%) than in the WLC group (SM=-13.89%, DM=28.61%, VL=22.22%), suggesting a possible trend toward greater improvement in the EXP group.

**Conclusions:** Greater improvement in Picture Memory performance in the EXP group suggests that the V/V intervention, which focuses on building visual imagery during reading, may have an impact on visual memory, specifically on the ability to learn and recall meaningful visual information.

Since V/V has been shown to improve reading comprehension (Maximo et al., 2017; Murdaugh et al., 2015; 2017), it is possible that contextual visual memory is one of the mechanisms through which improvements in reading comprehension are facilitated. The trend of improvement across the other subtests for the EXP group suggests that the intervention may have a positive impact on other types of memory as well. Additional data obtained through ongoing data collection will help fully elucidate the patterns behind these trends.

**503.028 (Virtual Poster)** Predictors of Treatment Use in Autistic Children

**E. Back<sup>1</sup>, K. Jonkman<sup>2</sup> and S. Begeer<sup>3</sup>,** (1)Department of Psychology, Kingston University London, Kingston upon Thames, United Kingdom, (2)Vrije Universiteit Amsterdam, Amsterdam, Netherlands, (3)VU University Amsterdam, Amsterdam, Netherlands

---

**Background:** Autism is a heterogeneous condition with characteristics that present in different ways and is often accompanied by co-morbid psychiatric disorders. Many different treatments are available for autistic individuals, some aimed at reducing core autism symptoms while others target co-occurring problems. The diverse nature of autism and its treatment options justify the need to understand which individual characteristics are associated with the use of which treatment.

**Objectives:** This study aimed to predict treatment prevalence, treatment types (interventions and medication), and treatment load (duration and intensity of treatments) from *demographic* factors (age, sex, parental education level, IQ, educational setting and co-occurring diagnosis) and *autism-specific* features (severity of symptoms, social skills, repetitive and/restrictive behaviours and interests, and sensory issues).

**Methods:** This study used parent reported data on autistic children (N=1464, aged 1-17 years) from the Netherlands Autism Register. Based on (inter)national guidelines (including: CDC, 2019 (US), ESCAP; Fuentes et al., 2020 (European) and NICE, 2013 (UK)) three treatment categories were devised: *Guideline* treatments targeted the core characteristics of autism (social communication and repetitive/restricted behaviours and interests), *Mainstream* treatments included interventions or medication not specifically for autism, targeting associated symptoms (e.g., sleep difficulties) and *Other* treatments are interventions or medications that are not included in the treatment guidelines (e.g., alternative therapies) or are actively discouraged in the guidelines.

**Results:** Most children (88%) had received interventions (77% had received *mainstream*, 77% *guideline* and 28% *other* interventions) and about half (52%) had received medication (51% had received *mainstream* medication and 5% *other* medication). The most commonly reported interventions included: physiotherapy, parent training and social skills training. Children in special education received more interventions and children with co-occurring diagnoses had a higher number of total hours of treatment. Older age, higher IQ and being female were related to more *guideline* (specifically for autism) or *mainstream* (associated symptoms) intervention use. Lower parental education was related to more *mainstream* medication use. Autism specific measures (severity of autism symptoms, social skills, repetitive and restrictive behaviours) did not relate to treatment use. However, more severe sensory issues increased the chance of medication use.

**Conclusions:** Treatment use is mostly guided by demographic factors (age, IQ, gender, parental education) rather than autism-specific characteristics (e.g., level of social skills, or repetitive behaviours). Ideally all children should receive the treatment they need based on the severity and profile of characteristics, regardless of demographic factors such as gender, IQ or parental education. Therefore, autism-specific characteristics should be taken into consideration more when selecting interventions for children as described in international treatment guidelines.

**503.029 (Virtual Poster)** Preliminary Outcomes for Mentors in the Autism Mentorship Program (AMP)

**R. L. Hudock, L. Weiler and N. Chandrasekharan,** University of Minnesota, Minneapolis, MN

---

**Background:** Research shows that relationships with caring, non-parental adult mentors are critical to healthy development and can positively influence a range of outcomes, such as peer and parent-child relationships, identity development, academic achievement, self-confidence, the prevention of problem behaviors, and reducing mental health problems (DuBois et al., 2011; Haft et al., 2019; Raposa et al., 2019; Taussig et al., 2019; Wyman et al., 2010). While mentoring is beneficial for youth, there is evidence that mentoring can be mutually beneficial and also provide positive outcomes for mentors. Mentoring in the autism community, particularly with autistic mentors, is relatively new and this experience has yet to be explored in-depth.

**Objectives:** The aim of this study was to examine preliminary outcomes for mentors participating in the Autism Mentorship Program (AMP).

**Methods:** AMP involves one-to-one mentorship of adolescents with ASD (ages 14-18) by adults with ASD. Mentoring sessions consisted of 22 weekly 60-minute virtual sessions conducted via Zoom. Pairs participated in semi-structured activities centered around common interests. Mentors included 14 autistic adults (ages 19-35; 57% male, 79% non-Hispanic) who were recruited from a local suburban community in the Midwest. All participants had a diagnosis of ASD without co-occurring intellectual disability or language impairments. The majority of participants had co-occurring diagnoses of anxiety, depression, or ADHD. Participants completed a variety of standardized questionnaires including the Social Skills Improvement System (SSIS), the Achenbach Rating Scales (ASR), the Rosenberg Self-Esteem Scale, and a study developed survey evaluating self-concept, quality of life, and daily activities. Descriptive and associational statistics were used to meet objectives.

**Results:**

Participants reported improvements in social and emotional functioning during AMP and also reflected on pieces they found rewarding and challenging about mentoring. Mentors reported a strong relationship quality with their mentees (rating 4.1 on a 5-point scale). They also reported enjoying aspects of mentoring such as being able to guide their mentees, building a positive relationship with their mentee, interacting with other

matches, getting to know autistic students, knowing they could make a small impact on someone's life, and playing games. Mentors noted challenges related to mentoring including maintaining conversations and having difficulty determining how their mentee was feeling. Mentors reported improvements in quality of life ( $d=.58$ ), initiating interactions with friends ( $d=.3.6$ ), and receiving communication from friends ( $d=.50$ ). However, they saw decreases in time spent with friends in person ( $d=-.80$ ), which may be related to the pandemic. Small positive changes were reported regarding self-esteem, social competence, externalizing, and internalizing symptoms.

Conclusions: AMP has the potential to positively impact the social and emotional functioning of autistic mentors. Mentor outcomes should continue to be explored with larger samples in future AMP cohorts.

**503.030 (Virtual Poster)** Satisfaction and Preliminary Outcomes of the PEERS Social Skills Program When Delivered Via Telehealth

**R. L. Hudock<sup>1</sup>** and **C. M. Lee<sup>2</sup>**, (1)University of Minnesota, Minneapolis, MN, (2)Department of Pediatrics, University of Minnesota - Twin Cities, Minneapolis, MN

---

**Background:**

Teens and young adults with autism spectrum disorder (ASD) experience increased social challenges as they experience more complex social environments (e.g., Bauminger & Kasari, 2000; Constantino, 2005). Social skills training can support individuals by improving social skills and knowledge, peer relationships, social-emotional well-being (e.g., Laugeson et al., 2012; Hill et al., 2017). The Program for the Evaluation and Enrichment of Relational Skills (PEERS; Laugeson & Frankel, 2010), a curriculum using a cognitive-behavioral approach to teach age-appropriate social skills, teaches ecologically valid social skills. PEERS has been adapted for telehealth to meet the increasing wide-spread social needs of those with ASD, including increased need during COVID-19.

Objectives: Investigate the initial response to the PEERS program when implemented via telehealth.

**Methods:**

The PEERS program includes 16 90-minute weekly sessions focused on teaching skills needed to make and maintain friendships. We delivered PEERS for telehealth using the officially adapted telehealth materials created and provided by Dr. Elizabeth Laugeson and the UCLA Semel Institute PEERS Clinic for certified PEERS providers (both authors).

Descriptive analyses included weekly online survey responses from 16 families of individuals (ages 14-22, 82% male) enrolled in two telehealth PEERS groups through an outpatient clinical setting. A total of 274 responses were obtained over the course of these two groups. Participants reported on the following aspects of the session: satisfaction with the session, satisfaction with technology used to host the session, helpfulness of the session, and ability to use the information learned.

Participants were administered outcome measures pre- and post-group to evaluate social and emotional outcomes. Eight families completed pre- and post-group measures. Analyses include pre- and post-test comparisons of mean scores on outcome measures, including the Social Responsiveness Scale, 2<sup>nd</sup> Edition (SRS-2), the Test of Adolescent Social Skills Knowledge (TASSK), the Brief Rating Scale of Executive Functioning – 2<sup>nd</sup> Edition (BRIEF-2), the Generalized Anxiety Disorder – 7 (GAD-7), the Patient Health Questionnaire – 9 (PHQ-9), and the Achenbach Rating Scales (Child Behavior Checklist). Additional pairwise comparisons will be conducted with a larger sample when the next phase of data is collected this winter (expecting an additional 16-20 families to complete data collection), including analysis of the Social Skills Improvement System (SSIS).

Results: Results from online surveys indicated high satisfaction with PEERS via telehealth. Eighty-three percent (83%) of respondents rated the session as Excellent or Very Good; 87% rated the technology used as Excellent or Very Good; 76% reported that the session was Completely or Very Helpful to them; 81% reported they were Completely or Very able to use the information learned. Preliminary analysis shows significant improvements related to social skills knowledge (TASSK), autism-related symptoms (SRS-2, including social communication, social motivation, total score, restricted and repetitive behaviors, and social communication and interaction), executive functioning (BRIEF-2, including inhibition, emotional control, planning/organization, task monitoring, cognitive regulation, and global executive composite), challenging behaviors (CBCL), and anxious and depressed symptoms (GAD-7, PHQ-9, CBCL). See Table 1 for a summary of mean scores.

**Conclusions:**

The PEERS program shows promising results when delivered via telehealth.

**503.031 (Virtual Poster)** Sex-Based Differences of Treatment Response to PRT for Emotional and Behavioral Symptoms

**S. Terroso<sup>1</sup>**, **D. J. Magin<sup>2</sup>**, **D. G. Sukhodolsky<sup>3</sup>** and **P. E. Ventola<sup>3</sup>**, (1)Child Study Center, Yale University, New Haven, CT, (2)Yale Child Study Center, New Haven, CT, (3)Yale Child Study Center, Yale University School of Medicine, New Haven, CT

---

Background: Psychiatric and behavioral comorbidities are prevalent among children with autism spectrum disorder (ASD), with an estimated 70% of children with ASD having at least one comorbid disorder (DeFilippis, 2018). Comorbidities negatively impact the social and adaptive functioning as well as the overall quality of life of children with ASD (Romero et al., 2016). Pivotal Response Treatment (PRT) is an empirically validated intervention that utilizes a naturalistic and play-based environment and targets social and communication skills (Koegel & Koegel, 2012). Few studies have investigated sex differences in comorbid symptoms in response to PRT.

**Objectives:** The present study examines sex differences in emotional/behavioral comorbidities of children with ASD in response to Pivotal Response Treatment (PRT).

**Methods:** The study included thirty children aged 4-11 years old, 10 girls (M = 95.50 months, SD = 29.36) and 20 boys (M = 84.65 months, SD = 31.30). All children had an ASD diagnosis as confirmed by the Autism Diagnostic Observation Schedule (ADOS). Participants received 6 hours of PRT for 16 weeks. Emotional and behavioral symptoms were assessed before and after treatment using the Child Behavior Checklist – Preschool and School Age (CBCL/1.5-5 ( $n = 14$ ) and CBCL/6-18 ( $n = 16$ )).

**Results:** At baseline, there were no significant sex differences in the CBCL scores of the domains considered (Internalizing Problems, Externalizing Problems, Total Problems, and subdomains Anxious/Depressed, Anxiety Problems, ADHD, and ODD). Following PRT, there were no significant differences in improvement between girls and boys: Internalizing Problems (girls M = 6.00, boys M = 4.60), Externalizing Problems (girls M = 3.80, boys M = 5.40), Total Problems (girls M = 5.70, boys M = 5.85) and subdomains Anxious/Depressed, Anxiety Problems, ADHD, and ODD. However, all participants individually improved significantly across the post-treatment CBCL categories of Internalizing Problems,  $t(29) = 3.3$ ,  $p = .002$ ; Externalizing Problems,  $t(29) = 3.5$ ,  $p = .002$ ; Total Problems,  $t(29) = 3.9$ ,  $p < .001$ ; and ODD subdomain,  $t(29) = 3.4$ ,  $p = .002$ . There was no significant individual change post-treatment in CBCL subdomains Anxious/Depressed, Anxiety Problems, and ADHD. No scores in the symptom domains were significantly worse following treatment.

**Conclusions:** These results indicate that there were no sex differences in comorbid behavioral/emotional symptoms at baseline. There was also no sex-based response to treatment. Notably, both girls and boys show improvement in emotional and behavioral problems following PRT, supporting the efficacy of PRT as an effective treatment for comorbidity symptoms in children with ASD across both sexes.

**503.032 (Virtual Poster)** The Effects of an Eight-Week Physical Exercise Intervention, LEGO and Minecraft Activities on Anxiety in Underserved Children with Autism Spectrum Disorder

**J. G. Gehricke<sup>1</sup>**, L. Lowery<sup>2</sup>, S. D. D. Alejo<sup>3</sup>, M. N. Dawson<sup>3</sup>, J. Chan<sup>4</sup>, R. A. Parker<sup>5</sup>, A. R. Archibald<sup>6</sup>, H. Benavidez<sup>6</sup>, T. Saini<sup>6</sup>, K. Kuhlthau<sup>4</sup>, Y. Trujillo<sup>6</sup>, O. Grigaux<sup>6</sup>, S. A. Cadondon<sup>6</sup>, M. G. Baconawa<sup>6</sup>, K. R. Bellesheim<sup>7</sup>, M. Sweeney<sup>8</sup>, F. Haddad<sup>9</sup> and S. Radom-Aizik<sup>10</sup>, (1)The Center for Autism & Neurodevelopmental Disorders, University of California, Irvine, Santa Ana, CA, (2)Thompson Center for Autism and Neurodevelopmental Disorders, University of Missouri, Columbia, MO, (3)Pediatrics, University of California - Irvine, Santa Ana, CA, (4)Massachusetts General Hospital, Boston, MA, (5)Biostatistics, Massachusetts General Hospital and Harvard Medical School, Boston, MA, (6)UC Irvine, Irvine, CA, (7)University of Michigan, Ann Arbor, MI, (8)Thompson Center for Autism and Neurodevelopmental Disorders, University of Missouri, Missouri, MO, (9)Pediatrics, University of California, Irvine, Irvine, CA, (10)University of California, Irvine, Irvine, CA

**Background:** Anxiety is a frequent comorbidity in children with autism spectrum disorder (ASD). Physical exercise has been shown to have therapeutic benefits for reducing anxiety in adults and adolescents and may be a low-cost and easy to access intervention for reducing anxiety in younger children with ASD.

**Objectives:** To examine the efficacy of an 8-week physical exercise intervention specifically designed for younger children with ASD from underserved populations to reduce anxiety, and to compare to a sedentary activity LEGO/Minecraft intervention.

**Methods:** 148 children (6-12 years old) with ASD were randomized into a clinical trial to evaluate the efficacy of an exercise protocol designed to reduce anxiety specifically in younger children with ASD. Participants were randomized to an exercise intervention group (N=76) or sedentary activity LEGO/Minecraft group (N=72). Both programs were administered 1-3 times weekly for 8 weeks. Anxiety was assessed with the Child Behavior Checklist DSM-5 anxiety (CBCL DSM-5) at weeks 1, 3, 6, and 8 as well as follow up at weeks 12 and 16. Secondary outcome measures included the Screen for Child Anxiety Related Disorders (SCARED), Child's Sleep Habits Questionnaire (CSHQ-ATN), Physical Activity Questionnaire (PAQ-C), and salivary cortisol measured at weeks 1, 3, 6, and 8.

**Results:** CBCL DSM-5 and SCARED anxiety scores showed improvements in both groups at 8-weeks with no significant differences between the physical exercise and sedentary activity LEGO/Minecraft groups. In addition, the CBCL DSM-5 anxiety scores decreased in the physical exercise group at weeks 12 and 16 compared to baseline. Follow up at weeks 12 and 16 were unavailable for most of the LEGO/Minecraft group, which was offered to participate in the physical exercise intervention after week 8. Sleep as measured by the CSHQ also showed improvements in the physical exercise group but not in the LEGO/Minecraft group with no significant differences between the groups. Physical activity levels were significantly increased in the physical exercise group compared to the LEGO/Minecraft group at week 8. Salivary cortisol did not show any significant changes in groups or differences between groups.

**Conclusions:** Anxiety decreased in the 8-week physical exercise as well as the sedentary LEGO/Minecraft interventions in 6–12-year-old underserved children with ASD with no significant difference between the intervention groups.

**503.033 (Virtual Poster)** School-Partnered Development of a Sleep Intervention for Autistic Students: Lessons Learned

**I. Schouwenaars<sup>1</sup>**, M. Magnee<sup>1</sup>, H. M. Geurts<sup>2</sup>, C. van Bennekom<sup>3</sup>, S. Pillen<sup>4</sup> and J. P. Teunisse<sup>1</sup>, (1)HAN University of Applied Sciences, Nijmegen, Netherlands, (2)University of Amsterdam, Amsterdam, Netherlands, (3)R&D, Heliomare, Wijk aan Zee, Netherlands, (4)Kempenhaghe, Heeze, Netherlands

**Background:**

Teachers at schools for special education observe that their autistic students experience sleep problems (Cortesi et al., 2010) that negatively impact their daytime functioning (Schouwenaars et al., 2021). Although we have seen that schools are willing to support their students in reducing sleep problems, the implementation of sleep interventions in schools remains unsuccessful because most are not developed for a school-based setting.

**Objectives:** We used our knowledge about successful sleep interventions and considered the context of special education to co-create a school-based sleep intervention. Our research question was: What were the lessons learned from the school-partnered development of a school-based sleep intervention for autistic students?

**Methods:** We used the first three phases of the Centre for eHealth Research and Disease Management (CeHReS) roadmap: contextual inquiry, value specification, and design (van Gemert-Pijnen et al., 2011). Each phase had specific goals and activities (Table 1) that led to iterative development involving future users (autistic adolescents, their parents, and teachers) and professionals (researchers, teachers, somnologist, software developers).

**Results:** Based on the previously described activities, we developed a school-based sleep intervention that consists of three parts: 1) monitoring the students' sleep and daytime functioning, 2) holding a sleep consultation with a teacher based on the monitoring, and 3) implementing the sleep recommendations. The future users and professionals indicated that it was important to include four factors with corresponding operationalizations in the sleep intervention: limited burden, sense of usefulness, clear guidance and structure, and additional support cues (Figure 1). In the usability questionnaire, the adolescents reported the sleep recommendations to be beneficial and useful, the instructions were easy to understand, and they had enough resources to be able to use the sleep recommendations. Applying and maintaining the sleep recommendations were most challenging. Students and parents mentioned that it was sometimes difficult to change their habits and fit the sleep recommendations into daily routines. This emphasizes the need for optimal guidance of the students in the implementation of the recommendations and motivation for long-term adherence.

**Conclusions:** Due to this roadmap's iterative development approach with an emphasis on stakeholder participation, we already noticed possible barriers to the intervention's application during its development. This approach enabled us to anticipate those barriers and adapt the sleep intervention during its development, which increases the likelihood of successful implementation. Moreover, engaging autistic people in co-creation can be difficult because co-creation involves collaborating with others, creating new ideas, and communicating those ideas, all of which could be challenging for autistic people (Benton et al., 2012). Due to the application of recommendations for a successful co-creation process with autistic students (e.g., of similar structure for each session, conducting the sessions in a familiar environment, and involving adults that are familiar to the students) we experienced that the engagement of autistic students in this study was successful.

#### **503.034 (Virtual Poster) Efficacy of a School-Based Sleep Intervention for Autistic Students**

**I. Schouwenaars<sup>1</sup>, M. Magnee<sup>1</sup>, C. van Bennekom<sup>2</sup>, H. M. Geurts<sup>3</sup>, S. Pillen<sup>4</sup> and J. P. Teunisse<sup>1</sup>,** (1)HAN University of Applied Sciences, Nijmegen, Netherlands, (2)R&D, Heliomare, Wijk aan Zee, Netherlands, (3)University of Amsterdam, Amsterdam, Netherlands, (4)Kempenhaghe, Heeze, Netherlands

---

**Background:** The majority of existing sleep interventions for autistic adolescents are delivered in clinical practice (e.g., (Loring et al., 2018), however, school-based sleep interventions could be more easily accessible for school-aged youth and, therefore, have a greater reach and make earlier treatment possible. Early interventions to reduce sleep problems are important to prevent its exacerbation (Morin & Benca, 2012). We co-created a school-based sleep intervention together with autistic adolescents, their parents and teachers to improve sleep and daytime functioning (Loring et al., 2018). In this study we investigate the effectiveness of our co-created school-based sleep intervention for autistic adolescents

**Objectives:** Our research questions are:

- 1) What are the effects of the school-based sleep intervention on sleep quality in adolescents with ASD?
- 2) What are the effects of the school-based sleep intervention on daytime functioning in adolescents with ASD?

**Methods:**

The study included 21 autistic adolescents each together with a parent and teacher. The inclusion criteria for adolescents were: (a) diagnosed with an autism spectrum disorder by a psychiatrist or psychologist, based on DSM-IV or DSM 5 criteria, (b) total score of >7 on the Insomnia Severity Index, and, (c) medication free or at a stable dose during the study. Exclusion criteria are: (a) intellectual disability, (b) diagnosed or suspected depression, anxiety disorder, substance dependence or game addiction, (c) disturbed parent-child relationship that can hinder the intervention, and (d) indications that pupil will have difficulties to perform the requested activities.

We used a multiple baseline design to investigate the effectiveness of the sleep intervention. In this design the intervention the baseline varies across participants. The duration of the baseline was two to three weeks and of the intervention period ten weeks. Follow-up data were collected eight weeks after the intervention. The sleep intervention consists of three repeating parts: 1) monitoring the adolescents' sleep and daytime functioning, 2) holding a sleep consultation with a teacher based on the monitoring, and 3) executing the sleep recommendations.

This study has two primary outcome variables: sleep quality (mean of questions about how well they slept, their feeling of being rested when waking up and difficulties with waking up) and daytime functioning as reported by adolescents (sum of scores on mood, concentration, daytime sleepiness). These variables are measured by daily self-reports and rated from 1 to 10.

Data will be first visually analyzed, conducted in four steps (Kratochwill et al., 2010): 1) determine whether the baseline shows a predictable and stable pattern, 2) compare the data of each phase with the data of the adjacent phase on level, and variability, 3) the previous information is supplemented with immediacy of the effect and overlap, 4) combine information of each of the phases. In addition, the statistical significance of the intervention effect is evaluated by randomization tests.

**Results:** The data collection started in September 2021 and will be finished in February 2022. The results and conclusions will be presented at the conference.

**Conclusions:** Conclusions will be presented at the conference.

**503.035 (Virtual Poster)** Improving Academic Performance through a School-Based Intervention Targeting Executive Functioning and Study Skills  
**L. B. Jones<sup>1</sup>, E. Hamik<sup>1</sup>, J. Patronick<sup>1</sup>, J. Yeung<sup>1</sup>, A. Duncan<sup>2,3</sup>, A. Zoromski<sup>1</sup> and L. Tamm<sup>1</sup>,** (1)Division of Behavioral Medicine and Clinical Psychology, Cincinnati Children's Hospital Medical Center, Cincinnati, OH, (2)Cincinnati Children's Hospital Medical Center, Cincinnati, OH, (3)College of Medicine, University of Cincinnati, Cincinnati, OH

---

**Background:** Students with autism spectrum disorders (ASD) often experience academic difficulties (e.g., missing assignments, losing materials, inefficient studying) in part due to their deficits in executive functioning (EF). Middle school is an important time to address EF skills such as organization, planning, prioritizing, and working memory given increasing demands for these skills in the transition from elementary to middle school. However, no evidence-based interventions currently target EF skills for middle schoolers with ASD. An outpatient intervention, Achieving Independence and Mastery in School (AIMS), was developed to target EF skills in middle-school students with ASD. AIMS was recently significantly modified to be delivered in the middle-school setting by school personnel.

**Objectives:** To test the feasibility, acceptability, and initial efficacy of the school-based version of AIMS in an open trial.

**Methods:** Participants were middle-school students with ASD without intellectual disability ( $n=6$ ; 83.3% male; 16.67% racial minority; age:  $12.83 \pm 0.41$ ; IQ:  $84.83 \pm 24.93$ ) attending a school specializing in ASD. AIMS included 34 student sessions targeting EF (i.e., problem-solving, organization systems, planning/prioritizing, and study strategies) delivered twice per week during a class period within one semester. Feasibility was measured using attendance, real-world practice assignment completion, and AIMS teacher fidelity to the manual (i.e., adherence). Acceptability was measured through student report on the Acceptability of Intervention Questionnaire (AIQ) on a Likert scale from 1-5 (5 being best). Due to the small sample size, pre to post effect sizes were computed to assess intervention efficacy for classroom teacher and/or parent ratings on the Children's Organizational Skills Scales (COSS), Adolescent Academic Problems Checklist (AAPC), Homework Problems Checklist (HPC), Classroom Performance Survey (CPS) and Academic Performance Rating Scale (APRS).

**Results:** All six students completed the study, although only five completed the AIQ. On average, 29 of 34 (85%) AIMS sessions were attended, and 23 out of 27 (85%) real-world practice assignments were completed. The AIMS teacher delivered content in compliance with the manual 93% of the time. Improvements with large effect sizes ( $\geq .8$ ) were observed for parent-rated HPC homework behaviors and AAPC academic skills (Table 1). Improvements with medium effect sizes ( $\geq .5$ ) were observed for parent-rated COSS memory and materials management and teacher-rated AAPC academic skills. Students gave high AIQ ratings ( $\geq 4$ ) for how well they understood backpack and locker organization skills, and study skills (e.g., breaking down assignments, summarizing, study cards), and reported that they would use the information learned in AIMS in the future. Students' ratings were acceptable ( $>3$ ) for their understanding of binder and computer organization skills, and lowest for how much they liked the handouts.

**Conclusions:** Results of the open trial suggest that AIMS has high feasibility and acceptability, and initial findings support an impact on academic performance and EF skills. Further intervention adaptation and replication with a larger sample size is warranted. Preliminary data from an ongoing pilot randomized trial in six schools (anticipated  $n=34$ ) will be available at the time of presentation.

**503.036 (Virtual Poster)** A Holistic Evaluation of Social Skills Group Programs for Autistic Adults According to the ICF: A Systematic Review  
**B. Afsharnejad<sup>1</sup>, E. D'Arcy<sup>2</sup>, M. Youell<sup>3</sup>, R. Mordant<sup>4</sup>, L. Rogalasky<sup>5</sup>, J. Berlinger<sup>6</sup>, S. McGarry<sup>4</sup>, S. Bolte<sup>5</sup> and S. J. Girdler<sup>6</sup>,** (1)Autism Research Team, Telethon Kids Institute, Perth, WA, Australia, (2)Cooperative Research Centre for Living with Autism (Autism CRC), Brisbane, Australia, (3)Curtin University, Bentley, WA, Australia, (4)Curtin Autism Research Group, Curtin University, Perth, WA, Australia, (5)Center of Neurodevelopmental Disorders (KIND), Centre for Psychiatry Research; Department of Women's and Children's Health, Karolinska Institutet, & Stockholm Health Care Services, Region Stockholm, Stockholm, Sweden, (6)School of Allied Health, Curtin University, Bentley, WA, Australia

---

**Background:** Although social skills group programs (SSGPs) are among the most frequently employed programs to support autistic adults navigating the neurotypical social world, it is unclear if a holistic view was used to develop these programs. The International Classification of Functioning, Disability and Health (ICF) is a biopsychosocial model of functioning, consisting of an interplay between an individuals' Personal Factors, Health Condition/s, Body Functions and Structures, Activities and Participation, and Environmental Factors.

**Objectives:** To identify and evaluate the quality of randomised controlled trials (RCTs) conducted of SSGP for autistic adults and identify and describe the components of these programs according to the ICF.

**Methods:** A systematic review (registration ID# CRD42021275848) of RCTs exploring the efficacy of SSGPs for autistic adults was conducted. Medline, PubMed, CINAHL, Scopus, and PsychInfo electronic databases were searched from January 2011 until August 2021 for peer-reviewed RCT studies published in English, evaluating the efficacy of an SSGP for autistic adults (Aged >18 years) with average or above-average IQ levels. In

addition to a quality appraisal and extraction according to the Preferred Reporting Items for Systematic Reviews and Meta-Analysis (PRISMA) statement, key components of the SSGPs were extracted (including aims, mechanisms, contexts, and outcomes). These were then classified according to the ICF using a standardised linking methodology.

**Results:** A search of title, abstract and keyword in the database searches identified ten studies, meeting the inclusion criteria. Although the studies demonstrated an adequate to strong methodological quality with scores ranging from 58-92% (Mean=81.2%), they were limited by small sample sizes, non-blinded outcome collection, and unclear reporting of estimates of variance, randomisation process, and participant characteristics. The main components (as described in the RCT study) of the included SSGPs were predominantly designed reflecting codes under the Activities and Participation chapter, including “Learning and applying knowledge”, “General tasks and demands”, “Communication”, “Self-care”, “Interpersonal interactions and relationships” and “Major life areas”. “Intellectual functions”, “Products and technology”, and “Support and relationships” were the only other subcodes identified under the Body Function and Environmental Factors.

**Conclusions:** While the literature suggests that SSGPs can support autistic adults navigating the neurotypical social world, there are still limitations to the current evidence. These include a lack of consideration and involvement of autistic adults in developing SSGPs, limitations relating to study design and limited understanding of the generalisability of social capabilities to everyday contexts. In addition, SSGPs appear to focus heavily on Activities and Participation with little consideration of the influence of Body Functions and Environmental Factors. Future research should consider co-producing the components of the SSGPs with autistic adults while taking a more holistic approach, particularly recognising the complex interplay between all components of the ICF which influence functioning.

**503.037 (Virtual Poster)** A Systematic Review of Social Skills Group Programs Delivered to Autistic Youth with a Co-Occurring Intellectual Disability

**B. Afsharnejad<sup>1</sup>, F. Parkhowell<sup>2</sup>, A. Y. Koh<sup>3</sup>, R. Rapheal<sup>4</sup>, R. Swarts<sup>5</sup>, S. McGarry<sup>3</sup>, S. Bolte<sup>4</sup> and S. J. Girdler<sup>5</sup>,** (1)School of Allied Health, Curtin University, Perth, WA, Australia, (2)Curtin University, Bentley, WA, Australia, (3)Curtin Autism Research Group, Curtin University, Perth, WA, Australia, (4)Center of Neurodevelopmental Disorders (KIND), Centre for Psychiatry Research; Department of Women’s and Children’s Health, Karolinska Institutet, & Stockholm Health Care Services, Region Stockholm, Stockholm, Sweden, (5)School of Allied Health, Curtin University, Bentley, WA, Australia

**Background:** Although social skills group programs (SSGPs) are among the most frequently employed programs to support autistic youth navigating the neurotypical social world, they are predominantly delivered to autistic participants with average or above-average cognitive abilities, with the efficacy of SSGPs delivered to autistic youth with a co-occurring Intellectual disability (ID) remaining largely unknown.

**Objectives:** To identify and investigate the design and quality of studies evaluating the efficacy of SSGPs delivered to autistic youth with a co-occurring intellectual disability and their outcome framework.

**Methods:** This study conducted a systematic review (CRD42021275841) of RCTs exploring the efficacy of SSGPs for autistic youth with co-occurring ID. CINAHL, Medline, ProQuest, Scopus, and Web of Science electronic databases were searched from January 2011 until July 2021 for peer-reviewed studies published in English, evaluating the efficacy of an SSGP delivered to autistic school-aged youth (5 to 18 years) with a co-occurring ID assessed via an experimental design. A quality appraisal and extraction were then delivered according to the Preferred Reporting Items for Systematic Reviews and Meta-Analysis (PRISMA) statement, identifying the components of the SSGPs (including aims, mechanisms, contexts, and outcomes).

**Results:** Overall, eight studies, half randomised controlled trials and half quasi-experimental, meeting the inclusion criteria were identified, searching the databases at a title, abstract, and keyword level. Although the studies demonstrated an adequate methodological quality for the included studies ( $M = 74.5\%$ , ranging from 63-93%), they were restricted by small sample sizes, non-blinded outcome collection, some having quasi-experimental design and reporting of the participants’ characteristics, especially the diagnosis and IQ level. Additionally, the RCT studies were limited by unclear reporting of confounding factors, estimates of variance and randomisation process. The SSGPs used implicit teaching strategies such as horse riding and martial arts or explicit ones such as peer or video modelling and were predominantly delivered within a school context, targeting varied skills. The majority of studies relied on parent proxy and observer reports to evaluate the SSGT, mostly reporting on autistic-like traits and adaptive functioning, with only a few collecting social interaction and communication outcomes.

**Conclusions:** Findings of this review demonstrated a paucity of understanding about how SSGPs improve the social competence of autistic youth with ID. Due to the limited understanding of the effect of cognitive capabilities on the youth’s social outcomes, Clinicians should be cautious in suggesting SSGPs for autistic youth with ID. Future research should consider using a more rigorous and youth-centred approach towards evaluating the efficacy of SSGPs for autistic youth with ID.

**503.038 (Virtual Poster)** A Neurocognitive Therapy Intervention to Develop Inner Speech Infor Autistic Children: Preliminary Results for a Remote, Synchronous Training Program for SLPs

**J. Nathan<sup>1</sup>, B. R. Nathan<sup>1</sup>, B. L. Baumann<sup>2</sup>, M. Sheynblyum<sup>3</sup>, V. Carr Copeland<sup>4</sup> and S. M. Eack<sup>5</sup>,** (1)Nathan Speech Services, LLC., Pittsburgh, PA, (2)aF-CBT Program, Univesity of Pittsburgh, Pittsburgh, PA, (3)Psychiatry, University of Pittsburgh, Pittsburgh, PA, (4)School of Social Work, University of Pittsburgh, Pittsburgh, PA, (5)University of Pittsburgh School of Social Work, Pittsburgh, PA

**Background:** Speech language pathologists (SLPs) play a critical role in supporting children on the autism spectrum. However, SLPs receive minimal autism training in graduate school. Effective autism interventions are essential to improve social and academic outcomes for autistic populations. Therefore, we developed a remote training program to train SLPs in a neurocognitive intervention that helps autistic children independently solve emotional, social or academic problems. The intervention, called *Thinking in Speech®* (TiS), develops inner speech, which is

essential for solving problems and self-regulation. Prior research found that autistic children seen by SLP graduate students trained to use *TiS* outperformed autistic children seen by experienced SLPs not trained in *TiS* (Nathan & Nathan, 2018). *TiS* received a 2019 Pitt Innovation Challenge (PInCh) Award from the University of Pittsburgh Clinical and Translational Science Institute, which funds this research.

**Objectives:** As a result of participation in a remote, synchronous *TiS* training program, and in preparation for using *TiS* therapy with autistic children, SLPs will report having improved knowledge of, and anticipated comfort using *TiS* strategies (e.g., asking for help, developing emotions vocabulary, category development; Hypothesis 1), taking responsibility for a child's dysregulation during therapy (Hypothesis 2) and interacting with the caregiver/parent after each therapy session (Hypothesis 3).

**Methods:** Experienced SLPs ( $n = 9$ ) were trained remotely by the *TiS* developer in two groups. Training consisted of: 1) readings; 2) four two-hour synchronous formal training sessions; 3) two one-hour synchronous feedback sessions; and 4) an individual asynchronous evaluation session of the recorded session. All trainees completed a post-training evaluation questionnaire. Group 2 trainees ( $n=5$ ), completed questionnaires on their knowledge and comfort with key components of the therapy at pre-and post-training on a 5-point Likert scale.

**Results:** Hypothesis 1 was supported; SLPs reported having improved knowledge of, and comfort with *TiS* strategies (e.g., asking for help, developing emotions vocabulary, category development),  $t(4)=-4.975^* p=.004$ ). Hypothesis 2 was supported; SLPs anticipated feeling more comfortable taking responsibility for a child's dysregulation during therapy,  $t(4)=-2.138^* p=.050$ ). supported; Hypothesis 3 was not supported; SLPs did not report anticipating they would have improved interactions with the caregiver/parent after each therapy session ( $t(4)=-.054 p=.480$ ). (Note: While nine SLPs were trained in total, pre-training scores were available only from five SLPs; post therapy scores will be available for all SLPs)

**Conclusions:** Though a small sample, results are encouraging. Even after a relatively short training program, SLPs report increased comfort with, and knowledge of an innovative neurocognitive therapy intervention for working with autistic children and their caregivers. Research is ongoing to examine whether SLPs report greater comfort and knowledge after therapy sessions are concluded compared to both pre- and post-training. More importantly, we will examine whether autistic children have less anxiety, less anger, less emotional dysregulation, higher executive functioning, and improved social responsiveness after eight weeks of *TiS* therapy, and whether these improvements remain an additional 10 weeks after therapy is concluded.

#### **503.039** (Virtual Poster) A Quality Evaluation of Intervention Outcomes for Transition-Age Autistic Youth

S. Crowley<sup>1</sup>, K. Bottema-Beutel<sup>1</sup>, S. Y. Kim<sup>2</sup>, S. Mohiuddin<sup>1</sup> and Q. Yu<sup>1</sup>, (1)Lynch School of Education and Human Development, Boston College, Chestnut Hill, MA, (2)Duksung Women's University, Seoul, Korea, Republic of (South)

**Background:** In the United States, the Individuals with Disabilities Education Act (IDEA, 2004) mandates the provision of educational supports to prepare transition-age students with disabilities for adulthood. These supports are meant to improve academic and functional skills relevant for success in adulthood. However, autistic students remain disengaged from employment and post-secondary education following high school (Shattuck et al., 2012; Wei et al., 2015). It could be that intervention research for this population has not focused on the outcomes that will have the greatest impact on adulthood. Sandbank and colleagues (2021) encourage researchers to differentiate between *proximal* outcomes; those that index behaviors or constructs directly taught or facilitated in the intervention, and *distal* outcomes; those that are developmentally beyond what was directly taught or facilitated in the intervention. They also encourage a distinction between *context-bound* outcomes; those that were measured in contexts similar to the intervention context, and *generalized* outcomes; that were measured in contexts that differ along several dimensions from the intervention context. While systematic reviews have characterized intervention outcomes in research for young autistic children (e.g., Sandbank et al., 2021), there have been no comprehensive efforts to assess outcome quality in research for transition-age autistic youth.

**Objectives:** In this systematic literature review, we examine outcome variables extracted from 191 studies, and characterize them according to: a) outcome domain, b) whether they indexed proximal or distal outcomes, and c) whether they indexed context-bound or generalized outcomes.

**Methods:** Included studies were: peer-reviewed, published in English, published between 1970 and 2020, and focused on non-pharmacological interventions; and included participants with a diagnosis of autism, PDD-NOS, or Asperger's Syndrome, and were between the ages of 14-22 years. Outcomes were categorized by two independent coders, based on domain (see Table 1 for outcome types and corresponding definitions), distality, and boundedness.

**Results:** At the time of submission, outcomes from 76% of the 191 included studies have been coded for proximity and boundedness, and 26% for outcome domain. Preliminary results reveal that, of 433 total outcomes, 94% were proximal and 72% were context-bound. The majority of outcomes (88%) measured discrete behaviors. In terms of outcome domain, 40% focused on social or verbal behaviors (e.g., initiations to a peer), 39% focused on transition-specific areas (academics, functional/daily living skills, or employment), and no outcomes focused on self-determination.

**Conclusions:** Interventions for transition-age autistic students have primarily focused on outcomes that were directly taught in the intervention, and were measured in contexts that are very similar to the intervention. These types of outcomes limit our confidence that learning gains will be maintained after students leave the intervention context. This is especially problematic for this age-group, as they are not expected to have the intervention supports offered during school upon school exit. Additionally, there is little focus on outcomes that are meant to be the focus of the transition period, such as academics, functional/daily living skills, and employment. A relatively weak evidence base for supporting transition-age autistic youth could explain persistently poor post-school outcomes for this population.

#### **503.040** (Virtual Poster) Evaluation of a Brief Telehealth PRT Training Program for Parents of Autistic Children

**Background:** Due to a variety of resource-related issues, many autistic individuals and their families aren't able to access the support and services that they need. Factors such as long provider waitlists, a lack of trained professionals, limited financial resources/funding issues, and geographical location prohibit large scale dissemination for certain populations. Additionally, immunocompromised status and other health related concerns and natural disasters/emergency situations, such as the COVID-19 pandemic present unique challenges for accessing services. Provision of services via telehealth and the use of parent-mediated interventions have been used by researchers and clinicians to address these issues. Multiple studies on such models of Pivotal Response Treatment (PRT) parent training show promise. However, at the present time, little is known about the effects on parent fidelity of implementation and related child gains of combining these modalities into more condensed, short-term telehealth parent training programs. As such, it is important to explore these shorter telehealth options to determine if professionals can be used more effectively in their dissemination of evidence-based support to autistic individuals and their families.

**Objectives:** The primary objective of this study was to assess the impact of a brief telehealth PRT parent training program on parents' fidelity of implementation (FOI) and changes in child social-communication skills.

**Methods:** Three parent-child dyads participated in a non-concurrent multiple-baseline study looking at the effects of an intensive (10 hour) week-long telehealth PRT parent training program. The children included two males and one female (mean age=2;5; 1 White/1 Hispanic/1 Asian). Though both parents participated, the mother was the primary research participant in all three families. Parents' FOI and child utterances were coded in parent-recorded videos collected during baseline, intervention, post-intervention, and follow-up. One third of the videos were double coded to ensure reliability. Though data presented below is only for two participants, data has been collected for three and will be analyzed and presented. Recruitment is ongoing.

**Results:** Parents' FOI of PRT and the number of child utterances per minute improved for both participants (see Figure 1). Specifically, parents' FOI improved from baseline to intervention and continued to improve post-intervention and at the one month follow-up. For participant 1, there were improvements in the child's rate of verbal utterances from baseline to intervention. Moreover, the child continued to improve his rate of verbal utterances one month after the intervention. For participant 2, though there was a slight decrease in average utterances per minute from baseline to intervention, there were improvements from baseline to post-intervention and follow-up.

**Conclusions:** This data suggests that a more condensed parent training program delivered via telehealth can be effective in teaching parents PRT and improve the social-communication skills of autistic children. This provides an immediate and cost-effective solution to delays and pauses in accessing intervention services. As such, it could be beneficial for this type of program to be widely adopted to support families who are waiting for more comprehensive interventions or who may not be able to access these types of services.

#### **503.041 (Virtual Poster) PEERS Intervention with Adolescents: Are There Broader Effects on the Family?**

**T. Choy<sup>1</sup>, E. Baker<sup>2</sup>, E. Veytsman<sup>3</sup>, J. Blacher<sup>4</sup> and K. K. Stavropoulos<sup>5</sup>,** (1)*University of California, Riverside, Riverside, CA*, (2)*UC Riverside, Riverside, CA*, (3)*Graduate School of Education, University of California Riverside, Riverside, CA*, (4)*School of Education, University of California, Riverside, Riverside, CA*, (5)*School of Education, University of California Riverside, Riverside, CA*

---

**Background:** Family functioning varies greatly among families with autistic (ASD) youth. ASD youth who present with greater problem behaviors may negatively impact the family unit and influence parent perceptions of their child (Sikora et al., 2013). Following the PEERS social skills intervention, Karst et al. (2015) found improvements in parenting self-efficacy, suggesting that parent involvement in the intervention can improve parents' views of their own confidence and parenting beliefs. Furthering our understanding of the potential change in parent and youth factors following PEERS may explain how individual or combined effects contribute to broader family functioning among families with autistic youth.

**Objectives:** To examine how improvements in ASD youth's social behavior following the PEERS intervention may impact youth's problem behaviors, parent perceptions of their youth, and broader family functioning.

**Methods:** Participants included autistic adolescents ( $n=13$ ,  $M=14.17$ ) and their caregivers who participated in PEERS, and a comparison group of neurotypical adolescents (TD) ( $n=20$ ,  $M=13.66$ ) and their caregivers who received no intervention. Caregivers reported on measures of their youth's problem behaviors and impact of the youth on the family at pre- and post- intervention. Standard scores of parent-reported problem behaviors were used from the Social Skills Improvement System (SSIS; Gresham and Elliott, 2008). Subscales of positive parent perceptions and negative family impact (a composite score of negative parent perception and negative impact of the adolescent on family social life) were assessed through parent completion of the Family Impact Questionnaire (FIQ; Donenberg and Baker, 1993). Parent involvement was measured using parent homework completion during the intervention.

**Results:** For the SSIS problem behaviors subscale, a significant group by time interaction effect was observed,  $F(1,29)=4.14$ ,  $p=.05$ . Post-hoc tests revealed significant improvements in problem behaviors for ASD adolescents across time ( $p=.05$ ), whereas TD adolescents showed no difference across time ( $p>.05$ ). For FIQ negative impact scale, a significant main effect of group was observed,  $F(1,30)=7.25$ ,  $p=.01$  such that FIQ negative family impact was higher as reported by parents of ASD versus TD adolescents. In a regression analysis predicting negative family impact post-intervention, problem behaviors at pre-intervention explained a significant proportion of the variance of negative family impact at post-intervention,  $R^2=.62$ ,  $F(2,10)=8.26$ ,  $p<.01$ , but parent involvement during intervention did not.

**Conclusions:** Findings suggest there were no significant second-hand effects found on broader family life following the PEERS intervention. Nevertheless, it was evident that ASD youth had a greater negative impact on their family compared to TD youth. Moreover, problem behaviors exhibited by ASD youth were a significant factor in predicting total negative impact on the family following intervention. These results suggest that PEERS did not have an effect on parents' views of broader family life, despite the fact that the intervention did decrease problem behaviors exhibited by ASD youth. Potentially, one way to improve parent perceptions of their autistic youth may be to incorporate youth self-regulation strategies and parent mindful coping strategies within the current social skills intervention.

**503.042 (Virtual Poster)** Effects of a Community-Based Social Skills Intervention for Children with Autism: Parent-Rated Skills Outside of the Treatment Setting

S. X. Tan, S. S. Mire, M. Keller-Margulis, H. J. Kim and J. E. Gonzalez, *Psychological, Health, and Learning Sciences, University of Houston, Houston, TX*

---

**Background:** Social skill challenges are well documented in children with autism spectrum disorder (ASD). These difficulties can interfere with academic achievement, post-school outcomes, and mental health (Hall et al., 2018). Though social skills intervention (SSI) is an evidence-based practice to improve the social skills of individuals with ASD, more studies are needed on how skills learned through SSI are used and maintained in settings outside of the treatment setting (Gates et al., 2018).

**Objectives:** This study examined participant baseline (T1), intermediate (T2) and end-intervention (T3) data from a 30-week novel, community-based SSI to evaluate whether the improvement in social skills, and emotional and behavioral problems in the treatment setting was observed by parents, beyond the intervention setting, and whether outcomes differed depending on where treatment was received (i.e., in a hospital clinic vs. community-based clinic).

**Methods:** Data from implementation of the aforementioned SSI were analyzed (total n = 114). One group of participants received the SSI within a hospital setting (HG), and the other group in a community-based agency setting (CG). For both groups, parents rated their child's severity of social problems on the *Social Responsiveness Scale – Second Edition (SRS-2)*, and their child's emotional and behavioral difficulties on the *Behavior Assessment System for Children Parent Rating Scales - Third Edition (BASC-3)*. Data were gathered at three time points across 30 weeks. A mixed ANOVA was conducted to determine whether participants' social skills, and emotional and behavioral problems improvement were observed across time outside of the treatment setting, and whether these observations differed depending on receiving treatment HG vs. CG.

**Results:** For social abilities, significant improvement over time was found for parent ratings of behavior outside the treatment setting for the following: *SRS-2* - Social Awareness, Social Communication, Social Motivation, Social and Communication Interaction, Total Score; *BASC-3 PRS* – Adaptability, Social Skills, and Functional Communication. For emotional and behavioral difficulties, significant improvement over time was found for the following parent-rated *BASC-3* subscales: Anxiety, Depression, and Withdrawal. Participants in HG showed better outcomes compared to CG.

**Conclusions:** Results suggested that participation in the SSI was associated with parent observations of increased social abilities, and decreased emotional and behavioral difficulties. This study contributes to limited research on the SSI outcomes observed and maintained outside of the treatment setting, and how SSI may improve not only the social but also emotional and behavioral functioning of individuals with ASD. Limitations include lack of a control group, missing data due to non-returns, and COVID-19 pandemic as a threat to internal validity. Future directions include determining the moderating factors that impact upon the effectiveness of SSIs, and examination of generalization of skills outside of the treatment setting into the school setting.

**503.043 (Virtual Poster)** Secondary Outcomes of a Parent-Mediated Intervention for Children with Autism & Disruptive Behaviors

Y. Sinai-Gavrilov<sup>a</sup>, A. Shoughry<sup>a</sup>, T. Graucher<sup>a</sup> and J. Koller<sup>a</sup>, (1)*Seymour Fox School of Education, The Hebrew University of Jerusalem, Jerusalem, Israel*, (2)*The Hebrew University of Jerusalem, Jerusalem, Israel*, (3)*Seymour Fox School of Education, Hebrew University of Jerusalem, Jerusalem, Israel*

---

**Background:** The Research Unit in Behavioral Intervention (RUBI) protocol is a manualized, parent-mediated intervention designed for young children with autism and disruptive behavior (DB). Several studies in the US have shown that RUBI reduces DB in these children in a one-on-one, lab-based setting (e.g. Bearss et al., 2015). Initial work from our lab indicates its efficacy when delivered in the community in a group format both in-person and virtually (Graucher et al., under review).

Disruptive behaviors in autism have been linked with elevated parenting stress, and reduced adaptive functioning, as well as with RRB severity (e.g. Koller et al., 2021). Beyond the explicitly targeted outcomes of RUBI, we hypothesized that participation in the intervention would associate with reduced parenting stress, improved adaptive functioning, and decreased RRB severity.

**Objectives:** The aim of the current study was to complement previous findings regarding improvement in primary outcomes (i.e. disruptive behavior) by investigating the secondary effects of the RUBI protocol delivered in community settings via a group format with Israeli and Palestinian parents in Israel. Given the onset of the Covid-19 pandemic during the initial phase of this study, no control group was recruited.

**Methods:** Fifty-five parents of children aged 3-10 years participated in the current study (26 Palestinians, 29 Jewish Israeli). These families participated in the 12-week RUBI intervention. Secondary outcome measures included the Repetitive Behavior Scale-Revised (RBS-R), Adaptive Behavior Assessment System, 2<sup>nd</sup> edition (ABAS-II), and the Parental Stress Index (PSI), and were administered pre- and post- intervention.

Results: Following participation in RUBI groups, paired sample t-tests indicate that parents reported a reduction in PSI total scores ( $t = -3.67$ ,  $p < .01$ ), a significant decrease in their children's compulsive behaviors as measured by the RBS-R ( $t = -2.11$ ,  $p < .05$ ), and a significant increase in their children's overall adaptive behavior scores as measured by the ABAS ( $t = 2.10$ ,  $p < .05$ ).

Conclusions: Findings from the current study indicate that, in addition to a reduction in child disruptive behaviors, children and families who participated in RUBI groups experienced secondary gains as well. Specifically, parents reported a reduction in their own parenting stress, improvement in their child's adaptive functioning, and a reduction in their RRB severity. Future studies should employ randomized -controlled designs in order to draw stronger conclusions regarding primary and secondary effects of the protocol, in the context of child and family outcomes.

**503.044 (Virtual Poster)** The Emotional Support Plan: Preliminary Results from a Brief Telehealth, Mobile Intervention to Support Autistic Adults **V. H. Bal<sup>1</sup>**, **N. Jadav<sup>2</sup>**, **J. Shinal<sup>3</sup>**, **G. B. Gunin<sup>4</sup>**, **E. Istvan<sup>5</sup>**, **E. Brennan<sup>1</sup>**, **E. Wilkinson<sup>2</sup>** and **E. Kleiman<sup>2</sup>**, (1)Graduate School of Applied and Professional Psychology, Rutgers University - New Brunswick, Piscataway, NJ, (2)Graduate School of Applied and Professional Psychology, Rutgers University-New Brunswick, Piscataway, NJ, (3)Columbia University Medical Center, New York, NY, (4)Rutgers University, Piscataway, NJ, (5)Psychology, Rutgers University, Piscataway, NJ

---

**Background:** Autistic adults are at high risk for co-occurring depression and anxiety (Hollocks et al., 2019), possibly due to difficulty regulating negative emotions. Autistic adults may be particularly vulnerable during stressful periods, such as the transition to postsecondary education or the COVID-19 pandemic (Mazefsky et al., 2015). There is a general lack of evidence-based interventions to support the mental health of autistic adults (Brugha et al., 2014). However, reports highlighting the impact of the pandemic on mental health and well-being of autistic adults (Adams et al., 2021; Bal et al., 2021; Hedley et al., 2021) underscores the dire need for brief, problem-focused interventions to support autistic adults through these periods.

**Objectives:** To evaluate the feasibility and preliminary efficacy of a brief telehealth and mobile intervention called the Emotional Safety Plan (ESP), modeled after similar suicide risk reduction interventions, designed to support autistic adults during stressful periods.

**Methods:** Participants are 35 autistic adults participating in studies evaluating the ESP to cope with emotional distress during the COVID-19 pandemic ( $N=20$ ) and postsecondary education ( $N=15$ ). Participants complete a 2-2.5 hour telehealth intervention followed by 8-15 brief (10-20 minutes) weekly monitoring visits to gather information about ESP use and mental health symptoms (PHQ-9, GAD-7). Participants were paid \$40 to complete the intervention, \$10 for each weekly monitoring visit and \$20 for each outcome and follow-up visit. Feasibility was assessed by completion of assessments; acceptability was evaluated by online survey and follow-up interview conducted at the end of the monitoring period and four weeks later.

**Results:** Preliminary data for the first 16 participants in the study ( $M_{age}=25.33$ ,  $SD=7.43$  years; 38% identifying as woman or other gender) who have already completed outcome visits demonstrate feasibility (97.6% completion rate across 8 monitoring and 2 outcome assessments). Overall, the ESP was well-received by participants. On a 5-point scale (1-strongly disagree to 5-strongly agree), participants rated the format as acceptable (4.3) and indicated the intervention was helpful (3.9), relevant (4.1) and that they would recommend to others (4.0). Reductions in depressive symptoms were also observed during the eight-week post-intervention monitoring period ( $F(9,146)=4.06$ ,  $p<.001$ ,  $d=.94$  to 1.39 in weeks 2-8;  $d=.52$  at week 12; Fig 1.). Anxiety symptoms followed a similar trend ( $F(9,146)=1.72$ ,  $p=.090$ ); though anxiety seemed to decline in weeks 2-6 ( $d=.37-.74$ ), there was a noticeable increase in anxiety after week 6, ending in a return to near-baseline levels by week 12 ( $d=.10$ ). Data examining use of the ESP by postsecondary students is currently being collected and suggests similarly high compliance (96.8% in the first 6 weeks of participation).

**Conclusions:** These results provide preliminary support for the ESP to support autistic adults in coping with distress. Although reduction in clinical symptoms suggest a potential therapeutic effect, the rise of anxiety symptoms in week 6 suggest a potential need for a "booster" session. Data from use of the ESP to cope with different types of distress will inform future modifications to this brief intervention and design of RCTs to evaluate its efficacy with autistic adults.

**503.045 (Virtual Poster)** The I-Socialise Study: A Cluster Randomised Controlled Trial Investigating the Social Competence and Isolation of Children with Autism Taking Part in LEGO® Based Therapy ('play brick therapy') Groups in Mainstream School Environments **E. ---

Background:

Children and young people (CYP) with autism spectrum disorder (ASD) often struggle with social skills which can affect friendships crucial to their development. Social skills interventions are commonly recommended to help CYP with ASD develop these skills, though engagement is often low. LEGO® based therapy (now Play Brick Therapy) is a child-led group social skills intervention which aims to make learning social skills interesting to CYP with ASD.

## Objectives:

To evaluate the clinical effectiveness of LEGO® based therapy on the social and emotional skills of CYP with ASD in a mainstream school setting as compared with usual support. Secondary objectives included assessing the intervention's cost effectiveness, acceptability, and treatment fidelity.

## Methods:

The study used a cluster randomised controlled trial (RCT) design with remote random allocation of each school to either LEGO® based therapy or usual support. Participants were CYP between seven and 15 in mainstream schools in the North of England with a diagnosis of ASD. For each CYP recruited, a parent/guardian, an associated teacher or teaching assistant (TA), and an interventionist teacher/TA (intervention schools only) were also recruited.

The intervention consisted of 12 weekly sessions of LEGO® based therapy delivered in school by a trained staff member. Usual support from school, GPs, and other professionals was also received. The control arm received usual support only.

The primary outcome measure was the social skills scale of the Social Skills Improvement System (SSIS) completed by the CYP's associated teacher or TA at 20 weeks post-randomisation. Other outcome measures were also completed by participants to answer additional objectives.

## Results:

A total of 250 CYP were recruited to the study. One hundred and twenty-seven CYP were allocated to the intervention arm and 123 to the control arm. A minimal clinically important difference (MCID) was pre-specified at between 9-10 points change on the primary outcome measure. Analysis of this primary outcome was carried out using intention to treat (ITT) analysis. This found a modest positive effect of 3.74 points ( $p=0.06$ , 95% CI: -0.16, 7.63) for the intervention arm. Per protocol analysis was also carried out which showed slightly increased statistical significance ( $p=0.036$ ). Cost-effectiveness of the intervention was found in reduced service use costs and a small but significant increase in quality adjusted life years. Fidelity and acceptability of the intervention were both assessed with positive results. No adverse events or effects related to the intervention were reported.

## Conclusions:

Analysis of the primary outcome showed a change score in social skills which did not reach the MCID. However, it did show a modest positive clinical effect for the intervention arm as compared with the control arm. Health economics and qualitative results were also positive. As such, consideration should be given to the contribution of LEGO® based therapy to the social skills of CYP with ASD in a mainstream school setting.

The study team recommend that future research continues to investigate LEGO® based therapy in school environments and the other possible avenues such as the intervention's effectiveness for CYP with less severe ASD symptomatology.

## 503.046 (Virtual Poster) Using Observed Child Affect & Parent-Report to Assess the Social Validity of a Brief, Intensive PRT Parent Training Program

**R. K. Schuck<sup>1</sup>, K. M. Baiden<sup>1</sup>, A. Jevtic<sup>1</sup>, C. Fong<sup>1</sup> and T. W. Vernon<sup>2</sup>,** (1)Gevirtz Graduate School of Education, University of California, Santa Barbara, Santa Barbara, CA, (2)University of California, Santa Barbara, Santa Barbara, CA

**Background:** An intervention's social validity—the degree to which stakeholders find the program goals, procedures, and outcomes acceptable—is an integral part of any intervention. Prior studies on Pivotal Response Treatment (PRT) that have assessed social validity suggest that it is an acceptable intervention. However, assessment of PRT social validity has often solely relied on parent- or clinician-report measures, and do not attempt directly ascertain evidence of the child's acceptance of the delivered intervention. While asking autistic individuals about their perspectives on treatment acceptability is a reasonable method assessing social validity, this is not always possible with young children with communication challenges who often receive early intervention. One promising approach for gauging an intervention's social validity is to examine nonverbal indicators of child affect. By observing a child's baseline affect and systematically assessing visible changes to their emotional state over the course of intervention exposure, we can reasonably obtain a proxy of a child's acceptance of intervention procedures.

**Objectives:** This study aimed to obtain indicators of PRT social validity using (a) observations of child emotional states during parent-child interactions and (b) parent-report measures.

**Methods:** Three parent-child dyads took part in a multiple baseline study examining the effects of a 10-hour, week-long PRT telehealth parent training program. Child participants were a 2y11m Hispanic female (Participant 1), a 2y2m White male (Participant 2), and a 2y0m Asian male (Participant 3). Child affect in videos of parent-child interactions obtained before, during, and after the intervention were coded for positive and negative affect. Graphs were visually inspected for decreases in positive affect and increases in negative affect between baseline and implementation of PRT. At the end of the intervention, parents filled out the Scale of Treatment Perceptions (STP; Berger et al., 2016), a 20-item 7-point Likert-scale measure designed for assessing social validity of autism interventions.

**Results:** Positive affect remained stable or increased for all participants across timepoints. Negative affect also remained stable across timepoints. Parents' average ratings on the STP indicated they found the intervention acceptable (Participant 1: 6.15/7; Participant 2: 6.35/7; Participant 3: 5.85/7). While all scored high on the STP safety subscale, Participant 1's and Participant 2's parents' average ratings were 7/7, whereas Participant 3's

parent rating was slightly lower (6/7). Of note, Participant 3's mother only slightly disagreed with the statement, "My child has experienced discomfort during the course of this treatment," as opposed to the others' strong disagreement.

**Conclusions:** Child affect observation and parent-report converged across participants, suggesting that this brief, intensive online PRT program was socially valid for these parent-child dyads. However, Participant 3's mother's answer to the the question regarding her child's discomfort potentially warrants further investigation. This preliminary analysis highlights the importance of frequent, detailed assessment of social validity from multiple stakeholder perspectives—including the autistic child's—as well as the need to individualize interventions based on client response.

**503.047 (Virtual Poster)** Using the Theory of Planned Behavior to Predict French-Speaking Practitioner' Intention and Behavior of Using Robot for ASD

**L. Charpiot<sup>1</sup>, A. P. Costa<sup>2</sup> and G. Steffgen<sup>3</sup>,** (1)Université du Luxembourg, Esch-sur-Alzette, Luxembourg, (2)University of Luxembourg, Esch sur Alzette, LUXEMBOURG, (3)Institute for Health and Behaviour, University of Luxembourg, Luxembourg, Luxembourg

**Background:** Society is facing several challenges in ASD care and education in terms of cost, accessibility, and turnover. One promising tool receiving research's attention is the use of robots in the care of children with ASD . While robots offer numerous possibilities in terms of therapeutic and educational applications, knowledge transfer, and care's accessibility (e.g. Diehl et al., 2012; Huijen et al., 2016), little is known regarding how practitioners perceive such robots use into their work. The Theory of Planned Behavior (TPB; Fishbein & Ajzen, 2010) is a popular models to predict health-related behaviours and it was successfully used to predict the use of research-recommended practices for ASD (e.g. Ingersoll et al., 2018). It posits that processes underlying human behaviour can be described by a small set of constructs that are intentions, attitudes towards behaviour, subjective norms, perceived behavioural control, and beliefs. The TPB framework could allow a better understanding of professionals's position concerning the use of robots in the ASD field.

**Objectives:** Our study investigated for the first time the extent to which TPB helps to predict the French-speaking practitioners' intent to use robots in the educational and therapeutic care of children with ASD.

**Methods:** Our questionnaire included demographic variables (gender, age, education, years of ASD experience, job title, and age of clients) as well as constructs from TPB and additional constructs (professional self-efficacy, perceived morality, and positive and negative emotions). In total, 326 professionals working in ASD were included in this online study. Intention to use a robot was assessed twice. Once in a general way and once by specifying a context (contextual intention) in which they may benefit a facility for doing the behavior (e.g., loan). The behaviour measured was that of signing up for participating in a field study involving actual use of this type of robot.

**Results:** A repeated measures t-test showed that the mean intention in general ( $M=3.42$ ,  $SE=1.02$ ) was statistically lower than the mean intention in a in a facilitated context ( $M=3.68$ ,  $SE=1.07$ )  $t(326) = -8.54$ ,  $p = .000$ . There was no difference in practitioner contextual intention depending on whether they were referring to the use of a robot with a child or an adult ( $F(1,325) = 1.10$ ,  $p = .29$ ). There was also no difference based on their country of origin ( $F(8,315) = 1.28$ ,  $p = .26$ ). Finally, to test TPB model while considering control variables (age and experience), we conducted two multiple hierarchical regressions, one on the behavior (table 1) and one on the contextual intention (table 2).

**Conclusions:** To our knowledge, this is the first time that a study highlights strong interest of professionals in using a robot for their adult patients with ASD. The reason of their interest will remain to be explore. Results from the hierarchical regressions also demonstrated the applicability of TPB to professionals' intentions to use a robot in the coming year. Those results bring deeper knowledge about intention's determinants but also suggest an important gap between intention and behavior that remains to be studied.

## Interventions - Pharmacologic

### POSTER SESSION — INTERVENTIONS - PHARMACOLOGIC

#### 413 - Interventions - Pharmacologic

**413.157 (Poster)** A Pilot Treatment Study of Low-Dose Ketamine Shows Improvement of Social Attention in Children with Adnp Syndrome  
**B. Lerman<sup>1</sup>, S. Barkley<sup>2</sup>, T. Levy<sup>3</sup>, H. Walker<sup>4</sup>, K. Keller<sup>5</sup>, D. Halpern<sup>6</sup>, J. Zweifach<sup>7</sup>, P. M. Siper<sup>8</sup>, M. P. Trelles<sup>9</sup>, J. D. Buxbaum<sup>10</sup>, A. Kolevzon<sup>11</sup> and J. H. Foss-Feig<sup>12</sup>,** (1)Seaver Autism Center for Research and Treatment, Department of Psychiatry, Icahn School of Medicine at Mount Sinai Hospital, New York, NY, (2)Teachers College, Columbia University, New York, NY, (3)Rosalind Franklin University of Medicine and Science, North Chicago, IL, (4)Psychiatry, Icahn School of Medicine at Mount Sinai, New York, NY

**Background:** Activity dependent neuroprotective protein (ADNP) syndrome is a genetic neurodevelopmental disorder characterized by sensory reactivity, cognitive delays, and social communication deficits. Moreover, ADNP syndrome is a leading genetic cause of autism spectrum disorder (ASD) and is associated with abnormalities in joint attention, demonstrated in previous eye-tracking studies. Ketamine, an NMDA receptor antagonist, has been shown to upregulate expression of the ADNP gene, suggesting that it might compensate for ADNP haploinsufficiency and mitigate symptoms associated with the disorder.

**Objectives:** To investigate whether a single low-dose of intravenous (IV) ketamine would improve joint attention in children with ADNP syndrome.

**Methods:** Ten children (7 male), ages 6 to 12 years ( $9.49 \pm 2.29$ ), received a single low-dose (0.5mg/kg) of ketamine infused IV over 40 minutes. A Joint Attention eye-tracking paradigm was conducted at baseline—one day before ketamine administration—and again one week after. A series of 16 pseudo-randomized trials were presented during which a video displays a woman seated at the center of the frame, first looking down for 5s, and then looking up and turning her head to direct attention using eye gaze at either an object on the lower right or lower left of the screen for 10s. Average latency to saccade to the target object, proportion of trials where the target item is looked at before the distractor, and average proportion of time spent dwelling on the target (versus distractor) were calculated. Data were successfully collected from nine participants, but only four participants (3 male,  $M_{age} = 9.38 \pm 2.32$ ) had >25% valid trials at both time points. In addition, a clinician-administered Visual Analogue Scale (VAS) was used to measure attention (N=10), and caregivers completed the Anxiety, Depression and Mood Scales (ADAMS) to examine social avoidance (N=10). Data were analyzed using Wilcoxon signed ranks tests.

**Results:** The proportion of trials in which participants made saccades to the target before the distractor increased from Baseline ( $0.53 \pm 0.14$ ) to Week 1 ( $0.70 \pm 0.14$ ) ( $r = 0.80$ ;  $p = 0.109$ ). Moreover, participants spent a greater proportion of time looking at the target at Week 1 ( $0.66 \pm 0.11$ ) versus Baseline ( $0.51 \pm 0.19$ ) ( $r = 0.913$ ;  $p = 0.068$ ). However, there was no significant change in saccade latency to target from Baseline ( $2319.38 \text{ms} \pm 1202.34$ ) to Week 1 ( $1674.18 \text{ms} \pm 301.93$ ) ( $r = 0.37$ ,  $p = 0.47$ ). These results mirrored clinical findings, wherein attention significantly improved ( $p = 0.028$ ) and social avoidance significantly decreased ( $p = 0.018$ ) over this one-week interval.

**Conclusions:** We found a trend toward improved joint attention after ketamine treatment in children with ADNP syndrome, demonstrated by both an increase in joint attention accuracy and in time spent looking at the target. Saccade latency to the target did not change, suggesting that accuracy and attention, but not speed, were sensitive to treatment. Eye-tracking results parallel clinical changes, providing promising evidence that social attention in ADNP syndrome is improved with ketamine and suggesting that eye-tracking may be a useful biomarker to index this change. This work provides important insights into potential therapeutic approaches for treating ADNP syndrome and offers preliminary data to support a placebo-controlled clinical trial to include these potential endpoints.

#### **413.158 (Poster)** A Randomized Double-Blind Clinical Trial with *L. Reuteri* in Autism Spectrum Disorder: Improvement of Social Behaviour and Gastrointestinal Symptoms, with Modulation of Immune Response

**L. Mazzone**<sup>1,2</sup>, **R. Abate**<sup>1</sup>, **L. Arturi**<sup>2</sup>, **A. Riccioni**<sup>1,2</sup>, **A. Sabatini**<sup>3</sup> and **E. Volpe**<sup>1</sup>, (1)Systems Medicine, Division of Child Psychiatry, University of Rome Tor Vergata, Rome, Italy, (2)Child and Adolescence Psychiatry Unit, Policlinico Tor Vergata Hospital, Rome, Italy, (3)Fondazione Santa Lucia IRCSS, Rome, Italy

#### **Background:**

Children with Autism Spectrum Disorder (ASD) are 3.5 times more likely to suffer from gastrointestinal (GI) issues than neurotypical individuals. Recent studies reported microbiota dysbiosis and immune dysregulation in ASD individuals. These evidence indicate that gut microbiota-brain axis is involved in ASD, and that the immune system may play a crucial role in this crosstalk. In such a scenario, probiotic supplementation is an emerging area of research in ASD, by modulating microbiota and immune system. It has been reported that a specific strain of *Lactobacillus Reuteri* (PTA6475) improves social behaviour in ASD mouse models. To our knowledge no prior study investigated the efficacy of *L. Reuteri* in ASD children.

#### **Objectives:**

The aim of the study was to assess the effect of 6 months *L. Reuteri* (DSM17938 and ATCC PTA6475) supplementation on behavioural profile, with a specific focus on social deficits, on GI symptomatology and on immune response, in ASD children.

#### **Methods:**

Forty-three ASD children (35 males 8 females; age range 3-8 years) were enrolled. At baseline participants were blindly randomized to *L. Reuteri* or placebo supplementation. A standardized clinical assessment of cognitive skills, socio-communicative behaviors and GI symptoms (Fig. 1) was performed for each patient at baseline (T0), after three months (T1) and after six months (T2) of supplementation. Blood samples were collected from all participants at T0, T1 and T2 and immune response was analysed in peripheral blood mononuclear cells by flow cytometry.

#### **Results:**

Behavioral results based on intelligence quotient (IQ) stratification reveals *L. Reuteri* efficacy on social and GI domains in ASD with normal range IQ (Leiter-R range score: 85-120). In particular *L. Reuteri*, and not placebo supplementation significantly increased scores of ABAS-II social subdomain ABAS-II\_SAD (mean T0=68.5±13.4; T2=74.5±13.5;  $p = 0.04$ ) and decreased total score of SRS (mean T0=85.1± 17.2; T2=76.7±17.4;  $p = 0.001$ ) and GSRS (mean T0=6.5± 5.0; T2=4.3± 3.4;  $p = 0.03$ ), at 6 months. No significant effects of probiotic supplementation on autistic core symptoms were observed on ADOS-2.

Analysis of immune frequencies reveals that *L. Reuteri*, and not placebo, decreases the frequency of inflammatory mucosal associated invariant T (MAIT) cells (mean T0=1.0±0.6; T2=0.7± 0.4;  $p = 0.001$ ) and natural killer cells (mean T0=8.7± 4.9; T2=7.3±4.3;  $p = 0.04$ ), within the total population of leukocytes, after 6 months of supplementation, while frequency of other immune cells were not modulated. Interestingly, GSRS and frequency of NK cells were significantly correlated ( $r = 0.31$ ;  $p = 0.005$ ), indicating that decrease of NK cells mediated by *L. Reuteri* could be associated to improvement of GI symptoms.

## Conclusions:

This study shows that *L.Reuteri* improves social deficits, GI symptoms and modulates inflammatory response in children with ASD. From a scientific point of view, modulation of immune response associated with improvement of GI symptoms and social behaviors reflects a strong link between gut, brain and immune system. From a clinical point of view, *L.Reuteri* supplementation represents a promising therapeutic area for ASD children with or without GI symptoms.

### **413.159 (Poster)** Changes in Parent- and Self-Reported Anxiety Symptoms in Children with and without ASD Receiving SSRI Medication: A Retrospective Chart Review

**K. G. Stephenson, P. Vandana and E. Butter, Nationwide Children's Hospital, Columbus, OH**

**Background:** Clinically significant anxiety symptoms are common in autistic children with prevalence estimates as high as 79%, significantly higher than typically-developing children (Kent & Simonoff, 2017). Selective serotonin reuptake inhibitors (SSRIs) are first-line pharmacological treatments for anxiety in the general pediatric population; however, their effectiveness in children with autism is unclear. A chart-review study of 29 children and adolescents diagnosed with ASD receiving SSRIs for anxiety showed a significant reduction in clinical global impression scores over a period of 12 months (Thorkelson et al., 2019). However, more research is needed to inform the use of SSRIs to treat anxiety in autistic children and youth.

**Objectives:** Our objective was to compare changes in parent- and self-reported anxiety symptoms in youth with and without a diagnosis of ASD using a retrospective chart review of clinical data. A secondary objective was to identify potential moderating factors of treatment response such as age, biological sex, and type of SSRI medication.

**Methods:** Data consisted of 2,026 patients seen for medication management within the psychiatry department of a large children's hospital in the Midwest region of the United States between 2015 and 2019. Inclusion criteria for the study included an ICD-10 anxiety disorder diagnosis and the prescription of an SSRI. 86 children had a clinical diagnosis of ASD. Among the 1,940 non-ASD participants, the mean age was 13.81 years ( $SD = 2.91$ ). Among the 86 ASD participants, the mean age was 12.97 years ( $SD = 2.92$ ). The majority of the non-ASD group was female (63.71%) while the majority of the ASD group was male (73.26%). Participants were predominantly white (non-ASD: 81.19%; ASD: 76.74%). Anxiety symptoms were measured using the Screen for Child Anxiety Related Disorders (SCARED). Changes in parent- and self-reported SCARED scores were tested using linear mixed effects models using the *lme4* package in R.

**Results:** The ASD group was 10 months younger ( $p = .01$ ) and started with a baseline SSRI dose of 8.56mg greater ( $p = .03$ ) than the non-ASD group; differences in dosage remained consistent over time. There were no group differences in baseline SCARED-Parent scores. A time $\times$ group interaction effect approached statistical significance ( $p = .08$ ) with a trend toward relatively slower reduction of anxiety scores in the ASD vs. non-ASD group (see figure 1A). For the SCARED-Child scores, children with ASD reported lower baseline SCARED scores, with similar rates of change between groups (see Figure 1B). Post-hoc analysis indicated a significant time $\times$ group $\times$ sex interaction showing that females with ASD reported significantly lower SCARED scores at Baseline (see Figure 2). Age and type of SSRI medication were not significant moderators.

**Conclusions:** Autistic youth may show similar reductions in anxiety with SSRI medication compared to typically-developing peers, although they may require higher doses. Females with ASD presenting for psychiatric consultation for anxiety reported overall lower levels of anxiety compared to their peers. Future research could elucidate whether this difference is due to differences in perception/awareness of anxiety symptoms. Replication in larger samples and controlled designs are needed to confirm these findings.

### **413.160 (Poster)** Children and Adolescents Treated with Cbd-Rich Cannabis Exhibit Significant Improvements in Social Symptoms of ASD in an Open Label Study

**M. Hacohen<sup>1,2,3</sup>, I. Dinstein<sup>4</sup>, O. Elkana<sup>5</sup>, E. Kohn<sup>5</sup>, A. Hazan<sup>5</sup>, E. Heyman<sup>5</sup>, Y. Sobol<sup>6</sup>, D. Weissengreen<sup>6</sup>, M. Berkovitch<sup>7</sup> and O. E. Stolar<sup>8</sup>, (1)Ben Gurion University of the Negev, Israel, Be'er Sheva, Israel, (2)Ben-Gurion University of the Negev, Beer Sheva, Israel, (3)Tel Aviv-Yaffo Academic College, Tel Aviv-Yaffo, Israel, (4)Cognitive and Brain Sciences Department, Ben-Gurion University of the Negev, Beer Sheva, Israel, (5)Shamir Medical Center, Be'er Ya'akov, Israel, (6)Israel National Autism Research Center, Be'er Sheva, Israel, (7)Clinical Pharmacology and Toxicology Unit, Assaf Harofeh Medical Center, Zerifin, Israel, (8)Autism Center, Assaf Harofeh Medical Center, Zerifin, Israel**

**Background:** There is considerable interest in the potential benefits of CBD enriched cannabis for treatment of individuals with ASD. However, there is little evidence regarding the efficacy of such treatment. While previous open label studies have reported that children with ASD respond well to treatments with CBD-rich cannabis, these studies did not utilize standardized assessments of core ASD symptoms and did not assess the specific impact of treatment on social communication and restricted and repetitive behaviors (RRB) symptoms.

**Objectives:** The current open label study examined the impact of treatment with CBD-rich cannabis over a period of 6 months on core ASD symptoms as assessed using clinical observations and parent reports.

**Methods:** Initially, 100 participants (5-25 years old) were recruited to this prospective open label study. The treatment protocol was preformed using a personalized medicine approach. Participants received medical cannabis extract with a CBD:THC ratio of 20:1 (Nitzan Spectrum®, Seach Medical Group) for six months. All participants started with one drop daily (each drop contains: 0.3mg THC and 5.7mg CBD), the dose was increased gradually until improvement was reported by parents. The final dose did not exceed 10mg/kg/day of CBD and 0.5mg/kg/day of THC. Efficacy of treatment was assessed using the Autism Diagnostic Observation Schedule 2<sup>nd</sup> edition (ADOS-2), the Vineland adaptive behaviors scale 3<sup>rd</sup> edition,

the Social Responsiveness Scale 2<sup>nd</sup> edition (SRS-2) and the Repetitive Behaviors Scale – Revised (RBS-R). The final analyses were conducted with 76 participants who completed at least one of the assessments described above both before and after 6 months of treatment.

**Results:**Results from the 76 participants who completed the 6 month treatment program revealed significant improvements in all measures of social communication (Figure 1) including the ADOS-2 Social Affect (SA) Calibrated Severity Score (CSS,  $M=-0.46$ ,  $SD=1.59$ ,  $t(62)=-2.29$ ,  $p=0.02$ ), the SRS-2 standardized social sub-scale ( $M=-4.2$ ,  $SD=9.2$ ,  $t(54)=-3.39$ ,  $p=0.001$ ), Vineland Socialization scale ( $M=6.76$ ,  $SD=13.06$ ,  $t(66)=4.2$ ,  $p<0.001$ ), and Vineland Communication scale ( $M=4.36$ ,  $SD=14.72$ ,  $t(66)=2.41$ ,  $p=0.02$ ).

In contrast, most measures of RRB symptoms did not exhibit significant improvement following treatment (Figure 2). These included the ADOS RRB CSS ( $M=-0.46$ ,  $SD=2.23$ ,  $t(62)=-1.64$ ,  $p=0.11$ ) and parent reported RBS-R sub-scales regarding Stereotyped Behavior ( $M=-0.62$ ,  $SD=3.94$ ,  $t(63)=-1.27$ ,  $p=0.21$ ), Self-injurious Behavior ( $M=0.06$ ,  $SD=2.12$ ,  $t(63)=0.22$ ,  $p=0.83$ ), Compulsive Behavior ( $M=-0.19$ ,  $SD=2.2$ ,  $t(63)=-0.68$ ,  $p=0.5$ ) and Restricted Behavior ( $M=-0.22$ ,  $SD=1.93$ ,  $t(63)=-0.91$ ,  $p=0.37$ ). Nevertheless, parents did report significant improvement in the SRS-2 standardized RRB sub-scale ( $M=-3.24$ ,  $SD=9.04$ ,  $t(54)=-2.65$ ,  $p=0.01$ ) and the RBS-R ritualistic/sameness behavior sub-scale ( $M=-2.12$ ,  $SD=6.25$ ,  $t(63)=-2.67$ ,  $p=0.009$ ).

**Conclusions:**Taken together, these results suggest that treatment with CBD-rich cannabis may yield significant improvement in the severity of core ASD symptoms, and particularly in social communication symptoms as reported by both parents and clinicians who performed the ADOS assessments. While open label studies are prone to large uncontrolled placebo effects, the dissociation between social and RRB symptoms suggests that improvement was specific to one symptom domain and not apparent in both as may be expected from a general placebo effect. Further double-blind placebo-controlled studies are highly warranted for determining the efficacy of this treatment.

#### **413.161 (Poster)** Effects of Propranolol on Gastrointestinal Problems in Children and Adults with Autism Spectrum Disorder

**K. N. Dovgan<sup>1</sup>, D. Q. Beversdorf<sup>2</sup>, B. J. Ferguson<sup>3</sup> and M. Hogg<sup>4</sup>,** (1)Psychology, Marist College, Poughkeepsie, NY, (2)Department of Radiology, Neurology, and Psychological Sciences, University of Missouri, Columbia, MO, (3)Health Psychology, Radiology, & Thompson Center for Autism & Neurodevelopmental Disorders, University of Missouri, Columbia, MO, (4)University of Missouri, Columbia, MO

**Background:** Many individuals with autism spectrum disorder (ASD) experience severe gastrointestinal (GI) problems, which can impact social interactions and exacerbate social communication deficits. Past treatments of GI problems in ASD mainly include medications targeted at individual symptoms (e.g., Miralax for constipation). It is vital that novel treatments be explored for GI disorders in ASD to improve their specific symptoms, but also the underlying root of the problem, to improve quality of life. Previous research shows that individuals with ASD experience an increased physiological stress response which is associated with GI problems. Drugs that target the gut-brain axis may provide GI relief for some individuals with ASD. The gut-brain axis is a bidirectional path that allows communication between the brain and GI tract via the vagus nerve that modulates digestion, GI motility, and the stress response. Propranolol, a central and peripheral beta-adrenergic antagonist that increases vagal tone, may lead to GI improvements in ASD.

**Objectives:** This study examined the effectiveness of propranolol in decreasing GI problems in children and young adults with ASD.

**Methods:** A sample of 37 individuals with ASD aged 7-24 participated in a 12-week open label trial of propranolol. The Gastrointestinal Severity Index (GSI) was administered at baseline and at the end of the trial period. The GSI is an 8-item questionnaire about GI functioning over the past week including constipation, diarrhea, stool consistency, stool smell, flatulence, abdominal pain, unexplained daytime irritability, and nighttime awakening. Total severity scores range from 0-16, wherein higher scores reflect greater or more severe GI symptoms. A paired sample *t*-test was used to compare baseline and follow-up severity scores. Descriptive statistics were used to determine the extent of improvement in GI symptoms, and an independent samples *t*-test and chi square analysis were used to assess the influence of age group (7-14 versus 15-24) on level and type of change.

**Results:** GI symptoms significantly improved at follow-up ( $M=2.03$ ,  $S=1.82$ ) compared to baseline levels ( $M=2.76$ ,  $S=1.52$ ),  $t_{paired}(33)=2.506$ ,  $p=.017$ . Nine individuals (26.5%) displayed more GI problems, eight individuals (23.5%) maintained the same level of GI problems, and seventeen individuals (50%) experienced fewer GI problems after the trial, with 8 people experiencing no (zero) GI symptoms at follow-up. Age group did not influence total amount of change over time,  $t(32)=-.193$ ,  $p=.848$ , or type of change (improvement, worsening, or stability),  $\chi^2(2)=1.581$ ,  $p=.454$ .

**Conclusions:** The results from this open label trial suggest that propranolol may reduce GI symptoms in some individuals with ASD. Propranolol increases parasympathetic tone both centrally and peripherally, which might explain the reduction in GI symptoms. However, it is unclear why some individuals reported increases in GI symptoms after the trial. Future studies should examine data from more sensitive GI questionnaires and identify biomarkers that may predict the response to treatment with propranolol. For example, individuals with high baseline stress levels or co-occurring anxiety disorders may receive the greatest benefit from propranolol due to dampening of sympathetic tone. These data should be interpreted with caution until randomized, double-blinded, placebo-controlled trials of propranolol are completed.

#### **413.162 (Poster)** Examining the Effects of Low Dose Ketamine on Neural Responses of Children with Adnp Syndrome

**S. Barkley<sup>1</sup>, B. Lerman<sup>1</sup>, T. Levy<sup>1</sup>, H. Walker<sup>2</sup>, K. Keller<sup>1</sup>, J. Zweifach<sup>1</sup>, D. Halpern<sup>1</sup>, P. M. Siper<sup>1</sup>, M. P. Trelles<sup>1</sup>, J. D. Buxbaum<sup>3</sup>, A. Kolevzon<sup>1</sup> and J. H. Foss-Feig<sup>1</sup>,** (1)Seaver Autism Center for Research and Treatment, Department of Psychiatry, Icahn School of Medicine at Mount Sinai Hospital, New York, NY, (2)Teachers College, Columbia University, New York, NY, (3)Psychiatry, Icahn School of Medicine at Mount Sinai, New York, NY

**Background:** ADNP syndrome is caused by pathogenic variants in the activity dependent neuroprotective protein (*ADNP*) gene and is characterized by intellectual disability, autism spectrum disorder (ASD), speech and motor delays, and medical comorbidities. Ketamine is an NMDA antagonist which has been suggested to upregulate expression of *ADNP* and affects excitatory and inhibitory neural systems by blocking glutamatergic binding and inhibiting GABA release. The auditory steady-state response (ASSR) measured by electroencephalography (EEG) assesses neural synchrony and has been shown to index the balance of excitatory and inhibitory neural pathways, modulated by GABAergic and glutamatergic systems.

**Objectives:** This study investigated if administration of low dose ketamine in children with ADNP syndrome would alter ASSR as measured by EEG. Based on research implicating glutamatergic functioning in neural oscillations across several frequency bands, we hypothesized that ketamine administration would alter 20Hz and 40Hz ASSR in this population.

**Methods:** EEG was recorded from 10 children ages 5-12 with ADNP syndrome (M age = 9; 3 Female). In separate runs, participants heard 150 trials of 500ms click trains with a stimulation rate of 20Hz or 40Hz. Inter-trial interval was 50ms. Data were cleaned before conducting time-frequency analysis to extract intertrial phase coherence (ITC) at 20 and 40Hz. ITC is a value between 0 and 1, where 0 reflects a random distribution of phase angles and 1 reflects absolute neural synchrony. Data were collected from all participants at Baseline and Day 1, Week 1, Week 2, and Week 4 following a single ketamine intravenous infusion at 0.5 mg/kg over 40 minutes. After excluding participants with unusable data at any time point, we included 7 participants in 40Hz analyses and 8 participants in 20Hz analyses. Average ITC at each time point was calculated from the Cz central electrode. Wilcoxon Signed Ranks Tests were used to compare average ITC values at Baseline against each subsequent time point.

**Results:** 40Hz (gamma) ITC significantly increased from Baseline to Week 1 ( $p = 0.05$ ). No significant differences were found between Baseline and Day 1, Week 2, or Week 4 ( $ps > 0.1$ ). 20Hz (beta) ITC significantly decreased from Baseline to Week 1 ( $p = 0.05$ ). No significant differences were found between Baseline and Day 1, Week 2, or Week 4 ( $p > 0.1$ ). These results align with findings from clinical measures (presented elsewhere) showing greatest improvement in behavior at one week following ketamine infusion.

**Conclusions:** The increase in evoked gamma band oscillations at Week 1 suggests an effect of ketamine related to enhancing glutamatergic functioning in ADNP syndrome, likely caused by NMDA receptor modulation. Conversely, the decrease in beta ITC at Week 1 may be indicative of an inhibitory effect of ketamine causing decreased GABA concentrations. These findings may be important in the treatment of ADNP syndrome, as gamma and beta neural oscillations are implicated in several important cognitive processes and may relate to clinical symptoms. This study suggests the potential of ASSR as a biomarker of ketamine treatment response in ADNP syndrome.

#### **413.163 (Poster)** Intranasal Esketamine in a Young Woman with Autism Spectrum Disorder and Resistant Depression

*M. Olivola, V. Arienti, N. Bassetti, S. C. Civardi, M. Nola, C. Guiot and N. Brondino, Department of Brain and Behavioral Sciences, University of Pavia, Pavia, Italy*

---

**Background:** Autism spectrum disorders are often associated with other psychiatric conditions, among which depression is one of the most frequent. It could be hard for the clinician to formulate an exact diagnosis of depression in the context of ASD as many symptoms can overlap. Additionally, women with ASD are often difficult to identify as they may have learnt several camouflaging techniques during the years. Pharmacological strategies for major depression are still ineffective in approximately one third of the patients and short acting treatments for suicidality are still lacking. This is particularly true in the context of ASD, as many subjects may experience adverse side effects and low efficacy compared to typically developing depressed individuals.

**Objectives:** to evaluate the efficacy of intranasal esketamine in a young woman with ASD and resistant depression

**Methods:** From week 1 to 4 she was administered esketamine 84 mg twice weekly; from week 5 to 8 she received esketamine 84 mg once a week. Esketamine was self-administered via an atomized nasal spray device under medical supervision. Vital parameters were collected during every session prior to the first administration and repeated after one hour of continuous observation of the patient. The following evaluation scales were administered before the first drug administration (T0) and repeated after one week (T1), four weeks (T2) and eight weeks (T3) of treatment: Montgomery Asberg Depression Rating Scale (MADRS), Columbia-Suicide Severity Rating Scale (C-SSRS), Dissociative Experiences Scale (DES-II), Psychache Scale (PSA), Reflective Functioning Questionnaire (RFQ-8).

**Results:** esketamine was well tolerated and no side effects were noticed; vital parameters were always within normal ranges. MADRS total scores decreased progressively, as well as PSA and DES-II scores. Mentalizing skills, assessed by means of RFQ-8, also showed meaningful improvement. This is particularly relevant in the context of autism spectrum disorders. Moreover, these positive effects were maintained over time, as assessed during the further follow-up of 2 months

**Conclusions:** The initial results of our experience of intranasal esketamine in the treatment of depression comorbid to autism demonstrated that it was well tolerated and efficacious in treating depressive symptoms and improving psychic pain.

#### **413.164 (Poster)** Pharmacotherapy of Adolescents with Autism Spectrum Disorder: Findings from Population Based Surveillance in a US Metropolitan Area

*C. Lescott<sup>1</sup>, M. Palmeri<sup>1</sup>, M. Jackson<sup>2</sup>, M. Verile<sup>3</sup>, K. Sidwell<sup>4</sup>, J. Shenouda<sup>5</sup> and W. Zahorodny<sup>6</sup>, (1)Rutgers New Jersey Medical School, Newark, NJ, (2)Biostatistics and Epidemiology, Rutgers University, Piscataway, NJ, (3)Rutgers University- New Jersey Medical School, Newark, NJ, (4)Department of Pediatrics, Rutgers New Jersey Medical School, Newark, NJ, (5)Department of Pediatrics, Rutgers University, Newark, NJ, (6)Department of Pediatrics, Rutgers--New Jersey Medical School, Newark, NJ*

---

**Background:** There are no pharmacological treatments for the core symptoms of Autism Spectrum Disorder (ASD); however, psychoactive therapy is used to target associated symptoms or comorbid conditions commonly seen in ASD patients. Two antipsychotic drugs, risperidone and aripiprazole, are FDA-approved for treatment of maladaptive behaviors such as irritability and aggression associated with ASD. Additional psychoactive drugs are used to treat associated symptoms and comorbid psychiatric conditions. Previous findings on psychoactive medication use by adolescents with ASD have been based on convenience samples and administrative datasets and may be biased or non-representative.

**Objectives:** The goal of this study is to estimate the proportion of adolescents with ASD receiving psychoactive drugs and polypharmacy and to determine if utilization of psychoactive drugs varies by sex, race/ethnicity, and/or socioeconomic status in a large, diverse population.

**Methods:** Data were collected as part of a population-based study monitoring ASD prevalence in New Jersey. The Autism and Developmental Disabilities Monitoring (ADDMM) method was utilized for active ascertainment. This approach is a population based, (2-phase) process involving comprehensive retrospective review, scoring and analysis of information contained in professional evaluations from multiple health and education sources. Demographic variables and case-specific data, including information on the prescription of psychoactive medicines was collected from records and analysed. The findings represent adolescents (age 16-years) born in 1998 and surveyed in 2014. Chi-square tests were used to test associations.

**Results:** We identified 557 adolescents with ASD. Prevalence was estimated at 17.6 per 1,000 (95% CI:16.2-19.2). Among individuals identified with ASD, 254 (46%) had indication of receipt of psychoactive drugs and 169 (30%) had indication of multiple psychoactive drugs (polypharmacy). Stimulants (28%) and anti-psychotics (19%) were the most frequently utilized drug categories, and medications targeting ADHD symptoms (stimulants and non-stimulants) were most frequently used, overall (34%). Differences in the receipt of psychoactive drugs were observed by sex, race/ethnicity and socioeconomic status (SES). Females were more likely to receive psychoactive drugs overall (55%) and antidepressants (31%), compared to males. Non-Hispanic White (54%) adolescents were more likely to be prescribed psychoactive drugs compared to their Non-Hispanic Black (34%) and Hispanic (39%) peers. Adolescents from high SES areas were more likely to receive psychoactive drugs (53%) compared to peers from mid SES areas (42%) and low SES areas (37%). Polypharmacy was prevalent among adolescents and use ranged from 1 to 18 psychoactive drugs. We identified 13 adolescents that were prescribed ten or more psychoactive drugs at any point by age 16-years old.

**Conclusions:** Approximately 1 in 2 adolescents with ASD residing in metropolitan New Jersey are prescribed psychoactive drugs. Among those, 2 in 3 are prescribed two or more psychoactive medications. Our findings are consistent with other studies describing the increasing prescription of psychoactive medications to adolescents with ASD. The high proportion of adolescents receiving pharmacotherapy and polypharmacy may reflect the high proportions of co-morbidity among adolescents with ASD. In our population, the utilization of pharmacotherapy varied by sex, race/ethnicity and SES. Research into the long-term effects of psychoactive medications on individuals with ASD is needed.

#### **413.165 (Poster) Psychophysiological Predictors of the Treatment Response to Propranolol on Core ASD Symptoms Using the Autism Impact Measure**

**C. Applig<sup>1</sup>, N. Nuraini<sup>2</sup>, D. Q. Beversdorf<sup>3</sup>, A. Kalathil<sup>4</sup> and B. J. Ferguson<sup>4</sup>,** (1)Interdisciplinary Neuroscience Program, University of Missouri, Columbia, MO, (2)University of Missouri Columbia, Columbia, MO, (3)Department of Radiology, Neurology, and Psychological Sciences, University of Missouri, Columbia, Columbia, MO, (4)Health Psychology, Radiology, & Thompson Center for Autism & Neurodevelopmental Disorders, University of Missouri, Columbia, MO

#### **Background:**

Autism spectrum disorder (ASD) is a condition characterized by the presence of social and communication impairments, with the presence of restrictive repetitive behaviors originating in early development. Pharmacotherapeutic interventions for ASD have primarily targeted psychiatric co-occurring conditions, such as atypical neuroleptics for aggressive behavior. However, at this time, no agent has yet proven beneficial for the core features of ASD. Propranolol is a relatively inexpensive, generic, nonselective beta-adrenergic antagonist that was originally FDA approved to treat hypertension. Previous studies have implicated propranolol in improving performance on language tasks, verbal problem solving, and facial scanning which are all important social behaviors (Zamzow, 2014; 2016; 2017). It is critical to better understand if propranolol can serve as a pharmacological intervention for core ASD symptoms, and if we can predict these changes using psychophysiological biomarkers.

#### **Objectives:**

This pilot study investigated the efficacy of using an adrenergic biomarker to predict the treatment response to propranolol. We hypothesized that baseline resting heart rate variability (HRV) would predict the score change on the Autism Impact Measure (AIM) from baseline to 12-weeks in children with ASD treated with propranolol.

#### **Methods:**

Children with ASD ages 7-14 (n=23) were invited to participate in this open label, double-blind clinical trial. Resting electrocardiogram (ECG) was collected, and HRV variables were calculated to represent autonomic nervous system functioning. HRV and AIM scores were obtained at baseline and again after 12-weeks of propranolol administration. The AIM assesses the symptoms of ASD in the domains of repetitive, atypical behavior, communication, social reciprocity, and peer interaction. The differences between baseline and 12-week AIM scores were calculated and linear regression was used to examine their relationship with baseline resting HRV variables.

#### **Results:**

A significant relationship was found between the peer interaction subdomain frequency change score and triangular interpolation of rhythm-to-rhythm interval (TINN) HRV measure. Furthermore, there were significant relationships between the Very Low Frequency (VLF) power log HRV measure and the atypical behavior subdomain change score for frequency and overall score (i.e., frequency plus impact score).

## Conclusions:

Baseline HRV may predict the change in core ASD symptoms, as measured by the AIM, in response to treatment with propranolol. HRV is a non-invasive measure of autonomic nervous system activity that could be used to predict outcomes prior to starting treatment. Future studies need to confirm whether baseline HRV assessment can help clinicians determine who may best benefit from propranolol in order to optimize targeted treatment. In general, the high degree of heterogeneity of ASD has created a challenge in clinical trials targeting core symptoms, making precision medicine approaches essential. The results presented herein are promising, but more research is needed to see if these effects are sustained in a larger population.

### **413.166 (Poster)** Randomized, Double-Blind, Controlled Trial of Probiotic Supplementation in Children with Autism Spectrum Disorder: Improvement of Gastro Intestinal Symptoms and Gut Microbiota Modulation.

---

## Background:

Recent data supports the hypothesis that the alteration of the microbiota plays a pivotal role in the pathogenesis of autism spectrum disorder (ASD). Several studies show that the gut microbiota of ASD individuals may be in part responsible for a deregulation of the gut-brain axis with particular relation to the onset of internalizing and externalizing symptoms. Besides, children with ASD are frequently characterized by gastrointestinal (GI) symptoms which may be linked to gut dysbiosis. Noteworthy, animal studies suggest that *Lactobacillus* (L.) *reuteri* PTA-6475 selectively rescues social deficits in genetic and idiopathic ASD models.

## Objectives:

Aim of this study is to assess the effect of a 6 month *L.Reuteri* (DSM17938 and ATCC PTA6475) supplementation on GI symptoms and gut microbiota in a sample of ASD children

## Methods:

We performed a randomized double-blind placebo-controlled trial on forty-three children with ASD (35 males 8 females; age range 3-8 years). Participants were randomized to L. Reuteri (DSM17938 and ATCC PTA6475) supplementation or placebo for a total of 180 days. At baseline (T0), after three months (T1) and at six months (T2), all participants underwent a standardized clinical assessment of GI problems (Gastrointestinal Symptoms Rating Scale), autism core symptoms and social behavior (Autism Diagnostic Observation Schedule-2<sup>nd</sup>; Social Responsiveness Scale; Adaptive Behavior Assessment 2<sup>nd</sup>). Gut microbiota analysis was performed at all timepoints by DNA extraction and then sequenced with MGI DNBT7.

## Results:

Preliminary results on gut microbiota analysis show that, at baseline, ASD children are characterized by a significant increase of Bacteroidetes ( $p<0.05$ ) and a decrease of Actinobacteria ( $p<0.034$ ) and Lactobacillus abundance ( $p<0.01$ ). After probiotic supplementation, we found that children receiving probiotic supplementation – in comparison to the placebo group - have a significant increase of: a) abundance of Bacteroidetes ( $p<0.006$ ), b) abundance of Intestinomonas butyriproducens family ( $p=0.02$ ). L. Reuteri was shown to change the microbiota composition of children treated with probiotic, leading to an increase in biodiversity as assessed by the Shannon Index.

## Conclusions:

The present clinical trial provides new insights into the gut-brain connection in ASD and shows that the supplementation with L. Reuteri (DSM17938 and ATCC PTA6475) fosters the abundance of anti-inflammatory species able to produce short chain fatty acids, increases microbiota diversity and improves GI symptoms. Further gut microbiota analysis that considers the social behavioral outcome after probiotic supplementation with L.Reuteri, may give a better understanding of the role played by microbiota in ASD.

### **413.167 (Poster)** Resting Heart Rate Variability As a Predictor of Anxiety Response to Propranolol in Autism Spectrum Disorder

*N. Nuraini<sup>1</sup>, C. Appling<sup>2</sup>, D. Q. Beversdorf<sup>3</sup>, K. Kovarik<sup>4</sup>, M. Prendergast<sup>4</sup> and B. J. Ferguson<sup>5</sup>, (1)Interdisciplinary Neuroscience Program, Thompson Center at the University of Missouri, Columbia, MO, (2)Interdisciplinary Neuroscience Program, University of Missouri, Columbia, MO, (3)Department of Radiology, Neurology, and Psychological Sciences, University of Missouri, Columbia, MO, (4)University of Missouri, Columbia, MO, (5)Health Psychology, Radiology, & Thompson Center for Autism & Neurodevelopmental Disorders, University of Missouri, Columbia, MO*

---

## Background:

Autism spectrum disorder (ASD) is a neurodevelopmental disorder characterized by persistent deficits in social communication and interaction as well as restricted and repetitive behaviors that occur early in development. Many individuals with ASD have been shown to have co-occurring anxiety disorders which have been shown to be associated with dysautonomia, including increased sympathetic and decreased parasympathetic tone. In general, there is a large amount of heterogeneity in ASD, resulting in where some individuals responding to particular pharmacological interventions while others do not. For the treatment of anxiety, it is plausible that those individuals with greater adrenergic tone at rest may receive the most benefit from propranolol, which is a nonselective, beta-adrenergic antagonist. Identifying predictive biomarkers for treatment response for those with ASD and co-occurring anxiety may lead to optimization of individualized treatment

## Objectives:

The present pilot study explored the ability of baseline resting heart rate variability (HRV), a measure of autonomic nervous system functioning, on the change in clinician-rated anxiety after taking propranolol for 12 weeks. We hypothesized that baseline resting HRV variables would predict the anxiety response to propranolol in ASD.

## Methods:

Patients diagnosed with ASD age 7-24 (n=31) took propranolol for 12 weeks in an open label manner. Baseline heart rate variability (HRV) was obtained through 5-minute electrocardiogram recordings. Before and after 12 weeks, anxiety outcomes were clinician-rated using the Clinical Global Impression of Severity (GCI-S).

## Results:

Among the HRV variables, Very Low Frequency Power (VLF), Low Frequency Power (LF power), and High Frequency Power (HF Power) in frequency domain were found to predict treatment response for anxiety in response to propranolol as assessed by the clinician rated change in CGI-S after 12 weeks of open label treatment.

## Conclusions:

Frequency domain aspects of baseline HRV predicted anxiety outcomes after 12 weeks of treatment with propranolol, as measured by GCI-S. HRV measurement is beneficial in investigating the pathophysiology of various psychiatric disorders. HF reflects vagal (i.e., parasympathetic) activity while LF indicates baroreceptor activity during resting conditions. Lower HF and LF may be associated with anxiety. VLF rhythm activity is generated by heart intrinsically due to physical activity and anxiety that modulates its frequency and amplitude. These findings begin to suggest a psychophysiological assessment that may be integrated to facilitate the prediction of treatment outcomes for anxiety treatments targeting the adrenergic system. Further exploration is needed with larger trials targeting anxiety in patients with ASD while monitoring HRV to establish the clinical utility of predictive markers for response to propranolol and potentially other agents.

## 413.168 (Poster) The Effect of Low-Dose Ketamine on Aberrant Behaviors in Children with ADNP Syndrome

**L. Massa<sup>1</sup>, T. Levy<sup>2</sup>, D. Halpern<sup>2</sup>, H. Walker<sup>3</sup>, B. Lerman<sup>2</sup>, S. Barkley<sup>2</sup>, C. F. Layton<sup>1</sup>, P. M. Siper<sup>2</sup>, J. H. Foss-Feig<sup>2</sup>, J. D. Buxbaum<sup>4</sup>, A. Kolevzon<sup>2</sup> and K. Friedman<sup>5</sup>,** (1)Seaver Autism Center, Department of Psychiatry, Icahn School of Medicine at Mount Sinai Hospital, New York, NY, (2)Seaver Autism Center for Research and Treatment, Department of Psychiatry, Icahn School of Medicine at Mount Sinai Hospital, New York, NY, (3)Teachers College, Columbia University, New York, NY, (4)Psychiatry, Icahn School of Medicine at Mount Sinai, New York, NY, (5)Vanderbilt University, Nashville, TN

## Background:

Activity-dependent neuroprotective protein (ADNP) syndrome is caused by pathogenic variants in the *ADNP* gene that lead to haploinsufficiency of the activity-dependent neuroprotective protein. Over 400 genes are regulated by ADNP and haploinsufficiency negatively impacts brain development, manifesting clinically as aberrant behavior, cognitive and language delays, attention deficits and hyperactivity, sensory seeking behaviors, anxiety, and sleep disturbance. Ketamine is an NMDA receptor antagonist that, in low doses, induces overexpression of ADNP at low doses in animal models (Brown et al., 2015). We hypothesized that treatment with low-dose ketamine would have a beneficial effect in individuals with ADNP syndrome by compensating for ADNP haploinsufficiency. To assess clinical outcomes, we used a variety of measures, including the Aberrant Behavior Checklist (ABC), which is a caregiver rating instrument developed for use in individuals with intellectual disability to assess the severity of aberrant behaviors across five subscales (Aman et al., 1985).

## Objectives:

To evaluate the safety of low-dose ketamine treatment in children with ADNP syndrome, as well as its efficacy for improving aberrant behaviors.

## Methods:

Ten individuals (7 male) with ADNP syndrome, ages 6 to 12 years ( $9.49 \pm 2.29$ ) participated in this single-dose, open-label clinical trial with low dose ketamine (0.5 mg/kg) infused intravenously over 40 minutes. Safety, tolerability, and efficacy measures were collected at (D0) Baseline before ketamine was administered, as well as post-infusion Day 1 (D1), Week 1 (W1), Week 2 (W2), and Week 4 (W4). To examine treatment effects, the Wilcoxon signed-rank test was calculated for the differences in data distributions (change over time) from D0 to D1, W1, W2, and to W4. All tests of statistical hypotheses were done on the two-sided 5% level of significance. Since this was an initial proof-of-concept study, no adjustments were made for multiple testing in the reported p-values. The Systematic Longitudinal Adverse Events Scale (SLAES) was administered by the study physician and the ABC was completed by the same parent at each time point. Adverse events were tabulated at each post-infusion visit.

#### Results:

No serious adverse events were reported; common adverse events included fatigue (n=5), aggression (n=5), elated/silly (n=4), decreased appetite (n=3), and anxiety (n=3) (Table 1). The Irritability, Social Withdrawal, Stereotypy, and Hyperactivity aberrant behavior subscales showed significantly decreased scores at W1, W2, and W4 in comparison to D0 (Table 2). No subscale scores significantly decreased from D0 to D1. The Inappropriate Speech subscale did not significantly decrease after drug administration (D0 to W1:  $p=0.606$ ).

#### Conclusions:

Ketamine was well tolerated and four of the five ABC subscales decreased significantly after ketamine was administered, suggesting overall improved aberrant behavior. The Inappropriate Speech subscale scores did not reflect improvement, likely because of the low verbal abilities of participants at baseline. Our results suggest that low dose ketamine is both safe for this cohort and potentially effective in reducing aberrant behaviors in children with ADNP syndrome. Future studies of ketamine in ADNP syndrome using placebo-controlled design in larger samples are warranted.

## VIRTUAL POSTER SESSION — INTERVENTIONS - PHARMACOLOGIC

### 513 - Interventions - Pharmacologic --- (V)

**513.111** (Virtual Poster) A Randomized Controlled Trial of Everolimus for Neurocognitive Symptoms in PTEN Hamartoma Tumor Syndrome  
S. Srivastava<sup>1</sup>, B. Jo<sup>2</sup>, B. Zhang<sup>1</sup>, T. W. Frazier<sup>3</sup>, A. S. Gallagher<sup>4</sup>, F. Peck<sup>4</sup>, A. R. Levin<sup>5</sup>, S. Mondal<sup>6</sup>, Z. Li<sup>6</sup>, R. Filip-Dhima<sup>7</sup>, G. Geisel<sup>1</sup>, K. Dies<sup>1</sup>, A. Diplock<sup>1</sup>, C. Eng<sup>8</sup>, R. Hanna<sup>9</sup>, M. Sahin<sup>1</sup> and A. Y. Hardan<sup>10</sup>, (1)Boston Children's Hospital, Boston, MA, (2)Department of Psychiatry and Behavioral Sciences, Stanford University, Stanford, CA, Stanford, CA, (3)Psychology, John Carrol University, Cleveland, OH, (4)Neurology, Boston Children's Hospital, Boston, MA, (5)Neurology, Boston Children's Hospital, Brookline, MA, (6)Stanford, Stanford, CA, (7)Boston Children's Hospital, Boston, MA, (8)Genomic Medicine, Cleveland Clinic Lerner Research Institute, Cleveland, OH, (9)Cleveland Clinic, Cleveland, OH, (10)Psychiatry & Behavioral Sciences, Stanford University, Stanford, CA

#### Background:

PTEN hamartoma tumor syndrome (PHTS) is a complex neurodevelopmental disorder associated with a high prevalence of autism spectrum disorder (ASD) and characterized by mTOR (mechanistic target of rapamycin) overactivity. Limited data suggest that mTOR inhibitors may be therapeutic. No placebo-controlled studies have examined mTOR inhibition on cognition and behavior in humans with PHTS with/without ASD.

#### Objectives:

We conducted a 6-month phase II, randomized, double-blinded, placebo-controlled trial to examine the safety profile and efficacy of everolimus (4.5mg/m<sup>2</sup>) in individuals (5-45 years) with PHTS.

#### Methods:

We measured several cognitive and behavioral outcomes, and electroencephalography (EEG) biomarkers. The primary endpoint was a neurocognitive composite derived from Stanford Binet-5 (SB-5) nonverbal working memory score, SB-5 verbal working memory, Conners' Continuous Performance Test hit reaction time, and Purdue Pegboard Test score.

#### Results:

Forty-six participants underwent 1:1 randomization: n=24 (everolimus) and n=22 (placebo). Gastrointestinal adverse events were more common in the everolimus group ( $p<0.001$ ). Changes in the primary endpoint between groups from baseline to month 6 were not apparent (Cohen's  $d=-0.10$ ,  $p=0.518$ ). However, several measures were associated with modest effect sizes ( $\geq 0.2$ ) in the direction of improvement, including measures of nonverbal IQ, verbal learning, autism symptoms, motor skills, adaptive behavior, and global improvement. There was a significant difference in EEG central alpha power ( $p=0.049$ ) and central beta power ( $p=0.039$ ) six months after everolimus treatment.

#### Conclusions:

Everolimus is well tolerated in PHTS; adverse events were similar to previous reports. The primary efficacy endpoint did not reveal improvement. Several secondary efficacy endpoints moved in the direction of improvement. EEG measurements indicate target engagement following 6 months of daily oral everolimus.

**513.112 (Virtual Poster)** Treatment of Missed ADHD with Significant Improvement in Three Adult Females with Mild Autism Spectrum Disorder and Recurrent Suicidality

**S. C. Singh<sup>1</sup>, I. Casubhoy<sup>2</sup> and J. A. Hellings<sup>3</sup>,** (1)University of Missouri-Kansas City, Kansas City, MO, (2)University of Missouri-Kansas City School of Medicine, Kansas City, MO, (3)Psychiatry, University of Missouri Kansas City and Truman Behavioral Health, Kansas City, MO

---

**Background:** Attention deficit hyperactivity disorder (ADHD) is often missed in adults, especially in females, including those with autism spectrum disorder (ASD). Antidepressants including selective serotonin reuptake inhibitors (SSRIs) may be activating in ASD and may worsen psychiatric problems including suicidality.

**Objectives:** To discuss overlooked ADHD comorbid with ASD, which may present as recurrent suicidality associated with adversity, including in adult females. Treatment with antidepressants, mood stabilizers and antipsychotics may then produce minimal if any improvement, or even worsening if the antidepressants cause activation. Three cases are described that demonstrated significant improvements after ADHD medications were added and antidepressants later cautiously tapered in small doses, and in two cases, tapered off completely with continued improvements in behavior and functioning.

**Methods:** We describe 3 adult females with mild ASD presenting on antidepressants, antipsychotics and mood stabilizers who tested positive for ADHD on the Adult ADHD-RS and met DSM-5 criteria for ADHD, however untreated. Each had significant environmental stressors, impulsivity and recurrent suicidality. We extracted their demographic data, diagnoses, medications at start and end, and outcomes on the Clinical Global Impressions-Improvement (CGI-I) subscale. ADHD medications are a focus of each case, together with very cautious, gradual antidepressant taper.

**Results:** All cases met DSM-5 criteria for mild ASD, ADHD-RS ratings for ADHD, and presented with mood disorder diagnoses. Final CGI-I on all 3 cases was Much Improved. **Case 1:** 18yr WF presented with failure in education, work and independent living accompanied by hopelessness and intermittent suicidal ideation (SI). Atomoxetine (ATX) was added and bupropion XL tapered gradually, with improvement. Aripiprazole was also tapered gradually. Later, mixed amphetamine salts were added, with more improvement. Further environmental stressors resulted in an ED visit for SI and bupropion XL was increased, resulting in manic-like symptoms, which responded to dose reduction, and individual therapy. **Case 2:** 33yr WF with stressors of residential living and interpersonal problems presented with recurrent outbursts, police calls and ED visits for hopelessness, SI and homicidal threats. Medications at presentation included antidepressants (bupropion XL), aripiprazole and lithium. ATX was added and gradually increased, and bupropion and lithium were tapered off, producing improvement. However she worsened again with more stressors, was admitted and ATX was tapered off. Following discharge, ATX was restarted and increased to 40mg qam, 25mg qhs with much improvement and better ability to ignore others, and holds a job. **Case 3:** 24yr WF presented with life stressors of residential living and family stressors, poor frustration tolerance, on antidepressants (sertraline 200mg daily, doxepin 10 mg daily), antipsychotics, and mood stabilizers. She had recurrent ED visits and hospitalizations for SI, until she was started on ATX followed by cautious, taper off antidepressants, producing significant improvement. Final ATX dose was 40mg qam, 25mg qhs.

**Conclusions:** Suicidality can be due to causes other than mood disorders, including environmental stressors, and impaired frustration tolerance associated with ADHD. Diagnostic assessment for ADHD, use of the Adult ADHD-RS, and treatment with ADHD medications as well as cautious antidepressant taper under surveillance may be important in improving outcomes.

**513.113 (Virtual Poster)** Medical Cannabis for Treatment of Comorbid Symptoms in Children with Autistic Spectrum Disorder: An Interim Analysis of Biochemical Safety

**O. E. Stolar,** Autism Center, Assaf Harofeh Medical Center, zerifin, Israel

---

**Background:** Autistic Spectrum Disorder (ASD) is a common neurodevelopmental disorder and no effective treatment for the core symptoms is currently available. The present study is part of a larger clinical trial assessing the effects of cannabis oil on autism co-morbidities.

**Objectives:** The aim of the present study was to assess the safety of a CBD-rich oil treatment in children and adolescents with ASD.

**Methods:** Data from 59 children and young adults (ages 5-25 years) from a single-arm, ongoing, prospective, open-label, one center, phase III study was analyzed. Participants received medical cannabis extract infused in MCT oil with a CBD:THC ratio of 20:1 for six months. Blood analysis was performed before treatment initiation, and after 3 months. Complete blood count, glucose, urea, creatinine, electrolytes, liver enzymes (AST, ALT, GGT), bilirubin, lipid profile, TSH, FT4, thyroid antibodies, prolactin, and testosterone measurements were performed at baseline, prior to starting treatment and at study midpoint, after three months of treatment.

**Results:** 59 children (85% male and 15% female) were followed for 18± 8 weeks (mean ±SD). The mean total daily dose was 7.88±4.24 mg/kg body weight. No clinical or statistically significant differences were found in any of the analytes between baseline and 3 month follow up. A comparison of patients who received additional medications (n=14), to those who solely received medical cannabis (n=45) showed no differences in biochemical tests.

**Conclusions:** CBD-rich cannabis oil (CBD: THC 20:1), appears to have a good safety profile. Long-term monitoring with a larger number of participants is warranted.

**513.114 (Virtual Poster)** Medical Cannabis for the Treatment of Comorbid Symptoms in Children with Autistic Spectrum Disorder: An Interim Analysis of Biochemical Safety

**O. E. Stolar**, Autism Center, Assaf Harofeh Medical Center, Zerifin, Israel

**Background:** Autistic Spectrum Disorder (ASD) is a common neurodevelopmental disorder and no effective treatment for the core symptoms is currently available. The present study is part of a larger clinical trial assessing the effects of cannabis oil on autism co-morbidities.

**Objectives:** The aim of the present study was to assess the safety of a CBD-rich oil treatment in children and adolescents with ASD.

**Methods:** Data from 59 children and young adults (ages 5-25 years) from a single-arm, ongoing, prospective, open-label, one center, phase III study was analyzed. Participants received medical cannabis extract infused in MCT oil with a CBD:THC ratio of 20:1 for six months. Blood analysis was performed before treatment initiation, and after 3 months. Complete blood count, glucose, urea, creatinine, electrolytes, liver enzymes (AST, ALT, GGT), bilirubin, lipid profile, TSH, FT4, thyroid antibodies, prolactin, and testosterone measurements were performed at baseline, prior to starting treatment and at study midpoint, after three months of treatment.

**Results:** 59 children (85% male and 15% female) were followed for  $18 \pm 8$  weeks (mean  $\pm$ SD). The mean total daily dose was  $7.88 \pm 4.24$  mg/kg body weight. No clinical or statistically significant differences were found in any of the analytes between baseline and 3 month follow up. A comparison of patients who received additional medications (n=14), to those who solely received medical cannabis (n=45) showed no differences in biochemical tests.

**Conclusions:** CBD-rich cannabis oil (CBD: THC 20:1), appears to have a good safety profile. Long-term monitoring with a larger number of participants is warranted.

**513.115 (Virtual Poster)** Psychotropic Medication Use in Autistic Children Enrolled in Medicaid

**J. Rast<sup>1</sup>, S. Tao<sup>2</sup>, L. Shea<sup>3</sup> and B. K. Lee<sup>4</sup>**, (1)A.J. Drexel Autism Institute, Drexel University, Philadelphia, PA, (2)Drexel University, Philadelphia, PA, (3)A.J. Drexel Autism Institute, Philadelphia, PA, (4)Epidemiology and Biostatistics, Drexel University, Philadelphia, PA

**Background:** Autistic children frequently present with complex mental health conditions. As many as 78% of autistic children have  $\geq 1$  co-occurring mental health condition, and half having  $\geq 2$  mental health conditions. The most common conditions are behavior/conduct problems (61%); anxiety (40%); ADHD (48%); and depression (16%). The use of psychotropic medication is an important consideration in the management of these conditions. The high rates of co-occurring mental health conditions in autistic children drive the use of polypharmacy, with 35% of children taking drugs from  $\geq 2$  psychotropic classes, and 15% taking drugs from  $\geq 3$  classes. In autistic children, the presentation of complex symptom profiles makes prescription and symptom management a difficult task that is often approached on a case-by-case and trial-and-error basis. The safety and efficacy of psychotropic medications in autistic populations is largely unknown.

**Objectives:** This study seeks to provide current estimates of use of psychotropic medications, and predictors thereof, in autistic children across the US enrolled in Medicaid. These medications often carry with them significant neurological, behavioral, or somatic side effects. Although there is emerging evidence regarding the effectiveness (or lack thereof) of several such off-label pharmacological treatments of autism, there is a general lack of understanding about off-label medications to treat autism. There is also little understanding of the distinction between medication for autism symptoms versus maintenance of co-occurring mental health conditions. Thus, it is important to characterize the extent to which these medications are used in the care of autism.

**Methods:** Using Medicaid Analytic eXtract (MAX) data from 2008-2016, we will examine trends and correlates of psychotropic medication use in autistic children and youth ages 6-21. Medications will be classified using the Multum Lexicon database using the following classes of psychotropics: antidepressants, neuroleptics (aka antipsychotics), anxiolytics (aka anti-anxiety), mood stabilizers, sedatives/hypnotics, stimulants, and anticonvulsants. We will examine 1) prevalence of overall medication use by age and year, 2) patterns of medication use including monotherapy, inter- and intra-class polypharmacy, and inconsistent medication use or switching, 3) most common medication combinations for polypharmacy and average length of time engaged, and 4) demographic and patient characteristic factors associated with any psychotropic medication and with polypharmacy using multivariable logistic regression.

**Results:** More than half (58%) of autistic children enrolled in Medicaid took a psychotropic medication in a given year. The most common were mood stabilizers (44%), stimulants (31%), and antidepressants (28%). Further analysis will explore polypharmacy and usage by key strata, including age, sex, and race; and logistic regression results.

**Conclusions:** Use of psychotropic medication is common in autistic children, but with a lack of clinical guidance and safety and efficacy information, it is important to understand use patterns so we can begin to examine how usage impacts health. More work is needed to understand the negative outcomes associated with psychotropic medication use, and polypharmacy in particular.

## Medical and Psychiatric Comorbidity

**Panel Chair:** Jessica Schwartzman, *Psychiatry and Behavioral Sciences, Vanderbilt University Medical Center, Nashville, TN*

**Discussant:** Katherine Gotham, *Department of Psychology, Rowan University, Glassboro, NJ*

**205.001 (Panel)** Is Camouflaging Autistic Traits Associated with Thwarted Belongingness, Perceived Burdensomeness, and Suicidality in Autistic Adults?

S. A. Cassidy<sup>1</sup>, H. Cogger-Ward<sup>1</sup>, L. Manning<sup>1</sup>, M. K. Pelton<sup>2</sup> and J. Rodgers<sup>3</sup>, (1)School of Psychology, University of Nottingham, Nottingham, United Kingdom, (2)Coventry University, Coventry, United Kingdom, (3)Population Health Sciences Institute, Newcastle University, Newcastle upon Tyne, United Kingdom

Background:

Autistic adults are at significantly higher risk of suicidality compared to non-autistic people, but there is little research exploring why. The Interpersonal Theory of Suicide posits that a lack of meaningful social connections (thwarted belongingness) and perceiving oneself to be a burden to others (perceived burdensomeness) increases risk of experiencing suicidal thoughts. A previous study found that in a community sample of young adults, those who reported camouflaging high autistic traits to 'fit in' in social situations were more likely to experience thwarted belongingness, which was in turn associated with suicidality. However, this model has not yet been tested in autistic people.

Objectives:

1. To test whether camouflaging significantly predicts: a) thwarted belongingness; and b) perceived burdensomeness.
2. To test whether the association between camouflaging with suicidality is mediated by: a) thwarted belongingness; and b) perceived burdensomeness.

Methods:

385 autistic adults (103 self-identifying autistic, 27.5% male gender, mean age=39.4 *SD*=13.3), completed measures of autistic traits (AQ), camouflaging autistic traits (CAT-Q), thwarted belongingness and perceived burdensomeness (INQ-15), current anxiety (ASA-A) and depressive symptoms (PHQ-9), and lifetime suicidality (SBQ-ASC), online. Multiple hierarchical regressions explored whether camouflaging significantly predicted thwarted belongingness or perceived burdensomeness, after controlling for age, gender, current depression and anxiety symptoms and autistic traits. Serial mediation analyses explored: a) whether the association between autistic traits and lifetime suicidality was significantly mediated by camouflaging and thwarted belongingness; and b) whether the association between autistic traits and lifetime suicidality was significantly mediated by camouflaging and perceived burdensomeness.

Results:

After controlling for age, gender, current depression and anxiety symptoms, and autistic traits, camouflaging did not account for significantly more variance in either thwarted belongingness ( $F(1,375)=1.03, p=.31$ ) or perceived burdensomeness ( $F(1,375)=.045, p=.83$ ). In the first serial mediation model, camouflaging was not significantly associated with thwarted belongingness, and therefore the full serial mediation path was not significant. However, there was evidence for two simple mediation effects, where the association between autistic traits and lifetime suicidality was significantly mediated separately by: a) camouflaging; and b) thwarted belongingness. In the second serial mediation model, the association between autistic traits with lifetime suicidality was significantly mediated by camouflaging and perceived burdensomeness.

Conclusions:

Consistent with previous research, camouflaging was significantly associated with lifetime suicidality in a sample of autistic adults. However, contrary to our hypotheses, camouflaging was more strongly associated with perceiving oneself to be a burden on others, rather than feelings of being socially disconnected from others. This pattern of results is different to that previously found in non-autistic people with high autistic traits, suggesting that the impact of camouflaging on suicidality could be different in autistic compared to non-autistic people. Specifically, non-autistic people who camouflage autistic traits tend to report feeling socially disconnected from others. In contrast, autistic people who camouflage tend to report feeling a burden on others. This suggests that reducing pressure to camouflage is an important transdiagnostic suicide prevention target, but programmes should take into account the potentially different impact of camouflaging on suicidality in autistic people and those with high autistic traits.

**205.002 (Panel)** Modeling Social Predictors of Depressive Symptoms across the First Semester in Autistic and Non-Autistic College Students

E. E. McKenney<sup>1</sup>, J. K. Richards<sup>1</sup>, T. C. Day<sup>2</sup>, B. Kofner<sup>1</sup>, R. G. McDonald<sup>1</sup>, K. Gillespie-Lynch<sup>3</sup>, E. Kang<sup>4</sup>, M. D. Lerner<sup>5</sup> and K. O. Gotham<sup>6</sup>, (1)Rowan University, Glassboro, NJ, (2)Psychology, Stony Brook University, Stony Brook, NY, (3)College of Staten Island, Staten Island, NY, (4)Department of Psychology, Montclair State University, Montclair, NJ, (5)Department of Psychology, College of Staten Island, City University of New York, Staten Island, NY, (6)Psychiatry and Behavioral Sciences, Vanderbilt University Medical Center, Nashville, TN

**Background:** Meta-analytic review has suggested autistic individuals are approximately four times more likely than non-autistic individuals to experience lifetime depression (Hudson et al., 2019). Autistic adults are more likely to endorse social rejection, lack of social support, and loneliness, which may contribute to depressive symptoms (Ee et al., 2019; Han et al., 2019; Mazurek, 2014). These concerns may be particularly salient during the first semester of college, as students enter a new, less structured social environment (Bailey et al., 2020; White et al., 2016). Autistic college students who do not feel as socially connected tend to report lower subjective well-being and greater difficulty balancing the demands of school (Bailey et al., 2020), which may in turn affect academic success and retention.

**Objectives:** The current study examines satisfaction with social connectedness as a prospective predictor of depression symptoms in a longitudinal sample of first-semester college students. We hypothesize that students who report lower social satisfaction in biweekly reports will experience greater depressive symptoms over the semester, and that this effect will be stronger for those who reported greater baseline capacity for social reward. While we predict no difference in this model between groups, we hypothesize that a higher proportion of autistic students will exhibit this lack of social fulfillment compared to non-autistic peers.

**Methods:** We recruited incoming college students from four universities in New York and New Jersey who reported either no history of autism ( $n=60$ ; 48% women; SRS-2  $M=53.83$ ;  $SD=8.31$ ) or suspected or previously diagnosed autism ( $n=36$ ; 41% women; SRS-2  $M=63.50$ ;  $SD=10.24$ ). Participants first completed a baseline survey of demographic, diagnostic, and behavioral health information, including the Beck Depression Inventory, 2nd edition (BDI-II; Beck et al., 1996), and Anticipatory and Consummatory Interpersonal Pleasure Scale (ACIPS; Gooding & Pflum, 2014). Participants then completed an 11-question survey twice per week for 12 weeks; this indexed social engagement and satisfaction, depressive and anxiety symptoms, and current stressors. Participants will complete a semester-end battery in mid-December 2021. We anticipate using latent difference score models to analyze the final longitudinal dataset.

**Results:** Across both groups, lower feelings of social connectedness were associated with greater sadness across biweekly surveys ( $F(1, 497) = 67.07$ ,  $p < 0.001$ ), and this relationship was strongest for those with highest baseline social motivation per ACIPS ( $F(1, 497)=10.24$ ,  $p=0.001$ ; see Figure 1). Autistic students reported lower average biweekly social satisfaction ( $M=54.02$ ,  $SD=20.02$ ) than non-autistic students ( $M=58.99$ ,  $SD=22.37$ ;  $F(1, 497)=7.04$ ,  $p<0.01$ ), though both groups showed increasing satisfaction over time (Figure 2).

**Conclusions:** Preliminary results indicate that, across diagnostic cohorts, lower social connectedness is associated with greater reported sadness within frequent, granular self-report, and that this relationship was strongest for those with the greatest baseline capacity for social reward. Autistic students tended to feel less satisfied with their social connection compared to non-autistic peers. At this point, the trajectory appears encouraging insofar as both autistic and non-autistic students tend to report increasing social satisfaction as the semester progresses.

### **205.003 (Panel) Depression and Quality of Life Directly and Sequentially Mediate the Association between Loneliness and Suicidal Ideation in Autistic Adults**

**J. M. Schwartzman<sup>1</sup>, Z. J. Williams<sup>2</sup> and K. O. Gotham<sup>3</sup>, (1)Psychiatry and Behavioral Sciences, Vanderbilt University Medical Center, Nashville, TN, (2)Medical Scientist Training Program, Vanderbilt University School of Medicine, Nashville, TN, (3)Department of Psychology, Rowan University, Glassboro, NJ**

**Background:** Autistic adults endorse suicidal ideation more frequently than neurotypical adults, prompting investigations into risk and resilience factors. Loneliness and social dissatisfaction may be salient risk factors in autism as one study reported an indirect pathway from loneliness through depression to suicidal ideation (PHQ-9 item #9) in 71 autistic adults (Hedley et al., 2018). However, it remains unknown whether these relationships reflect residual confounding by other risk factors such as social difficulties or trait neuroticism. In addition, despite the importance of quality of life (QoL) as a treatment target and goal for many autistic adults, its role in this pathway to suicidal ideation has not been investigated.

**Objectives:** The objective of this study was to expand upon the early work by Hedley and colleagues (2018) on the loneliness-depression-suicidal ideation pathway by investigating the mediating role of quality of life within this pathway, additionally controlling for relevant demographic and clinical variables that may confound these relationships.

**Methods:** The sample included 762 autistic adults (271 males, 414 females, 77 non-binary; 39.3% with current suicidal ideation) who completed self-report questionnaires at one timepoint as part of a larger SPARK dataset focused on repetitive thinking in depression (RM0030Gotham). Participants self-reported suicidal thoughts/wishes (BDI-II Item #9), depressive symptoms (BDI-II without item #9), loneliness (LiCQ), social anxiety (BFNE-S), neuroticism (IPIP-N10), autistic traits (SRS-2), quality of life (WHOQoL-4), and demographic factors (age, gender, education level). To examine the loneliness-depression-QoL-suicidality pathway, we fit a sequential Bayesian mediation model that additionally controlled for demographics, autistic traits, neuroticism, and social anxiety. Direct and indirect effects of loneliness were quantified using fully standardized path coefficients.

**Results:** The zero-order correlation between loneliness and suicidal ideation demonstrated a moderate-to-large association between the two variables ( $r_{\text{poly}}=0.400$ ,  $CrI_{95\%} [0.326, 0.466]$ ). Within the sequential mediation model (Figure 1), the combined direct and indirect effect of loneliness on suicidal thoughts/wishes was moderate in magnitude ( $\beta_{\text{Sid}}=0.362$ ,  $CrI_{95\%} [0.232, 0.495]$ ) and completely mediated by depressive symptoms and QoL (direct effect:  $\beta_{\text{Sid}}=0.080 [-0.038, 0.202]$ ; total indirect effect:  $\beta_{\text{Sid}}=0.281 [0.207, 0.357]$ ; 77.9% [52.4%, 109.8%] mediated). The indirect path through depression was larger than both the indirect path through quality of life and the sequential path through both depression and quality of life, though all three paths were statistically significant. In addition to the direct effects of depressive symptoms and quality of life, younger age, non-binary gender, and higher education level were all independently associated with greater suicidal ideation. Direct effects of female gender, autistic traits, social anxiety, and neuroticism did not reach statistical significance.

**Conclusions:** These findings confirm that loneliness is a robust predictor of suicidal ideation in autistic adults, even after controlling for demographic variables, neuroticism, and social difficulties. This relationship is fully mediated by a combination of increased depressive symptoms and reduced quality of life, with loneliness influencing suicidal ideation via multiple indirect paths. Future experimental studies that explicitly intervene on loneliness are necessary to further interrogate these causal relationships and investigate the utility of increasing social connectedness as a method of reducing suicidality in the autistic population.

**205.004 (Panel) A Mixed Methods Study of Suicidal and Non-Suicidal Self-Injurious Behavior in Younger and Older Autistic People**

**D. Hedley<sup>a</sup> and C. McMorris<sup>b</sup>,** (1)Olga Tennison Autism Research Centre, La Trobe University OTARC, Melbourne, VIC, Australia, (2)Department of Paediatrics, University of Calgary, Calgary, AB, Canada

**Background:** There is now substantial evidence of an increased prevalence of suicidal thoughts and behavior in autistic people when compared to the general population (Kölves et al., 2021). However, given research in this area is relatively recent, the reasons underlying suicidal thoughts and behavior within these individuals are relatively unexplored. In these two studies we used the Columbia-Suicide Severity Rating Scale (C-SSRS; Posner et al., 2011) to collect information on intensity and severity of suicidal ideation, history of suicidal behavior, and lethality of actual attempts in two samples of autistic people. Study 1 was conducted in Canada, and data were collected from caregivers of younger autistic people 8–26 years of age. Study 2 was conducted in Australia where the C-SSRS was administered via interview to older participants (18 years and older). In Study 2 a sub-sample of participants with a history of a suicidal attempt were invited to complete qualitative interviews concerning their experiences managing their mental health and suicidal behavior.

**Objectives:** To characterize suicidal thoughts and behavior in younger and older autistic people from Canada and Australia.

**Methods:** A mixed methods interview design was adopted. Both studies were approved by the relevant ethics review boards and all participants provided written informed consent. Participants in Study 1 were caregivers (91% female,  $M_{AGE}=41.25$ ,  $SD=6.7$ ) of 33 autistic children, youth, and young adults (male=78.8%), 8 to 26 years of age ( $M_{AGE}=13.28$ ,  $SD=4.42$  years) who completed a modified caregiver-report version of the C-SSRS. Participants in Study 2 were 98 autistic adults (women=58.2%, men=34.7%, non-binary=7.1%) 20 to 70 years of age ( $M_{AGE}=41.65$ ,  $SD=2.96$  years). A sub-sample of participants ( $n=19$ ; 58% women,  $M_{AGE}=43.11$ ,  $SD=11.38$ ) with a history of at least one suicide attempt completed semi-structured qualitative interviews. The C-SSRS was used to assess the presence and severity of suicidal behavior and was administered by interviewers who had completed the online training. Suicidal behavior was coded according to C-SSRS guidelines.

**Results:** For Study 1, 24.2% ( $n=8$ ) of caregivers reported their child had a suicide attempt and 60.6% ( $n=20$ ) reported engaging in non-suicidal self-injurious behavior. The mean age of first attempt was early adolescence ( $M_{AGE}=13.54$ ,  $SD=4.93$ , Range:7–24 years). Methods included cutting, running into traffic and overdose. For Study 2, 41.8% ( $n=41$ ) of participants reported a suicide attempt and 63.3% reported engaging in non-suicidal self-injurious behavior. The age of first suicide attempt ranged from 7 to 45 years ( $M=19.39$ ,  $SD=9.28$  years). The most frequent method was overdose (38%), followed by cutting (23.5%) and suffocation (14.7%). The qualitative interviews identified financial cost, the lack of services catering for autistic people, and a perceived lack of autism knowledge amongst mental health professionals as barriers to receiving appropriate mental health. Participants also identified a need for individualised treatment approaches.

**Conclusions:** The findings from these studies highlight that suicidal behavior is present and relatively high among autistic people and across age groups, with adolescence identified as a particularly vulnerable period. Qualitative results identified both shortcomings in existing services as well as new directions for developing appropriate prevention strategies.

## ORAL SESSION - 10A — MEDICAL AND PSYCHIATRIC COMORBIDITY

### 316 - Intersectional Comorbidities

**316.001 (Oral) Sex Differences in Mental Health in Young Autistic Adults: A Population Based Cohort Study**

**M. Martini<sup>1</sup>, R. Kuja-Halkola<sup>2</sup>, A. Butwicki<sup>3</sup>, E. Du Rietz<sup>4</sup>, B. D'Onofrio<sup>5</sup>, F. Happé<sup>6</sup>, A. Kanina<sup>7</sup>, H. Larsson<sup>8</sup>, S. Lundström<sup>9</sup>, J. Martin<sup>10</sup>, M. Rosenqvist<sup>11</sup>, P. Lichtenstein<sup>12</sup> and M. Taylor<sup>13</sup>,** (1)Karolinska Institute, Stockholm, Sweden, (2)Karolinska Institutet, Stockholm, Sweden, (3)Psychological and Brain Sciences, Indiana University, Bloomington, IN, (4)Social, Genetic and Developmental Psychiatry Centre, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (5)School of Medical Sciences, Örebro University, Örebro, Sweden, (6)Gillberg Neuropsychiatry Centre, Department of Psychiatry and Neurochemistry, Institute of Neuroscience and Physiology, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden, (7)Cardiff University, Cardiff, United Kingdom of Great Britain and Northern Ireland

**Background:**

Autistic individuals are at increased risk for mental health (MH) problems compared to the general population, with a majority receiving at least one psychiatric diagnosis. Young adulthood – the onset period for many psychiatric disorders – is a challenging transitional period, particularly for autistic individuals. Autistic females show a disproportionally increased risk for psychiatric disorders and might be particularly vulnerable in young adulthood.

**Objectives:**

We examined sex differences in the incidence of co-occurring psychiatric diagnoses in autistic young adults aged 16 to 24 years compared to the general population. We assessed severity of MH problems as indicated by hospitalizations.

## Methods:

Using a population-based cohort design, we identified all individuals born in Sweden between 1985 and 1997 from nationwide registers. A total of 1,335,753 individuals, including 20,841 autistic individuals (7,129 females, 34.21%), were followed up from age 16 to 24 years (end of follow up, 31<sup>st</sup> December 2013). We compared the incidence of 13 psychiatric disorders (see Figure 1) between autistic and non-autistic individuals, assessed through inpatient or outpatient diagnoses in the National Patient Register. To estimate relative risk for co-occurring disorders we calculated hazards ratios (HR) using stratified Cox proportional hazards regression and compared HR between sexes using a ratio of HR ( $HR_{females}/HR_{males}$ ). We computed absolute risk as cumulative incidence at age 25, with additional estimation of standardized survival probability and risk difference using standardization with Cox regressions comparing autistic males and females. Analyses were repeated for inpatient diagnoses to assess psychiatric hospitalization.

## Results:

Autism was associated with increased absolute (cumulative incidence, 0.67; 95%CI, 0.66 -0.68) and relative risk (HR, 6.85; 95%CI, 6.71-7.00) for any psychiatric diagnosis. Sex stratified analyses indicated elevated risk for all MH problems in autistic males and females compared to individuals without autism of the same sex (HR-range males, 2.99-18.67, HR-range females, 3.18-20.78, see Figure2). Comparing autistic females to non-autistic females yielded a higher HR than for males for psychotic disorders, alcohol and substance use disorders, and self-harm. Absolute risk was highest in autistic females for any disorder and 9 out of 13 individual disorders. We observed higher HR for males than females for depressive disorders, OCD, anorexia nervosa and other eating disorders.

Autistic individuals were more likely than non-autistic individuals to be hospitalized due to any psychiatric disorder (HR, 6.67; 95%CI, 6.43-6.92). Ratios of HR pointed toward increased relative risk in females to be hospitalized due to any psychiatric disorder, anxiety disorders, psychotic disorders, alcohol and substance use disorders, and self-harm. Absolute risk was higher in autistic females for any disorder and 6 out of 13 individual disorders.

## Conclusions:

Autistic females, who until now have been underrepresented in research and clinical practice, have similar or even higher MH needs than autistic males. Our findings, especially on self-harm in autistic females, highlight the importance of identifying underlying mechanisms – potentially grounded in delayed diagnosis due to differential autism presentation, masking of symptoms and biases in diagnosing autism in females – that contribute to MH problems in this population.

### 316.002 (Oral) Comorbidities of Autism Spectrum Disorder and Their Etiologies

**V. Khachadourian<sup>1</sup>, B. Mahjani<sup>2</sup>, S. Sandin<sup>3</sup>, A. Kolevzon<sup>4</sup>, J. D. Buxbaum<sup>4</sup>, A. Reichenberg<sup>5</sup> and M. Janecka<sup>5</sup>**, (1)Icahn School of Medicine at Mount Sinai, New York, NY, (2)Seaver Autism Center, Department of Psychiatry, Icahn School of Medicine at Mount Sinai, New York, NY, (3)Seaver Autism Center for Research and Treatment, Department of Psychiatry, Icahn School of Medicine at Mount Sinai Hospital, New York, NY, (4)Psychiatry, Icahn School of Medicine at Mount Sinai, New York, NY, (5)Seaver Autism Center for Research and Treatment Icahn school of Medicine at Mount Sinai, New York, NY

**Background:** Autism spectrum disorder (ASD) is a neurodevelopmental disorder manifested by social communication deficits and restricted and repetitive behaviors. In addition to the core features of ASD, affected individuals also experience a higher burden of co-occurring medical conditions.

**Objectives:** This study sought to examine the pattern of comorbidities in individuals with ASD and systematically evaluate the possibility that peri- and postnatal exposures (e.g., preterm birth, hypoxia at birth, traumatic brain injury, and fetal alcohol syndrome) associated with ASD may also be linked with distinct comorbidities.

**Methods:** We used the SPARK study database, launched by the Simons Foundation Autism Research Initiative (SFARI). Pregnancy and birth-related conditions served as the main exposure variables, including preterm birth (gestational age of <37 weeks), serious prenatal infection, fetal alcohol syndrome, hypoxia at birth, and bleeding into the brain during delivery. Postnatal exposures were lead poisoning, brain infections such as bacterial meningitis, and encephalitis, and traumatic brain injury requiring hospitalization. Outcomes were based on parent reported comorbidities, including neurological, cognitive, psychiatric, and physical conditions.

**Results:** The study sample consisted of 42,569 individuals with ASD and their 11,389 non-ASD siblings. Children with ASD had a substantially higher standardized (standardized for age, sex, and year of evaluation) prevalence of all comorbidities analyzed in this study compared to their siblings without an ASD diagnosis (all p-values <0.05). ADHD was the most common comorbidity, affecting 1 in every 3 children with ASD (35.3%), much higher than 1 in 6 (16.8%) among non-ASD siblings. Learning disability (23.5%) and intellectual disability (21.7%) were the next most-common comorbid conditions among children with ASD. Individuals with ASD also had a higher standardized prevalence of all the pre- and postnatal exposures, including preterm birth, hypoxia at birth, traumatic brain injury, and fetal alcohol syndrome. In logistic regression models adjusted for covariates (annual household income, and father's and mother's highest education levels, paternal age and maternal age, year of birth, age of the child at evaluation, survey version, race, and ethnicity), different exposures were associated with distinct patterns of comorbidities in ASD cases, including associations between preterm birth and anxiety disorder (OR = 1.30; 95%CI = 1.20-1.42), preterm birth and hoarding (OR=1.59; 95%CI=1.27-1.98), bleeding into brain and strabismus (OR = 2.74; 95%CI = 1.96-3.82), and traumatic brain injury and difficulty gaining weight (OR

= 2.36; 95%CI = 1.54-3.61). Figure 1 presents an overview of the associations between peri- and postnatal exposures and comorbidity in ASD. A similar pattern of associations was also observed in non-ASD siblings.

**Conclusions:** This study followed a systematic approach, evaluating pre- and postnatal exposure and comorbidity associations in ASD. The high burden of comorbidity in individuals with ASD highlights the importance of timely diagnosis and management of comorbidity in ASD. Study findings, if replicated in other samples, can inform the etiology of comorbidity in ASD, and help with stratification of individuals with ASD for targeted prevention and screening strategies.

### **316.003 (Oral) Network Analysis to Evaluate Relations Among Approach-Withdrawal Behavior and Co-Occurring Conditions in ASD**

**S. Kala<sup>1</sup>, G. T. Han<sup>2</sup>, A. Naples<sup>3</sup>, K. Chawarska<sup>4</sup>, G. Dawson<sup>5</sup>, R. A. Bernier<sup>6</sup>, S. Jeste<sup>7</sup>, C. A. Nelson<sup>8</sup>, J. Dziura<sup>9</sup>, S. J. Webb<sup>4</sup>, C. Sugar<sup>8</sup>, F. Shic<sup>8</sup> and J. McPartland<sup>6</sup>, (1)Child Study Center, Yale University School of Medicine, New Haven, CT, (2)Yale Child Study Center, New Haven, CT, (3)Department of Psychiatry and Behavioral Sciences, Duke Center for Autism and Brain Development, Durham, NC, (4)Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA, (5)University of California, Los Angeles, Los Angeles, CA, (6)Department of Developmental Medicine, Boston Children's Hospital, Boston, MA, (7)Yale University, New Haven, CT, (8)Center for Child Health, Behavior and Development, Seattle Children's Research Institute, Seattle, WA, (9)Child Study Center, Yale Child Study Center, New Haven, CT**

**Background:** Approximately 70% of children with autism spectrum disorder (ASD) present with at least one co-occurring psychiatric condition, with anxiety and mood disorders, obsessive compulsive disorder (OCD), oppositional defiant disorder (ODD), and attention-deficit hyperactivity disorder (ADHD) among the most common. Atypical patterns of behavioral approach and withdrawal may explain relationships among ASD and prevalence of these conditions. For example, ASD-specific social tendencies may reflect increased approach to non-social stimuli and/or decreased approach or increased withdrawal from social stimuli. Similarly, depression and anxiety have been associated with decreased approach toward emotional stimuli and increased withdrawal from feared stimuli.

**Objectives:** Characterize patterns of approach and withdrawal behaviors relevant to ASD in relation to co-occurring symptoms.

**Methods:** Participants included 276 children with ASD aged 7-11 years [ $M_{age}=8.56$  years, 23.6% female, 31.9% non-White] from the Autism Biomarkers Consortium for Clinical Trials. Parents/caregivers completed the Child and Adolescent Symptom Inventory (CASI-5) to evaluate co-occurring symptomatology and the Pervasive Developmental Disorder Behavior Inventory (PDDBI), an ASD rating scale that includes approach-withdrawal behavior. 35.5% exceeded the clinical cutoff for dysthymia, 40.2% for generalized anxiety, 14.1% for separation anxiety, 29.3% for social anxiety, 44.2% for hyperactive impulsivity, 60.1% for inattention, 17.8% for major depressive episode (MDE), and 24.6% for ODD. Interrelations among approach-withdrawal behaviors and clinical symptoms were probed using a regularized partial correlation network containing 35 nodes: 27 PDDBI facets of approach-withdrawal behavior and 8 CASI-5 clinical conditions. Community structure was determined using the walktrap algorithm, node centrality was computed using one-step expected influence, and stability was quantified using case-dropping bootstrap procedures.

**Results:** PDDBI approach-withdrawal behaviors were organized into five communities (Figure 1), which we interpreted as (1) Sensory Features, (2), Temperamental Characteristics, (3) Social Pragmatics, and (4) Preference for Predictability. ODD was situated in Temperamental Characteristics, social and separation anxiety in Preference for Predictability, and ADHD hyperactive impulsivity and inattention in Social Pragmatics. Generalized anxiety, dysthymia, and MDE clustered into their own independent community(5). The network was determined to be stable ( $CS=.44$ ). Examination of edges (i.e., significant partial correlations) connecting CASI to PDDBI nodes revealed that social anxiety was most strongly linked to ASD-related *social withdrawal*, and separation anxiety was associated with *anxious when caregiver is away*; both conditions were strongly associated with *fears and anxieties*. ODD was associated with *aggressive towards others* and *overall temperament problems*. ADHD hyperactivity/impulsivity was associated with *problems with social approach* and ADHD inattentiveness was related to *kinesthetic problems*.

**Conclusions:** Findings offer specificity in linking ASD-related approach-withdrawal behaviors to common co-occurring conditions. Specifically, social anxiety, separation anxiety, ODD, and ADHD were strongly associated with core ASD features, supporting symptom overlap in ASD and these clinical conditions. A notable proportion of the sample (18-40%) endorsed generalized anxiety, dysthymia, and MDE, which comprised a distinct cluster, suggesting that these conditions may emerge *in addition* to core ASD features. Sleep regulation was among the strongest bridge nodes; given that it is integral for daily functioning, sleep may represent an effective intervention target to reduce the development of undesired co-occurring symptoms.

### **316.004 (Oral) Elevated COVID-19 Risk: Children with Autism, Intellectual Disability, and Mental Health Diagnoses**

**W. Schott<sup>1</sup>, S. Tao<sup>2</sup> and L. Shea<sup>3</sup>, (1)A.J. Drexel Autism Institute, Drexel University, Philadelphia, PA, (2)Drexel University, Philadelphia, PA, (3)A.J. Drexel Autism Institute, Philadelphia, PA**

**Background:**

Adults and children with some developmental and mental health conditions are at risk of severe disease from COVID-19 (Schott et al. 2021, CDC 2021). With most children returning to in-person schooling in Fall 2021, it is important to assess COVID-19 risk among vulnerable children, such as children with autism and/or intellectual disability (ID).

**Objectives:**

We quantify risk factors related to service needs, health vulnerability, and co-occurring conditions among autistic children, children with ID, and children with mental health conditions, compared to children without these conditions.

#### Methods:

Using Medicaid Analytic eXtract (MAX) data from 2008-2012, we examine the full population of autistic children ages 0-18 (n=469,053) and of children with a diagnosis of ID but not autism (n=292,380), as well as a random sample of children with any mental health condition (n=372,403) and a random sample of children with no mental health or developmental conditions (n=1,301,727). We first quantify risk factors for each of these groups due to service needs (living in a residential facility, needing in-home services), health vulnerability (living in a primary care shortage area, having been hospitalized for a preventable condition), and underlying conditions (those identified by the Centers for Disease Control as putting individuals at risk of severe illness from COVID-19). Next, we conduct logistic regression to examine the odds of these risk factors among autistic children, children with ID, and children with mental health conditions, compared to children without autism, ID, or other mental health diagnoses, controlling for age group, sex, eligibility group, Medicare dual status, insurance type, and state.

#### Results:

Vulnerability to infection is higher among autistic children and children with ID. Living in a residential facility is more common for these children (7% of autistic children, 12% of children with ID, compared to less than 1% of children without any mental health or developmental conditions), as are avoidable hospitalizations (53%, 57%, and 32%, respectively). Autistic children and children with ID are also at greater risk of severe infection from COVID-19: the percent of autistic children and children with ID that have high-risk underlying conditions is more than twice as high as children without mental health or developmental conditions in Medicaid.

Controlling for demographic and insurance characteristics, the odds of living in a residential facility are six times greater for autistic children and 16 times higher for children with ID, compared to children in Medicaid without mental health or developmental conditions. The odds of autistic children having a high-risk underlying condition are twice as high and the odds of children with ID are three times as high as for children in Medicaid without mental health or developmental conditions.

#### Conclusions:

Children with autism, ID, and mental health conditions are at greater risk of COVID-19. It is important to ensure multi-faceted risk mitigation is followed for families with these vulnerable children. First, vaccination among all eligible individuals must be ensured, including children when eligible. Second, attention must be paid to mask-wearing while indoors and proper ventilation and filtration of indoor environments, especially residential facilities.

## ORAL SESSION - 10B — MEDICAL AND PSYCHIATRIC COMORBIDITY

### 322 - The Developmental Complexity Between Autism and Mental Health

**322.001** (Oral) ASD and Trauma: The Impact of Adverse Childhood Experiences on Posttraumatic Stress and Psychiatric Comorbidities Among a Nationwide Sample of Children with Autism Spectrum Disorder

A. *Bernardoni*<sup>1</sup> and T. W. *Vernon*<sup>2</sup>, (1)Bradley Hospital, Warren Alpert Medical School of Brown University, East Providence, RI, (2)University of California, Santa Barbara, Santa Barbara, CA

**Background:** Research shows that children with autism spectrum disorder (ASD) are at significantly increased risk for adverse childhood experiences (ACEs) and trauma. Children and families impacted by ASD possess several identifiable risk factors which further amplify their risk for ACEs. However, identifying posttraumatic stress symptoms in this population has been difficult due to the broad overlap between posttraumatic stress and ASD-related symptoms that may lead to diagnostic overshadowing and poor identification of victims.

**Objectives:** The current study assessed for comorbid mental health diagnoses, symptoms of posttraumatic stress, and symptoms of social impairment in 131 children with ASD and 84 typically developing children across the United States.

**Methods:** A diverse group of participants were recruited via Amazon Mechanical Turk Prime nationwide. Guardians completed measures of trauma exposure (CYW ACEs Questionnaire), posttraumatic stress (Trauma Symptom Checklist for Young Children; TSCYC), and ASD-related social impairment (Social Responsiveness Scale, Second Edition; SRS-2). A one-way MANOVA assessed for differences in prevalence rates of mental health diagnoses between groups and follow-up univariate ANOVAS and Tukey posthoc tests assessed for differences in specific diagnoses between groups. One-way MANCOVAs were conducted to assess for differences in posttraumatic stress symptoms and social impairment symptoms between participant groups while controlling for language ability. A standardized regression model was run to predict posttraumatic stress symptoms from ACEs count and level of social cognition impairments among children with ASD.

**Results:** Results found that children with ASD who experienced ACEs demonstrated significantly greater rates of comorbid mental health diagnoses ( $p<.001$ ), including ADHD ( $p=.001$ ), depression ( $p=.01$ ), and anxiety ( $p=.03$ ) compared to children with ASD who did not experience ACEs. Children with ASD and ACEs demonstrated significantly higher rates of posttraumatic stress ( $p=.003$ ), specifically in the areas of avoidance

( $p<.001$ ), depression ( $p=.001$ ), and anger/aggression ( $p=.004$ ) compared to their ASD peers without ACEs. Children with ASD were also shown to demonstrate a higher baseline measure of posttraumatic stress compared to their typically developing peers with ACEs (ASD  $SS=61.51$  vs TD  $SS=53.38$ ), providing evidence for the diagnostic overlap of ASD and post traumatic stress in children. Lastly, a standard multiple regression model revealed a positive association between ACEs count and total posttraumatic stress among children with ASD, with PTS Total t-scores increasing 2.81 points for every accumulated ACE. The model revealed a positive association between social cognition symptoms and posttraumatic stress symptoms, with PTS Total t-scores increasing 0.56 points for every 1.00 point increase in SRS-2 Social Cognition t-scores.

**Conclusions:** The results of this study provide new evidence for the relationship between adverse childhood experiences and comorbid mental health diagnoses in children with ASD. This study also details how posttraumatic stress symptoms present in children with ASD. Results provide evidence that reduced social cognition associated with ASD does not serve as a protective factor against the psychological consequences of interpersonal trauma. It is hoped that these results will highlight the importance of assessing for adverse and traumatic childhood experiences within diagnostic evaluations for individuals with ASD.

### **322.002 (Oral) Perceived Stress and Emotion Dysregulation As Mediators of Mental Health in Camouflaging Among Autistic Adults**

**L. Y. Sadowski<sup>1</sup>, G. A. McQuaid<sup>1</sup>, N. R. Lee<sup>2</sup> and G. L. Wallace<sup>1</sup>, (1)The George Washington University, Washington, DC, (2)Department of Psychological and Brain Sciences, Drexel University, Philadelphia, PA**

**Background:** Prior studies suggest that camouflaging (e.g., behaviors that mask social “challenges”) is associated with anxiety and depression in autistic adults<sup>1</sup>; however, it is unclear what drives this link. Two prime candidates are 1) perceived stress, based on reports of autistic adults who report stress and exhaustion related to camouflaging<sup>2</sup> and 2) emotion dysregulation based on its prevalence<sup>3</sup> in autism spectrum disorder (ASD) and its links to depression and anxiety.

**Objectives:** Examine, for the first time, whether perceived stress and emotion dysregulation drive links between camouflaging and elevated depression and anxiety in autistic adults.

**Methods:** 787 autistic adults (471 [59.8%] assigned female at birth) aged 18-78 years ( $M=40.2$ ,  $SD=13.7$ ) were recruited via Simons Powering Autism Research and Knowledge (SPARK) Research Match to complete a battery of online questionnaires. These included the Camouflaging Autistic Traits Questionnaire (CAT-Q), and measures of depression (Patient Health Questionnaire-9, PHQ-9), anxiety (Generalized Anxiety Disorder-7, GAD-7), perceived stress (Perceived Stress Scale, PSS), and emotion dysregulation (Self-Regulation of Emotions subscale of the Barkley Deficits in Executive Functioning Scale, BDEFS-SRE).

Using PROCESS in R, four moderated mediation models were tested (Figure 1). In all models, CAT-Q total score was the independent variable, and the moderator variable was birth-sex, with age and AQ-28 score serving as covariates. The dependent variable was PHQ-9 or GAD-7 total score, and the mediator variable was the PSS or BDEFS-SRE score. Modeling implemented bootstrap confidence intervals using 10,000 bootstrap samples. Confidence intervals that did not include zero were considered significant.

**Results:** Table 1 presents all model coefficients. *Perceived stress as mediator:* Camouflaging showed significant conditional direct (.05-.18; .02-.12) and indirect effects (.08-.18; .02-.11) on depressive symptoms through an effect on perceived stress (Table 1). Camouflaging also showed a significant conditional direct effect on anxious symptoms (.03-.17; .05-.16) and an indirect effect via perceived stress (.10-.22; .03-.12); additionally, the only significant moderated mediation effect was revealed here (-.16 to -.006), where male sex negatively moderated the indirect effect of camouflaging on anxiety through perceived stress.

*Emotion dysregulation as mediator:* Camouflaging showed a significant conditional direct (.12-.27; .04-.16) and indirect (.003-.10; .01-.07) effect on depressive symptoms through its effect on emotion dysregulation. Camouflaging also showed a significant conditional direct effect (.12-.28; .07-.20) on anxious symptoms and through its effect on emotion dysregulation (.004-.13; .01-.09).

**Conclusions:** For the first time, we present evidence for two potential drivers (perceived stress and emotion dysregulation) in the association between camouflaging and elevated anxious and depressive symptomatology in ASD. Importantly, birth-sex (a known factor associated with camouflaging) was included as a moderator, and both age and autistic features were controlled for. Heightened perceived stress and emotion dysregulation feature prominently in longstanding models of factors impacting the development of depression and anxiety in the general population<sup>4</sup>. These models, taken together with literatures reporting the autistic lived-experience of stress in the context of camouflaging, and associations of emotion dysregulation with poorer mental health in ASD, provide theoretical and empirical grounding for the findings reported here.

### **322.003 (Oral) Understanding the Heterogeneity of Anxiety in Autism Spectrum Disorder: A Subtyping Approach**

**E. K. Spackman<sup>1</sup>, J. W. Lerh<sup>2</sup>, J. Rodgers<sup>3</sup>, M. J. Hollocks<sup>4</sup>, M. South<sup>5</sup>, H. McConachie<sup>6</sup>, A. Ozsivadjian<sup>7</sup>, A. V. Magiati<sup>13</sup> and M. Uljarevic<sup>14</sup>, (1)The Melbourne School of Psychological Sciences, University of Melbourne, Parkville, VIC, Australia, (2)Psychology, National University of Singapore, Singapore, Singapore, (3)Population Health Sciences Institute, Newcastle University, Newcastle upon Tyne, United Kingdom, (4)King's College London, Cambridge, UNITED KINGDOM, (5)Brigham Young University, Provo, UT, (6)St. Thomas Hospital, Evelina London Children's Hospital, London, UNITED KINGDOM, (7)Psychology, Marquette University, Milwaukee, WI, (8)Psychiatry & Behavioral Sciences, Stanford University, Stanford, CA, (9)Wales Autism Research Centre, School of Psychology, Cardiff University, Cardiff, United Kingdom, (10)King's College London, Institute of Psychiatry, Psychology and Neuroscience, London, United Kingdom, (11)Psychology, John Carroll University, Cleveland, OH, (12)Telethon Kids Institute, University of Western Australia, Perth, WA, Australia, (13)School of Psychological Science, University of Western Australia, Perth, WA, Australia, (14)School of Psychological Sciences, University of Melbourne, Stanford, CA, Australia**

**Background:** The high prevalence and significant clinical impact of anxiety in autistic people has been well documented. Although the prevalence of anxiety is high, there is high heterogeneity in the experiences, presentation and severity of anxiety. Importantly, individual differences in anxiety among autistic individuals has been increasingly recognized as a potential contributor to the lack of consistent findings regarding how anxiety relates to core autism characteristics and other key developmental and clinically relevant factors in this population. Subtyping approaches have shown significant promise for understanding both core and co-occurring characteristics in autism, however, no study to date has utilized a person-centred subtyping approach to better characterize anxiety heterogeneity in the autistic population.

**Objectives:** The present study aimed to examine anxiety profiles among autistic children and adolescents. It further aimed to characterize the association between the identified anxiety profiles and key clinical and developmental variables.

**Methods:** Latent profile analysis (LPA) was conducted on Spence Children's Anxiety Scale-Parent Version (SCAS-P) data from a large international pooled sample of 870 caregivers of autistic children and adolescents (*Age* = 11.6 years, *SD* = 2.77; 107 females). Identified profiles were then compared on anxiety subscale scores, age, sex distribution, cognitive functioning, restricted and repetitive behaviours (RRB), social communication difficulties, and total autism related characteristics.

**Results:** LPA identified a three-anxiety profile solution exhibiting high entropy (.80) and high latent profile probabilities (Profile 1=.97, Profile 2=.91, Profile 3=.94), with good classification accuracy. Identified profiles fell along the anxiety severity spectrum and were labelled as the mild (*n* = 498), moderate (*n* = 272) and severe (*n* = 100) anxiety profiles. There were no statistically significant differences between the three anxiety profiles in terms of sex distribution. Participants in the mild anxiety profile were significantly younger than those in the severe anxiety profile (*d* = 0.42), had significantly fewer social communication difficulties than youth in the moderate anxiety profile group (*d* = 0.31), significantly fewer RRBs and lower cognitive functioning scores compared to both moderate (*d* = 0.69 and *d* = 0.22, respectively) and severe anxiety profile participants (*d* = 1.18; *d* = 0.57). In addition, significantly more participants in the mild anxiety profile had fewer difficulties in responding to others' feelings (*V* = .13), less adherence to routine/insistence on sameness (*V* = .13), circumscribed interests (*V* = .12), and fewer unusual sensory interests than participants in the moderate and severe anxiety profiles (*V* = .24).

**Conclusions:** Current findings further emphasise the high prevalence and diversity of restricted and unusual interests. Interestingly, RI were even more frequent in the current sample than has been reported in previous studies. Importantly, RI and UI showed distinct pattern of relationships with key demographic, cognitive and clinical variables. This may suggest distinct processes underlying the RI and UI subdomains and demonstrates the need for further research characterising the full range of RI behaviours and their mechanisms.

**322.004 (Oral)** Developmental Cascades between Insistence on Sameness Behavior and Anxiety Symptoms in Autism Spectrum Disorder  
**D. A. Baribeau<sup>1</sup>, S. Vigod<sup>2</sup>, E. Pullenayegum<sup>3</sup>, C. M. Kerns<sup>4</sup>, P. Mirenda<sup>5</sup>, I. M. Smith<sup>6</sup>, T. Vaillancourt<sup>6</sup>, J. Volden<sup>7</sup>, C. Waddell<sup>8</sup>, L. Zwaigenbaum<sup>7</sup>, T. Bennett<sup>9</sup>, E. Duku<sup>10</sup>, M. Elsabbagh<sup>11</sup>, S. Georgiades<sup>12</sup>, W. J. Ungar<sup>13</sup>, A. Zaidman-Zait<sup>4</sup> and P. Szatmari<sup>1</sup>**, (1)University of Toronto, Toronto, ON, Canada, (2)Women's College Hospital, Toronto, ON, Canada, (3)The Hospital for Sick Children, Toronto, ON, Canada, (4)University of British Columbia, Vancouver, BC, Canada, (5)Dalhousie University / IWK Health Centre, Halifax, NS, CANADA, (6)University of Ottawa, Ottawa, ON, Canada, (7)University of Alberta, Edmonton, AB, Canada, (8)Simon Fraser University, Vancouver, BC, Canada, (9)Offord Centre for Child Studies, McMaster University, Hamilton, ON, CANADA, (10)Offord Centre for Child Studies, McMaster University, Hamilton, ON, Canada, (11)Neurology and Neurosurgery, McGill University, Montreal, QC, Canada, (12)McMaster Autism Research Team, McMaster University, Hamilton, ON, Canada, (13)The Hospital for Sick Children Research Institute, Toronto, ON, Canada

**Background:** Children with Autism Spectrum Disorder (ASD) experience high rates of anxiety. Insistence on sameness behavior (IS) is a core symptom of ASD that appears correlated with anxiety severity.

**Objectives:** The objective of this study was to examine the longitudinal relations between anxiety and IS in ASD using a developmental cascade model.

**Methods:** A longitudinal cohort of 421 children with ASD was followed between 4 and 11 years of age. Anxiety was quantified using items from the Anxiety Problems subscale of the Child Behavior Checklist; sameness behaviors were measured using the Repetitive Behavior Scale- Revised, Ritualistic/ sameness subscale (both parent report measures). Structural equation modelling was used to examine the longitudinal and directional associations between anxiety and IS at four timepoints, through cross-lagged panel models (CLPM) with and without a random-intercepts component (RI-CLPM).

**Results:** Both the CLPM and the RI-CLPM had good fit. Significant directional associations were detected whereby a rise in IS preceded a rise in future anxiety symptoms 1-2 years later. Stable baseline tendencies toward anxiety and IS behavior as between-person traits (intercepts) were strongly associated (standardized estimate = 0.69, *p* < 0.001). The magnitude of the cross-sectional associations between anxiety and IS appeared to lessen with age.

**Conclusions:** IS and anxiety symptoms in ASD are closely related. They appear to be shared traits that mirror each other particularly in younger children. Increasing IS may be a sign of emerging future anxiety. Interventions that target IS to reduce/ prevent anxiety amongst school aged children with ASD merit further study.

**419.117 (Poster)** Anxiety in Adolescents and Young Adults with Autism Spectrum Disorder: Links to Symptom Severity, Aberrant Behaviors, Sensory Issues, and Medical Conditions

**Y. Chen<sup>1</sup>, R. Hantman<sup>2</sup> and H. Tager-Flusberg<sup>1</sup>, (1)Department of Psychological and Brain Sciences, Boston University, Boston, MA, (2)Department of Psychology, University of South Carolina, Columbia, SC**

---

**Background:** Anxiety is highly prevalent in individuals with autism spectrum disorder (ASD) (White et al., 2009). Previous studies predominantly relied on younger populations with ASD to examine associated factors with anxiety. Several studies, which included adults with ASD, mainly focused on social anxiety. Research is needed to investigate how anxiety manifests in adolescents and young adults with ASD beyond social contexts and how it is related to other autistic features and developmental factors. Moreover, previous research often used anxiety measures that were standardized to typically developing samples, which may not reliably reveal how anxiety manifests in ASD. Therefore, there is a critical need to adopt a measure that is standardized in ASD to examine anxiety in this population.

**Objectives:** This study examined the concurrent relations among anxiety and a set of empirically selected variables in adolescents and young adults with ASD, including autism symptom severity, aberrant behaviors, atypical sensory issues, and medical conditions. This study used an anxiety measure standardized in individuals with ASD, the Parent Rated Anxiety Scale for ASD (PRAS-ASD; Scahill et al., 2019).

**Methods:** A total of 66 adolescents and young adults with ASD ( $M_{age}=19.41$  years,  $SD=2.53$ , range from 16.03-25.47) participated in this study. They were recruited remotely and represented a sample from 21 states and regions in the United States. All participants had a clinical diagnosis of autism that was verified by a score of 60 or higher on the Social Responsiveness Scale (SRS-2). Participants' anxiety was reported by the PRAS-ASD. Autism symptom severity was measured on the SRS-2. The Adolescent and Adult Sensory Profile assessed atypical sensory issues. Aberrant behaviors and medical conditions were reported on the Aberrant Behavior Checklist. Adaptive Behaviors were obtained using the Vineland-3 interview form.

**Results:** Adolescents and young adults with more severe ASD symptoms reported higher levels of anxiety, especially those with more social cognition deficits ( $r=.44, p<.001$ ) and restricted and repetitive behaviors (RRBs) ( $r=.43, p<.001$ ). Participants with more aberrant behaviors, including irritability, social withdrawal, hyperreactivity, and inappropriate speech, had elevated levels of anxiety. Moreover, those who tended to be unable to detect sensory stimuli (low registration) and those who exhibited heightened responses to sensory stimuli (sensory sensitivity) demonstrated more severe anxiety. Last, participants with more severe chronic sleep problems and gastrointestinal (GI) issues also reported higher levels of anxiety. See Table 1. Further regression analyses showed that aberrant behaviors no longer predicted anxiety in the participants when controlling for low registration and sensory sensitivity. Sensory sensitivity, chronic sleep problems, social cognition deficits, and RRBs emerged as salient predictors of the participants' overall anxiety level. See Table 2.

**Conclusions:** Results suggest that sensory sensitivities, chronic sleep problems, social cognition deficits, and RRBs, were significant predictors of overall anxiety levels in adolescents and young adults with ASD. Given the current paucity of research regarding anxiety in adolescents and young adults with ASD, understanding how anxiety is associated with these features has important implications for the future provisions of targeted services and treatment for this population.

**419.118 (Poster)** Autistic Severity and Psychiatric Comorbidity Among Children with Autism Spectrum Disorder

**M. A. Zoromba<sup>1</sup>, H. El-Gazar<sup>2</sup>, A. Loutfy<sup>3</sup>, O. El-Sheikh<sup>4</sup> and A. El-Monshed<sup>5</sup>, (1)Mansoura University, Port Said, Egypt, (2)Port Said University, Port Said, Egypt, (3)Beni-suef University, Beni-Suef, Egypt, (4)Mansoura University, Mansoura, Egypt, (5)Mansoura University, El-Mansoura, Egypt**

---

**Background:** Autism Spectrum Disorder is a neurodevelopmental disorder with unclearly identified psychopathology.

**Objectives:** The aim of the current study was to evaluate the severity of autism in relation to demographic characteristics and children's developmental condition, clinical condition of mothers during pregnancy and labor, and psychiatric comorbidity among children with autism.

**Methods:** A descriptive study was utilized with a sample of (84) preschool children diagnosed with autism. Data collected using three tools; I- Demographic and developmental characteristics of children, and clinical condition of mothers during pregnancy, II- Gilliam Autism Rating Scale, and III- Mini International Neuropsychiatric Interview for children.

**Results:** revealed that 72% of studied children with moderate autism severity. Siblings number, age of the mothers during pregnancy, mother comorbid physical complaint during pregnancy, and child age of walking, related significantly to autism severity. More than two thirds (68%) of children with autism comorbid with psychiatric disorders. Anxiety is the most common (35.7%) followed by attention deficit hyperactivity disorder (32.1%). Numbers of comorbid disorders related significantly to autism severity.

**Conclusions:** Numbers of comorbid disorders related significantly to autism severity. Moreover, the severity of autism related significantly to socio-demographic, developmental characteristics and psychiatric co-morbidity.

**419.119 (Poster)** Clinical and Molecular Stratification of Autism-Associated Comorbidities

**C. Jose<sup>1,2</sup>, P. D. George-Zwicker<sup>3</sup>, L. Tardif<sup>4</sup>, A. Bouma<sup>5</sup>, J. Gaudet<sup>6</sup>, M. Robichaud<sup>6</sup> and A. McKenna<sup>7</sup>, (1)Family Medecine & Emergency Medecine, University of Sherbrooke, Sherbrooke, QC, Canada, (2)Centre de médecine de précision du NB, Vitalité Health Network, Moncton, NB, Canada,**

#### Background:

The social difficulties and precarious conditions experienced by autistic adults have traditionally been attributed to the core symptoms of autism. However, the mental and physical health problems associated with ASDs (comorbidities) have a significant impact on many areas of these adults' lives. The comorbidities found in ASD are the same as those found in the general population but with varying prevalence, chronicity, and severity, and they affect most body systems, including the cardiometabolic, immune, gastrointestinal, and neurological systems, interacting in a complex and highly interdependent manner.

Interestingly, several studies have highlighted that, despite their genetic heterogeneity, ASDs may be less functionally diverse. In many cases, the large number of genes involved in neurological disorders converge on a smaller number of biological pathways.

#### Objectives:

The participatory research CONTiNuity of care and sErviCes for Adults Living with AuTistic Spectrum Disorder (CONNECT) sought to address the needs and concerns of the Maritime autism community by focusing on their priorities. One component of the CONNECT project was to identify comorbidities in adults with ASD and assess whether some comorbidities tend to cluster, with the end goal of identifying profile-dependent unique biological pathways. It has to be noted that this study is exploratory given its limited sample size.

Methods: This study included 104 respondents from the CONNECT project cohort who completed the needs assessment survey: 41 self-reporting adults with ASD (aged 19-55 years) and 63 adults with ASD (aged 18-63 years) whose information was provided by their caregivers. Frequency distribution were calculated to examine comorbidities prevalence, by age and by sex or gender. We then modeled comorbidity assemblages and stratified the sample into comorbidity profiles.

#### Results:

Latent class analyses discriminated 6 distinct comorbidity profiles. The most discriminating comorbidities were depression, intellectual deficit, gastrointestinal disorders, attention deficit and hyperactivity disorder (ADHD) associated with musculoskeletal disorders, and ADHD associated with other neurodevelopmental disorders. Multivariate regressions are underway to identify socio-demographic correlates associated with each latent class. For each profile identified, the molecular pathways specific to each comorbidity of the profile will be extracted from the KEGG, Human Metabolome Database (HMDB) and GWAS platforms and modeled by a network analysis of their molecular protein-protein, gene and metabolite interactions (interactome). This analysis will allow the identification of convergent molecular pathways and their candidate genes. An analysis by functional annotation of the Gene Ontology (GO) terms of the candidate genes will finally allow the identification in silico of diagnostic biomarkers specific to each profile.

Conclusions: More and more researchers tend to target their attempts at therapeutic interventions towards the associated comorbidities rather than the autistic symptoms themselves, with the hope that by reducing these comorbidities, one could improve overall functioning, decrease the severity of ASD symptoms, and thus improve their overall well-being and quality of life. Examining those comorbidity profiles with a molecular lens might open new research perspectives on the etiology of autism-associated comorbidities and thus new therapeutic avenues to decrease the burden of medical conditions that impeded autistic individuals in their quest to a deserved fulfilling life.

**419.120** (Poster) Critical Review of Measuring Method for Assessing Prevalence of Gender Dysphoria Among Individuals with Autism Spectrum Disorder. - Based on the Results of Interview Survey about Gender Dysphoria Experience of ASD Individuals in Japan.-

*S. Shimoyama<sup>1</sup>, T. Endo<sup>1</sup> and N. Kato<sup>2</sup>, (1)The University of Tokyo, Tokyo, Japan, (2)Medical Institute of Developmental Disabilities Research, Showa University, Tokyo, Japan*

---

#### Background:

Recently, there has been increased attention to putative relationship between Autism Spectrum Disorder(ASD) and Gender Dysphoria(GD). GD refers to distress caused by a discrepancy between a person's gender identity and that person's sex assigned at birth (Fisk, 1974). On occasion, the distress meets criteria for a formal diagnosis in classification systems such as DSM-5.

There is no consensus on a putative link between ASD and GD because the previous studies suggesting high comorbidity of ASD and GD have several methodological problems(e.g. Turban & Schalkwyk, 2018).

One of the problems is unreliable method of measuring the prevalence of GD among ASD individuals. Particularly, intersectionality of ASD and GD has not been considered sufficiently in current methods. As some case studies have indicated that GD exhibited by ASD individuals have specificity under the influence of ASD characteristics(e.g., Goto, 2005), it is required to consider intersectionality of ASD and GD when assessing GD among ASD individuals.

#### Objectives:

In search for finding the appropriate measuring methods to assess GD among individuals with ASD, this study conducted interview survey to understand the intersectionality of ASD and GD in Japan.

#### Methods:

11 ASD individuals who were aware of GD and three caregivers completed semi-structured interviews. Questions were about experiences of having both GD and ASD from the past to the present. Also, 11 ASD individuals completed the "Japanese version of the Utrecht Gender Dysphoria Scale (UGDS-J)" (Ishimaru and Harima, 2011). Interview data were analyzed using Grounded Theory (Charmaz, 2020).

#### Results:

##### 1. Two types of GD experience among ASD individuals

The result indicated that participants experienced "(1) GD that meets diagnostic criteria" or/and "(2) ASD-specific discomfort with social gender norms." (2) ASD-specific discomfort with social gender norms appears to be similar to (1)GD, but it does not meet the diagnostic criteria and must be distinguished. ASD individuals have difficulty with conforming to the social gender norms due to the ASD characteristics such as difficulties with understanding social relationships or interactions. Also, even if they understand, they feel distress to conform to gender norms in addition to non-ASD norms.

##### 1. UGDS-J may not be able to identify categorical diagnoses of GD in ASD individuals.

It is suggested that ASD individuals found the existential questions (e.g. My life would be meaningless if I would have to live as a boy/man) difficult to answer because they have strength in concrete thinking ("I think I am not good at thinking the meaning of life. I can think of a day or a week, but when you say life, it's too abstract. ").

#### Conclusions:

For assessing prevalence of GD among ASD to clarify a putative link between ASD and the categorical diagnoses of GD, it is required to distinguish (1) GD that meets the diagnostic criteria, and (2) ASD-specific discomfort with social gender norms. However, at present, there is no screening tools for (2) ASD-specific discomfort with social gender norms, and should be developed. Also, when using UGDS-J for ASD individuals to assess categorical diagnoses of GD, modification for existential questions might be required.

#### **419.121 (Poster)** Differences in Predictive Relationships between Parent Reported Social Skills, Child Reported Social Skills, and Mental Health Outcomes

**E. Wilkinson, K. V. Christodulu and M. Rinaldi, Center for Autism and Related Disabilities, Albany, NY**

Background: Poor social skills put autistic youth at risk for low self-esteem and depressive symptomatology. Due to concerns that autistic youth may overreport abilities, studies don't often obtain youth report of social skills, potentially missing robust information (Stratis & Lecavalier, 2015). Understanding how both parent and child-reported social skills relate to mental health outcomes will yield insight about youth's perception of their social skills and provide potential targets for prevention/intervention efforts.

Objectives: The current study sought to compare predictive relationships between: 1. parent and youth-reported social skills and self-esteem, and 2. parent and youth-reported social skills and depressive symptoms in a community sample.

Methods: Participants were 68 youth (6-18, IQ > 70) who received an autism diagnosis following a comprehensive autism evaluation at a community clinic. Youth were administered the *Autism Diagnostic Observation Schedule, 2<sup>nd</sup> Edition* (Lord et al., 2012) to assess autism symptoms and the *Stanford-Binet Intelligence Scales, 5<sup>th</sup> Edition* (Roid, 2003) to assess cognitive ability. Parents and youth completed the *Social Skills Improvement System Rating Scales (SSIS)* (Gresham & Elliot, 2008) to assess social abilities. Youth completed the *Beck Youth Inventories, 2<sup>nd</sup> Edition (BYI-2)* (Beck et al., 2005) to assess symptoms in various mental health domains. Only the self-concept and depression scales from the *BYI-2* were used in the current study. All youth met DSM-5 criteria for ASD.

Results: To assess whether social skills predict self-esteem after controlling for age and IQ, hierarchical multiple regressions were conducted separately for parent and youth report. Parent-reported social skills were not a significant predictor,  $p > .05$ . Youth-reported social skills were a significant predictor,  $b = .29$ ,  $t(49) = 2.33$ ,  $p < .05$ , and the overall model was significant accounting for 25% of the variance in self-esteem,  $F(3, 49) = 5.42$ ,  $p < .05$ . Separate hierarchical regressions for parent and youth-report were run to assess whether social skills predict depressive symptoms. Parent-reported social skills were a significant predictor,  $b = -.37$ ,  $t(64) = -3.23$ ,  $p < .01$ , and the overall model was significant accounting for 17% of the variance in depressive symptoms,  $F(3, 64) = 4.35$ ,  $p < .01$ . Youth-reported social skills were not significant,  $p > .05$ .

Conclusions: Autistic youth's perception, but not parent's, of social abilities is related to how positively or negatively they see themselves. This suggests youth may internalize social failures, negatively impacting their self-esteem. Alternatively, youth who have low self-esteem may be more negative about their social abilities. By contrast, only parent-reported social difficulties predicted greater depressive symptoms. Possibly, parents notice social difficulties that are impacting their child's mood, perhaps due to loneliness or peer rejection, but youth are not attuned to these challenges. Parents may also be picking up on social consequences related to underlying depressive symptomatology. Overall, results demonstrate

that both parent and youth report of social abilities provide important information about current functioning and potential mental health concerns. Obtaining youth's perceptions of their social abilities is valuable in assessment and intervention. Furthermore, results suggest that social skills interventions could positively impact mental health.

**419.122 (Poster)** Familial Metagenomic Profiling Reveals Dysbiosis-Related Commonalities in Children with Autism Spectrum Disorder  
**S. J. Walker<sup>1</sup>, S. Hazan<sup>2</sup> and A. Papoutsis<sup>2</sup>, (1)Wake Forest Institute for Regenerative Medicine, Winston Salem, NC, (2)Progenabiome, Ventura, CA**

---

**Background:** Gut dysbiosis is reportedly a common finding in children with autism spectrum disorder (ASD), however the exact nature and source of the apparent microbial imbalance is not yet clear. One persistent confound in studies that evaluate the microbiome, specifically in children with ASD, is the extreme study sample (cohort) heterogeneity that arises from variability in factors such as genetic background, diet, medication history, medical status, geographic location, and ethnicity – to name a few. One way to mitigate some of this heterogeneity is by using familial metagenomic profiling, wherein the microbiome of the affected child is compared to the microbiome of healthy first-degree relatives.

**Objectives:** The primary objective of this study was to evaluate the microbiome in GI-symptomatic children with ASD, from three unrelated families, compared to their healthy parent and/or siblings, to determine: (1) if dysbiosis was apparent in the children with ASD, and (2) if there were common microbial features unique to the affected children.

**Methods:** Metagenomic sequence analysis was used to compare microbial abundance and diversity in stool samples from three children with ASD (each from a different family), and from one or more of their immediate family members. Family 1, of Indian/Asian descent, consisted of the mother and affected child. Family 2, of Assyrian/Armenian descent consisted of the affected child, the mother, and one unaffected sibling. Family 3, of Indian/Asian descent, consisted of an affected child, her mother, and her two healthy triplet siblings. Briefly, microbial DNA was extracted from individual stool samples, quantified, and prepared for metagenomic shotgun sequencing on the Illumina NextSeq 550 System. Read depth ranged from 13.1M to 15.4M total reads in the nine samples. Raw sequence reads were trimmed and analyzed to assess alpha diversity (Shannon Index) and relative microbial abundances.

**Results:** Overall, children with ASD displayed: (1) a higher Bacteroidetes/Firmicutes ratio and a lower relative abundance of Actinobacteria phyla, (2) a significant reduction in *Bifidobacteriaceae* and an increase in *Bacteroidaceae* families, and (3) a unique finding of *Bacteroides plebeius* species, compared to immediate family members (Figure 1). The ASD samples also displayed a statistically significant lower alpha (Figure 1) and beta microbial diversity.

**Conclusions:** At the outset of this study, we reasoned that using the microbiome profiles from close family members as the comparator samples would eliminate much of the environmental and genetic variability that can complicate interpretation of microbiome profiling results, and would provide some meaningful baseline characteristics of the ASD gut microbiome. The findings demonstrate that within a family, dysbiosis can occur in the child with ASD, and yet not in their siblings or parent who share the same environment and genetic background, suggesting a more complex (bidirectional?) relationship between ASD and gut dysbiosis.

**419.123 (Poster)** Identifying Disparities in Mental Health Services Among Racial/Ethnic Minority Children with Intellectual and Developmental Disabilities  
**S. Vanegas, School of Social Work, Texas State University, San Marcos, TX**

---

**Background:**

The study of racial/ethnic minority children and of children with intellectual and developmental disabilities (IDD) has found consistent health disparities in terms of access and quality of care (Magaña et al., 2013; Magaña & Vanegas, 2021). Much remains to be known for racial/ethnic minority children with IDD as they may experience higher levels of health disparities due to their intersectional identities. Studying mental health among children with IDD is important as mental health can be viewed in distinct ways across racially/ethnically diverse communities and across disabilities (Green et al., 2015). Furthermore, racial/ethnic minority communities may also experience additional stressors that can be associated with greater risk of mental health issues and/or health disparities (e.g., immigration, language acculturation, discrimination; U.S. Department of Health and Human Services Office of Minority Health, 2016; Coker et al., 2009; Ramirez et al., 2017). A better understanding of mental health disparities among racial/ethnic minority children with IDD is needed to develop more equitable services and supports.

**Objectives:**

This study focuses on identifying disparities related to mental health services among racial/ethnic minority children with IDD using a nationally representative sample.

**Methods:**

This study focused on the National Survey of Children's Health (NSCH: 2016-2017) to identify health disparities related to mental health among racial/ethnic minority children with IDD. The NSCH: 2016-2017 is a nationally representative survey of parents of children between 0 and 17 years of age in the United States. For this study, we focused on children with IDD, which included autism, Down syndrome, developmental disability, or intellectual disability. The overall sample of children with IDD was 5,308. See Table 1 for more details on the sample. We examined the prevalence of mental health conditions (e.g., anxiety, depression), coverage of mental health services through the child's insurance, and whether there were

unmet mental health care needs. We also explored the potential impact of sociodemographic factors on the prevalence mental health conditions, access to and receipt of mental health services.

#### Results:

Our initial analyses examined the prevalence of anxiety, depression, and behavioral problems among children with IDD across racial/ethnic groups. Chi-square analyses found significant differences across racial/ethnic groups on parent-report of anxiety,  $\chi^2(n = 5,290) = 101.8, p = .002$ , depression,  $\chi^2(n = 5,290) = 64.6, p < .001$ . No racial/ethnic differences were found for parent-reported behavioral problems,  $\chi^2(n = 5,290) = 34.7, p = .196$ . Percentages of parent-reported conditions are shown in Figure 1. We will present further analyses describing associations between sociodemographic factors (e.g., parent education, household income) on access to and receipt of mental health services.

#### Conclusions:

This study focuses on identifying health disparities that impact children with IDD from racial/ethnic minority backgrounds. The results thus far show that the prevalence of anxiety and depression varies significantly across racial/ethnic groups. These differences may be associated with access to diagnostic services or other sociodemographic factors. These findings are important as it can help identify key areas for advocacy and change to improve access and quality of services for racial/ethnic minority children with IDD.

#### **419.124 (Poster)** Identifying the Structure of Co-Occurring Neurodevelopmental/ Psychiatric Symptoms in Autism across Three Large-Scale Cohort Studies.

**B. Oakley<sup>1</sup>, M. C. Lai<sup>2</sup>, J. Tillmann<sup>3</sup>, R. Holt<sup>4</sup>, S. Georgiades<sup>5</sup>, T. Charman<sup>3</sup>, J. K. Buitelaar<sup>6</sup>, E. Anagnostou<sup>7</sup>, E. Loth<sup>1</sup> and D. Murphy<sup>3</sup>,** (1)Forensic and Neurodevelopmental Sciences, Institute of Psychiatry, Psychology, and Neuroscience, King's College London, London, United Kingdom, (2)Autism Research Centre, Department of Psychiatry, University of Toronto, Cambridge, ON, Canada, (3)Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (4)Autism Research Centre, Department of Psychiatry, University of Cambridge, Cambridge, United Kingdom, (5)McMaster Autism Research Team, McMaster University, Hamilton, ON, Canada, (6)Department of Cognitive Neuroscience, Donders Institute for Brain, Cognition and Behaviour, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands, (7)Autism Research Centre, Bloorview Research Institute, Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada

**Background:** ~70% of autistic people experience one or more significant co-occurring neurodevelopmental/ psychiatric symptoms. These co-occurring symptoms contribute substantially to reduced quality of life and represent a priority area for autism clinical research/ practice. Nevertheless, access to effective evidence-based strategies for managing co-occurring symptoms remains limited for autistic people. In part, this is due to a limited understanding of the profile(s) and structure of co-occurring symptoms in autism, where differential symptom presentation and symptom overlap/ overshadowing pose a challenge for assessment and provision of support.

**Objectives:** Thus, the aim of this study was to identify autism subgroups characterised by the structure of co-occurring symptoms - providing a basis for elucidating the underpinning mechanisms for these symptoms, which may represent key target areas for intervention.

**Methods:** Data from 3,291 autistic people (2,770 male; 521 female) aged 12-months-to-30-years was included in this study, from three large-scale cross-sectional cohorts - the Longitudinal European Autism Project (LEAP), Province of Ontario Neurodevelopmental Network (POND), and Simons Simplex Collection (SSC). Two of the most common psychiatric measurement systems in clinical research were used to assess co-occurring symptomatology – the Strengths and Difficulties Questionnaire (SDQ; LEAP) and Child Behaviour Checklist (CBCL; POND and SSC). To identify the structure of co-occurring symptoms within the sample, hierarchical clustering analysis was performed (Ward's linkage, Euclidean distance). Finally, we performed clinical validation by investigating relationships between co-occurring symptom clusters with demographic factors (e.g., age, sex) and core autism features.

**Results:** Analysis of SDQ data (LEAP) revealed a 2-cluster solution (Cluster One  $N=195$ ; Cluster Two  $N=128$ ), with Cluster One characterised by elevated co-occurring symptom severity across the board (particularly hyperactivity;  $p<0.001$ ;  $r$  effect size=0.21-0.63). Autistic people classified within Cluster One also scored higher than those in Cluster Two for core autism features, though there were few differences between clusters on age, IQ and sex. A 2-cluster solution was also revealed in analysis of CBCL data (POND/ SSC; 2-5-years Cluster One  $N=280$ ; Cluster Two  $N=545$  ; 6-18-years Cluster One  $N=1145$ ; Cluster Two=741). In both age ranges, Cluster One was characterised by elevated co-occurring symptom severity across all features (particularly aggression;  $p<0.001$ ;  $r=0.31$ -0.78). Once again, the Cluster scoring highest for co-occurring features also had elevated scores for core autism features, in the absence of significant effects of age and sex.

**Conclusions:** One-to-two-thirds of autistic people in this study were classified within a subgroup characterised by elevated co-occurring symptom severity across all features captured by the SDQ and CBCL. This subgroup was also characterised by higher autistic traits, in the absence of age, IQ and sex effects. In other words, the subgroups identified here were characterised by differences in overall *severity* of co-occurring symptoms, across the board, rather than qualitative differences in the *structure* of co-occurrence of these symptoms. These findings imply that shared underpinning mechanisms may give rise to diverse co-occurring symptoms in autism (including 'internalising' and 'externalising' features), and emphasise the importance of routinely and comprehensively screening autistic people for co-occurring mental health in clinical practice to facilitate access to appropriate support.

#### **419.125 (Poster)** Impact of the COVID-19 Pandemic on Challenging and Adaptive Behaviors in Children Diagnosed with Autism with and without Co-Occurring ADHD

#### Background:

The COVID-19 pandemic is a stressor rife with uncertainty and widespread consequences. Early examinations from China found that the COVID-19 pandemic is impacting child psychological health in the general population (Liu, 2020), and caregivers of children with developmental disabilities reported increased anxiety symptoms and behavioral changes in their children (Ashbury et al., 2020). The pandemic caused numerous changes in the daily lives of autistic children that could have led to changes in adaptive abilities and challenging behaviors. Disruptions in school attendance not only limited the opportunity for social interaction with peers, but also made daily life less predictable in a population known to benefit from routine and structure. A key question is how the presence of co-occurring psychiatric symptoms in autistic children might influence the impact of COVID-19 on children's outcomes, including their challenging and adaptive behavior and the potential worsening of psychiatric symptoms.

#### Objectives:

The present study aimed to characterize changes from before the pandemic to mid-pandemic in a) challenging behaviors, b) hyperactive and impulsive behaviors, and c) adaptive behaviors in children diagnosed with autism spectrum disorder (ASD), Attention-Deficit/Hyperactivity Disorder (ADHD), co-occurring ASD+ADHD, and neurotypical (NT) children.

#### Methods:

Families participated in this research study at two time points, once before the pandemic (Mean age = 5.5 years) and again during the pandemic (Mean age = 7.7 years), with an average of 24.83 months between time points. Before the pandemic, children were evaluated with gold-standard diagnostic assessments, including the ADOS-2 and ADI-R for autism diagnosis and the Mini Neuropsychiatric Interview for ADHD diagnoses. Parents completed the Aberrant Behavior Checklist (ABC), the ADHD Rating Scale (ADHD-RS), and a smaller subset completed the Vineland Scales of Adaptive Behavior-3 (VABS-3) at both time points. Families completed the surveys electronically for the second time point between March and July 2021, before school returned in person for many families. The final sample (N = 58) included 24 children with ASD, 10 with ASD+ADHD, 13 with ADHD alone, and 11 NT. Survey responses were analyzed using paired-samples t-tests.

#### Results:

Parents reported an overall reduction in challenging behaviors on the ABC ( $p=0.01$ ) as well as reductions in irritability ( $p=0.04$ ) and hyperactivity ( $p=0.004$ ). On the ADHD-RS, parents reported decreases in overall ADHD symptoms ( $p=0.0001$ ), which was driven primarily by reductions in hyperactivity ( $p<0.0001$ ). Improvements in adaptive behavior were also reported by parents ( $p=0.04$ ), and specifically observed in improvements in daily living skills ( $p=0.02$ ). Table 1 provides more information on parent reported before and during the pandemic. Ongoing analyses will examine group-based differences in behaviors.

#### Conclusions:

Parents reported improvements in hyperactivity, irritability, and daily living skills in their children. It is possible that reduced demands in the school setting (e.g., social pressures) may have behavioral health benefits. More time spent at home likely gave children opportunities to better develop daily living skills. These results warrant more detailed investigation into what factors might have led to improvements in children's behavior and daily living skills, so that these factors can be considered in the context of return-to-school plans.

#### **419.126 (Poster)** Influence of Co-Occurring ADHD on Working Memory Skills in Young Autistic Children

**K. L. Carpenter<sup>1</sup>, J. A. Summers<sup>2</sup>, M. Sabatos-DeVito<sup>3</sup>, N. O. Davis<sup>4</sup>, S. Compton<sup>1</sup>, M. Spanos<sup>1</sup>, L. Franz<sup>5</sup>, E. Abdelnour<sup>6</sup>, A. Kaniuka<sup>7</sup>, A. Welch<sup>2</sup> and G. Dawson<sup>1</sup>,** (1)Department of Psychiatry and Behavioral Sciences, Duke Center for Autism and Brain Development, Durham, NC, (2)Duke University, Durham, NC, (3)Psychiatry and Behavioral Sciences, Duke Center for Autism and Brain Development, Durham, NC, (4)Department of Psychiatry and Behavioral Sciences, Duke ADHD Program, Duke University Medical Center, Durham, NC, (5)Duke Center for Autism and Brain Development, Department of Psychiatry and Behavioral Sciences, Duke University, Durham, NC, (6)Washington University, St. Louis, MO, (7)Duke Center for Autism and Brain Development, Duke University, Durham, NC

---

**Background:** Difficulties with executive functioning (EF), including working memory skills, have been documented for individuals diagnosed with autism and those with attention-deficit/hyperactivity disorder (ADHD). Difficulties with EF can impact overall functioning (e.g. adaptive behavior, social skills, reciprocal language abilities) and are emerging as an important focus for intervention. Despite 40-60% of autistic children having co-occurring ADHD, little is known about how co-occurring ADHD influences EF in young autistic children, when working memory skills are developing. Until around 7-years of age, children develop increasingly complex working memory abilities, moving from retrieving simple information over a short delay (retrieval), to updating memory to include information from previous choices (substitution), and finally to manipulating information they are holding in memory (transformation). Understanding working memory development in young autistic children with and without ADHD and children with ADHD can inform treatment targets that improve overall functioning.

**Objectives:** Explore patterns of working memory skills in young autistic children, children with ADHD, and autistic children with co-occurring ADHD as compared to each other and to neurotypical children.

**Methods:** Participants were 99 children, 3-to-8 years old ( $M=75.39$ ,  $SD=14.63$  months) from four groups: neurotypical (NT;  $N=17$ ), autistic ( $N=30$ ), ADHD ( $N=24$ ), and Autistic+ADHD ( $N=28$ ). Working memory skills were assessed with two subtests from an adapted version of lab-based experimental tasks, the Preschool Executive Functioning Battery (PEFB): The Hide&Seek task, which measures retrieval and substitution, and the Magic Wand task, which measures transformation. Dependent variables were proportion (of total possible score) correct on retrieval, substitution, and transformation trials, and proportion of perseverative and non-perseverative errors. Group differences were tested using general linear models and covariates (full-scale IQ and age) that impeded overall model were iteratively removed until best model performance was achieved. Follow-up pair-wise t-tests were corrected for multiple comparisons using Tukey's HSD.

**Results:** For all children, after controlling for IQ, it was found that the older a child was, the better they were at in both retrieval ( $F=10.57$ ,  $P<.01$ ) and transformation ( $F=17.92$ ,  $P<.0001$ ), but not substitution ( $F=3.49$ ,  $P>.05$ ) abilities. Comparing across the four groups, there was no difference in the proportion of correct retrieval trials. Controlling for both age and IQ, Autistic+ADHD children had significantly lower proportion correct for substitution trials as compared to the other three groups ( $F=3.16$ ,  $P<.05$ ). Similarly, this group also had a higher number of non-perseverative errors compared to the other three groups ( $F=3.94$ ,  $P=.01$ ). Controlling for age, but not IQ as it was not significant in the model, Autistic+ADHD children also had significantly lower proportion correct for transformation trials than the NT and ADHD groups ( $F=3.22$ ,  $P<.05$ ), but performed comparably to the autistic children without ADHD.

**Conclusions:** Autistic+ADHD children demonstrate more working memory difficulties than autistic children without ADHD, children with ADHD, and NT children. This was evident on several dimensions of working memory, including both the ability to make substitutions and transformations. Understanding the relationship between co-occurring ADHD symptoms and working memory skills in young autistic children can help inform EF-based treatments that focus on these skills in both autistic and ADHD children.

**419.127 (Poster)** Mitochondrial Dysregulation Is Associated with Right-Sided Colonic Hypomotility in Children with Autism Spectrum Disorder  
**S. J. Walker<sup>1</sup>**, **T. Simon<sup>1</sup>** and **A. Krigsmann<sup>2</sup>**, (1)Wake Forest Institute for Regenerative Medicine, Winston Salem, NC, (2)Pediatric Gastroenterology Resources of New York and Texas, Austin, TX

**Background:** Gastrointestinal (GI) symptoms are more common in children with autism spectrum disorder (ASD) compared to typically developing (TD) children. Of the GI symptoms most commonly observed in children with ASD, chronic constipation is reported by parents to be especially problematic. In children with ASD who have sought medical assistance for chronic constipation on a background of colonic inflammation, two clinical trends (phenotypes) have been observed based on the children's response to anti-inflammatory therapy: (1) patients who experience remission from constipation while undergoing anti-inflammatory therapy (*fast responders*), and (2) patients who experience recurrent right-side fecal loading while undergoing anti-inflammatory therapy (*slow responders*). In an earlier study we showed that total gene expression derived from right colon biopsies of 35 patients (15 *fast responders*, 20 *slow responders*), distinguished the fast responders from slow responders.

**Objectives:** The objective of this study was further characterization in two distinct clinical subgroups of GI-symptomatic children with ASD, through microRNA (miRNA) and total gene (mRNA) co-expression analysis, to identify potential molecular regulators of the atypical constipation phenotype.

**Methods:** In the original pilot study, hierarchical clustering of the right colon gene expression profiles from 35 patients resulted in two distinct clusters; the separation was based largely on clinical phenotype (*fast* vs *slow* responder; **Figure 1** – left panel). In this follow-up study, miRNA expression profiles were assessed for 12 of the 35 original right colon biopsies (6 *fast responders*, 6 *slow responders*) and analyzed together with mRNA profiles. Total RNA was quantified using a NanoDrop spectrophotometer and miRNA expression was assessed through assay of ~800 known miRNAs using the NanoString nCounter SPRINT protocol. Differential expression of miRNA in *fast* vs. *slow* responders was determined using nSolver software and miRNA-mRNA co-expression was evaluated using Ingenuity Pathway Analysis (IPA).

**Results:** We identified 12 significantly differentially expressed miRNAs ( $p=0.05$ ; **Figure 1** – right panel) between *fast* and *slow* responders and 8 of those had been experimentally observed to target 400 unique mRNAs (IPA). IPA co-expression analysis showed that 24 of those 400 mRNA targets were found to be differentially expressed between *slow* and *fast responders* ( $p=0.01$ ). Results demonstrate an upregulation of transcripts involved in oxidative phosphorylation, reactive oxygen species and oxidative stress, and a downregulation of oxidative-stress response elements in *slow responders* that is suggestive of an overall decreased mitochondrial function in cells of the right colon.

**Conclusions:** The central finding of the co-expression analysis was an increased expression of genes involved in mitochondrial dysregulation pathways in *slow responders* compared to *fast responders*, resulting from a decreased expression of their respective inhibitory miRNAs. As mitochondrial function contributes to intestinal epithelial cell homeostasis, this dysregulation in the right colon suggests an underlying mechanism to explain atypical motility that is observed in *slow responders* even after treatment for inflammation.

**419.128 (Poster)** Resilience in the Face of a Pandemic: An Examination of Anxiety and Depression in Autistic Adolescents in a Post-COVID World  
**C. Keyler<sup>1</sup>**, **C. Moody<sup>2</sup>**, **S. Gonzalez<sup>3</sup>** and **E. A. Laugeson<sup>2</sup>**, (1)Semel Institute for Neuroscience and Human Behavior, PEERS lab: UCLA PEERS Clinic, Los Angeles, CA, (2)UCLA Semel Institute for Neuroscience and Human Behavior, Los Angeles, CA, (3)Semel Institute for Neuroscience and Human Behavior, UCLA, Los Angeles, CA

**Background:** The COVID-19 pandemic exacerbated anxiety and depressive symptoms worldwide (Salari et al., 2020). However, disruptions to services, routines, social activities, and supports during the pandemic likely disproportionately impacted the lives of autistic individuals, an already vulnerable population with high rates of co-occurring mental health diagnoses (Lai et al., 2019). Indeed, research has demonstrated that autistic adults showed greater increases in mental health symptoms in response to the pandemic as compared to neurotypical adults (Adams et. al, 2021; Oomen et. al, 2021). Parents have similarly reported that their autistic children have exhibited greater behavioral and mental health challenges following the pandemic (Colizzi et al., 2021; Vasa et al., 2021). Notably, qualitative themes illustrating some positive impacts of COVID-19 have also emerged, such as more quality time with family and improved youth mood (Mumbardo-Adam et al., 2021). As the pandemic continues, more research is needed to understand the impact of the pandemic and its broader sequelae (e.g., remote service provision, social distancing guidelines) on the autism community.

**Objectives:** This study aims to compare pre- and post-COVID levels of social anxiety and depressive symptoms in autistic adolescents presenting for social skills treatment at the UCLA PEERS® Clinic. Given even fewer opportunities for social interaction during the pandemic, we hypothesized that teens presenting for treatment post-COVID would have higher levels of mental health symptomatology as compared to those who presented to treatment pre-COVID.

**Methods:** Participants included 143 teens ( $M_{age}=14.00$ ,  $SD=2.01$ ; 70.6% Male) with pre-existing diagnoses of autism spectrum disorder who were screened for participation in the evidence-based social skills intervention, PEERS® for Adolescents program (Laugeson et al., 2012). Participants included were evaluated between 2018-2021 ( $n=64$  post-pandemic: March 2020-September 2021). The Social Anxiety Scale (SAS; La Greca, et. al, 1988) was used to assess social anxiety symptoms while depressive symptoms were measured through T-scores on the Children's Depression Inventory, 2<sup>nd</sup> edition (CDI-2; Kovacs, 2015). Independent samples t-tests were utilized to compare symptomatology pre- and post-pandemic.

**Results:** Initial results revealed no significant differences between pre-pandemic ( $M=51.69$ ,  $SD=15.56$ ) and post-pandemic ( $M=52.50$ ,  $SD=16.84$ ) self-reported social anxiety symptoms on the SAS,  $t(139)=0.21$ , *ns*. Similar findings were observed for parent-reported social anxiety symptoms, with no emergent significant differences,  $t(135)=0.86$ , *ns*. Further, depressive symptoms on the CDI-2 pre-pandemic ( $M=57.50$ ,  $SD=11.39$ ) did not significantly differ from those post-pandemic ( $M=59.17$ ,  $SD=13.27$ ),  $t(133)=-0.77$ , *ns*.

**Conclusions:** Contrary to our hypothesis, anxiety and depressive symptomatology of autistic adolescents did not worsen after COVID-19 pandemic. These results suggest resilience and adaptation in the face of the many changes caused by the pandemic. It is also possible that remote school instruction facilitated a reduction of social demands alongside increased control over environment (e.g., sensory stimulation, ability to take breaks) that mitigated deterioration of mental health for teens on the spectrum in the face of stress. Importantly, the current treatment-seeking sample may not be representative of autistic youth at large. As such, ongoing monitoring and nuanced examination of moderators of resilience is necessary to proactively identify and meet the needs of autistic adolescents and their families.

#### **419.129 (Poster) Risk of Cancer Among Autistic Individuals Compared to Non-Autistic Individuals**

**E. M. Weir<sup>1</sup>, C. Allison<sup>2</sup> and S. Baron-Cohen<sup>2</sup>, (1)Autism Research Centre, Department of Psychiatry, Autism Research Centre - University of Cambridge, Cambridge, United Kingdom, (2)Autism Research Centre, Department of Psychiatry, University of Cambridge, Cambridge, United Kingdom**

**Background:** Autistic individuals have greater mental and physical health risks than others, which may affect their longevity. Existing genetic and epidemiological studies examining cancer risk have found mixed results—with some studies suggesting decreased risk, no difference in risk, or even increased risk of cancer overall or of hormone-associated cancers specifically.

**Objectives:** To determine whether there are differences in risk of cancer overall or for hormone-associated cancers between autistic and non-autistic individuals in a large population sample.

**Methods:** We utilized anonymized general practitioner records from the Clinical Practice Research Datalink (CPRD) and linked records from the National Cancer Registration and Analysis Service (NCRAS) to test for cancer risk overall as well as for breast, ovarian, testicular, and prostate cancer risk specifically. The sample included  $n=13,994$  autistic individuals and  $n=69,970$  general population controls, matched 5:1 on age ( $\pm 2$  years), gender, and healthcare practice.

We utilized Cox regression to estimate unadjusted and adjusted models of cancer risk. All of our adjusted models controlled for time-varying binary measures of obesity, alcohol misuse, and smoking status; we also controlled for socioeconomic status based on quintiles provided from the Office of National Statistics Indices of Multiple Deprivation Score in 2015. Individuals with a record for birth control or hormone replacement use, as well as all autistic and non-autistic participants matched to them, were excluded from the adjusted analyses of overall cancer risk (leaving a subsample of  $n=12,392$  autistic individuals and  $n=61,960$  general population controls for this analysis). Finally, as some cancers tested are sex-specific, we used sub-samples by gender for relevant unadjusted and adjusted analyses.

**Results:** Autistic individuals who do not use birth control or hormone replacement therapy had far lower relative rates of cancer than their age, gender, and practice-matched general population peers of the same demographics (See Table 2 below). There were no differences in risk of breast or prostate cancer among autistic and non-autistic individuals in either the unadjusted or adjusted analyses. Due to low counts, we were unable to conduct adjusted analyses of ovarian and testicular cancers; however, unadjusted analyses suggest non-significant but greater than expected numbers of ovarian and testicular cancer cases among autistic individuals compared to non-autistic peers (See Table 1 below).

**Conclusions:** These results suggest that autistic individuals of certain demographics may be less likely to have cancer compared to others. This study cannot provide information on the cancer risk of autistic individuals who use birth control or hormone replacement therapy; this group must be

considered in future research, as autistic individuals are more likely to have co-occurring conditions like polycystic ovarian syndrome, which may require the use of birth control and increase cancer risk. Further, while this study uses records from individuals across the lifespan, the majority of records come from young participants (aged 30 years or younger); as such, the results must be interpreted with caution, as they may indicate lower risk of cancer overall or may indicate a different age-related pattern of cancer risk for autistic individuals.

**419.130 (Poster)** Serum Metabolome Profiles Distinguish Children with Gastrointestinal Inflammation and Autism Spectrum Disorder From Typically Developing Controls

**S. J. Walker<sup>1</sup>** and A. Krigsmann<sup>2</sup>, (1)Wake Forest Institute for Regenerative Medicine, Winston Salem, NC, (2)Pediatric Gastroenterology Resources of New York and Texas, Austin, TX

**Background:** We have previously shown that children with ASD and gastrointestinal (GI) inflammation display a unique gene expression profile both in GI biopsy tissue and peripheral blood, when compared to non-ASD GI-symptomatic children without GI inflammation. The differential gene expression patterns identified in peripheral blood can provide clues regarding the pathobiology that underlies the inflammation and/or ASD. To explore this hypothesis further we have assayed serum from the same individuals to determine if the metabolite profiles: (1) also differ significantly between the groups and, (2) if they provide additional mechanistic insight.

**Objectives:** The goal of this study was the measurement of serum metabolite profiles in GI-symptomatic children with ASD and ileocolonic inflammation (ASD<sup>IC+</sup>) and from GI-symptomatic typically developing children (without evidence of ileocolonic inflammation; TD<sup>IC-</sup>), to compare metabolite composition and abundance between these groups.

**Methods:** Global metabolite profiles were determined in serum samples derived from 40 individuals as follows: (a) the “control” group (TD<sup>IC-</sup>) consisting of 14 males and 5 females and, (b) the “case” group (ASD<sup>IC+</sup>) consisting of 17 males and 4 females. Sample processing involved metabolite extraction, followed by ultrahigh performance liquid chromatography-tandem mass spectroscopy (UPLC-MS/MS). Raw data were extracted, peak-identified and QC processed. Compounds were identified by comparison to library entries of purified standards or recurrent unidentified entities. Following log transformation and imputation of missing values, if any, with the minimum observed value for each compound, Welch’s two-sample t-test was used to identify biochemicals that achieved statistical significance ( $p \leq 0.05$ ), as well as those approaching significance ( $0.05 < p < 0.01$ ).

**Results:** The dataset comprises a total of 612 compounds of known identity (named biochemicals) measured in 40 individual serum samples. A comparison between the 2 groups showed that 292 metabolites (48%; 72 higher and 200 lower in ASD<sup>IC+</sup> compared to controls) reached a level of statistical significance and another 36 metabolites (12 higher/24 lower in ASD<sup>IC+</sup>) approached significance. Many of these metabolite level differences between ASD and TD samples have been reported in other studies, while some of the individual findings here are either in disagreement, or are altogether new, compared to published reports. Overall, the data showed that the two groups were distinguishable (i.e., significantly separated) by principal component analysis and the ASD<sup>IC+</sup> profiles, as a group, appeared to be more heterogeneous (**Figure 1** - top). Using the primary groupings of “case” and “control”, random forest analysis resulted in a predictive accuracy of 95% for the serum samples (**Figure 1** - bottom).

**Conclusions:** Comparison of metabolome profiles between ASD<sup>IC+</sup> and TD<sup>IC-</sup> showed that levels of nearly half of the serum metabolites are statistically significantly different between the two groups and that these metabolome profiles are largely phenotype-specific. Moreover, many of the specific metabolite level differences have previously been reported in metabolome studies comparing ASD and control samples, however in some cases the changes we found are either discordant or novel compared to published reports. This is not surprising since our pilot study examined differences in serum from children with ASD and gastrointestinal inflammation to serum from children with neither condition.

**419.131 (Poster)** Sleep Disturbances in Individuals with Autism Spectrum Disorder: Clinical, Developmental, Medical, Psychometric, Familial and Biological Correlates

**A. M. Persico<sup>1</sup>**, L. Turriziani<sup>2</sup>, F. Cucinotta<sup>3</sup>, A. Ricciardello<sup>4</sup>, P. Tomaiuolo<sup>2</sup>, G. Calabrese<sup>2</sup>, F. Bellomo<sup>2</sup>, M. Boncoddo<sup>2</sup>, G. Turturo<sup>2</sup>, S. Mirabelli<sup>2</sup> and R. Sacco<sup>5</sup>, (1)Dept. of Biomedical, Metabolic and Neural Sciences, University of Modena and Reggio Emilia, Modena, Italy, (2)Interdepartmental Program "Autism 0-90", "G. Martino" University Hospital, University of Messina, Messina, Italy, (3)IRCCS Centro Neurolesi "Bonino-Pulejo", Messina, Italy, (4)Villa Miralago, Center for the treatment of eating disorders, Cuasso al Monte, Italy, (5)Service for Neurodevelopmental Disorders & Laboratory of Molecular Psychiatry and Neurogenetics, University "Campus Bio-Medico", Rome, Italy

**Background:** Sleep disturbances (SDis), reported in 40-80% of individuals with ASD, have been associated with more severe daytime behavioral symptoms and worse quality of life (QoL) in the family. The neurobiological link between ASD and SDis has not been fully elucidated, although reduced melatonin synthesis and release is partly involved.

**Objectives:** (1) To assess the prevalence and characteristics of SDis in ASD; (2) to define their behavioral, medical, familial and biological correlates in a large sample of ASD patients.

**Methods:** A stage-I sample of 906 individuals with ASD (mean age  $8.2 \pm 5.7$ , range 1-47 yrs; M:F=764:137) was used to define the correlates of “presence/absence of SDis” through parental report. In a stage-II subsample including 276 of these 906 patients, SDis subtype was characterized. This information was then correlated with: (a) clinical, developmental, and family history information collected from parents; (b) medical (MRI, EEG, etc), neurological, behavioral and comorbidity information derived from direct observation, and (c) tests and questionnaires including ADOS, ADI-R, VABS, PEP-3, IQ/DQ measures, CBCL/TRF, SRS, SSP, ABC, RBS, CARS and parental WHOQoL. Biological variables include head circumference, serotoninemia, and urinary p-cresol. Chi-squared and t-tests were performed, applying Bonferroni’s correction. Multivariate analyses are under way.

Results: SDis were present in 457/906 (50.4%) stage I patients. Among 154/276 (55.8%) stage II patients with SDis, parents reported difficulty falling asleep (13.0%), night awakenings (21.7%), both (14.9%), early morning awakening (2.2%), mixed features (2.9%), and parasomnias (1.1%). SDis occurred more frequently in young adults compared to children and adolescents ( $P=3 \times 10^{-4}$ ,  $N=904$ ), and are associated with self-injurious behavior ( $P=3.2 \times 10^{-5}$ ,  $N=822$ ) and reduced pain sensitivity ( $P=0.007$ ,  $N=801$ ). The SSP confirms abnormal sensitivities especially through the visual and auditory channels ( $P<0.001$ ,  $N=207$ ). The timing of developmental milestones is generally typical, except for delayed/absent sphincter control ( $P=0.0033$ ,  $N=837$ ), but parents surprisingly report higher incidence of “loss of single words after initial development” ( $P=0.0043$ ,  $N=847$ ) and “behavioral regression at autism onset” ( $P=5.4 \times 10^{-5}$ ,  $N=870$ ), in coincidence with an “infectious disease at autism onset” ( $P=5.0 \times 10^{-6}$ ,  $N=886$ ). The CBCL documents greater aggressive ( $P=0.001$ ,  $N=194$ ) and externalizing behaviors ( $P=0.004$ ), whereas VABS composite IQ is significantly lower (73.3 vs 68.9,  $P=0.001$ ,  $N=538$ ). SDis in the proband worsens the QoL of both mothers ( $P=0.001$ ,  $N=225$ ) and fathers ( $P=0.002$ ,  $N=225$ ). SDis are associated with low serotoninemia ( $P<0.002$ ,  $N=602$ ), while brain MRI and blood aminoacids may influence SDis subtype. The presence and subtype of SDis is not significantly correlated with IQ, autism severity, gastrointestinal or allergic disturbances, EEG abnormalities or history of seizures, nor is co-sleeping linked to SDis.

Conclusions: To our knowledge, this is the largest national study assessing SDis in ASD to date. SDis are a highly prevalent co-morbidity with a very negative impact on the behavioral and adaptive skills of patients with ASD, as well as on the QoL of the entire family. These results provide some suggestions in reference to the mechanisms underlying SDis in ASD.

#### **419.132 (Poster)** The Health Impact of Insomnia on Children with Autism Spectrum Disorder

**S. Solomon<sup>1</sup>, G. Meiri<sup>2</sup>, A. Michaelovski<sup>3</sup>, I. Dinstein<sup>4</sup> and I. Menashe<sup>5</sup>,** (1)Ben-Gurion University of the Negev, Beer Sheva, Israel, (2)National Autism Research Center of Israel, Ben-Gurion University of the Negev, Beer Sheva, Israel, (3)Zusman Child Development Center, Soroka University Medical Center, Beer Sheva, Israel, (4)Cognitive and Brain Sciences Department, Ben-Gurion University of the Negev, Beer Sheva, Israel, (5)Public Health Department, Ben-Gurion University of the Negev, Beer Sheva, Israel

Background: Insomnia and poor sleep quality are frequently reported in children with autism spectrum disorder (ASD), with prevalence rates ranging from 40-80%. These sleep disturbances have been shown to be associated with higher sensory sensitivities and more severe aberrant behaviors. However, the association of sleep disturbances with other clinical co-morbidities and their potential impact on the utilization of health services in children with ASD is unknown.

Objectives: The aim of this study was to quantify the impact of insomnia on clinical and behavioral aspects and the utilization of health services in children with ASD.

Methods: We conducted a retrospective, cross-sectional study of 541 children with ASD, between the ages of 1-11 years old, registered in the database of the National Autism Research Center of Israel (NARCI; [www.autismisrael.org.il](http://www.autismisrael.org.il)). Children were included in the current study if they were members of Clalit Health Maintenance Organization, and their parents completed the Children's Sleep Habits Questionnaire (CSHQ). Pediatric insomnia was defined as a total sleep disturbance score of  $>48$  on the CSHQ. Sociodemographic and ASD diagnostic measures including the Autism Diagnostic Observation Schedule, 2nd edition (ADOS-2) comparison scores, DSM-5 levels of required support, cognitive scores, and Aberrant Behavior Checklist (ABC) scores of these children were obtained from the NARCI database. Data about chronic comorbidities, medication usage, hospitalizations, visits to the emergency room, and visits to specialists one year before and after completion of the CSHQ were obtained from the Clalit electronic patient record system. The association between pediatric insomnia and these sociodemographic and clinical characteristics were tested using standard univariate and multivariate statistical tests.

Results: Of the 541 children with ASD, 257 (47.5%) had insomnia. Children with insomnia compared to children without insomnia had significantly higher scores on all ABC subscales including irritability (17.90 vs. 9.31;  $p<0.001$ ), hyperactivity (14.50 vs. 9.32;  $p=0.0002$ ), lethargy/withdrawal (7.34 vs. 4.37;  $p=0.0004$ ), stereotypic behaviors (22.7 vs. 13.10;  $p<0.0001$ ), and inappropriate speech (4.54 vs. 3.12;  $p=0.0017$ ). In addition, ASD children with insomnia were more likely to suffer from other developmental and psychiatric comorbidities ( $OR=1.61$ , 95% CI [1.01, 2.58],  $P=0.0435$ ; and  $OR=2.42$ , 95% CI [0.99, 6.52],  $P=0.0516$ , respectively), and more likely to be prescribed medications for the management of chronic diseases ( $OR=1.72$ , 95% CI [1.22, 2.45],  $P=0.0031$ ). Finally, ASD children with insomnia had 50% more visits to the emergency room (mean[SD] = 0.63[1.19] vs. 0.42[1.01];  $p=0.0153$ ) and had 2.7 times higher rate of hospitalizations (mean[SD] = 0.19[0.60] vs. 0.07[1.30];  $p=0.0042$ ) when compared to ASD children without insomnia.

Conclusions: Our findings demonstrate that there is a significant association between insomnia and a greater clinical burden among children with ASD. Thus, treating sleeping problems in children with ASD may have a broad clinical impact that extends beyond the expected improvement in the sleep quality of these children and their parents.

#### **419.133 (Poster)** The Prevalence and Correlates of Somatic Symptoms, DSM-5 Somatic Symptom Disorder, and Functional Somatic Syndromes in Autistic Adults

**Z. J. Williams<sup>1</sup>, C. J. Cascio<sup>2</sup> and T. G. Woynaroski<sup>3</sup>,** (1)Medical Scientist Training Program, Vanderbilt University School of Medicine, Nashville, TN, (2)Department of Psychiatry and Behavioral Science, Vanderbilt University Medical Center, Nashville, TN, (3)Department of Hearing and Speech Sciences, Vanderbilt University Medical Center, Nashville, TN

**Background:** Nonspecific somatic health complaints and symptoms are common in the general population, varying on a continuum of severity. When these symptoms are persistent and impairing, they often result in a diagnosis of one or more functional somatic syndromes (FSS), such as fibromyalgia or irritable bowel syndrome. Despite the prevalence and impact of somatic symptoms and FSS in the general population, there has been very little research investigating these issues in autistic individuals. Furthermore, no study to date has quantified the prevalence of DSM-5-defined somatic symptom disorder (SSD) within the autistic population.

**Objectives:** To estimate the prevalence and clinical correlates of somatic symptoms and SSD in a large sample of autistic adults, including their associations with previous FSS diagnoses.

**Methods:** Independent autistic adults aged 18–60 years ( $n=830$ ,  $M_{Age}=34.96$  years, 64.3% female sex, 80.1% non-Hispanic White) were recruited from the Simons Powering Autism Research for Knowledge (SPARK) participant pool (Feliciano et al., 2018) as part of a study of sensory differences in autism (RM0111Woynaroski\_DST). Symptoms of SSD were quantified using the Somatic Symptoms Scale–8 (SSS-8) and Somatic Symptom Disorder–B Criteria Scale (SSD-12). A combination of  $SSS-8 \geq 9$  and  $SSD-12 \geq 23$  was used to classify participants as meeting SSD criteria (Toussaint et al., 2021). Participants also provided information regarding previous diagnoses of FSS. Bayesian regression models were used to investigate the clinical correlates of SSD status.

**Results:** Somatic symptoms were common in our sample, with individual SSS-8 items being endorsed “Quite a bit” or “Very much” by 7.1–52.4% of participants (Males: 4.4–37.8%; Females: 8.6–60.5%). Additionally, 48.9% of the sample (Males: 33.8%; Females: 57.3%) reported “High” or “Very high” levels of overall symptom burden ( $SSS-8 \geq 12$ ), and 27.7% of the sample (Males: 17.2%; Females: 33.5%) met SSS-8/SSD-12 criteria for SSD. Lifetime FSS diagnoses were present in 42.9% of the sample (Males: 25.7%; Females: 52.4%), with irritable bowel syndrome, migraine, and fibromyalgia being most common. Even after controlling for age, sex, and current symptoms of both anxiety and depression, SSD status was associated with higher levels of autistic traits (SRS-2;  $d=0.238$ ,  $CrI_{95\%}$  [0.100, 0.374]), more symptoms of decreased sound tolerance (IHS;  $d=0.298$ ,  $CrI_{95\%}$  [0.174, 0.425]), a higher prevalence of distressing tinnitus (OR=2.46,  $CrI_{95\%}$  [1.73, 3.49]), a slightly higher number of lifetime psychiatric diagnoses (IRR=1.19,  $CrI_{95\%}$  [1.08, 1.31]), and reduced overall quality of life (PROMIS Global–10;  $d=-0.426$ ,  $CrI_{95\%}$  [-0.554, -0.301]). Notably, only 48.4% of individuals with high/very high somatic symptom burden and 58.6% of individuals meeting criteria for SSD reported a prior FSS diagnosis from a medical professional.

**Conclusions:** Multi-organ somatic complaints were highly prevalent in the present sample of autistic adults, particularly those assigned female at birth, and over 25% of the current sample screened positive for SSD. After accounting for age, sex, anxiety, and depression, SSD status was independently associated with psychopathology, sensory complaints, and lower quality of life. Somatic symptoms and associated FSS diagnoses represent an often-overlooked area of autism comorbidity, and we urge clinicians working with autistic individuals to more routinely screen for and treat these often-disabling symptoms.

**419.134 (Poster)** The Recurrence Rate of First Nonfebrile Seizure in Pediatric Patients with Autism Spectrum Disorder.  
*L. Boursoulian, Pediatrics, Vanderbilt Childrens Hospital, Nashville, TN*

Background: Epilepsy prevalence is higher in children with Autism Spectrum Disorder (ASD) and is a contributor to morbidity and mortality. Little is known about the recurrence rate after the first nonfebrile seizure in this population, specifically regarding seizure type and electroencephalogram (EEG) findings.

Objectives: Despite the increased prevalence of Epilepsy in Children with ASD, there has been only few reports of the risk of seizure recurrence after a single unprovoked seizure. The American Academy of Neurology guidelines suggest not to treat the first nonfebrile seizure in general because of the risk of recurrence is not that high. The purpose of this study is to look at this specific patient population to better determine risk of further seizures and the development of epilepsy.

Methods: We reviewed de-identified pediatric medical records at our institution through the synthetic Derivative (SD) between 2006 and 2016 for subjects with ASD who had a first seizure. We then looked for risk of a recurrent non-provoked seizure within the next two years.

Results: The recurrence rate in this study was 70.9% . This is much higher than the general population. The recurrence rate was higher in patients who had a generalized convulsion compared to those who had a behavioral arrest. A logistic regression model adjusted for gender and EEG found that the odds of experiencing a recurrent generalized convulsion is 5.36-fold higher than in patients with a behavioral arrest seizure, 95% CI 2.14–13.42,  $p < 0.001$ . An abnormal EEG was a strong predictor of seizure recurrence in both seizure types.

The odds of experiencing recurrence in patients with an abnormal EEG is 19.23-fold higher than in patients with normal EEG, 95% CI 5.8–63.77,  $p < 0.001$ . Even with a normal EEG, generalized convulsions were more likely to recur within 2 years compared to behavioral arrest (OR 6.3, 95% CI 2.1–19).

Conclusions: The recurrence rate for nonfebrile seizures in children with ASD is much higher than the general population, especially for generalized convulsions. An abnormal EEG has a strong predictive value for seizure recurrence. However, even when the EEG is normal, the recurrence rate for generalized convulsions is quite high.

The higher recurrence rate of the first nonfebrile seizure in pediatric patients with ASD could impact clinical decisions of when to start anti-seizure medications. This is important because epilepsy contributes to morbidity and mortality in this group.

**419.135 (Poster)** The Relationship between Camouflaging and Co-Occurring Psychiatric Problems: Are There Differences Among Subgroups?  
*W. J. van der Putten<sup>1</sup>, C. Torenvliet<sup>1</sup>, T. A. Radhoe<sup>1</sup>, A. P. Groenman<sup>1</sup>, H. M. Geurts<sup>1</sup>, J. Agelink van Rentergem<sup>1</sup> and A. MoF<sup>1</sup>, (1)University of Amsterdam, Amsterdam, Netherlands, (2)dr. Leo Kannerhuis, Amsterdam, Netherlands*

Background:

The use of (un)conscious strategies to hide one's autistic traits (camouflaging) has been associated with the presence of co-occurring psychiatric problems in autistic adults. However, given the heterogeneity in autism spectrum conditions (ASC), the association between camouflaging and co-occurring psychiatric problems might differ across subgroups.

#### Objectives:

We aim to investigate whether camouflaging and co-occurring psychiatric problems are associated and if this association differs across subgroups.

#### Methods:

In this study, 657 (of which 349 autistic) adults aged 30 to 92 years filled in the Dutch Camouflaging Autistic Traits Questionnaire (CAT-Q-NL), the Symptom Checklist-90 Revised (SCL-90-R), the Autism Quotient (AQ) and the Positive and Negative Affect schedule (PANAS). Analyses were preregistered (Aspredicted #45095). First, we analyzed the association between camouflaging and co-occurring psychiatric problems. Second, we used model based recursive partitioning analyses to investigate whether the association between camouflaging and co-occurring psychiatric problems varied based on biological sex, age, education, autism characteristics and positive and negative affect.

#### Results:

Preliminary analyses showed a moderate correlation between CAT-Q-NL total score and SCL-90-R total score in autistic and non-autistic adults ( $r_{ASC} = .45$ ,  $r_{comparison} = .30$ ). Next, for autistic adults we found that (a) the association between the CAT-Q-NL and SCL-90-R only differed for varying levels of negative affect., (b) this association differed for varying levels of AQ-scores, but (c) negative affect explained more variance compared to AQ-score. Next to negative affect and AQ-score, positive affect played a role in this association in non-autistic adults but not in autistic adults. We will further investigate the stability of our results and whether we replicate our findings when co-occurring psychiatric problems are measured using interviews instead of self-report questionnaires. These analyses will be run before INSAR 2022.

#### Conclusions:

Based on preliminary analyses, we conclude that camouflaging and co-occurring psychiatric problems are associated. However, this association seems to differ based on someone's affect or ASC characteristics, while biological sex, age, and educational level do not seem to play a role. As the relationship between camouflaging and co-occurring psychiatric problems differs across individuals, one needs to be careful with group based conclusions regarding the (negative) impact of camouflaging.

#### **419.136 (Poster)** Understanding Psychiatrist's Knowledge and Attitudes to Suicidal Ideation and Behavior in Individual with Autism Spectrum Disorder

**M. Eyuboglu<sup>1</sup>, B. Sahbudak<sup>2</sup> and D. Eyuboglu<sup>1</sup>,** (1)Child and Adolescent Psychiatry, Eskisehir Osmangazi University Medical School, Eskisehir, Turkey, (2)Child and Adolescent Psychiatry, Manisa Mental Health and Diseases Hospital, Manisa, Turkey, (3)Child and adolescent psychiatry, Eskisehir Osmangazi University Medical School, Eskisehir, Turkey

**Background:** There has been increased attention to the association between suicidal behavior and autism. Studies showed high rates of suicidal thoughts and behaviors in individuals with autism spectrum disorder (ASD). Population-based studies also suggest that autistic individuals are over 7.5 times more likely to die by suicide and have higher rates of suicidal ideation. Despite the risk of suicidal behavior, little research has investigated how to determine and decrease this risk for the individual with ASD effectively.

**Objectives:** To date, little research has been done to study mental health professionals' behavior and knowledge of suicidal behavior in autism. The present study attempted to investigate the psychiatrists' perspective and awareness related to suicidal behavior during follow-up. In particular, we focused on psychiatrists' knowledge and attitudes towards investigating and preventing suicidal behavior in individuals with ASD. Our aims were to examine psychiatrists' assumptions and intervention practices about suicidal behavior in autistic adolescents and adults.

**Methods:** The authors created the online survey due to the lack of specific tools to assess clinicians' practice about suicidal behavior. Participants were asked to answer questions about assessing suicidal thoughts and behaviors in individuals with ASD and non-ASD clients. We also investigated the self-efficacy and safety planning intervention (SPI) of those clinicians.

**Results:** One hundred forty-three adult psychiatrists (n=55) and child and adolescent psychiatrists (n=88) completed the cross-sectional survey. Compared to non-ASD clients, clinicians reported lower suicidal ideation and behavior rates in ASD individuals ( $p<0.05$ ). The usage of screening tools was significantly lesser in the ASD group ( $p<0.05$ ). Clinician also significantly reported lower self-efficacy in assessing suicidal ideation and behavior in adolescents and adults with ASD. The majority of clinicians who have stated low self-efficacy reported not know how to evaluate the risk of suicidal behavior in the ASD group. Additionally, clinicians were more likely to use SPI with non-ASD clients ( %21 in individuals with ASD and %49.4 in non-ASD clients). Lastly, most clinicians agreed to make adaptation in SPI to be applicable to individuals with ASD.

**Conclusions:** Our study investigated the psychiatrists' knowledge, confidence, and screening practices for autistic adolescents and adults. Increasing knowledge about screening and intervention practice for risk of suicidality in individuals with ASD is essential. Encourage the clinicians' skills and usage of validated tools which is not common currently, may reduce the suicidal behavior in ASD clients.

#### **419.137 (Poster)** Using Canonical Correlation Analysis to Examine the Relationship between Creativity and Psychopathology

**Background:** Although creativity and neuropsychiatric conditions have been previously connected, the precise contours of that relationship remain unclear. Prior research has shown that creativity is supported, at least in part, by common genetic variants that show pleiotropic effects with neuropsychiatric conditions. Understanding the relationship between creativity and brain development has implications ranging from basic biology to minimizing stigma.

**Objectives:** Using a sample of over 760 children with autism, we aimed to model the relationship between creativity and mental health-related traits. We further aimed to quantify SNP-heritability of traits related to creativity phenotypes, thus laying the groundwork for identifying pleiotropic mechanisms.

**Methods:** In partnership with the nationwide (US) genetic study, SPARK, we distributed online parent- and self-report surveys assessing intellectual ability, creativity, and psychopathology in SPARK participants (children with autism and their parents). The analysis presented here is our first look at the Kaufman Domains of Creativity Scales(KDOCS ) data from this study, a 50-question *assessment* that yields a score that ranks a person's perceived creative abilities as compared to their peers. We conducted a Canonical Correlation Analysis (CCA) using the KDOCS subscale scores (measuring domains of creativity) along with the Child Behavior Checklist(CBCL) DSM subscale scores (measuring psychopathology). In addition, a generalized linear model was used to test if family history of mental illness significantly predicted creativity scores. SNP heritability estimates were carried out on a sub-sample of 747 children who also had complete genetic data available.

**Results:** The CCA of creativity and mental illness revealed 5 phenotypes(Scholarly creative, Somatic and Oppositional Defiant Nerd, High conduct/low everyday creativity, Somatic Art Creative, Depressive Somatic, Low overall creativity/psychopathology). Scholarly creativity was explained by combinations of scores from CBCL depressive, antisocial, and conduct problems subscales. Scholarly creativity and depressive, antisocial and conduct problems were inversely related ( $p<0.005$ ). A higher family history of schizophrenia, bipolar disorder and depression was predictive of higher creativity scores across all domains ( $p<0.01$ ). However, family history of eating disorders was predictive of lower creativity scores across all domains ( $p<0.01$ ). However, no significant SNP heritability was found in any of the KDOCS subscale scores. The relationship between the mother and father's KDOCS subscale scores and the child's KDOCS subscale scores were examined using a Spearman correlation test. The mother's subscale scores were positively correlated with the child's KDOCS subscale scores  $r(1300), 0.19, p<0.001$ . However the father's KDOCS subscale scores were not significantly correlated to the child's KDOCS subscale scores  $r(153), p=0.91$ .

**Conclusions:** These results suggest that creativity in autism broadly is significantly associated with family history of mental illness. The lack of heritability present in all the KDOCS subscales and its positive association with specific family histories of mental illness, may suggest that further work is needed to elucidate the relationship between creativity and mental illness. Further research should examine SNP heritability in a larger cohort of individuals and examine the role intellectual ability plays in the relationship between creativity and mental illness. In addition to this, self-reports of creativity should be examined in combination with ratings of psychopathology.

## VIRTUAL POSTER SESSION — MEDICAL AND PSYCHIATRIC COMORBIDITY

### 519 - Medical and Psychiatric Comorbidity --- (V)

#### **519.112 (Virtual Poster)** A Psychological Network Approach to Sleep and Daytime Functioning in Autistic Adolescents

**I. Schouwenaars<sup>1</sup>, M. Magnee<sup>1</sup>, H. M. Geurts<sup>2</sup>, C. van Bennekom<sup>3</sup>, S. Pillen<sup>4</sup> and J. P. Teunisse<sup>1</sup>, (1)HAN University of Applied Sciences, Nijmegen, Netherlands, (2)University of Amsterdam, Amsterdam, Netherlands, (3)R&D, Heliomare, Wijk aan Zee, Netherlands, (4)Kempenhaghe, Heeze, Netherlands**

**Background:** Sleep problems commonly occur among autistic adolescents, with prevalence rates of up to 88% (Hodge et al., 2014). While it is known that sleep is associated with increased daytime sleepiness, mood disturbances, and diminished concentration, it remains unclear which aspects of sleep are related to which aspects of daytime functioning. To unravel the relationship between specific sleep variables and daytime functioning it is important to include both objective measurements and self-reports of sleep since self-reports have shown mixed reliability compared to objective sleep measures in typically developing adolescents (Tremaine et al., 2010; Wolfson & Carskadon, 2003). Moreover, self-reports and objectively measured sleep could lead to a different outcome with regard to daytime behavior (Bruni et al., 2007; Mazurek & Sohl, 2016). To get a clear picture of the relationship between sleep and daytime functioning in autistic adolescents we used a network analysis approach involving both objective measurements and self-reports of several relevant sleep and daytime variables.

**Objectives:** To what extent are characteristics of sleep (objectively measured and self-reported sleep onset latency, total sleep time, wake time after sleep onset) related to aspects of daytime functioning (mood, concentration, daytime sleepiness)?

**Methods:** In a repeated measures design with daily measurements over a period of three weeks 32 adolescents completed a web-based sleep diary in the morning and questions about their daytime functioning in the evening. Additionally, sleep tracker data were collected from 16 of these 32 adolescents. We used a network approach to investigate the relationship between sleep and daytime functioning. A network contains of nodes (included variables) that are connected by edges (association among the variables). We computed two networks: (1a) adolescents' self-reported sleep together with their self-reported daytime functioning and (1b) adolescents' objectively measured sleep together their self-reported daytime functioning.

**Results:** In network 1a (self-reports of sleep) we found that a higher sleep quality was associated with a better concentration and mood and less daytime sleepiness the following day. Moreover, we saw that physical exercise was related to total sleep time (TST), indicating that more physical exercise before the night's sleep was associated to a shorter TST. Objectively measured sleep variables (1b) showed also that sleep quality was directly connected to concentration and daytime sleepiness, however, the connection to mood disappeared. Another difference with the previous network were the appearing connections between TST and mood, indicating that a shorter TST was associated with a better mood. Moreover, in this network we found direct connections between sleep hygiene and sleep; the longer the time of caffeine intake before bedtime the longer the TST and the more mental effort during the day the shorter the SOL.

**Conclusions:** The results revealed that in the network with self-reported sleep only perceived sleep quality was related to daytime functioning. However, in the network with objective measures of sleep also TST was associated to daytime functioning. This study showed that self-reports and objective measures of sleep were differently related to daytime functioning.

**519.113 (Virtual Poster)** Characteristics Associated with Injuries Requiring Emergency Care or Hospitalization in Pre-School Age Children with Autism

**C. DiGuseppi<sup>1</sup>, M. Bolt<sup>1</sup>, S. Schmiede<sup>1</sup>, B. Holst<sup>1</sup>, L. Tian<sup>2</sup>, B. Barger<sup>3</sup>, T. Crume<sup>4</sup>, S. E. Levy<sup>5</sup>, C. Nadler<sup>6</sup>, L. A. Schieve<sup>2</sup> and L. Wiggins<sup>2</sup>,** (1)Colorado School of Public Health, University of Colorado Anschutz Medical Campus, Aurora, CO, (2)Centers for Disease Control and Prevention, Atlanta, GA, (3)Georgia State University, Atlanta, GA, (4)Epidemiology, University of Colorado Anschutz Medical Campus, Aurora, CO, (5)Division of Developmental and Behavioral Pediatrics, Center for Autism Research, Children's Hospital of Philadelphia; Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA, (6)Children's Mercy Kansas City, Kansas City, MO

**Background:** Previous studies have reported associations between injury risk and several conditions that co-occur with autism spectrum disorder (ASD), e.g., attention-deficit/hyperactivity disorder (ADHD), anxiety and depression. Excess injury risk observed in children with ASD may also relate to their symptom severity or other characteristics associated with ASD, specifically, wandering (leaving a supervised space or care of a responsible person) or delayed adaptive behavior. For example, greater difficulties with social communication could affect comprehension of verbal or nonverbal warnings, wandering may expose children to potentially harmful situations, and delayed adaptive behavior may cause difficulties maintaining safety during daily routines or understanding and communicating about situational risks.

**Objectives:** We examined associations of ASD symptom severity, wandering, and delayed adaptive behavior, as well as other behavioral and developmental characteristics, with injury requiring emergency care or hospitalization among pre-school age children with ASD.

**Methods:** The Study to Explore Early Development is a multi-site case-control study of children aged 30-68 months. Detailed sociodemographic, health, behavioral and developmental data were gathered by caregiver interviews and self-administered questionnaires, and in-person child evaluations. ASD cases (n=693) were determined using gold-standard diagnostic instruments. The child's caregiver reported whether the child ever had an injury resulting in emergency care or hospitalization ("injury"). Principal independent variables were: ASD symptom severity assessed as a continuous variable using the Autism Diagnostic Observation Schedule Calibrated Severity Score; wandering, from the Child Behavior Checklist (CBCL) item asking whether the child "wanders away," categorized as "yes" if parent reported "very true or often true," otherwise "no"; and delayed adaptive behavior, from the Vineland Adaptive Behavior Scales-Second Edition composite score dichotomized as delay present/absent. We also examined associations of injury with CBCL internalizing and externalizing scales (continuous T-scores) and ADHD diagnosis. Associations of each principal independent variable with injury were examined in separate multivariable logistic regression models that also included other behavioral characteristics, adjusting for sociodemographic characteristics.

**Results:** Neither ASD symptom severity (Adjusted Odds Ratio=0.98 [95%CI: 0.87, 1.10]) nor delayed adaptive behavior (adjusted odds ratio (AdjOR)=1.13 [0.71, 1.84]) were associated with increased odds of injury. Wandering was moderately associated with increased odds of injury (AdjOR=1.53 [0.97, 2.40]). In this model, ADHD diagnosis was associated with increased odds (AdjOR=2.11 [1.11, 3.95]) and CBCL internalizing score with reduced odds (AdjOR=0.98 [0.96, 0.99]) of injury. Results were similar in an adjusted model including all of these characteristics.

**Conclusions:** Among pre-school children with ASD, we found a modest (albeit nonsignificant) association between wandering and injury that was not explained by co-occurring ADHD, ASD symptom severity, delayed adaptive behavior, internalizing symptoms or sociodemographics considered in the analysis. Further exploration of this association is warranted. More severe ASD symptoms and delayed adaptive behavior were not associated with injury risk. We confirmed the previously reported association of ADHD with injury risk in this population, highlighting the importance of proactive planning for injury prevention (e.g., secure medication storage, pool barriers) in children with co-occurring ASD and ADHD. The observed protective association between internalizing symptoms and injury differs from some previous reports, warranting further study.

**519.114 (Virtual Poster)** Chronic Stress Predicts Obesity in Autistic Individuals: An Analysis of U.S. Medicare and Medicaid Administrative Claims Data

**E. Hotez<sup>1</sup>, S. Tao<sup>2</sup> and L. Shea<sup>3</sup>,** (1)City University of New York, Hunter College, New York, NY, (2)Drexel University, Philadelphia, PA, (3)A.J. Drexel Autism Institute, Philadelphia, PA

**Background:** Autistic individuals are 40% more likely to experience obesity than the general population, and have disproportionate rates of type II diabetes mellitus, cardiovascular disease, and mortality. In other marginalized populations, chronic stress—persistent and cumulative stress over the life course that creates multi-systemic “wear and tear”—is a key mechanism underlying obesity. Indeed, autistic individuals experience pronounced chronic stress in the forms of lifelong stigma, abuse, and victimization. Despite these findings, chronic stress has not been investigated as a mechanism underlying obesity in autistic populations.

**Objectives:** Utilizing 2008-2012 administrative claims from the Centers for Medicare & Medicaid Services Medicaid Analytic eXtract, the current study aimed to estimate the risk ratio of obesity among a) autistic beneficiaries, relative to a random sample of beneficiaries without autism; and b) autistic beneficiaries with and without clinical service record encounters related to chronic stress.

**Methods:** The sample included 571,774 autistic Medicaid beneficiaries with and without co-occurring intellectual disability as well a random sample of 3.3 million beneficiaries without autism. All participants were under age 65 at first observed enrollment and enrolled in Medicaid for at least one year. Autistic beneficiaries were identified based on International Classification of Diseases, Ninth Edition (ICD-9) diagnoses of Autism Spectrum Disorder with or without co-occurring intellectual disability. Beneficiaries were identified as having autism or intellectual disability diagnoses if they had at least one inpatient claim or two outpatient claims with those diagnoses. Beneficiaries with chronic stress were identified utilizing ICD-9 V62-Codes, which reflect clinical service record encounter reasons of abuse, maladjustment, and/or other psychological or physical stress. We relied on diagnosis categories and rules from the Centers for Medicare & Medicaid Chronic Conditions Warehouse to identify beneficiaries with obesity and other medical conditions that served as control variables in our analyses. We utilized unadjusted and adjusted modified Poisson models to estimate the risk ratio of obesity among a) all beneficiaries with and without autism and b) autistic beneficiaries with and without clinical service record encounters related to chronic stress.

**Results:** The risk of obesity among autistic beneficiaries was 1.56 (95% CI: 1.53,1.58) times the risk of obesity relative to beneficiaries without autism or intellectual disability, adjusting for age at enrollment, sex, race, eligibility group and state. Among autistic beneficiaries, the risk ratio of obesity among those with chronic stress-related clinical service record encounters was 1.50 (95% CI: 1.46,1.54) times the risk for those without chronic stress-related clinical service record encounters, adjusting for co-occurring psychiatric diagnoses, anti-psychotic medication usage, co-occurring intellectual disability, age at enrollment, sex, race, eligibility group, insurance type and state.

**Conclusions:** The current study adds to the existing evidence base that finds that autistic individuals experience disproportionate rates of obesity. This is one of the first national studies to demonstrate that experiences of chronic stress predict obesity in this population. Findings have the potential to guide obesity interventions for this population and make them more effective.

**519.115 (Virtual Poster)** Co-Occurrence of Avoidant/Restrictive Food Intake Disorder and Its Impact on Psychosocial Functioning in Younger Adults with Autism

**S. C. Duane<sup>1</sup>, H. F. Zickgraf<sup>2</sup> and G. L. Wallace<sup>1</sup>, (1)The George Washington University, Washington, DC, (2)University of South Alabama, Mobile, AL**

**Background:** Eating-related challenges are commonly co-occurring with autism spectrum disorder (ASD). The DSM-5 indicates that avoidant-restrictive food intake disorder (ARFID) is fairly common in people with ASD. A recent study found indications of ARFID in 21% of a large cohort of autistic children and adolescents and in 17% of their parents. However, no studies have examined ARFID co-occurrence in a sample of younger autistic adults, nor has adequate attention been given to potential sex differences in ARFID co-occurrence among individuals with ASD.

**Objectives:** Evaluate the overall rate of and potential sex differences in co-occurring ARFID in a sample of younger adults with ASD and the impact that co-occurring ARFID has on psychosocial impairment in autistic adults.

**Methods:** 252 younger autistic adults (ages 20-41, M=31.3 years; 170 assigned female at birth) without a documented history of intellectual disability participated in this study. Participants were recruited via Simons Powering Autism Research and Knowledge (SPARK) research match and completed a battery of online questionnaires about eating-related behaviors, including two key measures utilized here, the Nine Item Avoidant/Restrictive Food Intake Disorder Screen (NIAS) and the Clinical Impairment Assessment (CIA) for disordered eating. Three types of ARFID were evaluated using the NIAS: Picky Eating (PE-ARFID), Appetite (A-ARFID), and Fear (F-ARFID). All analyses were run initially with the whole sample and then re-run after excluding those with dietary restrictions (e.g., vegetarianism, medical conditions impacting diet; n=142) that could affect NIAS scores.

**Results:** Screening positive for ARFID was relatively common in this younger adult sample with ASD (PE-ARFID: 77/252--31%; A-ARFID: 49/251--20%; F-ARFID: 29/251--12%). Autistic women reported greater rates of all three ARFID subtypes compared to men ( $\chi^2>6.85$ ,  $ps<.01$ ). While no differences in psychosocial impairment (using the CIA) were observed between PE-ARFID screen-positive vs. screen-negative groups ( $ps>.10$ ), those screening positive for A-ARFID reported greater social ( $F=11.33$ ,  $p=.001$ ,  $\eta^2=.04$ ) and cognitive ( $F=22.81$ ,  $p<.001$ ,  $\eta^2=.09$ ) impairments than those screening negative, and those screening positive for F-ARFID indicated more personal ( $F=5.24$ ,  $p=.02$ ,  $\eta^2=.02$ ), social ( $F=12.14$ ,  $p=.001$ ,  $\eta^2=.05$ ), and cognitive ( $F=25.82$ ,  $p<.001$ ,  $\eta^2=.09$ ) impairments than those screening negative (all three analyses controlled for the effects of age and sex). Re-running analyses excluding participants reporting any type of dietary restriction did not alter the pattern of results reported above.

**Conclusions:** First, we observed relatively high rates of all three types of ARFID in younger autistic adults, particularly in women. While the existing literature suggests that ARFID is more common among males in the general population, we observed more autistic females screen positive for all ARFID subtypes. This could be a function of the sample, which was composed of autistic adults and included a large number of autistic females. Secondly, while screening positive for A-ARFID or F-ARFID was associated with greater psychosocial impairments, screening positive for PE-ARFID was not. Why this might be is unclear, but mirrors findings from at least one study of neurotypical adults. More work is needed to fully understand eating-related challenges and their impacts on the daily lives of people with ASD across the lifespan.

**519.116 (Virtual Poster)** Longitudinal Changes in the Mental Health of ASD Individuals and the Role of Social Functioning, Low Self-Esteem, and Gender As Potential Risk Factors for Depression during the COVID-19 Pandemic.

**Background:** Depression and anxiety are common concerns in individuals with autism spectrum disorder (ASD). The interplay between depression and ASD symptoms poses a challenge for identifying individuals at risk for depression, the clinical diagnostic process, and meeting individual treatment needs. Moreover, gender differences in prevalence rates of both depression and ASD indicate a need for gender specific research.

**Objectives:** To assess and compare levels of depression and anxiety problems prior to and during the pandemic among autism spectrum disorder (ASD) and neurotypical (NT) individuals. To explore the underlying factors that contribute to depression, including social functioning, perception of self or self-esteem, and how these effects differ by diagnosis and sex assigned at birth.

**Methods:** Participants (N=145, ASD n=54, NT n=81) were tested at two different time points [Wave 1: 2012-2015] and [Wave 2: 2020-2022]. DSM-5 oriented depression and anxiety problem t-scores were obtained from the CBCL during Wave 1, and the Adult Self-Report (ASR) and Youth Self-Report (YSR) during Wave 2. We generated a self-esteem variable by combining line items from the YSR and ASR. Reliability of the self-esteem variable was calculated using Cronbach's alpha (coefficient alpha=.706/.843). Socialization domain scores were obtained from the Vineland-3 during Wave 1. All statistical analyses were completed using SPSS.

**Results:** There was a significant increase over time in depression ( $p<.001$ ) and anxiety ( $p=.001$ ) problems among NT participants, but not ASD participants (depression,  $p=.569$ ; anxiety  $p=.969$ ). NT females ( $n=37$ ) saw greater increases in levels of depression over time than NT males, but this difference was only marginally significant ( $p=.064$ ). No sex differences were observed in the NT participants for anxiety problems. Within the ASD participants, no sex differences were observed for longitudinal changes in depression or anxiety. In terms of current levels of depression, our data suggest that better parent report of social functioning was a significant predictor of depression in ASD but not in NT, independent of sex ( $p=.033$ ). Self-esteem was a significant predictor of depression in females but not males, independent of diagnosis ( $p=.016$ ).

**Conclusions:** Our results revealed heterogeneity in the specific risk factors for depression. ASD individuals with better social functioning were more vulnerable to developing depression concerns than NT individuals, for whom better social functioning appears to be protective. Moreover, low self-esteem increased the likelihood of having higher depression scores to a greater degree in females than in males. Notably, ASD individuals did not experience significant increases in depression and anxiety from pre-pandemic to current levels. Overall, our results indicate differences in the effects of certain depression risk factors among ASD vs NT individuals. Further research is needed to find the underlying cause of these differences, and how sex differences may contribute to depression prognosis.

#### **519.117 (Virtual Poster) Sex Differences in the Relationship between Depressive Symptoms and Pupillary Light Reflex in Children with ASD: Results from the ABC-CT Main Study**

**R. Iqbal<sup>1</sup>, A. Naples<sup>1</sup>, K. Chawarska<sup>1</sup>, G. Dawson<sup>2</sup>, R. A. Bernier<sup>3</sup>, S. Jeste<sup>4</sup>, C. A. Nelson<sup>5</sup>, J. Dziura<sup>6</sup>, S. J. Webb<sup>7</sup>, C. Sugar<sup>8</sup>, F. Shic<sup>7</sup> and J. McPartland<sup>8</sup>,** (1)Child Study Center, Yale University School of Medicine, New Haven, CT, (2)Department of Psychiatry and Behavioral Sciences, Duke Center for Autism and Brain Development, Durham, NC, (3)Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA, (4)University of California, Los Angeles, Los Angeles, CA, (5)Department of Developmental Medicine, Boston Children's Hospital, Boston, MA, (6)Yale University, New Haven, CT, (7)Center for Child Health, Behavior and Development, Seattle Children's Research Institute, Seattle, WA, (8)Child Study Center, Yale Child Study Center, New Haven, CT

---

**Background:** Depression and restricted and repetitive behaviors (RRBs) are commonly observed in autism spectrum disorder (ASD) and show sex differences (the former higher in non-ASD females, the latter higher in ASD males). Both are hypothesized to associate with function of the autonomic nervous system (ANS). Based on findings from the pupillary light response (PLR), a putative biomarker for ANS function, the ANS may function differently in ASD and typically developing individuals with depression. However, sex differences in the relationship between depressive and RRB characteristics and the PLR response have not been investigated in children with ASD.

**Objectives:** To examine the relationship between (a) depressive and (b) RRB features and PLR latency and relative pupil constriction (RPC) across sex.

**Methods:** PLR was collected across five sites from 278 children with ASD ages 6-11 (213 males; age  $M = 8.54 \pm 1.64$ ; FSIQ  $M = 96.58 \pm 18.11$ ) as part of the Autism Biomarkers Consortium for Clinical Trials (ABC-CT) study. Using the SR EyeLink 1000+, participants were shown white flashes of light during a passive eye-tracking task. In total, participants completed 16 trials with video clips dispersed between trials. PLR was characterized by latency and RPC. The Social Responsiveness Scale, Second Edition (SRS-2) was used to characterize ASD RRB symptoms. The Child and Adolescent Symptom Inventory, Fifth Edition (CASI-5) was used to obtain parent-reported depressive symptoms. Correlations and independent-samples t-tests were conducted to determine associations between SRS RRB scores, depressive symptoms (CASI-5 MDE subscale T-score), and PLR latency/RPC.

**Results:** There was a significant difference in PLR RPC across sex ( $p < 0.01$ ) such that males demonstrated larger RPC. PLR latency and RPC were significantly correlated with SRS RRB scores in females ( $r = 0.33, p < 0.01$ ;  $r = -0.28, p = 0.02$ , respectively) but not males ( $r = 0.01, p = 0.91$ ;  $r = 0.11, p = 0.11$ , respectively). In contrast to RRBs, PLR RPC was significantly correlated with depressive symptoms in males ( $r = 0.17, p = 0.01$ ) but not females ( $r = -0.09, p = 0.46$ ). Ongoing analyses are exploring the relationship between individual CASI item endorsements and PLR dynamics.

**Conclusions:** These findings provide initial evidence of sex-based relationships among depressive and RRB symptoms and PLR response in children with ASD. These results suggest that mechanistic differences in ANS function may influence differential expression of RRBs and depression in males and females. Future directions include utilizing PLR as an index to target diagnosis and treatment for different clinical presentations of ASD and depression. Understanding these relationships may help inform the impacts of psychiatric co-occurring conditions on the experience of individuals with ASD.

**519.118 (Virtual Poster)** Temperament in Infancy Predicts Internalizing and Externalizing Problem Behavior at Age 5 in Children with an Increased Likelihood of Autism Spectrum Disorder

**L. A. Sacrey<sup>1</sup>, L. Zwaigenbaum<sup>2</sup>, S. E. Bryson<sup>3</sup>, J. A. Brian<sup>4</sup>, I. M. Smith<sup>5</sup>, N. Garon<sup>6</sup>, T. Vaillancourt<sup>7</sup> and C. Roncadin<sup>8</sup>,** (1)Autism Research Centre, Glenrose Rehabilitation Hospital, Edmonton, AB, CANADA, (2)University of Alberta, Edmonton, AB, Canada, (3)Dalhousie University, Halifax, NS, Canada, (4)Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (5)Dalhousie University / IWK Health Centre, Halifax, NS, CANADA, (6)Mount Allison University, Sackville, NB, Canada, (7)University of Ottawa, Ottawa, ON, Canada, (8)Autism Spectrum Disorder Service, McMaster Children's Hospital - Hamilton Health Sciences, Hamilton, ON, Canada

**Background:** Differences in temperament have been linked to later mental health (Aldao et al., 2016; Bos et al., 2018; Gross & John, 2003). Children with autism spectrum disorder (ASD), including siblings of children with ASD, are at an increased likelihood of experiencing temperamental problems in toddlerhood (Garon et al., 2016; 2021; Clifford et al., 2013), as well as problems with mental health, including anxiety, depression, and attention deficit/hyperactivity disorder, during their school-age years (Jones et al., 2020; Simonoff et al., 2008). However, the relationship between early temperament and later mental health is not well understood within the context of ASD.

**Objectives:** To assess relations between temperament in infancy and internalizing and externalizing behavior at age 5 years in children at an increased likelihood (IL) of being diagnosed with ASD (i.e., younger siblings of children with ASD).

**Methods:** Participants included 178 infant siblings of children with ASD (107 boys; 71 girls), 51 of whom were diagnosed with ASD at age 3. Temperament was measured using the parent-reported Infant Behavior Questionnaire (IBQ) at 6 and 12 months of age and the Toddler Behavior Assessment Questionnaire-Revised (TBAQ-R) at 24 months of age. Mental health problems were measured using the parent-reported Child Behavior Checklist (CBCL) at age 5. The data were analyzed using hierarchical multiple regressions, with internalizing or externalizing behavior total score as the dependent variable and individual temperament subscale scores as single predictor variables (Subscale Score) in the first block, Autism Diagnostic Observation Schedule total severity scores at age 3 in the second block, and expressive and receptive language scores (from the Mullen Scales of Early Learning) at age 3 in the third block of each model.

**Results:** First, IBQ temperament subscale scores did not differentiate between IL siblings with and without ASD until 12 months of age. Second, 4 of 6 IBQ subscales at both 6 and 12 months significantly predicted internalizing and externalizing problems at age 5. Third, 9 and 8 of 13 TBAQ-R subscales at 24 months significantly predicted internalizing and externalizing problems, respectively, at age 5 (see attached Table 1).

**Conclusions:** The results of this study support the supposition that temperament is a trans-diagnostic risk factor for later mental health conditions (Aldao et al., 2016; Bos et al., 2018; Gross & John, 2003). Exploring temperament profiles and trajectories may illuminate early avenues for prevention in siblings of children with ASD who are at an increased likelihood of experiencing mental health problems, regardless of ASD diagnostic status.

**519.119 (Virtual Poster)** The Association between Social Skills, Anxiety, and Depression in Autism Spectrum Disorder: Parent and Youth Perspectives

**S. X. Tan, S. S. Mire, M. Keller-Margulis, H. J. Kim and J. E. Gonzalez,** Psychological, Health, and Learning Sciences, University of Houston, Houston, TX

**Background:** Social impairment is common among adolescents with autism spectrum disorder (ASD). While there is emerging evidence that social factors contribute to internalizing difficulties in this population, there is a dearth of research examining the explicit links between social skills difficulties and internalizing difficulties (Smith & White, 2020). A common hypothesis is that higher rates of internalizing difficulties amongst adolescents with ASD may be explained by a combination of greater social awareness, challenges navigating social environments, and more experiences with social failures (Bellini, 2004; Kerns and Kendall, 2013). In addition, the suggestion that social challenges are linked to internalizing difficulties comes from evidence demonstrating that social skills interventions (SSIs) indirectly affect internalizing symptoms (Schiltz et al., 2018). Existing research has largely relied on parent reports rather than self-reports, representing a significant gap in the literature, since the inclusion of self-reports capture a more comprehensive picture of internalizing and autism symptomology.

**Objectives:** This study aims to investigate the association between social skills deficits, and anxiety and depression in a community sample of youth with ASD (without Intellectual Disability [ID]) who are enrolled in a novel, community-based SSI program. In addition, the study will examine the concordance of parent-reported and youths' self-reported anxiety and depression scores.

**Methods:** Data collected at three time points from implementing a community-based SSI will be analyzed. Parents rated severity of social problems on the *Social Responsiveness Scale – Second Edition (SRS-2)*, and emotional and behavioral difficulties on the *Behavior Assessment System for Children Parent Rating Scales - Third Edition (BASC-3 PRS)*. The youth also rated their behavioral and emotional difficulties on the *BASC-3 Self-Report of Personality (BASC-3 SRP)*. Pearson correlations will be calculated between the scores of social skills (SRS-2), and the *BASC-3 PRS* and *SRP* Anxiety and Depression subscale scores. In addition, separate regression analyses will be computed for the parent-report and for the self-report to estimate the unique contributions of each *SRS-2* subscales on anxiety and depression scores. Finally, to analyze concordance/discordance between

parent and self-report of anxiety and depression scores, paired-samples t-tests between the parent and child-reported anxiety and depression scores will be carried out.

**Results:** It is hypothesized that poorer social skills are associated with greater internalizing symptoms in youth with ASD (without ID), and that social skills will explain a significant proportion of the variance in mental health difficulties in youth with ASD, without ID. In addition, it is anticipated that parents and participants will report on anxiety and depression differently.

**Conclusions:** The anticipated strength of association between social skills and internalizing mental health difficulties suggest that targeting social skills as part of a comprehensive treatment plan for youth with ASD may be a way to assist in treating mental health issues. Strengths in this study include a self-report of internalizing symptoms from youth with ASD, to obtain their personal perspective on the association between social skills and mental health. This study could be further extended by incorporating mixed methods to assess social competence, and adolescents' perspectives on anxiety and depression.

**519.120 (Virtual Poster)** The Clinical Profile of Referrals to the Gender and Autism Program, a Novel Clinical Service for Gender Diverse Autistic Youth and Young Adults

**A. Fischbach<sup>1</sup>, S. N. Bernstein<sup>1</sup>, J. F. Strang<sup>2</sup>, L. McClellan<sup>1</sup> and B. Parchem<sup>3</sup>,** (1)Division of Neuropsychology, Children's National Hospital, Rockville, MD, (2)Center for Autism Spectrum Disorders, Children's National Hospital, Washington, DC, (3)Department of Psychological and Brain Sciences, George Washington University, Washington, D.C., DC

**Background:** The intersection of autism and gender diversity (GD) is common: Autism spectrum disorder (ASD) is 3-6.4 times more prevalent in transgender compared to cisgender individuals (Warrier et al., 2020). Co-occurring ASD and GD is associated with increased mental health risks, above and beyond mental health risks in autistic or gender-diverse populations independently (Strang et al., 2021). The Gender and Autism Program (GAP) at Children's National Hospital (Washington, D.C.) is the first clinical service specifically designed for the many youth and young adults who are gender-diverse/transgender and autistic. The GAP provides evaluation services for autism and gender needs, consultation services to support youth and families and community integration, and support group programs (described in Strang et al., 2020).

**Objectives:** Examine patterns of referral, including reasons for referral and clinical profiles in youth accessing care through the GAP.

**Methods:** Clinical data for 50 consecutive GAP referrals were collected and characterized. Key patient demographics (i.e., age, gender identity, assigned sex at birth (ASAB), and race/ethnicity) and clinical/diagnostic characteristics (i.e., type of referral, ASD diagnostics/status, and gender-related medical status) are included. Brief qualitative analytic methods were used to categorize reasons for referral.

**Results:** Most referrals received were from older adolescents ( $M_{age} = 16.32$ ,  $SD_{age} = 4.18$ , 6.39-26.93) seeking gender-affirming medical care. Reasons for referral were as follows: gender-related needs in the context of autism/neurodiversity (90%), autism-related characterization in the context of GD (46%), transition to adulthood in the context of being autistic and GD (28%), and educational considerations in the context of being autistic and GD (20%). 66% of patients were referred for multiple reasons.

ASAB of clinic referrals was evenly split (46% female). The majority of referrals were binary transgender. Among assigned females, 57% were binary transgender male and 43% were nonbinary or another gender. Among assigned males at birth, nonbinary genders were much less common (19%).

Most referrals had existing ASD diagnoses (66%), and most seeking ASD diagnostic clarification were found autistic (71%). Of those requesting gender-related medical treatment (including youth already receiving some type of gender-care), gender-affirming hormone requests were the most common (65%). Requests for pubertal suppression were less common (proportionally), apparently due to the age at which youth arrived at the clinic (i.e., considerably older than the typical 8-12-year-old range for starting pubertal suppression). The ethno-racial identities of participants skewed toward White and non-Hispanic/Latinx.

**Conclusions:** This study provides information on the profiles of youth and young adults accessing a service specifically designed for autistic gender-diverse individuals. Most of these young people were seeking gender-affirming medical care, yet typically were too old upon clinic intake to access pubertal suppression medications, suggesting a disparity in care access compared to non-autistic GD youth. Autism diagnosis was confirmed in nearly all patients. Race/ethnicity-related disparities in access to autism care as well as gender care may be intensified for youth at the intersection of autism and gender diversity; the patient sample was significantly skewed toward White and non-Hispanic/Latinx. Future work should address disparities in access to care by age as well as race/ethnicity.

**519.121 (Virtual Poster)** Assessing the Moderating Role of Behavioral Regulation on the Longitudinal Relationships between Anxiety and Social Communication Among Autistic Children

**E. Ng-Cordell<sup>1</sup>, H. R. Pickard<sup>2</sup>, R. Bedford<sup>3</sup>, W. J. Ungar<sup>4</sup>, A. Zaidman-Zait<sup>5</sup>, L. Zwaigenbaum<sup>6</sup>, E. Duku<sup>7</sup>, T. Bennett<sup>8</sup>, S. Georgiades<sup>9</sup>, I. M. Smith<sup>10</sup>, A. E. Richard<sup>11</sup>, T. Vaillancourt<sup>12</sup>, P. Szatmari<sup>13</sup>, M. Elsabbagh<sup>14</sup> and C. M. Kerns<sup>15</sup>,** (1)Psychology, University of British Columbia Vancouver, Vancouver, BC, Canada, (2)Social, Genetic and Developmental Psychiatry, King's College London, London, United Kingdom, (3)University of Bath, London, United Kingdom, (4)The Hospital for Sick Children Research Institute, Toronto, ON, Canada, (5)Tel-Aviv University, Tel-Aviv, Israel, (6)University of Alberta, Edmonton, AB, Canada, (7)Offord Centre for Child Studies, McMaster University, Hamilton, ON, Canada, (8)Offord Centre for Child Studies, McMaster University, Hamilton, ON, CANADA, (9)McMaster Autism Research Team, McMaster University, Hamilton, ON, Canada, (10)Dalhousie University / IWK Health Centre, Halifax, NS, CANADA, (11)Autism Research Centre, IWK, Halifax, NS, Canada,

## Background:

Co-occurring anxiety disorders affect many autistic children, with far-reaching impacts on their adaptive functioning, physical health, and family relationships. Evidence suggests anxiety in autism is related to difficulties across social (i.e., social communication) and cognitive (i.e., executive functioning) domains. However, research has yet to examine these associations longitudinally in a community sample of autistic children. It remains unclear whether anxiety predicts greater social communication difficulties over time (or vice versa) in autism, and whether executive functioning – particularly behavioral regulation (BR) – acts as a protective factor, by moderating these relationships.

## Objectives:

To: (1) investigate longitudinal associations between anxiety and social communication difficulties among school-aged autistic children, and (2) assess the moderating effect of BR.

## Methods:

Participants were drawn from *Pathways*, a pan-Canadian, longitudinal cohort study of autistic children (N = 157; 15% female; mean FSIQ = 84.8). We focused on two time points during pre-adolescence (Age 9: mean age = 9.7 years, and Age 10: mean age = 10.7 years; mean interval between assessments = 12.2 months). To limit informant bias, parent and teacher reports were gathered at each time point. Specifically, the parent-reported Child Behavior Checklist (Anxiety Problems subscale) assessed anxiety, and the teacher-reported Social Responsiveness Scale (Social Communication Index) and Behavior Rating Inventory of Executive Function (Behavior Regulation Index; BRI) assessed social communication and BR difficulties, respectively.

We ran a cross-lagged panel model, controlling for IQ, to test whether anxiety levels at Age 9 predicted social communication difficulties at Age 10 and vice versa (cross-lagged pathways). Next, we ran a multigroup analysis to test for similarity in cross-lagged pathways across different levels of BR ability. Grouping was based on median BRI scores at Age 9 (high-BR difficulty: n = 57; low-BR difficulty: n = 55).

## Results:

Higher Age 9 anxiety scores predicted *fewer* social communication difficulties at Age 10 ( $\beta = -.169, p = .038$ ). Social communication difficulties at Age 9 did not predict levels of anxiety at Age-10 ( $\beta = .091, p = .183$ ). In the multigroup analysis, the association between higher Age 9 anxiety and lower Age 10 social communication difficulties was significant in the high-BR difficulty group ( $\beta = -.474, p < .001$ ), but not the low-BR difficulty group ( $\beta = .046, p = .949$ ), and the difference in the strength of these estimates was significant ( $p < .001$ ).

## Conclusions:

These unexpected results suggest that anxiety may lead to greater behavioural inhibition, especially among those with poorer BR, which in turn may reduce social communication difficulties over time. Our findings emphasize the importance of studying anxiety in community samples in order to gather a more complete picture of the developmental effects (both adaptive and maladaptive) of anxiety for autistic youth. Further research is required to clarify the mechanisms (e.g., behavioural inhibition) underlying the protective role anxiety may play, and to investigate how these associations continue developing into adolescence and adulthood for autistic people – in particular evaluating the longer-term mental health consequences of anxiety compared to its potential social benefits.

### 519.122 (Virtual Poster) Characterizing Adolescent Autism Diagnosis in Individuals with Prior Psychiatric Diagnoses

C. J. Bernardin<sup>1</sup>, M. N. Cissne<sup>2</sup>, K. Hirst<sup>3</sup>, M. Stevens<sup>4</sup>, K. Nowell<sup>5</sup> and T. N. Takahashi<sup>6</sup>, (1)Department of Psychological Sciences, University of Missouri - Columbia, Columbia, MO, (2)Psychological Sciences, University of Missouri, Columbia, MO, (3)Thompson Center, University of Missouri, Columbia, MO, (4)University of Missouri, Columbia, MO, (5)Health Psychology, Univ. of Missouri; Thompson Center for Autism & Neurodevelopmental Disorders, Columbia, MO, (6)Thompson Center for Autism & Neurodevelopmental Disorders, University of Missouri, Columbia, MO

---

**Background:** Many autistic individuals are also diagnosed with mental health conditions. Studies suggest that 70-80% of autistic individuals will be diagnosed with at least one psychiatric disorder in their lifetime (Buck et al., 2014; Lever et al., 2016). This high level of psychiatric comorbidity can make differential diagnosis difficult in individuals who do not receive a diagnosis of autism at a young age. In addition, some individuals may receive incorrect psychiatric diagnoses rather than the correct diagnosis of autism. It is important for researchers to explore how to improve diagnosis of this subset of the autism population in order to increase timely access to appropriate support and, if necessary, intervention.

**Objectives:** To characterize a sample of autistic individuals who were diagnosed during adolescence and who had existing psychiatric diagnoses at the time of their autism evaluation. The goals of this project are to 1) identify whether patterns in early signs of autism (e.g., developmental delays, social concerns) exist among this population, 2) identify whether patterns in sociodemographic factors (e.g., household income, parent education) exist among this population, and 3) describe the psychiatric histories of individuals in this population. Such information could aid in more timely autism diagnoses for individuals with similar presentations.

**Methods:** We reviewed assessment reports for individuals who received an autism diagnostic evaluation at a specialty clinic during adolescence (ages 13-18 years) between 2015 and 2020. Individuals were included in this study if they had previous and/or existing psychiatric diagnoses and they received a diagnosis of autism as a result of their evaluation. One hundred forty-two individuals (26% female, 93% Caucasian, *M* age=15.36 years) were included in the sample. Sociodemographic, phenotypic, and developmental milestone data were reviewed. In addition, information regarding current behavior concerns and medications, and current and past psychiatric and developmental diagnoses, suicidality, and non-suicidal self-injury was reviewed.

**Results:** Individuals in our sample had an average full-scale IQ of 94.22 (range=57-132) and presented with a wide range of pre-existing psychiatric and developmental diagnoses (e.g., anxiety, depression, bipolar disorder, learning disability, attention deficit hyperactivity disorder). Many individuals in our sample received these diagnoses from Psychologists or Psychiatrists, indicating they had been seen by individuals who could have provided the correct diagnosis of autism. Average age of caregiver's first concerns about social development, speech and language development, and behavior was 48 months, 38 months, and 44 months, respectively. Analysis of other data in this project is ongoing.

**Conclusions:** Individuals who receive an autism diagnosis during adolescence and who have previously received other psychiatric diagnoses are a group that may be difficult to accurately diagnose in a timely manner. This is evidenced by the fact that they are seen by diagnosticians capable of providing an autism diagnosis but nonetheless receive other diagnoses. While other psychiatric and developmental diagnoses may be accurate, it is essential to better identify these individuals with autism at younger ages in order to improve their access to appropriate support as early as possible.

**519.123 (Virtual Poster) Co-Occurrence of Externalizing Behaviors, Attention Problems, and Internalizing Symptoms Higher in Autistic Than Non-Autistic Adolescents**

**J. M. Phan<sup>1</sup>, E. Hilton<sup>2</sup>, H. Goldsmith<sup>3</sup> and E. Shirtcliff<sup>4</sup>,** (1)Waisman Center, Waisman Center, University of Wisconsin - Madison, Madison, WI, (2)University of Wisconsin - Madison, Madison, WI, (3)Psychology, University of Wisconsin-Madison, Madison, WI, (4)Human Development and Family Studies, Iowa State University, Ames, IA

---

**Background:** Adolescence is often a time of onset or increase in both internalizing and externalizing behaviors. Puberty may exacerbate behaviors in vulnerable youths with existing challenges. For instance, externalizing behaviors (e.g., risk-taking, aggression) occur alongside maturation, and mental health symptoms can also pervade the adolescence experience, such as depression and anxiety. The pubertal process has a role in increasing internalizing symptoms and externalizing behaviors in non-autistic adolescents, but few studies have investigated puberty's effect on autistic adolescents. We conducted a model that accounted for commonalities among internalizing symptoms (INT), externalizing behaviors (EXT), attention problems (ATT), and repetitive behaviors and restricted interests (RRB) in a sample of autistic and non-autistic youths. Within this model, other relevant factors, such as pubertal status (PUB) and gender, were considered when examining symptom and behavior domains.

**Objectives:** The main aim of the present study was to test current "comorbidity" models and adolescent developmental models usually applied in research on non-autistic adolescents and test these models with autistic adolescents in comparison, as puberty may uniquely affect autistic adolescents. Such a model can provide insight into commonalities across symptoms and behaviors that may also relate to maturational experience.

**Methods:** Data were obtained from the National Database for Autism Research. A sample of 268 non-autistic and 241 autistic youths ages 8 to 18 years (*M* = 12.79, *SD* = 2.96, 46% female) were included in the study. Racial groups included white (80%), Asian (8%), Black or African American (7%), Hawaiian or Pacific Islander (1%), Hispanic or Latinx (12%), and more than one race (5%). Multiple linear regressions tested behavior domains (EXT, ATT, RRB) as predictors of internalizing symptoms, and then commonality analyses were conducted to test unique and common variances between and among variables. Pubertal status and gender were examined as moderators of symptom-behavior domains. Within-group analysis were conducted to examine symptom-behavior associations and moderator effects within neurotype (i.e., within non-autistic youths, within autistic youths).

**Results:** Autistic (AT) adolescents had higher INT than non-autistic (NA) adolescents with girls showing higher symptoms than boys ( $b=2.28$ ,  $p=0.03$ ). EXT and ATT co-occurred with INT ( $b=0.53$ ,  $p<0.001$ ;  $b=0.58$ ,  $p<0.001$ , respectively) for both AT and NA adolescents. Within-group analysis found AT girls had higher INT than AT boys ( $b=4.54$ ,  $p<0.001$ ) when accounting for EXT co-occurrence. The same result was found within the NA group ( $b=1.42$ ,  $p=0.03$ ). PUB did not moderate behaviors and symptoms co-occurrence in both groups, and RRB did not predict INT. Commonality analysis found co-occurrence across INT, EXT, ATT, and RRB in both AT and NA youths. Behavior domains combined shared 32% of the total variance in predicting INT for AT adolescents, while 26% of the variance were explained by EXT and ATT for NA adolescents.

**Conclusions:** This study adds to a growing literature that adolescence can be a tougher time for autistic adolescents, especially girls. Unexpectedly, pubertal status did not influence co-occurring symptoms and behaviors in this sample. Consequently, future research is needed examining longitudinal assessments to elucidate puberty's role in heterotypic co-occurring symptoms and behaviors in autistic youths.

**519.124 (Virtual Poster) Content and Extent of Worry in Autistic Adults**

**D. Greenwood<sup>1</sup>, J. Choo<sup>1</sup>, J. Pivac<sup>2</sup>, J. Tang<sup>3</sup>, P. Clarke<sup>3</sup> and M. H. Black<sup>1</sup>,** (1)School of Allied Health, Curtin University, Perth, WA, Australia, (2)Curtin University, Perth, WA, Australia, (3)Affective, Behavioural, and Cognitive Neuroscience Research Group, School of Population Health, Curtin University, Perth, WA, Australia

---

**Background:**

Autistic individuals are at a greater risk of experiencing poor mental health compared to neurotypical adults and have a higher prevalence of psychiatric conditions including anxiety and depression. While poor mental health is highly prevalent in the autistic population, few studies have

explored the presentation of worry in autistic individuals and there is limited knowledge on how worry presents, and whether the content, extent, and experiences of worry are similar to non-autistic individuals.

#### Objectives:

The aims of this study were to compare the content and extent of worry in autistic adults compared to non-autistic adults. The study objectives were to explore the differences and similarities in the content and extent of worry compared between autistic and non-autistic adults and the specific experiences of worry in the autistic population.

#### Methods:

A convergent parallel mixed-method study to explore the content and extent of the experience of worry in autistic people to identify the specific factors influencing worry and to what extent this impacts on their lives. A quantitative survey compared the content and extent of worry in 52 autistic and 169 non-autistic participants using the Penn State Worry Questionnaire (PSWQ) and Worry Domains Questionnaire (WDQ). Qualitative interviews were undertaken with 14 autistic adults and analysed thematically to explore the experiences, and impacts of worry from the perspectives of autistic adults.

#### Results:

Comparisons of worry between autistic and non-autistic adults using the PSWQ and WDQ demonstrated autistic adults had a significantly higher trait worry and extent of worry than non-autistic populations. Autistic adults had significantly greater worry across all worry domains including relationships, lack of confidence, aimless future, work incompetence, and financial domains. Qualitative interviews with autistic individuals highlighted the experiences, content and impact of worry from the perspectives of autistic adults. Worry experienced within the autistic population was grouped into four themes; 1) definition of worry, 2) impacts on daily living, 3) time of day worry is present and 4) contributions to worry. Worry was described as a never-ending cycle involving overthinking where thoughts circulated through participants' minds throughout their daily lives. One participant expressed that "... worry can be a rabbit warren of fears...". Worry was reported by autistic adults to decrease their mood and increase their fear socialising, impacting their relationships with family and friends. Worry further reduced autistic adults access to the community and was reported to contribute to health and financial issues, job instability, and overall impacting their ability to remain independent and support themselves.

#### Conclusions:

Autistic adults worry more than non-autistic adults in every aspect of daily living, with autistic adults reporting this led to more isolating behaviours. Rumination on negative thoughts was commonly expressed participants due to their feelings of uncertainty and thinking about future events. Worry was reported to have negative impacts on daily functioning including sleep, positive relationships, future planning, financial wellbeing, and general health. Worry is likely to contribute to the already known higher mortality rate among autistic adults.

#### **519.125 (Virtual Poster) Experiences and Impact of Anxiety on the Everyday Participation of Autistic Adults**

*C. McKenzie<sup>1</sup>, K. Romanczuk<sup>1</sup>, J. Waddell<sup>1</sup>, B. Zettels<sup>1</sup>, P. Clarke<sup>2</sup>, B. T. Milbourn<sup>1,3</sup> and M. H. Black<sup>1,3</sup>, (1)School of Allied Health, Curtin University, Perth, WA, Australia, (2)Affective, Behavioural, and Cognitive Neuroscience Research Group, School of Population Health, Curtin University, Perth, WA, Australia, (3)enAble Institute, Curtin University, Perth, WA, Australia*

---

#### Background:

Anxiety is commonly experienced by autistic individuals, with some evidence suggesting that over half of autistic individuals experience anxiety. While the prevalence anxiety is known to be greater in autistic individuals compared to the neurotypical population, few studies have sought to explore the experiences and impact of anxiety on autistic adults. The World Health Organisation (WHO) International Classification of Functioning, Disability, and Health (ICF) provides a biopsychosocial approach to appraise health, disability, and its effect on participation in everyday activities. The ICF therefore provides a comprehensive framework through to explore the impacts of anxiety on autistic adults' participation in everyday life.

#### Objectives:

Explore the experiences and impact of anxiety on everyday activities and participation from the perspectives of autistic adults.

#### Methods:

A qualitative approach was used to explore experiences of anxiety and its impact on everyday participation from the perspective of autistic adults. Semi-structured interviews were conducted with 14 autistic adults with a mean age of 40.5 years including four females and ten males. Interview data were transcribed verbatim and analysed thematically. The activity and participation domains of the ICF were used to guide data analysis, providing a comprehensive exploration of the experiences and impact of anxiety on activities and participation from the perspectives of autistic adults.

#### Results:

Autistic adults described anxiety as an uncontrollable sense of uncertainty and reluctance to commit to participating in everyday activities. A majority of autistic adults perceived anxiety to be intertwined with their identity, reporting difficulty imagining life without it: “[Anxiety] is just something you live with... it gets better, it gets worse. You don't know what it's like to live without it”.

Autistic adults described how anxiety, particularly related to uncertainty, impacted the frequency and quality of participation in home and community life, education, employment, and relationships. Illustrative examples include the impacts anxiety had autistic adults' ability to enter the community and perform self-care: “If I'm really anxious... I'll get so overwhelmed and not be able to function, cook for myself or get groceries. On some days... I'll have difficulty just leaving my bed, so even basic hygiene... getting in the shower, brushing my teeth, it will impact my ability to care for myself” and participate in leisure occupations: “I've isolated myself in the anxiety from actually breaking out and even doing some of the things that I used to enjoy”. While anxiety had largely negative impacts, autistic adults also reported some positive impacts anxiety, finding that in some cases it could as a motivator to participate in relationships, employment, and education.

#### Conclusions:

Experiences of anxiety negatively impacted autistic adults' participation in all activity and participation domains of the ICF including home and community life, education, relationships and employment. Everyday activities which were unpredictable or uncertain, or that had the potentially to be sensory overwhelming were found to contribute to anxiety, resulting in autistic adults limiting their participation in daily life.

#### **519.126 (Virtual Poster)** Exploring the Relevance of the Interpersonal Theory of Suicide in Autistic People

**R. Moseley<sup>1</sup>, N. J. Gregory<sup>2</sup>, P. Smith<sup>3</sup>, C. Allison<sup>4</sup>, S. A. Cassidy<sup>5</sup> and S. Baron-Cohen<sup>4</sup>,** (1)*Bournemouth University, Poole, United Kingdom,* (2)*Department of Psychology, Bournemouth University, Poole, United Kingdom,* (3)*University of Cambridge, Cambridge, United Kingdom,* (4)*Autism Research Centre, Department of Psychiatry, University of Cambridge, Cambridge, United Kingdom,* (5)*School of Psychology, University of Nottingham, Nottingham, United Kingdom*

---

**Background:** While there are known risk factors for suicidality in autism, these are often unconnected from theoretical frameworks that might explain *how* risk is elevated and guide clinical interventions. One such theory, the Interpersonal Theory of Suicide (ITS), asserts that unmet interpersonal needs (perceived burdensomeness and thwarted belongingness) are the principle drivers of suicide ideation, over and above state psychopathology, but that ideation is only translated into action if individuals have acquired capability for suicide. At present, these hypotheses have been under-investigated in autistic people.

**Objectives:** In an autistic sample, we examined the relevance of perceived burdensomeness and thwarted belongingness for suicide ideation, and acquired capability for suicide attempts. We further examined these constructs as the mediators through which certain autism-relevant factors (relationship status, co-occurring ADHD) might elevate suicide risk.

**Methods:** Autistic adults (n = 314) completed an online study including measures of depression, anxiety, ADHD symptoms and constructs from the ITS. Linear and multinomial regression analysis disentangled contributions of ITS variables from effects of depression and anxiety for past-year suicide ideation, past-year and lifetime suicide attempts. Mediation analyses examined associations between risk factors and these suicide outcomes via mechanisms proposed by the ITS.

**Results:** Past-year suicide ideation was associated with burdensomeness, mental rehearsal of suicide plans (a facet of acquired capability), and depression. Burdensomeness and reduced fear of death differentiated those who had attempted suicide from those who had (and had not) experienced suicidal ideation in the past year. Relationship status was indirectly associated with past-year suicide ideation via the mediators of depression and burdensomeness, and was associated with past-year attempts via its effect on ideation. ADHD co-occurrence was associated with past-year suicide ideation via anxiety, depression, and burdensomeness; this elevated sense of burdensomeness also mediated an association with more lifetime suicide attempts. A closer look at ADHD symptoms revealed that individuals with hyperactive and impulsive symptoms were also more likely to experience painful and/or traumatic life events, and through this more likely to acquire capability for suicide: these symptoms were associated with more numerous suicide attempts via each of these mediators.

**Conclusions:** Contrary to ITS predictions, perceived burdensomeness may be a potent factor in suicide ideation *and* attempts in autistic people. Facets of acquired capability, notably reduced fear of death and mental rehearsal of suicide plans, may likewise contribute to both ideation and attempts. These associations may underpin some of the increased risk associated with variables like relationship status and co-occurring ADHD, which justifies further investigation of how ITS constructs are conceptualised and how they should be measured in autism. The existence of a direct pathway from traumatic events to suicide attempts, contrary to the ITS hypothesis that traumatic events increase suicide risk via acquired capability, corroborates the need to explore the nature and impact of trauma and post-trauma symptoms in autistic people. As cross-sectional research is insensitive to directionality, researchers must collaborate with the autistic community to devise safe and scientifically rigorous methods to examine temporal dynamics in suicide trajectories.

#### **519.127 (Virtual Poster)** Impact of Sleeping Disorders on Anxiety-Related Clinical Scales in Individuals with Autism

**Y. Zhu<sup>1</sup>, Y. Liu<sup>2</sup>, T. Wiese<sup>3</sup> and M. del Valle Rubido<sup>3</sup>,** (1)*F. Hoffmann-La Roche Ltd, Welwyn Garden City, United Kingdom,* (2)*Genesis Research, Real World Evidence Solutions, Hoboken, NJ,* (3)*Roche Pharma Research and Early Development, Roche Innovation Center, Basel, Switzerland*

---

#### **Background:**

Sleep disturbances are a common comorbidity of individuals with autism. Sleep hygiene training and non-pharmacological interventions are often implemented as first-line therapies, with mixed evidence regarding their clinical efficacy. Commonly prescribed pharmacological interventions include melatonin and iron supplementation. Research has shown associations between sleep difficulties and the core symptoms of autism in children, suggesting that improving sleep could be an approach for the treatment of autism and other neurodevelopmental conditions. The impact of sleeping disorders on the clinical characteristics of autism has not been studied in a large cohort spanning a broad age range.

### Objectives:

To evaluate the demographics and longitudinal performance on anxiety and sleep-related scales in a cohort of individuals with autism with/without comorbid sleeping disorders and/or melatonin treatment.

### Methods:

oRBiting (NCT03611075) is a non-interventional, longitudinal study of participants with autism with an intelligence quotient (IQ)  $\geq 50$ , Clinical Global Impression-Severity scale  $\geq 4$  and CY-BOCS-ASD total score  $\geq 12$ . Demographics, comorbidities and trajectories of sleep and anxiety-related clinical scales (Pittsburgh Sleep Quality Index [PSQI] global score, Children's Sleep Habits Questionnaire [CSHQ] total score, Beck Anxiety Inventory score [BAI] and Hamilton Rating Scale for Anxiety [HAM-A]) measured at Week 2 and Week 12 were compared in: (1) those with versus without comorbid sleeping disorders; (2) those receiving melatonin or melatonin agonists versus those not receiving these treatments; and (3) those with sleeping disorders with versus without treatment with melatonin or melatonin agonists.

### Results:

In total, 95 participants with autism aged 5–36 years were evaluated. Based on descriptive analyses, there were no differences in the demographics and comorbidity profiles between individuals with autism with sleeping disorders versus those without. Among those with sleeping disorders ( $n=23$ , 24%), trajectories of sleep-related scales (CSHQ and PSQI) were stable; trajectories remained stable in those with a sleeping disorder receiving treatment with melatonin or melatonin agonists ( $n=16$ ). Higher baseline levels of anxiety, as indicated by mean (SD) HAM-A score, were observed among individuals receiving melatonin or melatonin agonists ( $n=18$ ) compared with non-melatonin users ( $n=77$ ; 16 [8] vs 10 [8], respectively). This was followed by a steady decline in anxiety over time. No differences between these groups were observed on the BAI scale. However, in participants with sleeping disorders, mean (SD) baseline HAM-A and BAI scores were lower for those receiving melatonin or melatonin agonists ( $n=16$ ) compared with non-melatonin users ( $n=7$ ; HAM-A: 12 [4] vs 21 [13], respectively; BAI: 17 [13] vs 19 [16], respectively). HAM-A and BAI trajectories were also more stable for those with sleeping disorders receiving melatonin versus non-melatonin users.

### Conclusions:

In this observational study, the prevalence of sleep comorbidities was lower than previous reports. While there were no clear differences in demographic characteristics between those with/without sleeping disorders, baseline anxiety levels were lower with a more stable trajectory for those with sleeping disorders receiving melatonin treatment versus non-melatonin users. Statistical analyses will be conducted to contextualize these descriptive results and will lead to improved understanding of the impact of sleeping disorders and their therapeutic management in people with autism.

### 519.128 (Virtual Poster) Pubertal Timing and Tempo in Females and Males with Autism Spectrum Disorder Compared to Typically Developing Youth

**B. A. Corbett<sup>1</sup>, R. A. Muscatello<sup>1</sup>, A. Kim<sup>2</sup>, S. Vandekar<sup>2</sup>, S. Duffus<sup>3</sup> and Y. Tanguturi<sup>2</sup>,** (1)Psychiatry and Behavioral Sciences, Vanderbilt University Medical Center, Nashville, TN, (2)Department of Biostatistics, Vanderbilt University Medical Center, Nashville, TN, (3)Vanderbilt University Medical Center, Nashville, TN

Background: Autism spectrum disorder (ASD) is characterized by impaired social communication and poor adaptation to change; thus, pubertal development may be precarious. Puberty refers to biological maturation leading to significant cognitive, emotional, and physiological changes. Research has shown that pubertal timing, involving the onset of secondary sexual characteristics, generally provides a more robust explanation for the physical and psychosocial changes that occur during adolescence than chronological age. Pubertal tempo refers to how rapidly or slowly an individual progresses from the onset of puberty until full sexual maturation. Differences in the timing and tempo of puberty can have significant psychological, social and physiological consequences.

Objectives: The purpose of the current study was to examine interindividual differences in pubertal timing and tempo in a large sample of early-to-middle adolescents at two time points, one year apart based on biological sex (female vs. male) and group (ASD vs. TD).

Methods: Pubertal timing and tempo were measured in 244 youth with ASD ( $N=140$ ) and typical development ( $N=104$ ). Pubertal development was measured using Tanner Staging of Genital (G, males), Breast (B, females) and Pubic Hair (PH) in both sexes at Time 1 (10-13-years) and Time 2 (11-14-years). A nonlinear mixed effects model (NLME) was used to fit Tanner stage (G/B or PH stage) as a function of covariates using a sigmoid model.

Results: Interindividual differences in timing and tempo were analyzed using nonlinear mixed effects models. For both sexes, ASD and higher Body Mass Index (BMI) were associated with earlier pubertal timing. Males generally exhibited faster tempo than females. Specifically, the results for males showed that diagnosis and BMI are strong predictors of genital stage such that males with ASD enter puberty 4.9 months earlier than TD

males. For females, the results corroborate previous findings of advanced pubertal onset in females with ASD. Breast development showed a nearly 9-month difference in onset for females on the autism spectrum compared to TD peers.

**Conclusions:** To our knowledge, this is the first study examining pubertal tempo in youth with ASD and among only a few rigorously examining tempo in TD participants. Findings showing advanced and faster pubertal maturation in ASD youth suggest greater risk of psychological, social, and physiological challenges due to their lack of preparedness for the increased demands of adolescence. The initial findings underscore the importance of considering timing and tempo in adolescents with and without ASD.

**519.129 (Virtual Poster) Sleep Problems in Autism: Sex Differences in the School-Age Population**

**A. M. Estes<sup>1</sup>, J. Munson<sup>2</sup>, T. St. John<sup>3</sup>, R. Finlayson<sup>4</sup>, J. Pandey<sup>5</sup>, B. Gottlieb<sup>6</sup>, J. D. Herrington<sup>5</sup> and R. T. Schultz<sup>5</sup>,** (1)Speech and Hearing Sciences, University of Washington, Seattle, WA, (2)Psychiatry & Behavioral Sciences, University of Washington, Seattle, WA, (3)University of Washington, Seattle, WA, (4)College of Education, University of Washington, Seattle, WA, (5)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (6)Children's Hospital of Philadelphia, Philadelphia, PA

---

**Background:** Clinically significant sleep problems are highly prevalent in autism spectrum disorder (ASD); affecting from 45-86% of this population in school-age. Sleep problems can negatively impact child cognition, behavior, and health. In typical development, sleep problems decrease sharply from 4-7 years of age, so sleep problems in the school-age period may be particularly salient. In typical development, sex differences in sleep have been noted as early as 6 months of age and continue to be observed through adolescence. Two recent studies of large databases with wide age-ranges suggest that sex differences may also be evident in sleep problems in ASD (Angell et al 2021; Sara & Smith, 2020). However, very little is known about sex differences in the prevalence and type of sleep problems in ASD or about how sex differences in sleep problems may manifest during school-age.

**Objectives:** To evaluate sex differences in parent-reported sleep problems in ASD and TD school-age children.

**Methods:** Parents reported sleep problems on the Children's Sleep Habits Questionnaire (Owens, 2000) and examiners conducted assessments to establish diagnosis and intellectual ability in 6-12-year-old children (ASD n=260; TD n=114). Participants were recruited and procedures were IRB approved and conducted at the Children's Hospital of Philadelphia.

**Results:** 84.4% of the ASD female group demonstrated sleep problems compared to 65.8% of ASD males, 44.8% of TD females, and 42.4% of TD males. Linear regression models revealed a significant group by sex interaction, with the ASD female group demonstrating the highest level of sleep problems ( $p=0.047$ ). Intellectual ability was not related to sleep problems in this sample. ASD females demonstrated more difficulty than TD females across all CSHQ sleep problem subtypes except sleep disordered breathing and more difficulty than ASD males in bedtime resistance, sleep duration, sleep anxiety, and sleepiness. Future analyses will evaluate potential mediators of these relationships.

**Conclusions:** Sleep problems were highly prevalent in 6-12 year old ASD females. The pattern of sex differences in sleep problems (ASD female > ASD male > TD female = TD male) suggests a disorder-specific effect of sex on sleep problems. This is one of the first studies to evaluate sex differences in sleep in ASD utilizing a standard measure of sleep and direct assessment of ASD. Sleep problems that have not resolved by school-age may have high clinical significance. Current assessment and intervention practices may benefit from increased attention to sleep problems in ASD females to reduce negative impacts on behavior and health. Future studies are needed to evaluate contributors to sleep problems in ASD females.

**519.130 (Virtual Poster) Impact of Associated Co-Morbidities in Autism Spectrum Disorder**

**S. Gulati<sup>1</sup>, S. Sharma<sup>2</sup>, S. R. Chowdhury<sup>3</sup>, A. Wander<sup>4</sup>, S. Singh<sup>1</sup>, G. Kamila<sup>4</sup>, K. Purkayastha<sup>5</sup>, A. K. Meena<sup>4</sup>, P. K. Choudhary<sup>3</sup>, S. Khan<sup>2</sup>, A. Bhattacharyya<sup>3</sup>, R. Tiwari<sup>3</sup>, A. Chaudhary<sup>3</sup>, A. Rath<sup>3</sup>, S. Ojha<sup>2</sup> and M. Aakash<sup>1</sup>,** (1)Centre of Excellence and Advanced Research for Childhood Neurodevelopmental Disorders, Child Neurology Division, Department of Pediatrics, All India Institute of Medical Sciences, New Delhi, India, (2)Child Neurology Division, Department of Pediatrics, All India Institute of Medical Sciences, New Delhi, New Delhi, India, (3)All India Institute of Medical Sciences, New Delhi, India, (4)All India Institute of Medical Sciences, New Delhi, New Delhi, India, (5)Child Neurology Division, All India Institute of Medical Sciences, New Delhi, India

---

**Background:** Current standard management of Autism Spectrum Disorder (ASD) targets its core features and management of co-morbidities. The co-morbidities associated with ASD affect quality of life of these children. It is to be seen how these comorbidities affect response to applied behavioural analysis (ABA), the standard behavioural therapy as measured by childhood autism rating scale (CARS).

**Objectives:** To study the prevalence of comorbidities in Indian children with ASD and how it affects the response to standard therapy, as measured by CARS

**Methods:** Children aged 2-18 years, with ASD (DSM 5 criteria) from January 2017 to March 2021 were enrolled in the study after obtaining parental consent. These children were followed in Autism clinic at 1-3 monthly intervals. Detailed history from parents was obtained using a standard clinical proforma. Further evaluation for symptom severity and behavioral co-morbidities was done by performing Childhood Autism Rating Scale (CARS), Autism Behavior Checklist (ABC), and Childhood Behaviour Check List (CBCL) at baseline as well as on follow up visits. Children were provided ABA and medications as required. If the child had epilepsy or suspicion of ESES (n=122), sleep EEG was performed. Screening for Fragile X syndrome, Rett syndrome, chromosomal microarray, and next-generation sequencing was performed when suspected. Children were categorised according to the comorbidity noted at baseline, prospectively followed and their outcomes at 6 months were compared.

## Results:

A total of 1551 children with ASD (1310 boys, median age of 4.8 years with IQR 3.2-7 years) were enrolled. Proportion of children with comorbidity was 80% (1255/1551). Attention deficit hyperactivity disorder (ADHD) was the most common comorbidity (57.55%), followed by global developmental delay/intellectual disability (GDD/ID), sleep disturbances and epilepsy which were found in 55.58%, 47.29% and 12% of the children respectively. Learning disability was higher in females ( $p=0.013$ ). The comorbidities associated with higher CARS score at baseline were feeding disorder ( $p=0.02$ ) and disruptive behaviour ( $p=0.008$ ).

A subset of 1273 children with complete follow up records were analysed. Overall, when compared to baseline, children showed significant decrease in mean CARS score at 6 months (37.17 vs 33.88,  $p < 0.000$ ). Response to ABA was better in younger children with decrease in CARS maximum in 2-5 years (3.06,  $p < 0.000$ ) and least in those aged 15 years and above (1.44,  $p < 0.000$ ). Both males and females showed response to ABA with mean decrease in CARS score being -3.30 ( $p < 0.000$ ) and -3.23 ( $p < 0.000$ ) respectively. All the children with or without comorbidity showed decrease in mean CARS score, with differences in scores being -3.41 ( $p < 0.000$ ) and -2.74 ( $p < 0.000$ ) respectively post therapy.

Children categorised in different groups based on their associated comorbidity showed decrease in post therapy CARS score. Difference of mean CARS score (post therapy -pre therapy) amongst those with epilepsy (-3.18,  $p < 0.000$ ), sleep disturbance (-3.73,  $p < 0.000$ ), mood disorder/depression (-2.40,  $p = 0.0004$ ), ADHD (-3.63,  $p < 0.000$ ), GDD/ID (-3.01,  $p < 0.000$ ) were significant.

**Conclusions:** The burden of comorbidity in children with ASD is high. Once we manage the children holistically, presence of comorbidities does not affect ultimate response to ABA therapy significantly.

### **519.131 (Virtual Poster)** Prevalence of Sleep Problems in Preschool Children with Neurodevelopmental Disorders and Correlation with Behavioral or Serum Ferritin in Community Surveys

**A. Terui<sup>1</sup>, M. Saito<sup>1</sup>, A. Kuki<sup>2</sup>, Y. Sakamoto<sup>1</sup>, T. Mikami<sup>3</sup>, A. Osato<sup>3</sup> and K. Nakamura<sup>3</sup>,** (1)Department of Neuropsychiatry, Graduate School of Medicine, Hirosaki University, Hirosaki, Japan, (2)Hirosaki University, Hirosaki, Japan, (3)Research Center for Child Mental Development, Graduate School of Medicine, Hirosaki University, Hirosaki, Japan

**Background:** It has been reported that children with neurodevelopmental disorders (NDDs) have more sleep problems than children with typical development (TD) (Johansson et al, 2018). Decreased serum ferritin is known to be associated with restless legs syndrome, one of the common sleep problems.

**Objectives:** To estimate the prevalence of sleep problems in preschool children (5-year-old children) with NDDs including TD children in community surveys, and to clarify the effects of sleep problems on behavioral aspects and the relationship with serum ferritin levels.

**Methods:** We included 2336 children who participated in the health check-up for children aged 5 years in City A in the 2018-2019 year. We used the total score and subscale scores of the JSQP (Japanese Children's Sleep Questionnaire) to assess sleep and the SDQ (Children's Strengths and Difficulties Questionnaire) to assess behavior. We defined children with a JSQP score  $\geq 86$  as having sleep problems. The children were screened for developmental characteristics and diagnosed using the DSM-5 and grouped into TD ( $n=1890$ ), ASD ( $n=115$ ), ADHD without ASD ( $n=93$ ), other developmental disorders (Other DD) ( $n=103$ ) and Unknown ( $n=115$ ). In addition, the diagnosis of ASD was confirmed by ADOS-2. We excluded the Unknown group and included 2201 children in our analysis. We measured serum ferritin using the CLEIA method in 180 subjects who consented to a blood test. We used the  $\chi^2$  test, the Kruskal-Wallis test and multiple regression analysis for statistical analysis.

**Results:** The prevalence of sleep problems was 14.8% in the TD group, 50.4% in the ASD group and 39.8% in the ADHD group (Fig.1). The ASD and ADHD groups had significantly more sleep problems than the TD and Other DD groups. Restless legs syndrome (movement), Obstructive Sleep Apnea Syndrome, Parasomnias, Insomnia/Circadian rhythm disorders, Morning symptoms, Excessive daytime sleepiness and Daytime behavior were significantly higher in the ASD and ADHD groups than in the other groups. In terms of behavior, there was a significant positive correlation between the JSQP total score and the SDQ total score in the ASD group ( $\beta=.575$ ,  $R^2=.229$ ). The ASD group also showed a significant association with SDQ subscale scores or total scores in several of the JSQP subscale scores, suggesting that there may be an association between sleep problems and problematic behavior compared to other developmental disorders. Serum ferritin levels (mean 22.8 ng/ml) were not significantly different between the diagnostic groups, but parasomnias and serum ferritin levels showed a significant positive correlation ( $\beta=.550$ ,  $R^2=.310$ ).

**Conclusions:** Japanese 5 years old children with ASD and ADHD have more sleep problems than children with TD and Other DD. In particular, sleep problems in ASD children may be related to their daily activities and serum ferritin levels, and these need to be examined comprehensively. One part of parasomnias is known to be associated with neurological diseases. Neurological diseases may lead to high ferritin levels. The results of this study may help us to consider the pathogenesis of parasomnias and sleep problems.

### **519.132 (Virtual Poster)** Sleep Patterns in Hospitalized Children with Autism Vary By Age and Pubertal Status

**B. J. Taylor<sup>1,2</sup>, C. F. Reynolds<sup>1,3</sup>, C. Peura<sup>4</sup> and M. Siegel<sup>1,4,5,6</sup>,** (1)Center for Psychiatric Research, Maine Medical Center Research Institute, Portland, ME, (2)Psychiatry, Tufts School of Medicine, Boston, MA, (3)Psychiatry, University of Pittsburgh School of Medicine, Pittsburgh, PA, (4)Spring Harbor Hospital, Westbrook, ME, (5)Psychiatry, Tufts School of Medicine, Boston, ME, (6)The Glickman Lauder Center of Excellence in Autism and Developmental Disorders, Portland, ME

**Background:**

Sleep problems are common and detrimental for youth with autism spectrum disorder (ASD). In non-ASD youth, age- and puberty-related changes in circadian rhythms cause a shift toward “night owl” tendencies, typified by later bed and wake times. Due to early school start times, sleep/wake timing often shifts considerably between school and weekend nights, similar to moving across several time zones every week and is referred to as social jetlag. Despite the relevance of sleep for behavioral functioning in youth with ASD, the developmental course of sleep has not been examined in this population.

#### Objectives:

The primary aims of this study are to evaluate: 1) age and puberty associations with sleep and 2) the moderating role of demographic and clinical characteristics.

#### Methods:

Participants were 147 psychiatrically hospitalized children with ADOS-2 confirmed ASD, ages 5.1-20.6 (mean age=12.6±3.5 years old), 85% (N=125) male, 90.5% (N=133) white, 36.7% (N=54) minimally-verbal, 49.7% (N=73) with intellectual disability, 53.1% (N=78) with comorbid ADHD, 47.6% (N=70) with a comorbid anxiety disorder, and 19% (N=28) with a comorbid mood disorder. Following hospital admission, caregivers completed a pubertal-development rating-scale and provided information to calculate: sleep duration on school and weekend days, sleep midpoint (i.e., halfway between bedtimes and wake times) on school and weekend days, and social jetlag (i.e., the difference in sleep midpoint between school and weekend days). To control for Type I Error, we used a generalized linear multivariate model with Bonferroni adjustment for pairwise comparisons. Covariates and moderators included sex, race, non-verbal IQ, ASD severity, verbal ability, and comorbid psychiatric diagnoses.

#### Results:

In fully adjusted models, older age was associated with later sleep midpoint on weekends ( $F=9.60$ ,  $p=0.002$ ) and more social jetlag ( $F=8.94$ ,  $p=0.003$ ). Significant age by race interactions revealed that these associations were only significant for white children ( $F=4.76$ ,  $p=0.031$  and  $F=5.79$ ,  $p=0.017$ , for weekend sleep midpoint and social jetlag, respectively). Older age was associated with shorter sleep duration on school days ( $F=5.56$ ,  $p=0.02$ ) and weekends ( $F=9.26$ ,  $p=0.003$ ) for non-white children only. Associations between age and sleep also varied between children with and without a mood disorder. The positive association between age and sleep midpoint on weekends was significant only for children without mood disorders ( $F=5.02$ ,  $p=0.027$ ). Older age was associated with later school day sleep midpoints for children without mood disorders and earlier sleep midpoints for children with mood disorders ( $F=4.87$ ,  $p=0.029$ ). Finally, older age was associated with longer sleep duration on weekends for children with a comorbid mood disorder ( $F=4.41$ ,  $p=0.038$ ). Sleep midpoint on weekends was on average  $65.5\pm22.0$  minutes later for children who were in late-puberty relative to those who were pre-pubertal ( $F=2.82$ ,  $p=0.03$ ). Cell sizes for pubertal stage categories were insufficient to run moderation analyses.

#### Conclusions:

Sleep timing may follow the developmental trajectory seen in non-ASD youth. More racially diverse samples are needed to understand if non-white children with ASD experience different age-related changes in sleep and large prospective studies are needed to evaluate within-person changes in sleep and if developmental trajectories vary by descriptive characteristics or indices of clinical severity.

#### **519.133** (Virtual Poster) Seizure Events and Abnormal Epileptiform Activity Reports in People Carrying CHD8 Genetic Variants

**Y. K. Kim<sup>1</sup>, M. L. Krenzer<sup>2</sup>, K. Hazzard<sup>3</sup> and R. A. Muhle<sup>4</sup>,** (1)New York State Psychiatric Institute, New York, NY, (2)Psychiatry, Yale University, New Haven, CT, (3)Barnard University, New York, NY, (4)Psychiatry, Columbia University, New York, NY

#### Background:

Exome sequencing studies have shown that likely gene damaging (LGD) mutations in CHD8 are highly associated with autism spectrum disorder (ASD). People harboring LGD mutations in CHD8 may have additional disorders that are co-morbid with ASD, including intellectual disability, anxiety, and attention deficit hyperactivity disorder. Additional neurological complications such as epilepsy can be particularly disruptive to quality of life, but the current literature describing the clinical phenotype of people carrying CHD8 mutations is lacking a comprehensive overview of the association of CHD8 LGD mutations with seizures and abnormal EEG that may predispose for epilepsy.

#### Objectives:

Survey current literature and databases for cases describing the clinical phenotype of CHD8 variants and to examine the prevalence of reported seizures and abnormal epileptiform activity.

#### Methods:

We reviewed the literature and publicly available databases for reported CHD8 variants (Pubmed; n=243, denovo-db; n=40, ClinVar; n=249, gnomAD; n=2545). Papers were manually curated for CHD8 variants and cases were annotated to indicate the cDNA and protein changes in CHD8 caused by the variant, the affected protein domain, the reported sex of the carrier, mode of inheritance, and clinical phenotyping information. The cases were filtered to remove duplicate reports, copy number variants, and non-exonic variants, as well as splice-site variants more than 10 base pairs from the nearest exon.

## Results:

We found 1392 reported variants in CHD8 exons and splice sites (Pubmed, n=180; denovo-db, n=24; ClinVar, n=189; gnomAD, n=999) from our literature and database survey. Of these, 16 studies described additional phenotypic information (corresponding to 115 cases) and were further screened for reports of seizures and/or abnormal EEG tests. Seizure/abnormal EEG events were reported in 14 phenotyped cases (12%). In this group, there was a 2.5: 1 male:female ratio, and all cases were reported to have ASD or intellectual disability (ID), with 71.4% reporting co-morbid ASD and ID. All of the variants carried by cases in this subgroup were LGD mutations (single nucleotide variants, n=12 and splice-site variants, n=2). An additional 6 CHD8 variant carriers were reported to have seizures and/or abnormal EEGs in the ClinVar database (3.2% of ClinVar reported variants in CHD8), and one missense mutation in CHD8 was found via targeted sequencing after Sudden Unexplained Death in Epilepsy (SUDEP).

## Conclusions:

Published reports describing people who harbor CHD8 variants are highly variable in the extent of clinical phenotyping and are particularly variable in reporting seizures and abnormal EEGs. The finding of seizure/abnormal EEG reports in 14% of phenotyped cases is likely an underestimate, as none of the studies performed additional testing to document brain activity over an extended period, and there are no longitudinal studies to determine the incidence of epilepsy with increasing age. Future studies focusing on the evolution of seizures and abnormal epileptiform events in people carrying CHD8 variants are needed to fill this gap in literature. These studies would help elucidate which specific variants have higher risk for seizure/abnormal EEG and give additional insight to design preclinical models and studies to improve treatment of CHD8-related seizures and abnormal epileptiform activity.

### 519.134 (Virtual Poster) Characteristics of Children Diagnosed with Late Childhood Autism Spectrum Disorder

**E. Zilbershot Fink<sup>1</sup>, H. Nagar Shimon<sup>2</sup>, R. Orbach<sup>3</sup>, H. Cohen<sup>4</sup>, A. Avinir<sup>4</sup> and Y. Leitner<sup>4</sup>, (1)Maarot Autism Center, Child Development, Tel Aviv Souraski Medical Center, Tel Aviv, Israel, (2)Child Development, Marrot Autism Center/Ichilov Hospital, Tel Aviv, Israel, (3)Child Development, Tel Aviv Souraski Medical Center, Tel Aviv, Israel, (4)Tel Aviv Souraski Medical Center, Tel Aviv, Israel**

**Background:** We hereby describe our preliminary results of the data analysis of a unique group of school-aged children with prolonged difficulties in social communication functions referred to our autism and social communication difficulties center at a tertiary hospital in Israel. Our clinic serves mostly children within the normal range of intelligence, learning in the regular education system.

**Objectives:** We aimed to describe the characteristics of those children eventually diagnosed with autism spectrum disorder.

**Methods:** In total, 172 children were included (80% males, mean age 10.6+- 3.3 years), most of them ( 88%) with a history of developmental difficulties. After a multi- disciplinary evaluation, 35% were eventually diagnosed with ASD. The ADOS score (9.25 vs. 5.32, p<0.001) AND the CAST score (16.9 vs 14.85, p=0.04) correlated with the clinical diagnosis of autism according to the DSM 5.

**Results:** We did not find an association of perinatal data, early developmental interventions, or comorbid ADHD and anxiety with the diagnosis of autism. A trend was found for the association of autism in family relatives with the diagnosis of ASD in the referred child (17.4% vs. 6.1%,p=0.056). Sensory difficulties showed a second trend with the diagnosis of ASD (83% vs.68%, p=0.057).

**Conclusions:** We did not identify significant anamnestic features associated with the eventual diagnosis of late childhood ASD in this specific group of children. Further studies are needed to seek surrogate markers to guide clinicians with the diagnostic evaluation in these children.

Arora<sup>5</sup>, A. Falk<sup>6,7</sup>, C. O. Daub<sup>8,9</sup>, I. Lanekoff<sup>8</sup> and K. Tammimies<sup>1,2,3</sup>, (1)Center for Neurodevelopmental Disorders at Karolinska Institutet (KIND), Department of Women's and Children's Health, Karolinska Institutet, Stockholm, Sweden, (2)Astrid Lindgren Children's Hospital, Karolinska University Hospital, Region Stockholm, Stockholm, Sweden, (3)Center for Psychiatry Research, Region Stockholm, Stockholm, Sweden, (4)Department of Chemistry - BMC, Uppsala University, Uppsala, Sweden, (5)Department of Environmental Medicine and Public Health, Icahn School of Medicine at Mount Sinai, New York, NY, (6)Department of Neuroscience, Karolinska Institutet, Stockholm, Sweden, (7)Lund Stem Cell Center, Division of Neurobiology, Department of Experimental Medical Science, Lund University, Lund, Sweden, (8)Department of Biosciences and Nutrition, Karolinska Institutet, Stockholm, Sweden, (9)Science for Life Laboratory, Stockholm, Sweden**

**Background:** Autism spectrum disorder (ASD) is a heterogenous childhood developmental disorder with multifactorial aetiology. There are hundreds of genes and genetic variants that contribute to ASD. Additionally, several environmental factors, such as neurotoxic compounds, endocrine

modulators, neuropsychiatric medication, and environmental pollutants, have been associated with ASD outcomes. There is a lack of studies in human neurons showing the effects of environmental factors. Here, we investigate a high-throughput experimental design to study multiple environmental risk factors and human induced pluripotent stem cell (iPSC) lines in context of ASD.

**Objectives:** We aim to (1) establish the fractional factorial experiment design for the *in-vitro* study of extrinsic risk factors in context of different genetic backgrounds, (2) perform transcriptomic profiling of the effects of six adverse environmental conditions associated with ASD in iPSC derived early neurons, and (3) validate the identified transcriptomic pathway-based changes using a multi-omics approach.

**Methods:** iPSC lines from two neurotypical donors (male and female) and two male donors with ASD and associated rare genetic conditions were included. The iPSC-derived neuroepithelial stem cells were differentiated into pre-mature neurons for five days. The culture conditions were modulated with a combination of six ASD associated environmental risk factors (lead, bisphenol A, ethanol, valproic acid, fluoxetine and zinc deficiency) in accordance with a fractional factorial experiment design (L8 Orthogonal Array). Transcriptomic changes were identified with bulk RNA sequencing followed by differential gene expression analysis and gene-set enrichment analysis. Significantly modulated pathways for all environmental factors, jointly and independently, were visualized using EnrichmentMap. Validation of relevant changes in the identified pathways were done using direct infusion electrospray ionisation mass spectrometry.

**Results:** Significantly expressed genes were identified in early neurons exposed to lead and fluoxetine. For lead, significant upregulation was detected in pathways related to synapse structure/activity ( $q=0.0192$ ), and axon guidance ( $q=0.0196$ ). For fluoxetine, significant upregulation was observed in pathways related to steroid biosynthesis ( $q=0.0036$ ). Significant downregulation was seen in pathways related to axonemal dynein assembly ( $q=0.0150$ ). In our joint analysis across different exposures, the converging (with at least two contributing factors) top gene-ontology terms upregulated were steroid/phospholipid metabolism, synaptic vesicle priming and cholinergic neurotransmission, and downregulated was microtubule formation. Subset analysis of pathway effects in ASD and neurotypical cell lines separately revealed more changes for single factors in ASD cell lines than in neurotypical cell lines but less converging changes across the environmental exposures. The validation of the findings using metabolomics is on-going and preliminary results have confirmed the changes in lipid metabolism after fluoxetine exposure.

**Conclusions:** Our research aims to elucidate the effects of environmental exposures at neuronal level and their connection to genetic background. We have shown that the fractional factorial design can be used for high-throughput transcriptomic analysis to detect relevant changes at the pathway level. We have also shown that lead and fluoxetine respectively modulate pathways related to synaptic function and lipid metabolism. However, the changes are more coherent in the cell lines without genetic predisposition for ASD. Further studies are needed to understand the role of these findings in ASD.

### **306.002 (Oral)** Thyroid Hormone Therapy in the Differentiation of Neural Progenitor Cells into Cortical Neurons: Potential Contribution to Autism Spectrum Disorders

**S. Salloum-Asfar<sup>1</sup>, K. C. Shin<sup>2</sup>, R. Taha<sup>3</sup>, A. K. Elsayed<sup>4</sup>, N. T. Swaidan<sup>5</sup>, S. Khattak<sup>5</sup>, Y. Park<sup>2</sup> and S. A. Abdulla<sup>1</sup>,** (1)Qatar Biomedical Research Institute (QBRI), HBKU, Qatar Foundation, Doha, Qatar, (2)Neurological Disorders Research Center, Qatar Biomedical Research Institute, Hamad Bin Khalifa University, Qatar Foundation, Doha, Qatar, (3)Neurological Disorders Research Center, Qatar Biomedical Research Institute (QBRI), Hamad Bin Khalifa University (HBKU), Education City, Qatar Foundation (QF), Doha, Qatar, (4)Neurological Disorders Research Center, Qatar Biomedical Research Institute, Hamad Bin Khalifa University, Qatar Foundation,, Doha, Qatar, (5)Royal College of Surgeons in Ireland, Bahrain, Bahrain

**Background:** Thyroid hormone (T3) is crucial for brain development and during the first years of life. Irregularities in T3 can affect behaviors, the nervous system functioning and cognitive development. In our ASD-IDRP-QBRI cohort (Qatar), we observed that mothers of ASD children have thyroid irregularities (hypothyroidism) being treated with T3 at high dose throughout their pregnancy.

**Objectives:** To investigate the role of T3-treatment (in hypothyroidism) in the functionality and neuronal development and explore how it influences neural cell development using neural precursor cells (CRTD5-NPCs) and cortical differentiated neurons.

**Methods:** Cytotoxicity was performed before and after exposure to 10 different T3 gradient concentrations (10nM - 1000nM). The time course study consisted of 4 points of analysis: week 0 (W0), which represented NPCs after 5 days of T3-treatment, and differentiated cortical neurons measured at weeks 3 (W3), 6 (W6) and 8 (W8). Each time frame was performed in triplicates and included respective controls. BrainPhys™ Neuronal Culture Medium was used to differentiate CRTD5-NPCs to cortical neurons. To assess neuronal function, voltage-gated Ca<sup>2+</sup> channels (VGCCs) and whole-cell patch clamp electrophysiology were used. IHC staining was used to detect mature neuron markers: MAP2, NeuN and phosphorylated-neurofilament-H. RNA-seq was performed for the molecular profiling of cortical neurons with high T3-treatment and controls. MitoTracker dye was used to assess mitochondrial presence within neurons.

**Results:** VGCCs results showed that starting from W3, cells differentiated to neurons and responded to KCL stimulus. However, readings obtained at W3 and W6 on cells subjected to high T3-treatment, showed a lower response, from neurons, to KCL. However, at W8, a higher quantity of neurons responded compared to controls, suggesting that these neurons, under high T3-treatment, may have matured at a faster rate compared to controls. The patch clamp results further showed that the percentage of neurons generating multiple action potentials increases as neurons differentiate, suggesting that CRTD5-derived cortical neurons physiologically mature and functional over time. Starting from W6, the high T3-treatment significantly increased the percentage of neurons generating action potentials compared to their respective control. Moreover, the frequency of action potentials increases significantly in neurons under high T3-treatment at W6 (from 5 to 7) and W8 (from 5 to 10) differentiated neurons,  $p=0.03$  and  $p=0.03$ , respectively. Additionally, the peak increase and the intervals shorten significantly in W6 neurons by 50% ( $p<0.01$ ), suggesting that both expression of voltage-gated Na and K channels increase because of high T3 doses. In W8 neurons, T3-treatment causes no changes in the peak and interval, suggesting that it is saturated, and T3-treatment advances the cortical neuronal differentiation. IHC staining showed that the expression of neuronal markers was present. Whole transcriptome showed that ion receptor pathways are upregulated in W8.

**Conclusions:** High T3-treatments might increase neuronal maturity and be considered to be a model of ADHD, main comorbidity in ASD. The results further open areas of investigation that involve the effect of unregulated T3-treatments during pregnancy, its influence on the dopaminergic system, and its association with neuronal tonic spikes and dopamine release on the outcome of learning and motor function.

**306.003 (Oral)** Uncovering Novel Neuroimmune Mechanisms Regulating Brain Overgrowth in Autism Using Human Pluripotent Stem Cells

---

Background:

Approximately 15-20% of individuals with Autism Spectrum Disorder (ASD) have disproportionate megalencephaly (ASD-DM), with disproportionate enlargement in both gray and white matter volume. Individuals with ASD-DM have more severe behavioral and cognitive problems and are less responsive to standard therapeutic interventions, leading to very poor prognoses relative to individuals with ASD and normal head circumferences. Increases in brain size often precede clinical symptoms, suggesting that understanding the underlying mechanisms regulating brain overgrowth could provide a window of opportunity for intervention or mitigation of symptoms.

Objectives:

Here, we use human induced pluripotent stem cell (hiPSC) technology to model brain overgrowth in ASD-DM and investigate the underlying cellular and molecular mechanisms involved. The overarching goals are: 1) to investigate whether gray and white matter enlargement are due to an increase in cell proliferation, increase in cell survival, improper elimination of damaged cells, and/or a combination of all; and 2) to identify therapeutic targets by understanding the underlying cellular and signaling mechanisms involved.

Methods:

As part of the UC Davis MIND Institute Autism Phenome Project (APP) and Autism Centers of Excellence (ACE), we generated ~30 human iPSCs from cohorts of children (2-4 years old) with complete clinical and phenotypic data, including A) ASD subjects with megalencephaly, ASD-DM; B) ASD subjects with normal sized brains, ASD-N; C) Typically developing (TD) subjects with megalencephaly, TD-DM; and D) TD subjects with normal sized brains, TD-N. We differentiated each of the iPSC lines into neural progenitor cells (NPCs) and oligodendrocyte progenitor cells (OPCs) and investigated changes at the molecular and cellular levels and alterations in phagocytosis in *in vitro* and *in vivo* models.

Results:

In the differentiated neural and glial progenitor cells, we observe increased proliferation and suppressed phagocytosis of NPCs/OPCs by macrophages in ASD-DM. RNA-sequencing of the differentiated progenitor cells reveals important signaling mechanisms related to the neuroimmune system in regulating cell survival, including the type 1 interferon signaling pathway. We also show that CD99 (a marker commonly upregulated on the surfaces of leukemic stem cells) and CD99 Molecule Like 2 (CD99-L2) are significantly upregulated in ASD-DM. Similarly, in genetic models of autism associated with brain enlargement, we have shown that proteins commonly associated with cancer (e.g. CD47, a 'don't eat me' signal) are overexpressed in unhealthy NPCs and OPCs in 16p11.2 deletion carriers with macrocephaly contributing to reduced phagocytosis *in vitro* and *in vivo*. Treatment of 16p11.2 deletion NPCs and OPCs with an anti-CD47 antibody to block CD47 restores phagocytosis to control levels.

Conclusions:

While CD47 and CD99 are commonly implicated in cancer progression, we document novel roles for these genes in regulating brain overgrowth in psychiatric disorders and identify new targets for therapeutic intervention. We demonstrate that anti-CD47 treatment (potentially in combination with antibodies against CD99) can act as therapeutic agents for clearing unhealthy cells in cellular and mouse models, potentially indicating that these forms of therapy could be translated to selected autistic individuals with brain overgrowth early in the disease.

---

Background:

Cortical surface area hyper-expansion in infancy prior to diagnosis has been associated with increased risk for autism spectrum disorder (ASD) (Hazlett et al., 2017). Increased cortical progenitor neurogenic fate decisions during fetal development may lead to decreased cortical surface area by depleting the progenitor pool as predicted by the radial unit hypothesis (Rakic, 2009). Induced pluripotent stem cell (iPSC) derived human brain organoids model cortical progenitors on an individual's genetic background, but have known limitations in maturation, fidelity, and reproducibility (Bhaduri et al., 2020). It remains unknown if inter-individual variability in organoid progenitors correlate with infant brain growth and clinical outcomes of the individuals from which they were derived.

#### Objectives:

We generated iPSC lines from participants in the Infant Brain Imaging Study (IBIS) at low familial risk for ASD, high familial risk without ASD, and high familial risk with ASD at 2 years old. Using organoid differentiations from 18 unique participants with representation from each group, this study aims to identify *in vitro-in vivo* correlations regardless of diagnosis, and if no correlation exists, identify possible technical factors that mask biological effects.

#### Methods:

iPSCs were generated from IBIS participants with at least 2 MR images at 6, 12, or 24 months of age and reprogrammed using a non-integrating Sendia virus into 3 clones. All experiments and analyses were performed blind to participant data and batches were randomized across diagnostic status before experiments began. Our organoid differentiation protocol generates neuroepithelial buds by differentiation day 14, and can produce cortical wall-like organization. Organoids were harvested at day 14 and day 84. One organoid per clone per participant was processed for scRNA-seq and all organoids were randomized again before barcoding. Three to five organoids were imaged for expression of PAX6 (cortical progenitors), N-Cadherin (tight junctions), Ki-67 (proliferation) and To-PRO-3 (nuclei).

#### Results:

Sixty-six cell lines were harvested at day 14, and forty-three cell lines at day 84, representing all 18 participants at both timepoints. 3-D images were used to quantify N-Cadherin+ lumens and PAX6+ germinal zone-like areas. A preliminary analysis of scRNA-seq data from a subset of 8 participants suggests that day 14 organoids contain predominately *EMX2*+ cortical neuronal progenitors, their *DCX*+ neuronal progeny, and some off-target midbrain cells. Using RNA velocity estimates of future cell states based on mRNA expression, progenitors were predicted to be undergoing self-renewal or neurogenic fate decisions (Lange et al., 2020). Neurogenic fate decisions were negatively correlated with cortical surface area size at 24 months of age ( $r=0.49$ , when controlling for sex  $p=0.002$ ).

Conclusions: Preliminary analyses suggests that organoid-derived early progenitor populations favor neurogenic fate decisions in participants with smaller cortical surface areas. This agrees with the radial unit hypothesis that postulates increased neurogenesis reduces the progenitor pools resulting in decreased cortical surface area. Imaging analysis will add support if participants with smaller cortical surface area have decreased germinal-zone-like areas. Our current analyses require replicate due to small sample size, but future analysis including all 18 participants will enable more rigorous hypothesis testing in *in vitro-in vivo* correlations.

## POSTER SESSION — MOLECULAR AND CELLULAR BIOLOGY

### 404 - Molecular and Cellular Biology

#### 404.080 (Poster) Characterizing the Impact of TBR1 De Novo Mutations on in Vitro Human Brain Development

A. B. Mar<sup>1</sup>, B. A. DeRosa<sup>1</sup>, R. M. Mulqueen<sup>1</sup>, D. Krenik<sup>1</sup>, M. Co<sup>1</sup>, A. Nishida<sup>1</sup>, A. C. Adey<sup>1,2</sup> and B. J. O'Roak<sup>1</sup>, (1)Molecular and Medical Genetics, Oregon Health & Science University, Portland, OR, (2)Knight Cardiovascular Institute, Oregon Health & Science University, Portland, OR

Background: The *in vitro* differentiation of forebrain-like organoids from induced pluripotent stem cells (iPSCs) has been shown to recapitulate many processes that occur during *in vivo* midfetal cortical development. This midfetal period is a potential critical window when many autism risk genes begin to function as a network, especially in deep layer neurons. However, our understanding of how specific *de novo* mutations (DNMs) impact brain development is limited.

Objectives: Here, we perform an intensive genomic characterization of these forebrain-like organoid models using immunohistochemistry (IHC) and single-cell genomics, and utilize this system to understand the effects of DNMs in *TBR1*, a key transcriptional regulator of deep layer neuronal fate.

Methods: Using CRISPR-Cas9, isogenic pairs of a control iPSC line were edited to contain DNMs in *TBR1*. Forebrain-like organoids were generated over 90 days *in vitro* (Qian et al. 2018, StemCell Technologies Dorsal Forebrain Organoid Kit). IHC was utilized to characterize the cell-types and quality of each differentiation. Dynamic changes in epigenetic state during organoid differentiation were assessed using single-cell combinatorial indexing (sci) ATAC-seq (Mulqueen et al. 2019). Single-cell profiles were collapsed into groups using cisTopic then analyzed for enrichment of specific transcription factor binding motifs. Pseudotemporal analysis was performed to uncover the succession of putative transcription factor activity.

**Results:** To establish protocol reproducibility and to test epigenome correlation to primary samples of neurodevelopment, we first performed IHC and single-cell ATAC-seq on a control iPSC line. From the sci-ATAC assays, we obtained 31,280 cells with 183,391 open regions of chromatin passing quality control from 16 organoids (two independent organoid differentiations). Across differentiation time points, we observed clear shifts in cell-type populations and epigenomic reconfiguration consistent with waves of transcriptional regulatory activity controlling differentiation and neurogenesis. Leveraging new publicly available data sets on primary fetal tissue, we observed correlating chromatin signatures of cell cycle stages and improved our differentiation trajectory through chromatin dynamics of differentiation. Using the same control line, we are currently generating forebrain-like organoids with two well-established organoid protocols. We are comparing between the two protocols, which have different *in vitro* time scales, the trajectory of development, reproducibility, and robustness of organoid formation. These data will be used to select the optimum method for modeling *TBR1* DNMs. We have generated multiple isogenic pairs with and without *de novo* autism-associated *TBR1* frameshift mutation, A136PfsX. Data from the analogous mutation generated in mouse suggests this is a loss-of-function mutation. With these lines, we are conducting the same organoid differentiation and single-cell characterization, which will be evaluated prior to the meeting.

**Conclusions:** *In vitro* modeling allows us to manipulate the cellular genome and study the impact of specific DNMs on early human brain development. Our data on control lines demonstrates these models recapitulate the transcriptional waves of activity that are key controllers of cell-fate during corticogenesis. We believe this system will be a powerful model for discovering the molecular and cellular impacts of autism-associated DNMs, specifically in transcriptional regulators like *TBR1*.

#### Background:

Growing evidence reported an abnormal expression of Human Endogenous Retroviruses (HERVs) within Autism Spectrum Disorder (ASD). HERVs are genetic elements derived from their exogenous retroviral counterpart by a process of germline infection and proliferation within the human genome. Our previous works showed that ASD children and their mothers share abnormal expression of HERV families (HERV-H) and cytokines (TNF- $\alpha$ , IFN- $\gamma$ , IL-10) suggesting a close mother-child association in ASD and supporting the hypothesis of an interplay between HERVs and the innate immune response in autism. Increasing evidence pointed out the relationship between maternal conditions of inflammation – including Perinatal Depression (PD) - and derailed developmental trajectories in offspring, highlighting the role of inflammation and immune response in ASD pathogenesis.

#### Objectives:

Given research attention for the possible involvement of HERVs in psychiatric disorders' etiopathogenesis and based on our previous findings, we aimed to evaluate HERVs' activity and the inflammatory profile (IL-10, TNF $\alpha$ , IFN $\gamma$ ) of mother-child pairs according to both maternal and child diagnosis: presence or absence of maternal Perinatal Depression (PD or NO-PD); presence or absence of ASD diagnosis in offspring (ASD or NO-ASD).

#### Methods:

A total of 58 mother-child pairs were enrolled:

-9 mothers (median age 43 years) with a history of PD and their respective 11 children (median age 5 years) of which 3 NO-ASD (males), 8 ASD (2 females, 6 males);

-21 mothers (median age 44) without Perinatal Depression (NO-PD) and their 21 children with typical development (median age 5.1; 5 females, 16 males);

-28 mothers (median age 43) without PD (NO-PD) and their 31 ASD children (median age 5; 3 females 28 males).

Expression of HERV-H, HERV-K, HERV-W, IL-10, TNF $\alpha$  and IFN $\gamma$  was evaluated in peripheral blood mononuclear cells by quantitative Real-time PCR.

#### Results:

PD women and their offspring shared a specific transcriptional profile with higher HERVs' (HERV-H, HERV-K) and cytokines levels (TNF- $\alpha$ ) in comparison to NO-PD mother-child pairs (Fig.A). Only in offspring of PD women was also observed a higher levels HERV-W and IL-10. Considering PD (Fig.B-C), women with ASD children presented higher levels of HERVs (HERV-H, HERV-W) in comparison to PD women with No ASD children. The comparison between women with and without PD who had ASD children, showed similar levels of HERV-H, HERV-K,

IL10; while higher of HERV-W and TNF $\alpha$ , and lower of INF $\gamma$  have been found in PD women. ASD children of PD women presented higher values of HERV-H, HERV-K, HERV-W, IL10, TNF  $\alpha$ . Among ASD children - of mothers affected or not by PD- , higher levels HERV-H, HERV-K, HERV-W, emerged in offspring of PD women.

#### Conclusions:

Although preliminary, our findings report that specific transcriptional profiles emerged both in terms of maternal PD and ASD condition in offspring and that, at a biological level, PD may represent a possible detrimental factor leading to a more abnormal transcriptional profile in both mothers and their ASD offspring. The investigation of HERVs re-activation in PD represents a possible pathway for the future identification of a molecular signature of psychiatric conditions.

#### 404.082 (Poster) The Intellectual Disability Gene DDX3X in Sex-Specific Neuronal Morphogenesis

Background: DDX3X syndrome is a rare form of intellectual disability caused by mutations in the *DDX3X* gene. Most *DDX3X* mutations are *de novo*, lead to haploinsufficiency, and are found only in females. The few mutations found in males are inherited from healthy mothers. *DDX3X* regulates mRNA translation, but the mechanisms of action in neurons, the target genes, and the impact of clinical mutations have not been studied yet. Also, the influence of sex remains unknown.

Objectives: Our goal is to: 1) capture sex-specific neuronal changes resulting from mutations in *DDX3X*; 2) map the molecular mechanisms underlying *DDX3X* syndrome to identify new therapeutic targets.

Methods: We generated a mouse with loxP sites around exon 2 of *Ddx3x* (*Ddx3x<sup>lox</sup>* mice). Using this model, we generated male (*Ddx3x<sup>lox/y</sup>*) and female (*Ddx3x<sup>lox/+</sup>*) cortical neurons and transfected them with Cre and mCherry constructs. With this strategy, we can model *Ddx3x*-haploinsufficient female neurons or *Ddx3x*-null male neurons (and respective controls). We also introduced sex-specific mutations in female and male neurons, after manipulating *Ddx3x* dosage. We then examined morphogenesis, synaptogenesis, *DDX3X* targets and interactors, translation of specific mRNAs.

Results: *DDX3X* contributes to sex differences in neuronal morphogenesis. Sex-specific *DDX3X* mutations have differential impact, with female-pathogenic mutations being more severe. Indeed, *Ddx3x* loss differently affect neuronal morphology towards a more simplified dendritic arbor in females and males. Moreover, female pathogenic mutations completely disrupt neuronal morphology, while male pathogenic mutations cause a milder phenotype. In addition, the lack of *Ddx3x* also affects spine density in males but not in females, supporting a sex-specific role for *DDX3X* in regulating neuronal development.

Conclusions: Our data lay the bases to understand the sex biases in the prevalence and severity of *DDX3X* syndrome. A deeper insight on the molecular mechanisms underlying this sex difference will also shed the light for more personalized treatment for girls and boys.

## Sensory, Motor, and Repetitive Behaviors and Interests

### PANEL — SENSORY, MOTOR, AND REPETITIVE BEHAVIORS AND INTERESTS

#### 212 - Where Do Motor Impairments Fit within the Broader Framework of Autism Spectrum Disorder (ASD) and What Is Their Value in Screening/Diagnosis and in Predicting Future Outcomes?

**Panel Chair:** Anjana Bhat, Department of Physical Therapy, University of Delaware, Newark, DE

**Discussant:** Catherine Lord, UCLA Semel Institute for Neuroscience and Human Behavior, Los Angeles, CA

**212.001 (Panel)** Persistent Barriers to Motor Assessment and Intervention, Despite Early Caregiver Awareness of Motor Symptoms.

H. L. Miller<sup>1</sup>, N. E. Fears<sup>2</sup>, A. Luna-Smith<sup>3</sup>, S. Mupparapu<sup>3</sup>, A. Ganesh<sup>3</sup>, K. Martinez<sup>3</sup>, G. M. Sherrod<sup>4</sup> and N. L. Bugnariu<sup>5</sup>, (1)School of Kinesiology, University of Michigan, Ann Arbor, MI, (2)School of Kinesiology, University of Michigan, Ann Arbor, MI, (3)University of North Texas Health Science Center, Fort Worth, TX, (4)Department of Psychology, University of Alabama at Birmingham, Birmingham, AL, (5)University of the Pacific, Sacramento, CA

Background: Motor symptoms of autism are not formally evaluated as part of the diagnostic process, and are only partially captured by autism-specific assessments in the context of stereotyped motor behaviors. Despite this, a growing body of literature suggests that both gross- and fine-motor

problems are evident and clinically-significant in autism across the lifespan. These include postural instability, difficulty with handwriting, and challenges with activities of daily living. Some autistic people are assessed for motor problems because of the line of service through which they enter the diagnostic pipeline, for example, pediatric neurology. Severe motor problems often warrant a co-occurring diagnosis of Developmental Coordination Disorder (DCD). However, caregivers and clinicians do not consistently recognize motor problems as early signs related to autism. As a result, there is a striking lack of uniformity in the manner by which families access motor assessment and corresponding accommodations and interventions, particularly in comparison to behavioral and social-communication symptoms.

**Objectives:** To characterize caregivers' and self-advocates' understanding of the relationship between motor symptoms and autism.

**Methods:** We administered a service utilization questionnaire to a racially- and ethnically-diverse sample of 100 caregivers and autistic adults ( $M_{age} = 42.67$ ,  $SD = 9.86$ ,  $Range = 20-70$  years), and subsequently interviewed 49 families (caregivers and autistic adults) about their experiences with the diagnostic process and their awareness of motor symptoms. Interviews were transcribed and we conducted a qualitative analysis, extracting key concepts using thematic analysis. We then used this information to contextualize the results of the survey and assess relationships between caregivers' and autistic adults' knowledge, experiences, and perceived barriers to care for motor problems.

**Results:** Preliminary results suggest that most participants were aware of the presence and functional impact of motor symptoms. Caregivers expressed difficulty knowing whether the motor symptoms they observed were "worth bringing up" to clinicians, versus part of development. They noted early differences in gait, manual dexterity and handwriting, balance, and coordination. Pediatricians, occupational therapists, and neurologists were most often reported as lines of service where motor symptoms were discussed or addressed; but caregivers often reported that clinicians "dismissed" or "glossed over" motor concerns. Almost unanimously, caregivers reported that no one had discussed risk of falls or injury with them.

**Conclusions:** Taken in context with prior work, the results of this study suggest that while some caregivers identify motor symptoms early in their autistic children, many do not recognize that they are related to autism. This may be in part because they are not a standard component of the diagnostic process, despite high observed rates of clinically-significant motor problems in our studies of autism and others. We discuss these new results as they relate to our recent finding that over 90% of children with autism meet the diagnostic criteria for DCD. Finally, we discuss how this information can be used to inform attempts to create more uniform processes for assessment of motor development in autism, identification of motor problems across the lifespan, and the development and provision of appropriate accommodations and interventions that serve person-centered goals.

#### **212.002 (Panel) Value of the Developmental Coordination Disorder Questionnaire (DCD-Q) As a Screener for Co-Occurring Motor Problems in Children with Autism Spectrum Disorder**

**T. Van Damme**, *Department of Rehabilitation Sciences, Research group Adapted Physical Activity and Psychomotor Rehabilitation, KU Leuven, Leuven, Belgium; Child Psychiatry, Expertise center Autism, UPC Z.Org KU Leuven, Leuven, Belgium*

---

**Background:** Most children with autism spectrum disorder (ASD) demonstrate motor problems, but the prevalence rates tend to differ depending on the instruments and cut-off points being used. Moreover, the impact of co-occurrence with other neurodevelopmental disorders, such as intellectual disability or ADHD, is rarely considered. Due to the high occurrence rates and the fact that motor problems are easily overlooked and often remain underdiagnosed, it has been recommended to include motor assessment as part of the routine clinical investigation of children with ASD. However, there is also a subset of children with ASD who do not demonstrate motor problems. In these cases, a comprehensive motor assessment is time-consuming, expensive, and redundant; especially since the procedures can put a substantial burden on the child as they can be challenging and can cause significant stress. Therefore, screening for motor problems can provide valuable information to guide the decision whether referral to a full motor assessment is required.

**Objectives:** In this presentation, I will discuss the sensitivity and specificity of the DCD-Q screening tool to identifying/rule out true motor impairments in a large number of children with Autism Spectrum Disorder.

**Methods:** Children referred to the Expertise Center for Autism (Leuven, Belgium), receive an extensive multidisciplinary diagnostic assessment protocol, allowing a rigorous examination of each developmental domain. A comprehensive motor assessment battery is included in the standard assessment procedure.

**Results:** We will present data on the prevalence, severity, and heterogeneity of motor problems of children referred to our center (>300 children), across a full range of cognitive abilities. Furthermore, we will present data on the precision of the Developmental Coordination Disorder Questionnaire (DCDQ) as a screening tool for co-occurring motor problems in children with ASD. Lastly, we will outline the agreement in classification between the results on a standardized motor assessment battery, a parent-based screening questionnaire (DCDQ), and clinical decision making.

**Conclusions:** There is a high prevalence of motor problems in children with ASD. However, the high levels of heterogeneity in motor profiles and the existing subset of children with ASD without motor problems, suggest that motor impairment should be considered as a specifier within the diagnostic criteria for ASD in the DSM-V.

#### **212.003 (Panel) Motor Impairment Relates to Social Communication Impairment More Than Repetitive Behavior Severity in School-Age Children with Autism Spectrum Disorder (ASD): A SPARK Dataset Analysis.**

**A. N. Bhat**, *Department of Physical Therapy, University of Delaware, Newark, DE*

---

**Background:** Eighty-seven percent of a large sample of children with Autism Spectrum Disorder (ASD) from the SPARK study cohort are at risk for motor impairment based on their performance on the Developmental Coordination Disorder Questionnaire (DCD-Q) (Bhat, 2020). Moreover, motor impairments were associated with both core social communication impairments and repetitive behaviors as well as general delays in cognition, language, and functioning (Bhat, 2021). In spite of the high prevalence for motor impairment in children with ASD, it is not considered among the diagnostic criteria or specifiers within DSM-V. Motor impairments in school-age children with ASD remain under-recognized and unaddressed due to lack of effective motor screening, assessment, and intervention.

**Objectives:** In this presentation, I will describe data from the Vineland Adaptive Behavioral Scales (VABS-3) and relate it to other core and co-morbid impairments using other standardized measures, to better understand how motor impairments in children with ASD fit within the broader diagnostic framework of ASD.

**Methods:** The SPARK study dataset (N=4,257) was analyzed to examine associations between multiple developmental domains (social, communication, daily living, and motor) of the Vineland Adaptive Behavior Scales, Third Edition (VABS-3), social communication impairment using the Social Communication Questionnaire (SCQ), repetitive behavior severity using the Repetitive Behaviors Scale – Revised (RBS-R), motor impairment using the Developmental Coordination Disorder Questionnaire (DCD-Q), and parent-reported current level of cognitive, functional, and language impairments (i.e., some being ASD specifiers).

**Results:** In terms of the VABS-3 dataset, children's overall adaptive functioning based on the Adaptive Behavior Composite (ABC) standard scores were moderately associated with social communication performance ( $r=-0.45$ , using the SCQ total) and motor performance scores ( $r=0.5$ , using the DCD-Q total) and weakly correlated with repetitive behavior severity ( $r=-0.2$ , using the RBS-R total). Children's VABS communication, daily living, and socialization scores were also moderately associated with social communication performance ( $r=-0.38$  to  $-0.48$ , using the SCQ total) and motor performance scores ( $r=0.42$  to  $0.48$ , using the DCD-Q total) and weakly associated with RB severity ( $r=-0.15$  to  $-0.21$ , using the RBS-R total). In terms of gross-motor performance, "control during movement/gross motor" totals on DCD-Q were associated with personal care subdomain of VABS daily living skills ( $r=0.44$ ). In terms of fine-motor performance, fine motor total scores on DCD-Q were moderately associated with the communication domain ( $r=0.51$ ) and related VABS subdomain scores (receptive, expressive, and written,  $r=0.45$  to  $0.48$ ). Once again, various VABS subdomain scores weakly correlated with RB severity ( $r=-0.1$  to  $-0.26$ ).

**Conclusions:** These findings provide evidence for linkages between motor and social communication functioning in children with ASD and opens up the possibility of including motor problems as part of ASD criteria. It is important to facilitate early motor development and its cascading effects on social communication development through appropriate motor screening and assessment. Timely evaluations and motor intervention referrals could help improve the plateaued and persistent motor and social communication deficits observed in the school-age children with ASD from the current study.

#### **212.004 (Panel) Unique Motor Differences in ASD and Their Structural and Functional Neurological Basis**

**L. aziz-Zadeh**, USC Mrs. T.H. Chan Division of Occupational Science and Occupational Therapy, USC, Los Angeles, CA; USC Mrs. T.H. Chan Division of Occupational Science and Occupational Therapy; Psychology, University of Southern California, Los Angeles, CA; Brain and Creativity Institute, Dornsife College of Letters, Arts and Sciences, University of Southern California, Los Angeles, CA

---

**Background:** Most motor studies of ASD compare with typically developing (TD) groups and indicate motor deficits in ~80% of the ASD group. However, for motor measures to characterize and facilitate diagnosis of ASD, it is critical to discriminate between ASD and developmental motor differences that occur independently of ASD, such as developmental coordination disorder (DCD). Few prior studies have compared ASD to DCD, with equivocal findings. Thus, we conducted behavioral and brain imaging studies comparing ASD, DCD, and TD groups. To further distinguish ASD from DCD, we applied machine learning (ML) to kinematic data from an iPad game, which has previously classified TD from ASD with ~93% accuracy.

**Objectives:** Define unique motor differences in ASD, their neurobiological basis, and their relationship with social functioning.

**Methods:** We compared youth aged 8-17 years with ASD to those with DCD or TD youth in behavioral ( $Ns = 33$  ASD, 28 DCD, 35 TD), ML ( $Ns = 18$  ASD, 16 DCD, 20 TD), fMRI ( $Ns = 30$  ASD, 23 DCD, 33 TD), and DWI ( $Ns = 22$  ASD, 16 DCD, 22 TD) studies. Assessments included motor (MABC-2) and praxis (FAB-M) abilities, social skills (SRS-2), alexithymia (low emotional awareness), and theory of mind (ToM; NEPSY-II) skills. ML was used to classify groups using kinematic feature data (e.g., gesture acceleration) from a 5-min iPad coloring game. During fMRI, children performed hand and face action observation and execution tasks.

**Results:** Imitation of meaningful gestures (on FAB-M) was the only motor or praxis measure that distinguished ASD from DCD ( $p<.05$ ; ASD significantly worse), with or without controlling for FSIQ, SRS-2, ToM, age, and sex. Further, classification accuracies derived from iPad motor data were: 76% ASD from TD, 71% ASD from DCD, and 78% DCD from TD. fMRI data indicated that the IFG was hypoactive during action observation in ASD, and during imitation in both ASD and DCD. DWI data further showed that the underlying motor (and/or social) deficits in ASD may derive from structural connectivity patterns. We found diffusion differences in the ASD group in the cingulum, compared to both TD and DCD groups, which significantly correlated with motor (MABC), social (SRS-2), alexithymia, and autism severity (ADI-R). Further we found that the ASD group alone showed differences in quantitative anisotropy (QA) compared to TD in the inferior fronto-occipital fasciculus (IFOF), a ventral pathway important for connecting visual body-form processing with frontal areas (e.g., IFG), and IFOF integrity is significantly correlated with autism severity (ADOS) as well as a trend with praxis and motor ability. These fMRI and DWI differences may underlie some of the unique motor (and social) deficits observed in ASD.

Conclusions: These findings indicate unique motor differences in the ASD group (imitation of meaningful gestures, control of acceleration and distance of actions) compared to other neuro-developmental motor disorders, which could be used for screening. Underlying neurological markers may include hypoactivity in the IFG, and diffusivity differences in the cingulum and IFOF. These motor and related neurological differences may assist with ASD characterization, and screening/diagnosis.

## PANEL — SENSORY, MOTOR, AND REPETITIVE BEHAVIORS AND INTERESTS

### 217 - Utilizing Sensory Phenotypes to Understand Sensory Processing Abilities in Autism

**Panel Chair:** Nichole Scheerer, *Psychology, Western University, London, ON, Canada*

**Discussant:** Ryan Stevenson, *University of Western Ontario, London, ON, Canada*

#### 217.001 (Panel) Utilisation of Sensory Subtyping to Understand Functional Impacts and Intervention Responsiveness in Autism

A. E. Lane<sup>1</sup>, D. Blackwell<sup>2</sup>, J. Brent<sup>3</sup>, G. Easey<sup>3</sup>, L. Rowlandson<sup>3</sup>, T. Johnson<sup>3</sup>, R. Lange<sup>4</sup>, U. Schall<sup>5</sup>, L. E. Campbell<sup>5</sup> and S. J. Lane<sup>6</sup>, (1)Olga Tennison Autism Research Centre, La Trobe University, Melbourne, VIC, Australia, (2)La Trobe University, Melbourne, VIC, Australia, (3)University of Newcastle, Callaghan, NSW, Australia, (4)University of Newcastle, Newcastle, NSW, Australia, (5)School of Psychology, University of Newcastle, Newcastle, Australia, (6)Occupational Therapy, Colorado State University, Fort Collins, CO

Background: Phenotyping based on meaningful clinical features has been proposed as a method by which the significant diversity of needs associated with autism can be better understood (Beversdorf et al. 2016). Substantial progress has been made in this area with relation to sensory features. To date, there are seven published proposed models of sensory subtypes, all of which have identified distinct patterns of sensory features within autistic toddlers, children and adolescents (Lane, 2021). Significantly, the work completed to date indicates a high degree of congruence between sensory subtype models suggesting that variation across the autism spectrum may be productively examined using a sensory lens. Importantly, insights into sensory subtype may promote the understanding of likely functional impacts and intervention responsiveness which will inform customised support approaches.

Objectives: The objectives of this presentation are to: 1) summarise what is known from the extant literature about functional impacts and intervention responsiveness as a function of sensory subtype in autism; and 2) report preliminary findings from new work examining responsiveness to the Alert Program for self-regulation by school-aged autistic children with varying sensory subtype profiles.

Methods: 1) A narrative review of the literature examining the relationship of sensory subtype to functional impacts and intervention responsiveness will be conducted and reported. 2) Participants were autistic children (n=19; mean age=9.4 years; females=7) with sensory features and an IQ>70. All participants and their caregivers completed the Alert Program in a clinic setting with a trained, registered occupational therapist in individual sessions over 10 weeks. Prior to the intervention, caregivers identified two self-regulation goals relating to daily activities utilising Goal Attainment Scaling and completed questionnaires regarding adaptive behaviour, sensory features, anxiety and parent effort and stress. Follow up ratings were completed at the conclusion of the intervention. At baseline, all participants were profiled using the sensory subtyping model developed by Lane and colleagues (2014) using the Short Sensory Profile (McIntosh et al. 2001). Each participant was assigned a sensory reactivity score and a sensory integration score using Lane et al.'s (2014) algorithm.

Results: Paired sample t-tests indicate that all participants regardless of sensory subtype benefited from the intervention through: improved daily self-regulation behaviours (p=0.001), reduced overall anxiety (p=0.001) and reduced parent effort at home (p=0.04). Elevated sensory reactivity at baseline, however, was associated with less reduction in generalised anxiety (rho=0.35) and less improvement in adaptive behaviour (rho=0.55). Conversely, difficulties with sensory integration at baseline were associated with more reduction in parent effort at home (rho=-0.33) versus the community (rho=0.54), and greater reduction in generalised anxiety (rho=-0.3).

Conclusions: Sensory subtype models are well-established in the autism literature, however, confirmation of their utility in understanding both functional impacts and intervention responsiveness is required. Preliminary data from our group indicates that sensory subtype may be associated with the level and nature of gains made in response to the Alert Program for self-regulation.

#### 217.002 (Panel) Cluster Analysis Reveals Sensory Phenotypes Associated with Specific Genetic Profiles in Autism Spectrum Disorder

A. M. Lyons-Warren<sup>1</sup> and Y. W. Wan<sup>2</sup>, (1)Pediatrics, Baylor College of Medicine, Houston, TX, (2)Molecular and Human Genetics, Baylor College of Medicine, Houston, TX

Background: The diagnostic criteria for Autism spectrum disorder (ASD) include unusual interest in sensory aspects of the environment or demonstrating hyper or hypo reactivity to sensory input. Indeed, up to 94% of patients with ASD exhibit symptoms in at least one sensory modality. However, individual sensory phenotypes are heterogeneous and the relationship between which sensory areas will be affected remains unknown. Prior studies have proposed sensory profiles as a distinguishing feature to better categorize ASD subtypes, but have not correlated these groups with genetic features.

Objectives: To test if sensory subtypes within ASD are associated with unique genetic profiles.

**Methods:** Short Sensory Profile (SSP) and whole genome sequencing data from 378 individuals with ASD were obtained from Autism Speaks' MSSNG database. We performed cluster analysis on responses to all 38 questions, followed by a second cluster analysis using only a subset of questions selected specifically to assay hyper- and hypo-sensitivity to sensory stimulation. Cross-comparison of the resulting clusters characterized the final subgroups. To test for shared underlying etiologies, we correlated gene variant frequency across subgroups for each of 24,896 genes. Gene variant frequency (GVF) combined all single nucleotide variants with a CADD score greater than 15 within each gene. To be significantly associated with a subgroup, a gene variant frequency had to be greater than four standard deviations (SD) from the mean frequency for all subgroups and 3 SD different from each subgroup.

**Results:** We identified six distinct sensory-based subgroups characterized by (1) atypical sensory responses in all areas, (2) typical responses in all areas, (3) isolated differences in tactile and auditory responses, (4) hyposensitivity in tactile and auditory responses, (5) isolated differences in taste and auditory responses and (6) mixed. There was no difference in mean age, adaptive behavior score, socialization score or full-scale IQ between subgroups.

The mean GVF for all genes across all individuals was 8.44%. Most genes had a low GVF, with the mean GVF at 2SD being only 27%. The mean GVF for each *subgroup* was less than 10% (range 7.0% - 9.9%) indicating that for more than half of the genes, less than 10% of participants in each subgroup had a variant. However, each of the subgroups was associated with a small number of genes ranging from 5 to 58 genes per subgroup.

**Conclusions:** Sensory features can reliably be used to generate clinically distinct subgroups within a heterogeneous population of individuals with ASD. Further, these subgroups correlate with specific genetic profiles that may provide clues to underlying molecular mechanisms leading to those sensory-phenotypes.

**217.003 (Panel) Sensory Profiles of Children on the Autism Spectrum: A Six Year Longitudinal Study**

**K. Simpson<sup>1</sup>, M. Stainer<sup>2</sup> and D. Adams<sup>3</sup>, (1)Autism CRC, Brisbane, QLD, Australia, (2)School of Applied Psychology, Griffith University, Gold Coast, QLD, Australia, (3)Autism Centre of Excellence, Griffith University, Brisbane, Australia**

---

**Background:** Children on the autism spectrum are reported to display heightened differences in their response to sensory information. Previous cluster analysis has identified heterogeneity in children's responses and mixed responses based on age, however, little is known about an individual's profile development over time.

**Objectives:** To explore the sensory profile patterns of children on the autism spectrum across a six-year period using the Short Sensory Profile 2 (SSP-2).

**Methods:** Two groups of children on the autism spectrum (4-5 years, n= 130; 9-10 years, N = 140) were followed across four time points, over a six-year period. At each time point, caregivers completed the SSP-2. Group z-scores were compared for each subdomain (avoiding, sensitivity, seeking, registration) in the two age groups. Latent profile analysis was used to identify profiles at each time point.

**Results:** Parents of children in the younger group reported heightened differing responses on the four domains. The number of best fit profiles varied across the time period (between 4-6) and there was a high degree of movement between these profiles. Children in the older group were also reported to have heightened differing responses across the four domains but there was a decreasing trend in these differences over time. There was also a more consistent cluster profile of four profiles generated.

**Conclusions:** The difference in profiles between age groups, and the movement between profiles, particularly evident in the younger cohort, suggests an individual's profile may change over time. Awareness changes may occur in an individual's sensory profiles has important implications for practitioners supporting the sensory needs of children on the autism spectrum.

**217.004 (Panel) Exploring Sensory Phenotypes in Autism Spectrum Disorder and Attention-Deficit / Hyperactivity Disorder**

**N. E. Scheerer<sup>1</sup>, A. Pourtousi<sup>2</sup>, C. Yang<sup>3</sup>, B. Stojanoski<sup>4</sup>, E. Anagnostou<sup>5</sup>, R. Nicolson<sup>6</sup>, E. Kelley<sup>5</sup>, S. Georgiades<sup>6</sup>, J. Crosbie<sup>7</sup>, R. Schachar<sup>8</sup>, X. Liu<sup>9</sup> and R. A. Stevenson<sup>9</sup>, (1)Psychology, Western University, London, ON, Canada, (2)Western University, London, ON, Canada, (3)Autism Research Centre, Bloorview Research Institute, Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (4)Department of Psychiatry, University of Western Ontario, London, ON, Canada, (5)Department of Psychology, Queen's University, Kingston, ON, Canada, (6)McMaster Autism Research Team, McMaster University, Hamilton, ON, Canada, (7)Department of Psychiatry, The Hospital for Sick Children, Toronto, ON, Canada, (8)Genomics, Queen's Genomics Lab at Osgowada, Kingston, ON, Canada, (9)University of Western Ontario, London, ON, Canada**

---

**Background:**

Atypical reactions to the sensory environment are often reported by both autistic individuals and individuals with attention-deficit/hyperactivity disorder (ADHD). These sensory difficulties are highly heterogeneous, varying across individuals and sensory modalities. Recently, researchers have identified stable sensory phenotypes, or sensory processing patterns that reliably co-occur within autistic individuals, that can help parse this sensory heterogeneity. These phenotypes have not been investigated in individuals with ADHD. Given autism and ADHD share many diagnostic features, a better understanding of sensory processing differences across these groups may improve differential diagnosis.

**Objectives:**

This research aimed to identify whether the sensory phenotypes that have been identified in autistic individuals are transdiagnostic in nature. To this end, we first aimed to identify sensory phenotypes in autistic individuals and individuals with ADHD. Next, we explored the similarity of these phenotypes. In addition, we examined whether these sensory phenotypes are differentially associated with autism-related characteristics, such as social communication difficulties and repetitive behaviours, and ADHD characteristics, such as inattention and hyperactivity.

#### Methods:

Short Sensory Profile data measuring sensory processing abilities across 7 domains (tactile, taste/smell, movement, underresponsive/sensory seeking, auditory filtering, low energy/weakness, and visual/auditory) was collected from parents of 495 autistic children and 461 children with ADHD between the ages of 1-21 years. Data were subjected to a K-means cluster analysis. Clustering involves grouping individuals with similar sensory processing abilities together in such a way that individuals in the same cluster have more similar sensory processing abilities to each other than individuals in other clusters. The resultant clusters can be thought of as sensory phenotypes. Follow up analyses compared age, IQ, sex assigned at birth, as well as autism and ADHD traits across the diagnostic groups, the resultant sensory phenotypes, and their interaction.

#### Results:

Overall, autistic children and children with ADHD demonstrated highly similar patterns of sensory processing abilities. A five-cluster solution characterized sensory processing abilities in both diagnostic samples (see Figure 1). The resultant sensory phenotypes are best described as sensory adaptive, generalized sensory differences, taste and smell sensitive, under-responsive and sensation seeking, and low energy with weakness. Age differed across these sensory phenotypes ( $p < .001$ ), but showed relatively similar patterns across diagnostic groups (see Figure 2). IQ was higher in the ADHD group, but did not differ across sensory phenotypes ( $p = .909$ ; see Figure 2). Sex assigned at birth did not differ across the sensory phenotypes, or diagnostic groups ( $p > .05$ ). Autism and ADHD traits differed across the five phenotypes ( $ps < .001$ ), but these patterns were very similar across the diagnostic groups (see Figure 2).

#### Conclusions:

Sensory difficulties in autistic individuals and individuals with ADHD can be clustered into sensory phenotypes, representing a meaningful transdiagnostic way to parse the heterogeneity in sensory abilities. These sensory phenotypes are associated with unique behavioural/clinical profiles. Given that these sensory phenotypes do not differ in IQ, these results suggest that sensory abilities may provide a novel, meaningful way to understand behavioural heterogeneity in autism and ADHD. Further, these results suggest that transdiagnostic etiologies may underlie sensory abilities in these groups.

## ORAL SESSION - 11A — SENSORY, MOTOR, AND REPETITIVE BEHAVIORS AND INTERESTS

### 317 - Sensory, Motor, and Repetitive Behaviors and Interests

#### **317.001** (Oral) The Sensory Observation Autism Rating Scale (SOAR): A New Measure of Early Sensory Behaviours in Autism

**K. L. Unwin**, A. A. Hussain, M. E. Chetcuti, J. Barbaro and A. E. Lane, Olga Tennison Autism Research Centre, La Trobe University, Melbourne, VIC, Australia

**Background:** Sensory symptoms are highly prevalent in autistic individuals, with previous research demonstrating that these symptoms negatively impact a range of outcomes including daily living skills, academic performance, and psychological wellness. It is vital that sensory difficulties are quantified as early and accurately as possible so that the necessary supports can be provided. However, sensory measures are typically designed for older children and are heavily reliant on parent report, introducing bias. Additionally, of the more objective observation measures available, many do not assess all sensory modalities of interest and importantly, they all require the administration of tasks within the observation. Assessments requiring administration of tasks are often inaccessible to children with attention or cooperation difficulties, along with increasing administration time and training costs, all of which limit useability. Therefore, the Sensory Observation Autism Rating Scale (SOAR) was created specifically for young autistic children, with all relevant modalities and without requiring the administration of tasks.

**Objectives:** To examine initial reliability and validity of the Sensory Observation Autism Rating Scale (SOAR).

**Methods:** Target behaviours to be assessed using SOAR were identified following a rigorous and systematic review of current validated measures and the literature. Further, a series of focus groups with autistic individuals and parents of autistic children ( $n=13$ ) were conducted to ensure the measure reflected autistic experience. SOAR items assess behaviours across six sensory modalities (auditory, tactile, visual, oral/gustatory, proprioceptive and vestibular) combined into three subscales (hyper-responsivity, hypo-responsivity, and sensory seeking, e.g. “peering at an unusual angle” – Visual-Seeking code). Five-minute video recordings of 105 age- and gender-matched autistic and developmentally delayed children (aged 13-36 months; 38 female) were coded retrospectively using SOAR by researchers blinded to diagnosis. The video recordings were of the free play session within Autism Diagnostic Observation Schedule-2 assessment. An additional 25% of the sample were coded by both researchers to investigate interrater reliability (IRR; Intraclass Correlations, ICC). Discriminant validity (autistic vs developmentally delayed children) was assessed using a series of MANOVAs (hyper-responsivity, hypo-responsivity and seeking behaviours).

Results: Excellent IRR was achieved ( $ICC=.83-.93$ ,  $p<.001$ ) across the frequency and duration of hyper-responsivity, hypo-responsivity and seeking behaviours. Discriminant validity analyses demonstrated that SOAR scores differed between the two groups on the hyper-responsivity domain, with developmentally delayed children assessed as more hyper-responsive than autistic children ( $F(2, 99)=3.79$ ,  $p=.03$ ; Wilks'  $\Lambda = .93$ ; partial  $\omega^2 = .05$ ).

Conclusions: These preliminary indications of excellent interrater reliability and discriminant validity suggest that SOAR is a promising measure to assess early sensory behaviours in autistic children. Indeed, SOAR is the first measure to include a range of modalities, as well as not requiring the administration of tasks, suggesting its utility in a wide range of contexts including retrospective investigations of sensory profile. Additional analyses confirming and expanding these findings to other psychometric properties (e.g. internal consistency) is required. Following this, SOAR could be used by clinicians and researchers to fully characterise sensory behaviours in autistic children, and where appropriate, identify and implement supports.

**317.002 (Oral) Sensory Processing Subtypes in Young Children with ASD: Differences in ASD Symptomatology, Adaptive Skills, and Attentional Problems**

**G. Kadlaskar<sup>1</sup>, P. H. Mao<sup>2</sup>, A. M. Iosif<sup>3</sup>, D. G. Amaral<sup>4</sup>, S. J. Rogers<sup>5</sup>, C. W. Nordahl<sup>1</sup> and M. Miller<sup>1</sup>,** (1)Department of Psychiatry & Behavioral Sciences, University of California, Davis - M.I.N.D. Institute, Sacramento, CA, (2)UC Davis, Sacramento, CA, (3)Public Health Sciences, University of California Davis, Davis, CA, (4)Department of Psychiatry and Behavioral Sciences, The Medical Investigation of Neurodevelopmental Disorders (MIND) Institute, UC Davis School of Medicine, University of California Davis, Sacramento, CA, (5)Department of Psychiatry and Behavioral Sciences, University of California at Davis, Sacramento, CA

---

Background: High, but variable, prevalence rates of sensory differences are reported among individuals with autism spectrum disorder (ASD). Additionally, sensory differences have been associated with social and adaptive skills in ASD. However, our understanding of sensory profiles in ASD has been complicated due to the heterogeneity of sensory symptom presentation. One way to better understand this heterogeneity is to use statistical approaches that allow for the identification of more homogeneous sensory subtypes in otherwise heterogeneous groups.

Objectives: (1) Using Short Sensory Profile (SSP) subscale scores to identify homogenous subtypes of sensory processing in children with ASD based on both severity and modality, and (2) to examine whether sensory subtypes differ in terms of ASD symptomatology, adaptive skills, and attentional problems.

Methods: Participants included 211 children with ASD between 2-4 years of age. ASD diagnoses were confirmed using the Autism Diagnostic Observation Schedule-2 (ADOS-2) and Autism Diagnostic Interview-Revised (ADI-R) along with expert clinical judgment by a licensed clinical psychologist. Using latent profile analysis (LPA), we sought to identify distinct patterns of sensory profiles based on subscale SSP scores. Analysis controlling for age and nonverbal Developmental Quotient and accounting for multiple comparisons were then conducted to examine whether sensory subtypes differed in ASD symptomatology (ADOS-2 severity scores, Social Responsiveness Scale-2 [SRS-2] subscale and Total scores), adaptive skills (Vineland Adaptive Behavior Scale-2 [VABS-2] Socialization and Communication subscales), and attentional problems (Childhood Behavior Checklist [CBCL] Ages 1.5-5 attention and ADHD subscales).

Results: Based on the pattern of both severity and sensory modalities (Figure 1), the four subtypes identified by LPA were named Moderate/Mixed (35.5% i.e., probable-to-definite differences in all modalities except in MS and LEW), Severe/Broad (8.5% i.e., definite sensory differences in all modalities except in LEW), Moderate/Broad (14.6% i.e., probable-to-definite differences in all modalities), and Low/Mixed (41.1% i.e., typical scores in most modalities with only probable differences in TSS, USS, and AF). Subsequent analysis showed that the Severe/Broad subtype had greater ASD symptomatology and lower social skills compared to the remaining subtypes. Finally, the Moderate/Mixed, Severe/Broad, and Moderate/Broad subtypes showed higher levels of attentional problems and ADHD-related behaviors compared to the Low/Mixed group (Table 1).

Conclusions: We found evidence of distinct sensory subtypes in a sample of young children with ASD. While a subset of children with ASD displayed normative sensory-related behaviors, the majority showed a combination of both hypo- and hyper-reactivity to various types of sensory stimuli. The subtype characterized by Severe/Broad sensory differences exhibited greater problems in variety of areas such as social, adaptive, and attentional skills, whereas the Low/Mixed subtype showed overall fewer problems. Identification of homogenous subtypes may be useful for neurophysiological/imaging studies that aim to study underlying mechanisms linked with specific sensory patterns. These findings may also help clinicians identify children with greater differences in sensory processing, which might have a role in difficulties the child is having in social, adaptive, or attentional domains with potential implications for intervention.

**317.003 (Oral) Development of Restricted, Repetitive, Behaviors and Internalizing Symptom Outcomes in Longitudinal Study of Autism**  
**N. Masjedi<sup>1</sup>, E. B. Clarke<sup>2</sup> and C. Lord<sup>3</sup>,** (1)Psychiatry, UCLA, Los Angeles, CA, (2)CART, UCLA, Providence, CA, (3)UCLA Semel Institute for Neuroscience and Human Behavior, Los Angeles, CA

---

Background: Restrictive and repetitive behaviors (RRBs) are a core feature of autism spectrum disorder (ASD). Factor analyses of the Autism Diagnostic Interview, Revised (ADI-R) have identified Insistence on Sameness (IS) and Repetitive Sensorimotor (RSM) factors. (Richler, 2010). The literature suggests RSM and total RRBs decline with age while IS increase. (Bishop, 2013; Evans et al, 2006). However, there is little research examining RRB trajectories beyond mid-childhood. Additionally, prior work has found associations between IS and total RRBs and internalizing symptoms (Rodgers, 2012; Gotham, 2014; Lam, 2004), however, the connection between RRBs and internalizing in adulthood remains unexplored.

Objectives: Investigate trajectories of raw ADI-R current RRB, RSM, and IS scores from 2-18, and compare internalizing symptoms in early adulthood across trajectory groups.

**Methods:** 197 adults were drawn from a longitudinal study. Raw current scores from the C-Section of the ADI-R were used to create total RRB, RSM, and IS scores. Trajectories were identified via group-based modeling. Multilevel modeling was used to investigate change in the slopes of trajectory groups. Internalizing symptoms were measured at ages 18 and 26 using Beck's Depression Inventory (BDI) and the Adult Manifest Anxiety Scale (AMAS).

**Results:** Three total RRB trajectory groups emerged: Low-Stable (30.8%), Some-Stable (50.9), and High-Declining (18.3%; Figure 1). Two IS groups emerged: Slight-Increasing (81.5%) and Mild-Decreasing (18.5%). Three RSM groups emerged: Low-Stable (28.2%), Mild-Decreasing (44.4%), and High-Fluctuating (27.3%).

There was a significant effect of trajectory group on the slope of all three models, indicating the rate of change in total, RSM, and IS scores varied by trajectory group (Table 1). There was no significant effect of age in the total and RSM models, suggesting participants' total and RSM -raw scores at ages 2 and 18 were similar. The IS model included a significant effect of participant age ( $p < .001$ ); on average, IS scores decreased.

There were no significant differences between total RRB, RSM, and IS trajectory groups in internalizing symptoms at 18. Participants in the mild-decreasing RSM trajectory had significantly higher AMAS scores at 26 than participants in the low-stable and high-fluctuating groups ( $p = .028$ ).

**Conclusions:** As increasing numbers of autistic individuals enter adulthood, understanding developmental changes in the presentation of ASD becomes increasingly important. These results provide insight into how RRBs may shift from early childhood into adulthood. On average, RSM and total RRBs were stable; IS behaviors decreased with age. This study failed to replicate prior findings relating IS and total RRBs to internalizing symptoms, but found preliminary evidence that RSM development may be related to anxiety in adulthood.

### **317.004 (Oral) Early Developmental Profiles of Sensory Patterns in a Community Sample: Associations with Later Autistic Traits and Adaptive Functioning**

**Y. J. Chen<sup>1</sup>, J. Sideris<sup>2</sup>, L. R. Watson<sup>3</sup>, E. Crais<sup>3</sup> and G. T. Baranek<sup>2</sup>,** (1)Chan Division of Occupational Science and Occupational Therapy, McMaster University, Los Angeles, CA, Canada, (2)Chan Division of Occupational Science and Occupational Therapy, University of Southern California, Los Angeles, CA, (3)Department of Allied Health Sciences, University of North Carolina at Chapel Hill, Chapel Hill, NC

**Background:** Previous sensory-based subtyping studies have demonstrated the heterogeneous manifestation of sensory patterns in children with ASD. However, there is a lack of evidence on sensory subtypes as defined by longitudinal variability beyond ASD populations.

**Objectives:** The current study aimed to identify subtypes of sensory pattern trajectories from age 1 to 6 years among a large community sample of young children, and to characterize these subtypes in terms of their demographics and school-age outcomes, including autistic traits and adaptive/maladaptive behaviors.

**Methods:** Sensory patterns of 1,517 children were assessed at three time-points (infancy, preschool-age, and school-age) with parent-report questionnaires (First Years Inventory and Sensory Experiences Questionnaires). Multivariate latent class growth analysis (LCGA) was fitted with two to six classes to identify distinct subtypes based on trajectories across three sensory patterns (hyperresponsiveness [HYPER], hyporesponsiveness [HYPO], and sensory interests, repetitions and seeking behaviors [SIRS]) with child's sex, race, and parent education as covariates. Associations between class membership and school-age outcomes (measured by Social Responsiveness Scale and Vineland Adaptive Behavior Scales) were examined on a subset sample with outcome data (N=389) using Bolck-Croon-Hagenaars three-step approach that adjusts for classification errors.

**Results:** Based on the model fit indices (Table 1) and clinical interpretability of these class solutions, five distinct sensory-trajectory classes were identified (see Figure 1): an *Adaptive-All Improving* class with very low sensory features (Class 1; 35%), an *Elevated-All Worsening* class (Class 5; 3%), and three other classes (Class 2 to 4; 62% combined) generally characterized by moderate levels of sensory features with varying patterns across constructs. Children in Class 5 were more likely to be boys and have parents with lower education levels and were associated with the most elevated autistic traits and poorest adaptive/maladaptive outcomes at school age ( $\chi^2=46.2$  to  $133.3$ ,  $p$  all  $< .001$ ; compared to Class 1). Also, children in this class were almost 123 times more likely than those in the most adaptive class (i.e., Class 1) to have parent-reported ASD-related outcomes/elevated autistic traits (odds ratio=122.9, 95% CI=[28.8, 524.6]). Children who were classified to the moderate-severity classes with increasing trajectories in some sensory constructs, particularly HYPER and HYPO, tended to show weaknesses in certain domains of adaptive functioning: Comparing to Class 1, Class 2 had lower social communication skills ( $\chi^2=6.7$  to  $16.2$ ,  $p<.05$ ) while Class 4 had lower daily living and motor skills ( $\chi^2=5.7$  to  $11.6$ ,  $p<.05$ ). Both these classes were also associated with more maladaptive behaviors ( $\chi^2=9.5$  to  $58.5$ ,  $p$  all  $< .01$ ).

**Conclusions:** Large longitudinal variability of sensory patterns was observed in a community sample of children and could be parsed out into clinically meaningful subtypes given their differential associations with autistic traits and adaptive/maladaptive behaviors at school age. Thus, profiling children based on their early sensory trajectories may help to identify those who are more likely to experience developmental challenges at school age, thus introducing opportunities for early intervention. Moreover, the presence of a sensory trajectory profile that was highly associated with ASD-related outcomes indicated the potential utility of sensory features for early identification of ASD.

#### **405.085 (Poster)** A Pilot Study of Active Social Touch in Autism

**A. Zoltowski<sup>1</sup>, E. Eyoh<sup>2</sup>, K. Dunham<sup>1</sup>, T. G. Woynaroski<sup>3</sup>, M. D. Failla<sup>4</sup>, J. I. Feldman<sup>5</sup>, T. S. Chow<sup>6</sup>, J. L. Krichmar<sup>5</sup> and C. J. Cascio<sup>6</sup>,** (1)Vanderbilt University, Nashville, TN, (2)Institute of Child Development, University of Minnesota, Minneapolis, MN, (3)Department of Hearing and Speech Sciences, Vanderbilt University Medical Center, Nashville, TN, (4)Psychiatry, Vanderbilt University, Nashville, TN, (5)Cognitive Science, University of California, Irvine, Irvine, CA, (6)Department of Psychiatry and Behavioral Science, Vanderbilt University Medical Center, Nashville, TN

---

**Background:** Social/affective touch processing has been an area of interest in autism, as our earliest social interactions tend to occur in the context of caregiver touch that is processed via distinct neural pathways from those tuned to process nonsocial touch. Accordingly, this sensory system plays a foundational role in socioemotional development and is increasingly processed reciprocally between individuals as one matures and gains motor autonomy. Though some studies provide evidence of altered social touch perception in autism, to our knowledge, no prior approaches have characterized how individuals on the autism spectrum apply social touch during interactions with others. CAREtaker RoBot (CARBO), an animal-like robot containing an array of trackballs used as tactile sensors, was designed to objectively measure properties of active touch while approximating affective touch preferences of animate beings.

**Objectives:** This study aimed to preliminarily characterize active social touch in youth on the spectrum compared to typically developing youth.

**Methods:** Participants included  $n=15$  autistic youth (AUT, ages 8-17) and  $n=15$  typically developing youth (TD, ages 6-12). One individual in the autism group was excluded from analyses due to difficulty with task comprehension, leaving  $n=14$  individuals in final analyses. We compared performance between groups on CARBO's "ColorMe" game. In the "ColorMe" game, participants are instructed to swipe across CARBO's trackballs in a specific direction, mimicking petting an animal. CARBO's trackballs are illuminated with the desired color if swiped in the preferred direction and velocity; corrective feedback is generated in response to non-preferred speed or direction. The "ColorMe" game ended when the number of illuminated trackballs surpassed the game's threshold. Accuracy in preferred velocity, average speed, variation in speed, and number of trackballs targeted per swipe were compared between groups.

**Results:** In this initial pilot study, we did not find differences in accuracy, speed, or number of targeted trackballs between the groups that met criteria for statistical significance. However, several preliminary trends in performance may warrant further investigation. Most notably, the speed of swipe was slower for autistic participants than typically developing participants (Cohen's  $d = -0.41$ , Figure 1A). Additionally, group patterns may suggest greater movement consistency in autism, including a more stereotypical number of trackballs targeted ( $d = 0.32$ , Figure 1C).

**Conclusions:** Trending differences in speed of swipe are consistent with known differences in motor development in autism; future work may aim to disentangle the extent to which differences in active social touch may relate to general motor differences versus specific to social touch processing. Additionally, a more stereotypical number of targeted trackballs per swipe in the autism group suggests that autistic individuals may apply a more consistent strategy towards game completion, compared to typically developing individuals. One limitation of the current work is that our typically developing participants were on average younger than our autistic participants, so age-matched samples may further clarify findings. In addition to collecting more data, future directions also include studying the extent to which patterns of active touch to an "animal-like" robot may translate to humans.

#### **405.086 (Poster)** Adherence to the Two-Thirds Power Law and Kinematic Differences in Children with Autism during Ellipse Drawing and Tracing Activities on Smart-Tablet

**E. Fourie<sup>1</sup>, S. C. Lu<sup>2</sup>, J. Delafield-Butt<sup>3</sup> and S. M. Rivera<sup>1</sup>,** (1)Psychology, University of California, Davis, Davis, CA, (2)Laboratory for Innovation in Autism, University of Strathclyde, Glasgow, United Kingdom, (3)Department of Psychology, University of California, Davis, Davis, CA

---

**Background:** Individuals with autism often demonstrate atypical motor control, especially in the area of fine motor skills. Studies assessing writing and drawing have revealed larger peak velocities and more variable trajectories in autistic participants. Similarly, during upper limb reaching movements, those with autism show greater levels of jerk and more movement units than those with typical development. These atypical kinematic features require further investigation. One method that can be used to characterize motor control is the two-thirds power law ( $\frac{2}{3}$  PL) that produces movement in which velocity co-varies with curvature ( $Tangential\ Velocity = K * Radius\ of\ Curvature^{\frac{1}{3}}$ ). The  $\frac{2}{3}$  PL extends to several types of human movement, including of the hand and foot, for example during drawing, and of the eyes during tracking.

**Objectives:** The goal of this study is to assess adherence to the  $\frac{2}{3}$  PL during drawing movements in children with autism and children with typical development (TD). The law has yet to be studied in autism, and it may offer deeper insight into atypical motor development and provide a better metric by which to assess motor kinematics.

**Methods:** The present study uses an innovative approach by capturing movement kinematics through an iPad activity that is accessible and appealing to children. Participants included 10 children with autism ( $Age=87$  months) and 26 children with TD ( $Age=82$  months), ages 4 through 8 years. Participants were instructed to first (i) Draw then (ii) Trace ellipses, chosen in order to elicit varying degrees of curvature. The bespoke application recorded these movements on the screen, in the form of x and y coordinates of finger location over time. For each continuous segment of movement, kinematic features of curvature and tangential velocity were computed and an exponent ( $\beta$ ) representing their relationship (i.e., adherence to the  $\frac{2}{3}$  PL) was derived (Figure 1). Jerk and acceleration values were also calculated.

**Results:** (i) For Drawing trials, there was a trend toward significance, in which the TD group showed lower beta values ( $M=.21$ ) than the autism group ( $M=.27$ ),  $p=.058$ . (ii) Tracing trials showed no group difference. Beta values ( $\beta$ ) for each segment are displayed in Figure 2. For both Drawing and Tracing trials, autistic participants demonstrated greater individual variability across segments (Drawing:  $M=0.072$ ; Tracing:  $M=.077$ ), compared

to TD participants (Drawing  $M=.045$ ; Tracing  $M=.051$ ),  $p=.009$  and  $p=.028$ , respectively. Participants with autism also showed greater acceleration and jerk in both Drawing and Tracing movements (Figure 3).

**Conclusions:** This novel iPad methodology revealed group differences in kinematics, with autistic participants showing more individual variability and a greater beta value, as well as greater levels of acceleration and jerk. Future investigation will examine the quality of the movement executed (e.g. size and shape of ellipses), and the relationship between these kinematic variables and other measures of social and motor functioning. This approach may provide a useful method for studying kinematics and help to expand our understanding of motor atypicality in autism, a growing area of interest and focus.

**405.087 (Poster)** Age-Related Differences in Behavioral and Physiological Responses to Sensory Stimulation in Children and Adolescents with and without Autism Spectrum Disorder (ASD)

**S. Ramappa<sup>1,2</sup>, J. Jung<sup>3</sup>, R. Chu<sup>4</sup>, K. K. Cummings<sup>5</sup>, G. Patterson<sup>6</sup>, M. Dapretto<sup>2</sup>, S. Y. Bookheimer<sup>2</sup> and S. A. Green<sup>6</sup>,** (1)University of California, Los Angeles, Los Angeles, CA, (2)Dept of Psychiatry and Biobehavioral Sciences, University of California, Los Angeles, Los Angeles, CA, (3)Growing Healthy Children Therapy Services, Inc., Rescue, CA, (4)The University of North Carolina at Chapel Hill, Chapel Hill, NC, (5)University of Denver, Denver, CO, (6)Dept of Psychiatry and Biobehavioral Sciences, UCLA, Los Angeles, CA

### **Background:**

Individuals with autism spectrum disorder (ASD) often exhibit sensory modulation atypicalities, such as sensory over-responsivity (SOR), which is characterized by demonstrating an exaggerated negative response to aversive sensory input (Leekam et al., 2007; McCormick et al., 2015; Miller et al., 2017). However, a majority of existing ASD sensory-related studies examine parent-reported data; thus, there is a strong need to develop standardized observational assessments of sensory processing atypicalities that can be used across childhood and adolescence. Additionally, heart rate (HR) responses to sensory stimulation have been shown to correlate with SOR (Jung et al., 2021), so combining observed behavior with physiology may provide insight into sensory reactivity, especially in older adolescents who may find sensory sensations unpleasant but regulate their behavioral responses.

### **Objectives:**

To explore the relationship between age and SOR in parent-reported data and an observed behavioral assessment to improve understanding of sensory processing in school-aged children and adolescents with autism spectrum disorder (ASD) and typically developing (TD) peers, and to examine how HR responses relate to observed behavior during sensory stimulation.

### **Methods:**

Forty-one ASD and 33 age- and performance IQ-matched TD participants, aged 8-17 years participated in the Sensory Processing 3-Dimensional (SP3-D) Assessment (Mulligan et al., 2019). This assessment uses ecologically valid sensory stimuli (e.g., flashing lights, musical instruments, scratchy materials) to examine participants' sensory responsivity. Behavioral responses to the stimuli were scored in tactile, visual, and auditory domains, based on whether they showed aversive or avoidant responses to the stimuli. Electrocardiogram data was collected from participants during the SP3-D to measure HR responses to sensory stimulation. Additionally, parents completed the SP3-D Inventory (Miller et al., 2017) to report on participants' SOR symptoms.

### **Results:**

Compared to TD participants, the ASD group had more atypical SOR ( $t(72)=-2.49$ ,  $p=0.015$ ) responses across visual, tactile, and auditory domains on the SP3-D Assessment. Total SOR in the SP3-D Assessment was negatively correlated with age in both TD ( $r=-0.60$ ,  $p<0.001$ ) and ASD ( $r=-0.30$ ,  $p=0.05$ ) groups. However, parent-reported SOR was not correlated with age in either group, suggesting that either older participants in the sample are able to better regulate their SOR behaviors during the lab assessment, or as children get older, parents are less attuned to improvements in their SOR behaviors. Additional analyses will correlate behavioral responses with heart rate responses using the same tasks, with discrepancies between behavior and physiology examined as a possible indication of regulation to determine whether older ASD youth are regulating more (i.e., showing high physiological arousal despite low behavioral reactivity).

### **Conclusions:**

SOR behaviors during the SP3-D Assessment were negatively correlated with age, whereas parent-reported SOR was not correlated with age. This disparity between observational data and parent-reported data may be due to the assessment's shorter timeframe and more controlled environment, whereas parents report SOR using a global impression of their children's behavior across development. Additional physiological analyses and the discrepancies between behavior and physiology could provide insight into participants' regulatory behavior during the assessment, through which older participants suppress behavioral responses to aversive stimuli during the observational assessment.

**405.088 (Poster)** An Observational Study of the Relationship between Sensory Reactivity Differences and Classroom Behaviour of Autistic Children.

**H. Marcham<sup>1</sup> and T. Tavassoli<sup>2</sup>,** (1)School of Psychology and Clinical Language Sciences, University of Reading, Reading, United Kingdom, (2)Centre for Autism, School of Psychology & Clinical Language Sciences, University of Reading, Reading, United Kingdom

**Background:** Sensory reactivity (SR) differences are a core diagnostic criteria for autism. The classroom environment can be a difficult place for autistic children to regulate their behaviour, reducing their ability to reach their learning potential. SR differences has previously been linked to classroom behaviours using teacher reports.

**Objectives:** This research aimed to use direct observational methods to investigate how SR differences, such as hyperreactivity, hyporeactivity and sensory seeking, might be linked to classroom behaviour.

**Methods:** The Sensory Assessment for Neurodevelopmental Disorders (SAND) was used to measure SR, while classroom behaviour was assessed using the Behaviour Assessment for Children, Student Observation System (BASC-SOS). Study 1 consists of data from 24 participants aged 9-18. The study was then repeated (Study 2) with a further 30 participants from a second school aged 5-11, to replicate the findings.

**Results:** In Study 1, increased SR differences were found to be significantly correlated to both increased maladaptive ( $r = .48, p < .05$ ) and decreased adaptive classroom behaviour ( $r = -.45, p < .05$ ). Sensory seeking symptoms were found to be linked to both decreased adaptive ( $r = -.47, p < .05$ ) and increased maladaptive classroom behaviour ( $r = .42, P < .05$ ). In Study 2, there was a trend between increased SR differences and increased maladaptive behaviour ( $r = .34, p = .07$ ). Sensory hyporeactivity was linked to increased maladaptive classroom behaviour ( $r = .40, P < .05$ ).

**Conclusions:** Results from both studies demonstrated there is a link between SR differences and classroom behaviour. However, the studies differed in specific SR subtype. Findings will be discussed in terms of sample characteristics as well as school setting (specialist residential school versus specialist day school).

#### **405.089 (Poster)** Are Interests Harmonious or Obsessive? A Look at Passion in Autistic Emerging Adults

**A. J. Meilleur<sup>1,2</sup>, N. Cusson<sup>2,3</sup>, R. J. Vallerand<sup>4</sup>, I. Soulières<sup>5</sup> and E. L. Bussières<sup>5</sup>,** (1)Department of Psychology, Université du Québec à Montréal, Montréal, QC, Canada, (2)Autism Research Group, CIUSSS du Nord-de-l'Île-de-Montréal, Montréal, QC, Canada, (3)Department of Psychology, Université du Québec à Montréal, Montréal, QC, Canada, (4)Psychology, Université du Québec à Montréal (UQAM), Montréal, QC, Canada, (5)Psychology, Université du Québec à Trois-Rivières, Trois-Rivières, QC, Canada

**Background:** While intense interests can lead to interference with daily functioning, they are sometimes beneficial, namely concerning social inclusion, learning, and positive emotions. However, the impact of interests on well-being and functioning is poorly understood. Fortunately, the Dualistic Model of Passion describes two types of passions associated with negative or positive functioning. Harmonious passion is a flexible form of engagement that leads to positive emotions, a state of flow and *optimal functioning* (i.e. well-being, physical health, relationship quality, performance and contribution to society). In contrast, obsessive passion is a rigid form of engagement associated with conflict, rumination, negative emotions, and that negatively impacts optimal functioning.

**Objectives:** Using the Dualistic Model of Passion framework, the first aim was to characterize passion in autistic emerging adults. Secondly, the relation between passion, conflict, rumination, emotions, flow, and optimal functioning was examined. It was expected that harmonious passion and obsessive passion would respectively be positively and negatively associated with optimal functioning. In an exploratory aim, categories of interests (e.g.: video games) were compared to determine which interests were more adaptive in terms of passion and optimal functioning.

**Methods:** Participants were recruited on social media through different autism associations. A total of 109 autistic individuals (58 women;  $M=23.66$  years;  $SD=5.09$ ) took part in an online study. Thinking of their favorite interest, participants completed questionnaires on passion, conflict, rumination, emotions, flow and optimal functioning. Descriptive statistics and correlations were used to characterize passion and examine relations between variables, and ANOVAs were used to compare categories of interest.

**Results:** Participants were passionate about their interest, showing both high levels of harmonious ( $M=5.46/7$ ;  $SD=1.04$ ) and obsessive passion ( $M=4.20/7$ ;  $SD=1.41$ ). They spent on average 25.45 hours/week ( $SD=16.72$ ) on their interest and had been practicing it for approximately 10.6 years ( $SD=6.63$ ). Harmonious passion was positively associated with optimal functioning ( $r=.32$ ), flow ( $r=.27$ ), and positive emotions ( $r=.34$ ). Obsessive passion was associated with conflict ( $r=.79$ ), rumination ( $r=.71$ ), negative emotions ( $r=.21$ ), and lower optimal functioning ( $r=-.43$ ). Finally, passions were categorized as video games ( $n=23$ ), artistic pastimes ( $n=23$ ), knowledge acquisition ( $n=27$ ), reading and watching tv ( $n=24$ ), and active pastimes ( $n=11$ ) by two independent researchers ( $kappa=.83$ ). Knowledge acquisition was the category with the highest levels of harmonious and obsessive passion, as well as the one associated with most rumination. Video games were the category associated with the highest levels of negative emotions and the lowest harmonious passion levels. Categories did not differ in terms of optimal functioning, flow, positive emotions and conflict.

**Conclusions:** Autistic individuals are highly passionate about their interest, and more harmoniously passionate than obsessively passionate as a group. Moreover, as expected, the presence of harmonious passion is related to optimal functioning, whereas obsessive passion is related to lower optimal functioning. Results highlight that the category of interest might not be as important as the type of passion associated with the interest in predicting optimal functioning. As seen in neurotypical populations, high levels of harmonious passion may foster positive outcomes and protect against the negative impacts associated with high levels of obsessive passion.

#### **405.090 (Poster)** Characterization of Sensory over-Responsivity in a Broad Neurodevelopmental Concern Cohort Using the Sensory Processing Three Dimensions (SP3D:A) Assessment

**M. C. Lazerwitz<sup>1,2</sup>, M. A. Rowe<sup>3</sup>, K. J. Trimarchi<sup>2</sup>, R. D. Garcia<sup>2</sup>, R. Chu<sup>1,4</sup>, S. Parekh<sup>1</sup>, J. Wren-Jarvis<sup>1</sup>, I. Bourla<sup>1</sup>, I. Mark<sup>1</sup>, E. J. Marco<sup>2</sup> and P. Mukherjee<sup>1,5</sup>,** (1)Department of Radiology and Biomedical Imaging, University of California, San Francisco, San Francisco, CA, (2)Cortica Healthcare, San Rafael, CA, (3)Department of Psychology and Neuroscience, University of Colorado, Boulder, Boulder, CO, (4)Growing Healthy Children Therapy Services, Rescue, CA, (5)Department of Bioengineering and Therapeutic Sciences, University of California, San Francisco, San Francisco, CA

**Background:** Sensory Over-Responsivity (SOR), the negative response to typically non-noxious stimuli, occurs in 2.5% of elementary school children and up to 70% of children with Autism Spectrum, Anxiety, Attention Deficit/Hyperactivity, and Developmental Coordination Disorders<sup>1-7</sup>. To date, SOR in specific sensory domains (i.e. auditory and/or tactile) in community clinics treating children with neurodevelopmental concerns (NDC) has not been explored using a direct assessment of sensory processing.

**Objectives:** To characterize the incidence of auditory and/or tactile SOR in children between the ages of 8 and 12 years old referred to Cortica Healthcare, a community based neurodevelopmental clinical research center in Marin County, California.

**Methods:** This study employs an observational cross-sectional study design with direct sensory characterization by a licensed pediatric Occupational Therapist using the Sensory Processing Three Dimensions (SP3D:A) Assessment to investigate the frequency of auditory and tactile SOR in a pediatric NDC population. Children are screened for eligibility in part through a brief questionnaire of neurodevelopmental challenges (Gillberg ESSENCE-Q), to which the responses range from 'No,' 'Maybe / A Little,' to 'Yes' (Table 1). Participants are additionally evaluated for research designation of Autism Spectrum Disorders (ASD) using the Social Communication Questionnaire. If a child scores  $\geq 15$ , an Autism Diagnostic Observation Schedule (ADOS-2) is conducted to confirm research diagnosis.

**Results:** Of the total NDC population enrolled (60 male, mean age 10.4 years), 35/82 (42.7%) meet criteria for auditory SOR (AOR), 18/82 (22.0%) meet criteria for tactile SOR (TOR), 9/82 (11.0%) meet criteria for both auditory and tactile SOR and 44/82 (53.7%) meet criteria for AOR and/or TOR. 13 children (11 male) additionally meet research criteria for ASD. Of the ASD population enrolled, 5/13 (38.5%) meet criteria for AOR, 3/13 (23.1%) meets for TOR, 1/13 (7.7%) meet criteria for both AOR and TOR, and 7/13 (53.8%) meet criteria for AOR and/or TOR. Of the non-ASD population enrolled (47 male), 30/66 (45.5%) meet criteria for AOR, 14/66 (21.2%) meet criteria for TOR, 8/66 (12.1%) meet criteria for both AOR and TOR, and 36/66 (54.5%) meet criteria for AOR and/or TOR.

**Conclusions:** This glance into a broader ongoing study on sensory processing emphasizes the prominence of SOR as a presenting concern in a community-based clinic. The same percentage (54%) of each cohort (combined sample, ASD, and non-ASD) were assessed to have auditory and/or tactile over-responsivity, which suggests several key findings – first, SOR is highly prevalent with over 50% of children presenting with this as a chief concern. Second, the incidence of AOR and TOR is roughly the same in children with and without ASD, which suggests sensory modulation is likely independent from the primary social communication deficits characteristic of ASD. Third, auditory SOR is over twice as common in children with NDC as tactile SOR. And finally, these findings point towards a need for more robust delineation of the neural mechanisms of SOR both within and separate from ASD, as well as a need to define whether genetic contributors are independent or overlapping among children with SOR, attention, and social communication challenges.

#### **405.091 (Poster)** Defining and Assessing the Construct of Food Pickiness in Autistic and Neurotypical Adolescents and Young Adults

**R. A. Rivera<sup>1</sup>, P. Allen<sup>2</sup> and L. Bennetto<sup>1</sup>,** (1)Psychology, University of Rochester, Rochester, NY, (2)University of Rochester Medical Center, Rochester, NY

**Background:** Picky eating is a common and well-documented phenomenon among autistic individuals, which can lead to significant health problems including obesity, malnutrition, and disordered eating. Prior research in this area has focused primarily on children, and little is known about the persistence of food pickiness into adolescence and young adulthood. Understanding the nature of food pickiness in these populations is critical for designing appropriate interventions to support long-term health.

Feeding behavior is driven by a complex integration of systems spanning sensory, perceptual, biological, social, and other factors. While the nature of pickiness is likely to be similarly complex, extant research in both ASD and neurotypical populations has defined pickiness based on individual factors, like food neophobia or broadly defined food selectivity, rather than as an integrated latent construct.

**Objectives:** The present study aimed to address these limitations by applying confirmatory factor analysis and structural equation modeling to develop and test a measurement model of food pickiness that includes multiple theoretically hypothesized indicator variables. These aims were carried out with autistic and neurotypical adolescents and young adults, allowing for assessment of model fit accounting for diagnostic status. Analyses additionally examined the factor structure of food selectivity. We hypothesized that the latent construct of food pickiness would be a common factor across the empirically driven indicator variables. Furthermore, we hypothesized that autistic adolescents and young adults would have greater levels of food pickiness compared to their neurotypical counterparts.

**Methods:** The present sample comprised 429 participants, including well-characterized autistic adolescents and young adults ( $n=80$ ) and unaffected siblings ( $n=41$ ), neurotypical adolescents ( $n=63$ ), and neurotypical college students ( $n=245$ ). The predictor variable was ASD diagnostic status. Indicator variables for the latent construct of pickiness were derived from a comprehensive assessment of preference and frequency of eating individual food items, assessment of preference based on food qualities, food neophobia (e.g., refusal to try new foods), and parent- or self-reported food pickiness (e.g., preferring variety or sameness in daily diet).

**Results:** Preliminary results indicate that autistic adolescents and young adults had greater parent- or self-reported picky eating,  $t(428) = -8.12, p < .001$ , and food selectivity,  $t(416) = -3.62, p < .001$ ; however, participants did not differ in food neophobia based on diagnostic status,  $t(426) = -1.04, p = .30$ . Additional planned analyses further examine the latent construct and potential mediators and moderators, and the factor structure of individual food item preferences to improve operationalization of food selectivity.

**Conclusions:** This novel study improves the conceptualization of food pickiness in ASD by defining it as a latent construct composed of multiple observed variables. Additionally, results indicate that food pickiness is present in autistic adolescents and young adults compared to their

neurotypical peers providing support for its persistence beyond the childhood years. The results of this study will help caregivers and providers address the nature of picky eating in ASD to promote better long-term physical, mental, and emotional outcomes.

**405.092 (Poster)** Differential and Shared Pathways to Sensory over-Responsivity and Anxiety: The Role of Hot and Cool Self-Regulation  
*E. Glenn, A. Taiwo and L. L. McIntyre, Special Education and Clinical Sciences, University of Oregon, Eugene, OR*

---

**Background:** Sensory over-responsivity (SOR), characterized by heightened reactivity to sensory stimuli, occurs in approximately 56% of children with autism spectrum disorder (ASD). Research has established a strong theoretical linkage between SOR and anxiety disorders. Anxiety disorders are also common in children with ASD, occurring in around 40% of children. SOR and Anxiety share similar bottom-up, perceptual processes (physiological arousal in anxiety, sensation in SOR) and top-down regulatory processes, which relate to degree of impairment. Despite these connections, little research has examined how to conceptualize SOR within therapeutic approaches for anxiety.

Self-regulation (SR) is one process that is amenable to intervention and potentially related to congruent mechanisms between SOR and anxiety, as it encompasses top-down cognitive and behavior regulation. Conceptually, SR has been dichotomized by the degree it involves affective components, with “hot” SR entailing greater affective processes than “cool” SR. Thus, elucidating how these components differentially predict the manifestation of anxiety and SOR may inform more specialized anxiety treatment for individuals with ASD.

**Objectives:** This study aims to examine how “hot” and “cool” self-regulatory processes differentially predict anxiety and SOR, among children with developmental disabilities (DD), including ASD. We also examine how ASD and cognitive functioning affect these relationships.

**Methods:** This sample consisted of 94 school-age children ( $M = 9.25$  yrs;  $SD = 1.9$  yrs) participating in a longitudinal study exploring shared neurobiological etiology between ASD and DD. Data was collected at two time points, approximately 1 year apart. Anxiety, SOR, and cognitive functioning were measured using the CBCL, SSP, and WASI, respectively. We used BRIEF subscales to measure hot SR (emotional control) and cool SR (inhibit + shift), with higher scores indicating greater dysfunction. ASD diagnosis was confirmed using the ADOS, with 45% of the sample meeting clinical criteria. We used hierarchical regression models to test our research questions, entering ASD diagnosis and cognitive functioning as predictors in successive steps.

**Results:** Cool SR best predicted each outcome across models – anxiety, SOR-related avoidance, and SOR-related sensitivity ( $p$ 's < .001), with differential patterns across outcomes concerning the role of ASD, cognitive functioning, and hot SR. For anxiety at time 2, hot SR marginally predicted the log-odds of this outcome ( $p$ 's < .1) in addition to cool SR. For SOR-related avoidance at time 2, ASD diagnosis significantly predicted ( $p$ 's < .05) higher scores, in addition to cool SR. For SOR-related sensitivity, cognitive functioning marginally predicted ( $p$ 's < .07) lower scores, in addition to cool SR. SR and cognitive or ASD variables explained 45-47% of variance in SOR.

**Conclusions:** Our results suggest dysregulation in cool SR may underlie both SOR and Anxiety. Interestingly, SOR-related avoidance, which shares behavioral features with anxiety, was predicted by ASD status. These results suggest increasing behavioral self-regulation and decreasing behavioral avoidance may be important treatment targets for alleviating the clinical impact of anxiety and SOR for individuals with ASD. As these targets are readily incorporated into treatment protocols for anxiety, future intervention studies might examine how targeting less affective aspects of SR may influence SOR.

**405.093 (Poster)** Dynamic Complexity of Atypical Postural Control in Autistic Toddlers

*P. R. Krishnappa Babu<sup>1</sup>, J. M. Di Martino<sup>1</sup>, R. E. Aiello<sup>2</sup>, K. L. Carpenter<sup>2</sup>, S. Compton<sup>2</sup>, N. O. Davis<sup>3</sup>, S. Espinosa<sup>1</sup>, J. Flowers<sup>2</sup>, A. Harris<sup>4</sup>, J. Howard<sup>2</sup>, S. Perochon<sup>1</sup>, M. Spanos<sup>2</sup>, G. Dawson<sup>2</sup> and G. Sapiro<sup>1</sup>, (1)Department of Electrical and Computer Engineering, Duke University, Durham, NC, (2)Department of Psychiatry and Behavioral Sciences, Duke Center for Autism and Brain Development, Durham, NC, (3)Department of Psychiatry and Behavioral Sciences, Duke ADHD Program, Duke University Medical Center, Durham, NC, (4)Boston University, Durham, NC*

---

**Background:** Early delays in motor-functioning and differences in social communication are early signs of autism spectrum disorder (ASD). Studies documented the autistic individuals have difficulties in maintaining postural control throughout the lifespan. Recent advancements in digital-technologies and computer-vision open avenues to develop scalable behavioral analysis tools that have the potential to quantify subtle dynamic changes in motor behavior with high spatiotemporal resolution. In a previous study, our group designed a scalable computational phenotyping tool capable of recording and measuring postural sway. Using this tool, we reported higher rates of postural sway of young autistic children compared to neurotypical children while watching strategically-designed movies consisting of social and non-social components, shown on a tablet (Dawson et al., 2018)

**Objectives:** This study sought to replicate and extend our earlier findings with a larger, independent sample of young autistic and typically developing (TD) children. Here, we employed new methods designed to capture the complexity of head movements.

**Methods:** Toddlers aged 17-37 months were recruited at four pediatric primary care clinics during their well-child visit (TD:  $N=410$  and ASD:  $N=38$ ). Children were shown short movies consisting of social and non-social components presented on a tablet while they sat on their caregiver's lap. The tablet's front-facing camera recorded the toddlers' video while they watched the movies. Computer-vision algorithms were used to track and detect the facial landmarks, which were processed to extract the head postural sway across frames synchronized with the movies (Dawson et al., 2018). Measurements included (1) acceleration - physically related to the instantaneous control force, and (2) complexity - formally defined using multiscale sample entropy. These features can characterize the magnitude of postural sway patterns and how periodic or mathematically unpredictable they are.

**Results:** Autistic toddlers exhibited, on average, significantly higher postural sway acceleration (Actor Blowing Bubbles Movie:  $p<0.00001$ ; Make Me Laugh Movie:  $p<0.00001$ ) and complexity (Actor Blowing Bubbles Movie:  $p<0.001$ ; Make Me Laugh Movie:  $p<0.05$ ) compared to neurotypical children. These differences were accentuated when children were watching movies with high social content (see Figure 1). During movies with low social content, the differences in the patterns of postural sway between the groups were smaller for both the acceleration (Floating Bubbles Movie:  $p<0.005$ ; Dog in Grass Movie:  $p<0.001$ ) and complexity (Floating Bubbles Movie:  $p=0.12$ ; Dog in Grass RRL:  $p=.08$ ).

**Conclusions:** During movies with high social content, autistic toddlers exhibited higher acceleration in postural sway characterized by more rapid, less structured, and frequent motions. The autistic children also had higher MSE values, suggesting that the movements were less predictable. Balance relies on the integration of multisensory cues, a process requiring attentional demands. Decreased postural control during processing of social stimuli may reflect differences in the ability to adapt to the sensory information in the complex social movies. A novelty of this work is that this can be quantified using ubiquitous devices in primary care clinical settings.

#### **405.094 (Poster) EEG Proxy Markers of Sensory Sensitivities of ASD**

**A. Javed<sup>1</sup>, J. L. He<sup>2</sup>, N. A. Puts<sup>3</sup>, J. Ahmad<sup>4</sup>, R. Jeyaraj<sup>5</sup>, E. J. Jones<sup>6</sup> and G. McAlonan<sup>7</sup>,** (1)Department of Forensic and Neurodevelopmental Sciences, Institute of Psychiatry, Psychology and Neuroscience, Kings College London, Institute of Psychiatry, Psychology & Neuroscience, London, United Kingdom, (2)King's College London, London, MD, United Kingdom, (3)Russell H. Morgan Department of Radiology and Radiological Science, Institute of Psychiatry, Psychology & Neuroscience, King's College London, UK, Baltimore, MD, United Kingdom, (4)Forensic and Neurodevelopmental Sciences, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (5)King's College London, London, United Kingdom, (6)Centre for Brain and Cognitive Development, Birkbeck University of London, London, United Kingdom, (7)NIHR-Biomedical Research Centre for Mental Health at the Institute of Psychiatry, Psychology and Neuroscience, South London and Maudsley Foundation NHS Trust, London, United Kingdom

#### **Background:**

Biomarkers are an objective measure of biological processes which underpin more complex symptoms of behaviours. These have a range of potential purposes, including facilitating of diagnosis, prognosis, treatment target and or treatment response. Recent efforts have tried to develop biomarkers for core and associated symptoms of autism. Despite their potential usefulness, there are challenges in defining and understanding different biomarkers, and limited consensus as to how they should be used in research and clinical practice.

A number of neurophysiological markers measured using electroencephalography (EEG) have been reported in Autism Spectrum Disorder (ASD). Of particular interest are those related to sensory difficulties, which are common, emerge early, and have relatively clear biological underpinnings. However, the data are inconsistent and the use of these EEG findings with respect to biomarker development remains unclear. Critically, there are currently no formal criteria against which the performance of such biomarkers can be evaluated.

#### **Objectives:**

We aimed to screen the existing EEG studies of sensory processing in autism, alongside available biomarker guidelines to develop a tool to assess how well biomarkers achieve their intended function (diagnosis, prognosis, etc.).

#### **Methods:**

**Literature search:** 71 studies that were systematically identified across three databases; EMBASE, OVID and APA. Search terms relating to; ASD, EEG and sensory sensitivities across visual, auditory and tactile EEG studies were examined. Two independent researchers searched and extracted data from each database.

**Tool development:** The development of the assessment tool was based on current Food and Drug Association (FDA) guidelines for biomarkers. These guidelines provide information on the different types of biomarkers, however, very little information on what research studies require for biomarker qualification. Therefore, characteristics from previously approved biomarkers were also used to create a list of criteria required for biomarker qualification. A group of experts were then asked to review the criteria for different types of biomarkers to incorporate into the biomarker tool.

#### **Results:**

We identified  $n=71$  relevant papers in total;  $n=28$  papers in visual,  $n=40$  papers in auditory and  $n=3$  papers in the tactile domain (see figure 1). Based on this search and expert opinion we identified characteristics for the tool. These included general and specific characteristics and surrogate end point status (see figure 2). Our preliminary results indicate that many potential biomarkers are in the early stages of development and require further research in order to fulfil the criteria specified in our tool.

#### **Conclusions:**

Reference to biomarker guidelines and a screen of studies reporting EEG biomarkers for sensory processing in autism supported the development of a structured method to assess biomarker qualities. Preliminary application of this tool indicated that biomarker development remains at early stages for the majority of candidates reported in the literature. Building on this exercise, going forward we hope to recommend a minimum set of reporting criteria for biomarker studies to provide consensus and facilitate the translation of biomarker research into clinical settings.

**405.095 (Poster)** Examining the Association between Categories of Restricted Repetitive Behaviors and Parent Stress for Parents of Children with ASD

**S. F. Fernandes<sup>1</sup>, E. Harrington<sup>1</sup>, J. E. Nauman<sup>2</sup> and B. R. Ingersoll<sup>1</sup>,** (1)Psychology, Michigan State University, East Lansing, MI, (2)Psychology, Michigan State University Psychology Department, East Lansing, MI

---

**Background:**

Parents of children with autism spectrum disorder (ASD) report higher levels of parenting stress than children identified with other developmental disabilities (Eisenhower et al., 2005; Hayes & Watson, 2013). Previous studies have found links between parenting stress and child behavior problems, adaptive skills, and autism symptom severity; however, few studies have investigated the effects of restrictive, repetitive behaviors (RRBs) specifically. The limited work in this area suggests that rates of RRBs in preschool-aged children with ASD are related to parenting stress, and that increases in RRBs are associated with increases in parenting stress over time (Harrop, McBee, & Boyd, 2016). However, less is known about the relationship between parenting stress and specific subtypes of RRBs.

**Objectives:**

The goal of this study was to examine how different types of restricted and repetitive behaviors contribute to parenting stress for parents of children with ASD.

**Methods:**

This exploratory study was conducted as part of a larger randomized controlled trial investigating the efficacy of an online parenting program (Ingersoll, PI). Our sample included 60 children with an autism diagnosis, ages 18-90 months ( $M = 46.27$  months,  $SD = 17.49$  months). Data for the current study were obtained from the intake assessment. Restrictive and repetitive behaviors were measured using the Repetitive Behaviors Scale-Revised (RBS-R), and parenting stress was assessed using the Parenting Stress Index-Short Form (PSI-SF). First, we used zero-order correlations to examine whether parent demographic variables (parent age, sex, minority status, marital status, and education level), child characteristics (age, sex, verbal and nonverbal IQ, adaptive functioning, autism symptom severity), and child RRBs were significantly associated with parent stress. Only child autism symptom severity on the Social Responsive Scale (SRS) and RBS-R Subscale scores (Compulsive, Ritualistic, Self-injurious, Restricted, and Stereotyped Behavior) were correlated with parenting stress ( $p \leq .05$ ). A hierarchical linear regression predicting parenting stress was then conducted with autism symptom severity entered in step 1 and the five RBS-R Subscale scores (Compulsive, Ritualistic, Self-injurious, Restricted, and Stereotyped Behavior) entered in step 2.

**Results:**

The overall model was significant,  $F(6,53) = 4.27$ ,  $p = .001$  and accounted for approximately 25% of the variance in parent reported stress. The addition of RBS-R subscale scores resulted in a significant change in the adjusted  $R^2$  ( $\Delta R^2 = .17$ ,  $p = .03$ ). In the final model, only ritualistic behaviors ( $\beta = .49$ ,  $p = .004$ ) was an independent predictor of parenting stress.

**Conclusions:**

This study found that all 5 subtypes of restrictive and repetitive behaviors on the RBS-R were significantly associated with parenting stress and predicted parenting stress above and beyond autism symptom severity. After controlling for autism symptom severity and other RRBs, only ritualistic behaviors was a unique predictor of parenting stress. Further investigation of how different RRBs influence parent stress may indicate why certain behaviors have a larger impact on parenting stress than others and inform how to best manage parenting stress related to RRBs.

**405.096 (Poster)** Examining the Role of Attention Problems in Motor Stereotypy in Children with ASD

**J. E. Nauman<sup>1</sup> and B. R. Ingersoll<sup>1</sup>,** (1)Psychology, Michigan State University Psychology Department, East Lansing, MI, (2)Psychology, Michigan State University, East Lansing, MI

---

**Background:** Motor stereotypy, repetitive behaviors that occur with little conscious effort and are suppressible by sensory stimuli or distraction, is a subcategory of restricted and repetitive behavior commonly associated with Autism Spectrum Disorder (ASD). They are not exclusive to ASD, and visual descriptions of motor stereotypies cannot distinguish between stereotypy in those with and without ASD. Individuals without ASD who have motor stereotypy often struggle with executive function and attention, suggesting a relationship between motor stereotypy and attention dysfunction. Our previous cross-sectional work found an association between attention problems on the Child Behavior Checklist (CBCL) and motor stereotypy on the Repetitive Behaviors Scale – Revised (RBS-R) in a large sample of children with ASD from the Simons Simplex Collection (SCC). However, due to the cross-sectional nature of the dataset, causality cannot be inferred.

**Objectives:** The goal of this study is to examine whether attention problems predict change over time in motor stereotypy in children with ASD.

**Methods:** Data were collected through the Simons Simplex Collection, a permanent repository of behavioral and genetic samples from >2,600 simplex families. Our sample included 274 children ages 4-13 years who had a diagnosis of ASD and completed follow-up assessments for the measures of interest between 46-94 months after the initial study ( $M = 67.93$  months,  $SD = 11.88$  months). Stereotypy was measured using the Stereotypy Factor derived in a prior factor analysis (Russell et al., 2019) from the RBS-R. Attention problems were measured using the Attention Problems T-Score from the CBCL. Changes over time in attention problems and motor stereotypy were examined by conducting paired samples  $t$ -tests using Time 1 and Time 2 data. We used hierarchical regression to examine the association between attention problems and motor stereotypy in the follow up sample, controlling for age, sex, and IQ. In addition, we used hierarchical regression to examine the association between Time 1 attention problems and Time 2 motor stereotypy, controlling for age, sex, IQ, and Time 1 motor stereotypy.

**Results:** CBCL Attention Problems T-Scores significantly decreased from intake ( $M=66.03$ ,  $SD=10.26$ ) to follow up ( $M=64.21$ ,  $SD=10.18$ ) assessment,  $t(273)=2.96$ ,  $p=.003$ , as did the RBS-R Stereotypy Factor Scores from intake ( $M=5.89$ ,  $SD=4.10$ ) to follow up ( $M=4.11$ ,  $SD=3.69$ ),  $t(273) = 9.01$ ,  $p<.001$ . Attention problems significantly predicted stereotypy after controlling for age, sex, and IQ at Time 2 ( $p < .001$ ), replicating our previous findings from the larger sample at Time 1. However, attention problems at Time 1 did not significantly predict stereotypy at Time 2 when controlling for Time 1 stereotypy ( $p = .354$ ).

**Conclusions:** Despite a consistent relationship between attention problems and motor stereotypy in children with ASD, attention problems do not appear to play a causal role in stereotypy. Further investigation is necessary to determine the mechanisms that influence stereotypy in ASD.

#### **405.097 (Poster)** Executive Function As a Predictor of Restricted and Repetitive Behaviors (RRB) Severity in Kindergarteners with ASD

**A. M. Viggiano<sup>1</sup>, E. P. McKernan<sup>1</sup>, K. Tang<sup>2</sup> and S. H. Kim<sup>1</sup>,** (1)Psychiatry, Center for Autism and the Developing Brain, White Plains, NY, (2)Center for Autism and the Developing Brain, White Plains, NY

**Background:** Past studies have found the link between restricted and repetitive behaviors (RRBs) and impairments in executive function (EF) in individuals with ASD. However, studies focusing on ecologically valid measures examining the association between RRBs and EF in everyday settings are still limited. More in-depth investigations on how varying patterns of EF skills affect specific RRBs in young children can also guide the development of early intervention targeting EF and RRBs.

**Objectives:** To examine the link between RRBs and EF measured in everyday settings using parent reports in children aged 4-5 years with ASD and matched controls.

**Methods:** Participants included 50 children (26 ASD, 15 females) (Age:  $M=64.6$  months,  $SD=5.1$ ) (NVIQ:  $M=108.8$ ,  $SD: 12.6$ ). RRBs were measured by the Repetitive Behaviors Scale-Revised (RBS-R) Total and Subscale scores. EF was measured the Behavior Rating Inventory of Executive Function (BRIEF) Total (GEC; Global Executive Composite) and Subdomain scores (CRI; Cognitive Regulation Index, BRI; Behavior Regulation Index, ERI; Emotional Regulation Index). Regression models were used to predict RBS-R Total and Subscale scores with the BRIEF GEC while controlling for cognitive skills (NVIQ), age, gender, and diagnosis. For RBS-R scores that showed significant effects of GEC, we further explored which specific BRIEF Subdomain scores were associated with those RBS-R scores. The analyses were also repeated with the ASD sample only.

**Results:** BRIEF GEC significantly predicted total RBS-R Totals (GEC;  $B=.577$ ,  $p\leq.001$ ) and Subdomain scores (Stereotyped Behavior;  $B=.088$ ,  $p=.007$ , Routine Behavior;  $B=.160$ ,  $p\leq.001$ , Sameness Behavior;  $B=.150$ ,  $p=.001$ , Restricted Behavior;  $B=.072$ ,  $p=.031$ ). For BRIEF Subdomain analyses, ERI emerged as a significant predictor of Stereotyped Behavior ( $B=.084$ ,  $p=.013$ ), Sameness Behavior ( $B=.212$ ,  $p\leq.001$ ) and Routine Behavior ( $B=.086$ ,  $p=.038$ ) and BRI for Routine Behavior ( $B=.105$ ,  $p=.026$ ). Diagnosis was also significant for all of these models ( $p<0.05$ ). When the analyses were repeated with the ASD sample only, GEC significantly predicted total RBS-R totals (GEC;  $B=.704$ ,  $p=.023$ ) and Subdomain scores (Routine Behavior;  $B=.214$ ,  $p=.005$ , Sameness Behavior;  $B=.205$ ,  $p=.026$ ). For BRIEF Subdomain analyses, BRI significantly predicted Routine Behavior ( $B=.210$ ,  $p=.024$ ) and ERI for Sameness Behavior ( $B=.319$ ,  $p\leq.001$ ).

**Conclusions:** EF deficits predict the severity of RRBs in children with ASD and their matched peers in everyday settings. Impairments in the overall EF skills are associated with both lower and higher order RRBs. Results suggest that targeting EF, specifically emotion dysregulation, could ameliorate the symptoms of RRBs in young children with ASD.

#### **405.098 (Poster)** Gain Control for Sensory Processing in Autism Spectrum Disorder

**G. Parra<sup>1</sup>, K. Takach<sup>1</sup>, L. Cornelissen<sup>2</sup> and A. R. Levin<sup>3</sup>,** (1)Boston Children's Hospital, Brookline, MA, (2)Anesthesiology, Boston Children's Hospital, Boston, MA, (3)Neurology, Boston Children's Hospital, Brookline, MA

**Background:** Psychophysical paradigms have found reduced gain control of sensory responses in Autism Spectrum Disorder (ASD), compared to typical development (TD). Gain control refers to the modulation of responses based on context or the state of an input. These findings are intriguing for biomarker development but are based on subjective reports of sensation from participants. In order to develop biomarkers that (a) capture the wide range of ages, cognitive, and linguistic abilities in ASD, and (b) can be used for translation of findings across species, it is crucial to create paradigms that do not require following instructions or specific responses from participants. Electroencephalography (EEG)-based measures are promising in this regard, as they can be passively collected across a variety of ages, developmental levels, diagnoses, and species.

**Objectives:** We develop novel EEG-based measures of gain control and evaluate them in relation to diagnosis of ASD or TD.

**Methods:** In an ongoing pilot study, we are collecting data from children aged 36-47 months with ASD (n=5) and typically developing controls (n=5), matched across groups for age and gender. EEG was recorded while our stimuli were presented. To measure gain control in the form of habituation, an auditory temporal habituation (AuTH) paradigm consisted of repeated tones. Another set of stimuli measuring auditory spatial suppression (AuSS) consisted of tones presented at varying loudness levels. Published automated pipelines and platforms were used to clean and process the EEG. Gain control was evaluated through differences in global field power (GFP) across paradigm conditions.

**Results:** We successfully created EEG-based paradigms that measure neural responses to sensory stimuli in young children. In AuTH, we found GFP decreased with successive tone repetitions. This pattern of temporal habituation occurred at different timescales in TD (148-165ms after stimulus onset) and ASD (176-212ms). In AuSS, GFP generally increased with tone loudness in both groups; however, ASD demonstrated greater GFP in response to the loudest tones.

**Conclusions:** We have developed objective EEG measures that can be used to study the neural circuitry underlying differences in sensory processing in ASD. While based on small samples thus far, our results suggest our paradigms can measure gain control in young children. Given their objective nature, these measures could be promising for back-translation into animal studies. Future studies will be conducted with larger samples to continue exploring gain control in ASD and young children, including across different modalities and forms of gain control.

#### **405.099 (Poster)** Identification and Quantification of Stereotypical Movements from Video Recordings of ADOS Assessments Using Computer Vision and Deep Learning Techniques

**T. Barami<sup>1</sup>, M. Ilan<sup>2</sup>, N. Gabbay<sup>1</sup>, M. Faroy<sup>3</sup>, A. Michaelovski<sup>4</sup>, G. Meiri<sup>4</sup>, A. Sharf<sup>5</sup> and I. Dinstein<sup>3</sup>,** (1)Ben Gurion University, Beersheba, Israel, (2)Psychology Department, Ben-Gurion University of the Negev, Beer Sheva, Israel, (3)Preschool Psychiatric Unit, Soroka University Medical Center, Beer Sheva, Israel, (4)National Autism Research Center of Israel, Ben-Gurion University of the Negev, Beer Sheva, Israel, (5)Cognitive and Brain Sciences Department, Ben-Gurion University of the Negev, Beer Sheva, Israel

---

#### **Background:**

Children with autism spectrum disorders (ASD) often exhibit stereotypical movements such as hand flapping and body rocking. There is ongoing debate regarding the beneficial or detrimental effects of these behaviors. For example, stereotypical movements may enable children with ASD to self-regulate in situations involving anxiety but can interfere with social communication. A key necessity for research in this domain is the ability to identify and quantify multiple types of stereotypical movements presented by different children (Figure 1). To date, quantification of stereotypical movements has been mostly estimated with binary questions regarding their general presence or absence as reported by parents or clinicians. However, identifying and quantifying stereotypical movements is critical for assessing their impact on other symptom domains and determining changes in severity over time.

#### **Objectives:**

To develop an automated algorithm that identifies video segments containing multiple types of stereotypical movements that are exhibited by children with ASD.

#### **Methods:**

We manually annotated video recordings of ADOS assessments of 250 children with ASD who participated in research at the National Autism Research Center of Israel. The recordings were marked manually by students who identified 5333 video segments with the following stereotypical movements: hand flapping (n=1091), tapping (n=573), clapping (n=334), fingers (n=187) body rocking (n=121), tremor (n=177), running back and forth (n=129), spinning (n=239), jumping in place (n=349), head movement (n=90), playing with object (n=250), toe walking (206) and other idiosyncratic types of stereotypical movements that did not fit into the categories above (n=1587).

In parallel, we used computer vision algorithms to identify and track the skeleton of the child undergoing assessment. We extracted the skeleton on each frame using the OpenPose algorithm and detected the child using a YOLO-V5 algorithm trained specifically for this task. We then applied a spatio-temporal graph convolutional network (ST-GCN) to learn the examples described above, while training the algorithm on 80% of the exemplars and testing its accuracy on the remaining 20%.

#### **Results:**

Children with ASD exhibited large heterogeneity in the number of stereotypical movements exhibited during the ADOS assessment (Figure 1). In an initial analysis we examined the accuracy of the ST-GCN algorithm in identifying video segments containing stereotypical movements. To simplify the task, we united movement classes with similar characteristics and tested the recall/identification accuracy for the following categories:

- Hand Flapping & Clapping (recall = 76.47%)
- Tapping (recall = 65.05%)
- Body Rocking & Tremor (recall = 81.43%)

- Running back and forth & spinning (recall = 73.13%)
- Head Movements (recall = 84.44%)
- None (recall = 98.36%)

We achieved top-1 accuracy of 86.95% and a top-2 accuracy of 94.67%.

#### Conclusions:

These results demonstrate the large value of applying computer vision and deep learning techniques to the quantification of ASD symptoms. We hope that the presented algorithm will be useful for both basic and clinical research focused on understanding the causes of stereotypical movements and developing treatments for reducing their severity. Further development of the algorithm will focus on improved accuracy and extending its use to other settings (e.g., home, day care, etc.).

#### **405.100** (Poster) Sensory Processing and Autistic Traits in Young Adult Females

**G. J. Cardon<sup>1</sup>, M. McQuarrie<sup>2</sup> and S. Calton<sup>1</sup>, (1)Brigham Young University, Provo, UT, (2)Brigham Young University, Provo, UT**

---

#### Background:

Though the ratio has fluctuated, far more males than females are currently diagnosed with Autism Spectrum Disorder (ASD; henceforth *autism/autistic*). While some have assumed autism to truly be more common in males (e.g., the Female Protective Effect), others have suggested that the diagnostic discrepancy may be due to differences in autistic trait expression between the groups, male-centric diagnostic practices, and/or enhanced camouflaging of autistic traits by females.

Few studies have examined sex differences in sensory processing and its relationship to autistic traits and other associated characteristics-i.e., anxiety, social camouflaging, and intolerance of uncertainty. While such autistic traits are commonly observed in diagnosed individuals, they are also found to varying degrees across the neurotypical population (i.e., termed the Broad Autism Phenotype; BAP). Thus, we propose that examining autistic traits in neurotypical individuals can provide insight into autistic males and females' different experiences with sensory processing and its associated behaviors.

#### Objectives:

We aimed to examine sensory processing differences between males and females and to understand its relationship with anxiety and autistic trait camouflaging in females. We hypothesized significant differences in sensory processing and its correlates between neurotypical young adult males and females.

#### Methods:

Participants were 1020 neurotypical young adults (513 female), ages 18-26 years. Subjects completed multiple questionnaires, each measuring our behaviors of interest, including sensory processing, autistic traits, intolerance of uncertainty, anxiety, and autistic trait camouflaging. One-way ANOVA was used to test differences between males and females' questionnaire scores. Furthermore, relationships between the questionnaires were calculated and compared between females and males using correlation, regression, and mediation analyses.

#### Results:

Results revealed notable differences in sensory processing and associated behaviors between males and females. For instance, these groups differed in their taste, smell, movement, visual, and auditory sensitivity, as well as their low energy sensory scores, such that females expressed more sensory atypicalities and presented with increased sensory hyperactivity than males. Furthermore, both males and females showed significant positive correlations between autistic traits and sensory processing, though they did not differ in levels of overall autistic trait expression.

We also observed significantly more anxiety in females than males in our sample, even though significant positive correlations were found between sensory processing and anxiety, and this relationship was mediated by intolerance of uncertainty similarly in both groups. Interestingly, females showed a significantly stronger association between camouflaging and anxiety.

## Conclusions:

Our findings suggest that while the overall level of autistic traits and general relationship between sensory processing and autistic traits may be similar between neurotypical females and males, sensory processing profiles might differ between these groups. In addition, our study further supports the notion that autistic traits may be expressed differently in females, in that anxiety seemed to play a larger role in female participants. Finally, according to our findings, camouflaging of autistic traits may be a significant correlate of anxiety, especially in females. Appreciating the above similarities, differences, and relationships in neurotypical individuals may improve understanding of autism in females, potentially allowing for improved diagnostic practices and supports.

**405.101** (Poster) Intolerance of Uncertainty, Sensory Processing, and Related Correlates in Autistic Children during the COVID-19 Pandemic  
**G. J. Cardon** and **M. Bradley**, *Brigham Young University, Provo, UT*

---

## Background:

Autistic individuals tend to show intolerance of uncertainty (IU), a trait that is significantly associated with sensory processing and anxiety. While life situations with heightened unpredictability are challenging for most, such circumstances are potentially more difficult for autistic individuals.

The COVID-19 pandemic brought great uncertainty. Circumstances such as periods of lockdown and quarantine, social distancing, mask wearing, cancellation of school/work, and isolation from or increased exposure to family and friends have led to mental health challenges.

Recent publications have shown that disruption to routines and unpredictable circumstances were particularly negative for autistic children and their caregivers during COVID. Given the association between sensory processing and IU, it's possible that increased uncertainty was associated with concomitant increases in atypical sensory processing. However, no study to date has investigated these factors and their correlates in autism.

## Objectives:

We aimed to examine the relationship between IU, sensory processing, and other correlates in autistic children during the COVID-19 pandemic using both quantitative methods and in-depth interviews. We hypothesized that COVID-19 conditions led autistic children to experience increased IU, which was associated with heightened atypical sensory processing and stress.

## Methods:

Participants were parents of 51 children with clinical diagnoses of Autism Spectrum Disorder (ASD). All participants completed a survey detailing the experiences of their household and children during the initial months of the COVID-19 pandemic. Parents also filled out the Short Sensory Profile (SSP) and the Intolerance of Uncertainty Scale (IUS-12) twice each--once as if they were filling them out pre-COVID and another as if they were in the first six months of the COVID-19 pandemic. Furthermore, ten participants took part in interviews where they gave an in-depth recollection of their experiences during the pandemic. We used quantitative analysis (repeated measures ANOVA) to compare the pre- and during-pandemic SSP and IUS-12 scores, and conducted correlation analysis to examine associations between questionnaire scores and factors such as household, parent, and child stress. Finally, we used qualitative thematic analysis to analyze interviews.

## Results:

31 participants (61.0%) presented with significantly less favorable SSP scores following the initiation of COVID ( $F=4.96; p=0.05$ ). Similarly, 28/51 subjects (54.9%) received significantly worse scores on the IUS during early vs. pre-COVID ( $F=9.56; p=0.005$ ). In contrast, those whose SSP and IUS scores improved did not show significant improvements. Additionally, atypical sensory processing during the pandemic significantly correlated with stress in autistic children, their parents, and households. Further quantitative results concerning associations between sensory processing, IU and other relevant factors, as well as insights from in-depth interviews will be discussed.

## Conclusions:

Our findings show that COVID-19 conditions were associated with increased IU and abnormal sensory processing for the majority of participants, though others presented with more favorable or equivalent scores during vs. pre-pandemic. Additionally, our findings provide evidence of a correlation between increased atypical sensory processing and stress for autistic individuals, and their families. Increasing our understanding of these factors and their associations may lead to improvements during future times of uncertainty.

#### 405.102 (Poster) Motor Skills Predict Adaptive Behavior in Children and Adolescents with Autism Spectrum Disorder

N. E. Fears<sup>1</sup> and H. L. Miller<sup>2</sup>, (1)School of Kinesiology, University of Michigan, Ann Arbor, MI, (2)School of Kinesiology, University of Michigan, Ann Arbor, MI

**Background:** There is a well-documented difference between the IQ and adaptive behavior scores of children with Autism Spectrum Disorder (ASD, autistic). Specifically, autistic children often have lower adaptive behavior scores than would be predicted based on their IQ scores. There are also well-documented differences in motor skills in individuals with ASD. These findings range from differences in grasping and arm movements to static and dynamic postural control. These differences in motor skills may explain, at least in part, the variability in autistic individuals' adaptive behavior scores, even when controlling for IQ and ADOS scores.

**Objectives:** The current study aimed to determine how measures of motor skills might explain autistic individuals' low adaptive behavior scores and which individual components of IQ (i.e., verbal comprehension and perceptual reasoning) and motor skills (i.e., manual dexterity, aiming and catching, and balance) may drive this effect.

**Methods:** We tested 45 children and adolescents with ASD (Male=38, Female=7;  $M_{age}=12.30$ ,  $SE_{age}=3.48$ ,  $Range_{age}=5.18-17.80$ ). Participants were tested on the ADOS-2, MABC-2, WASI-II. Participants' guardians reported the participants' adaptive behavior abilities on the Vineland-3.

**Results:** As expected, we found a significant difference ( $M_{diff}=25.38$ ,  $t=8.91$ ,  $p<.001$ ) in the full-scale IQ mean ( $M=103.87$ ) and the adaptive behavior score mean ( $M=78.49$ ) indicating that our participants' adaptive behavior scores were lower than would be expected given their full-scale IQ. We used correlation analyses to examine the relations between participants' age and each of the variables derived from the standardized assessments (See table 1).

We investigated whether motor skills predict adaptive behavior in children and adolescents with ASD by regressing adaptive behavior scores onto full-scale IQ scores, movement total scores, and ages. Results indicated that age ( $F_{1,40}=9.76$ ,  $b=-1.59$ ,  $SE=0.51$ , Cohen's  $f^2=0.24$ ,  $p=.003$ , Figure 1) and movement total score ( $F_{1,40}=5.67$ ,  $b=1.81$ ,  $SE=0.76$ , Cohen's  $f^2=0.14$ ,  $p=.022$ , Figure 1) were related to adaptive behavior standard scores, but ADOS-2 calibrated severity scores and, as expected, full-scale IQ scores were not ( $ps>.05$ ). As participants' movement total scores increased, their adaptive behavior scores increased. As participants' age increased, their adaptive behavior scores decreased.

To further investigate these relationships, we regressed adaptive behavior scores onto age, ADOS-2 calibrated severity scores, individual component scores of full-scale IQ (i.e., verbal comprehension, perceptual reasoning), and the individual component scores of the movement total scores (i.e., manual dexterity, aiming and catching, balance). Results indicated that age ( $F_{1,37}=9.96$ ,  $b=-1.63$ ,  $SE=0.52$ , Cohen's  $f^2=0.27$ ,  $p=.003$ ) and manual dexterity standard scores ( $F_{1,37}=4.75$ ,  $b=2.12$ ,  $SE=0.97$ , Cohen's  $f^2=0.13$ ,  $p=.036$ ) were related to adaptive behavior scores. As participants' manual dexterity scores increased, their adaptive behavior scores increased. As participants' age increased, their adaptive behavior scores decreased.

**Conclusions:** Motor skills are related to autistic individuals' adaptive behavior scores. Specifically, autistic individuals' manual dexterity explains a significant proportion of the variability in their adaptive behavior scores even when controlling for ADOS, IQ, and other motor skills scores. These results are highly impactful, clearly illustrating the need for further understanding of autistic individuals' difficulties with adaptive behavior and the potential role of motor skill difficulties that may underlie, at least in part, these difficulties.

#### 405.103 (Poster) Paired Tactile Stimulation Enhances Tactile Perception in Children with and without Autism

M. Balabanovska<sup>1</sup>, J. L. He<sup>2</sup>, H. Powell<sup>3</sup>, P. A. Celnik<sup>4</sup>, R. A. Edden<sup>5</sup>, S. H. Mostofsky<sup>6</sup> and N. A. Puts<sup>7</sup>, (1)King's College London, London, United Kingdom, (2)King's College London, London, MD, United Kingdom, (3)Institute of Psychiatry, Psychology & Neuroscience, King's College London, London, United Kingdom, (4)Department of Physical Medicine and Rehabilitation, The Johns Hopkins University School of Medicine, Baltimore, MD, (5)Russell H. Morgan Department of Radiology and Radiological Science, The Johns Hopkins University School of Medicine, Baltimore, MD, (6)Center for Autism and Related Disorder, Kennedy Krieger Institute, Baltimore, MD, (7)Russell H. Morgan Department of Radiology and Radiological Science, Institute of Psychiatry, Psychology & Neuroscience, King's College London, UK, Baltimore, MD, United Kingdom

**Background:** Tactile difficulties are among the most prevalent sensory symptoms in Autism Spectrum Disorders (ASD). Adaptation, a mechanism by which perception is modulated by prior exposure to a stimulus, is often reported as impaired in ASD. A sub-threshold tactile pre-stimulus can modulate the response to a subsequent stimulus. The timing between pre- and test-stimuli is thought to engage different inhibitory mechanisms. We previously showed that exposure to a sub-threshold train of stimuli worsens sensory threshold in neurotypical (TDC) but not autistic children (ASD). Few studies have systematically assessed the role of stimulus-type and -timing in adaptation in ASD. Understanding these roles may inform the biology underlying altered sensory processing.

**Objectives:** 1) Investigate group differences in adaptation on detection thresholds in ASD and TDC. We hypothesized that sub-threshold pre-stimulation would worsen detection threshold in TDCs but have a more limited effect in ASD, reflecting atypical adaption. 2) Investigate the effect of interstimulus intervals; ISI (30 ms and 100 ms) to explore the effect of ISI reflecting different inhibitory mechanisms. We hypothesized ASD to have reduced effects of paired-stimulation in both ISI conditions.

**Methods: Demographics.** Twenty-four autistic children and fifty-one controls (TDC) (8-12 yrs old,  $IQ > 100$ ) took part in the study. *Psychophysical assessment of vibrotactile perception.* All stimuli (25 Hz) were delivered to the left index and left middle finger using a Cortical Metrics tactile stimulator. Two-alternative forced choice approaches were used to estimate detection threshold (Figure 1). In the baseline condition, participants were asked on which of their fingers they felt a stimulus. In the two pre-pulse conditions, the tasks were identical with the exception that the test-stimulus was preceded by a weak (3 mm) stimulus by either 30 ms (SDT30) or 100 ms (SDT100). The order in which the tasks were completed was

counterbalanced. *Analysis.* A repeated-measures two-way (2x3) ANOVA was used to test main effects of, and the interaction between, condition and diagnosis on threshold. Pearson correlations were used to examine the relationship between condition and adaptation effect on outcomes (ADOS-2 and SEQ).

**Results:** Both pre-stimulus stimulation conditions significantly enhanced detection thresholds in both groups (ASD and TDC) for both SDT30 and SDT100 conditions compared to baseline (both  $p < 0.001$ ; Figure 2). We did not find associations between adaptation effects and clinical features (all n.s.).

**Conclusions:** In prior pre-stimulus work in which a stimulus train slowly increased in amplitude, we found worse threshold in TDC but not ASD. We expected the same effect here. Contrary to our hypothesis, detection improved at short and long ISI in both groups. Strikingly, recent work in adults reports a differential impact of single (enhanced perception) versus pulse-train (worse perception) pre-stimulation, explaining our current and prior findings. This work suggests that mechanisms underlying single-pulse pre-stimulation (linked to sensory priming) are intact in ASD, whereas those associated with pulse-trains (our prior work) are altered (linked to sensory gating). Given the clinical implication of perception on sensory and social difficulties, enhancement of sensory thresholds through pre-stimulation might have useful implications for interventions.

**405.104 (Poster)** Postural Control during Preparation and Execution of Voluntary Arm Movements in Children with Autism Spectrum Disorder  
*S. W. Park<sup>1</sup>, S. Bond<sup>2</sup>, A. Cardinaux<sup>3</sup>, P. Sinha<sup>1</sup> and D. Sternad<sup>1</sup>, (1)The University of Texas at San Antonio, San Antonio, TX, (2)Northeastern University, Boston, MA, (3)Massachusetts Institute of Technology, Cambridge, MA*

---

**Background:** Motor clumsiness has often been observed in autistic individuals (Fournier et al., 2010; Bhat et al., 2011; Gowen & Hamilton, 2013). Although many studies have reported postural differences in autism spectrum disorder (ASD; Lim, et al., 2017), causal underpinnings remain unclear. A recent theoretical framework suggests that the seemingly disparate symptoms of ASD in multiple domains may share a common core: a reduced ability to make predictions (Sinha et al., 2014; Lawson et al., 2014; van de Cruys, et al., 2014; Pellicano & Burr, 2012). Since voluntary actions require anticipatory postural adjustments (APAs) to avoid perturbations to postural balance (Aruin, 2003), this study focused on postural control prior to action execution with four motor tasks that present different degrees of postural challenges.

**Objectives:** We hypothesize that children with ASD show atypical postural dynamics, specifically during motor preparation. We examined whether the postural differences depended on the degree of self-generated perturbation.

**Methods:** Fourteen children with ASD (13 males and 1 female, age 9-12 years,  $M=11.2$ ,  $SD=1.0$ , IQ (non-verbal WISC Index),  $M=107$ ,  $SD=15.5$ ) and 14 non-autistic (NA) children (11 males and 3 females, age 9-12 years,  $M=11.0$ ,  $SD=1.0$ , IQ  $M=117$ ,  $SD=9.7$ ) participated in a series of motor tasks involving the control of standing posture. Age and IQ did not significantly differ between ASD and NA. All NA and 12 of 14 ASD children participated in all four tasks. The tasks were 1) quiet standing, 2) reaching and grasping a static object (suspended ping-pong ball) at a comfortable distance, 3) same task as 2) at full arm length, and 4) rapid lifting of straight arms above the head. For the tasks that involve voluntary actions, children were instructed to move as rapidly as possible. Arm kinematics and center of pressure (CoP) were measured with 3D motion capture (Qualisys) and force plates (AMTI), respectively. When standing still, the area of postural sway was quantified as a 95% confidence ellipse of CoP. For other tasks, we analyzed reaction and movement time as well as the CoP during the preparation and execution periods. Specifically, the CoP path length normalized by net CoP displacement change served as a metric for active postural control.

**Results:** For the arm lifting task, ASD participants exhibited less active postural control during the preparation compared to the NT participants ( $p=0.024$ ), indicating reduced APA in ASD. The metric did not show a group difference during the movement execution period. Reaction and movement time did not show any significant group differences for all tasks that require voluntary actions. Postural sway during quiet standing did not show any significant group difference.

**Conclusions:** ASD children manifest atypical CoP dynamics during movement preparation specifically in the task that generated the largest perturbations. We suggest that the reduced APA may underlie postural deficits that have frequently been found in individuals with ASD. Further, the results align with studies that support the hypothesis of reduced predictive ability in autism. With this theoretical embedding, the results have implications beyond motor control towards a more encompassing understanding of autism.

**405.105 (Poster)** Quantification of Fine Motor Skills Via a Tablet-Based Video Game in Young Autistic and Neurotypical Children

---

## **Background:**

Delays in early motor abilities are common in autistic children. Evidence suggests that the presence of early motor impairments is predictive of later acquisition of language skills. Our goal was to develop a scalable assessment tool that could provide quantitative, objective metrics of early motor skills. To this end, we developed a mobile application that can be administered on a smartphone or tablet and contains a strategically designed "bubble popping" game (Figure-1a). We also examined the association between performance on this assessment tool and standardized measures of motor and cognitive skills on the Mullen Scales for Early Learning.

## Objectives:

Develop and study a developmentally-appropriate mobile game that elicits specific motor-behavioral patterns associated with pointing, motor planning and control, and repetitive and exploratory behavior. From the touch data collected by the device, we developed a set of lower-dimensional features that can potentially be used to assess behavioral patterns in children diagnosed with autism spectrum disorder (ASD).

## Methods:

This study included 214 children, separated by age into two groups matched in terms of age, IQ, and previous experience playing videogames. The younger sample, aged 18-36 months, included 151 toddlers (128 neurotypical and 23 diagnosed with ASD). The older sample, aged 48 months to 10 years, included 63 children with ASD, 32 of whom had co-occurring attention-deficit/hyperactivity disorder (ADHD). We gathered information from the touchscreen and the kinetic device sensors and engineered features that characterize the child's motion patterns in a low-dimensional space. We quantified, among others, the number of bubbles accurately popped, the popping precision, the screen exploration, and the touch speed and force (Figure-1). We studied the correlation (Spearman's) of the motor-related features with standardized measures of motor and overall cognitive ability. Then we tested the diagnostic prediction power of the most promising set of motor features.

## Results:

Combining both samples, motor features were strongly correlated with the participants' age (e.g., number of touches  $\rho=.65$ , average touch duration  $\rho=.73$ ). After correcting for age, several of the motor features remained significantly correlated with clinical measures of motor ability. Specifically, the Mullen fine motor T-score was positively associated with the popping accuracy ( $\rho=.41$ ). Furthermore, the Mullen early learning composite score was correlated with the percentage of bubble pops that were repeated ( $\rho=.41$ ). For the younger cohort, Mullen composite score was correlated with the average error ( $\rho=-0.36$ ). In the older cohort, the total score of the ADHD Rating Scale was associated with the average touch duration ( $\rho=0.40$ ) and touches frequency ( $\rho=0.39$ ). Finally, we used a machine-learning classification paradigm combining these features and demonstrated that the motor features discriminated between autistic and neurotypical toddlers in the younger cohort (Figure-2a) and between autistic children with and without co-occurring ADHD in the older cohort (Figure-2b).

## Conclusions:

We demonstrated that an attractive on-tablet game can collect information about fine motor abilities with autistic children. Specifically, we showed that the motor variables derived from the game correlate with standardized measures of motor abilities, and that a combination of them can be beneficial for assessing early fine motor skills.

### 405.106 (Poster) Reduced Autonomic Response to Pleasant Touch in ASD Children

**M. R. Bufo**<sup>1,2</sup>, **M. Guidotti**<sup>1,2,3</sup>, **Y. Mofid**<sup>1,2</sup>, **F. Bonnet-Brilhault**<sup>1,2,3</sup>, **N. Aguilon Hernandez**<sup>1,3</sup> and **C. Wardak**<sup>1,2</sup>, (1)UMR 1253, iBrain, Université de Tours, Inserm, Tours, France, (2)Exac-t, EXcellence Center in Autism and neurodevelopmental disorders, Tours, France, (3)Université François Rabelais de Tours, Tours, France

## Background:

Touch includes different aspects like discrimination and affective components. Affective and social touch, essential in the development of interpersonal non-verbal interactions, could be affected in some neurodevelopmental disorders such as Autism Spectrum Disorders (ASD). This affective and social touch would mainly be mediated by the tactile affective pathway, whose input is the caress-like stimulation of the C-tactile fibers (CT-fibers) of the hairy skin. In order to study affective touch in ASD patients, even with low IQ or no language, we focused on the easily accessible responses of the Autonomic Nervous System (ANS). ANS, via its parasympathetic and sympathetic branches, influences several organs and has a key role in regulating socioemotional functions. A few previous studies have shown that affective touch can evoke measurable ANS responses, however it has never been tested in ASD patients.

## Objectives:

This study aimed at measuring several ANS responses during pleasant tactile stimulation targeting the affective and/or the discriminative tactile pathways in ASD children and typically developing (TD) children.

## Methods:

We recruited twenty 6-12 years old ASD children ( $108\pm16$  months; 18 males) and twenty TD age-matched children ( $111\pm18$  months; 7 males). We performed, in a pseudo-randomized order, 10 stimulations on the forearm (high CT-fibers density) and 10 stimulations on the palm of the hand (very low CT-fibers density) with a soft texture tool. Each stimulation lasted 4 seconds, the texture moving back and forth on a 6 cm segment of skin at a 6 cm/s speed. Three ANS measures were recorded simultaneously: pupil diameter, thanks to a 500 Hz eye-tracker (SMI RED500®); skin conductance, thanks to two electrodes on the right index and medium fingers (1 kHz, BIOPAC MP36®); and heart rate, thanks to two electrodes on the sternum and right shoulder (2 kHz, BIOPAC MP36®). Participants had to look at a screen for the whole length of the procedure while staying still on the armchair.

## Results:

We discarded pupil data in eleven ASD children due to head movements and SCR in one ASD child due to excessive hand movements. The two different sites of stimulation (affective/discriminative pathways) did elicit differences in pupil and SCR parameters in TD children, while no pupil, SCR or cardiac parameter was affected in ASD children. Comparison between ASD and TD children revealed that our pleasant stimulation evoked a heart rate deceleration, larger in TD than in ASD children ( $p < 0.01$ ). We also found a reduced SCR latency ( $p < 0.05$ ) and larger SCR amplitude ( $p < 0.01$ ) in TD compared to ASD children. The small sample of ASD children with a pupil recording prevented any significant statistical analysis, even if pupil dilation following the tactile stimulation seemed reduced in ASD compared to TD children.

## Conclusions:

Overall, we observed a diminished ANS reactivity to pleasant tactile stimulation in ASD compared to TD children, whether the stimulation targeted the more affective or more discriminative tactile pathway. We showed that accessible ANS measures in children could be relevant to characterize affective touch processing in children with ASD.

### **405.107 (Poster)** Relationship between Sensory Processing and Behavioral and Physiological Distress during Routine Dental Cleanings in Children with Autism Spectrum Disorder

**L. I. Duker (Stein)<sup>1</sup>, C. Jolette<sup>2</sup>, C. Vigen<sup>2</sup> and S. Cermak<sup>3</sup>**, (1)Chan Division of Occupational Science and Occupational Therapy, University of Southern California, Los Angeles, CA, (2)University of Southern California, Los Angeles, CA, (3)USC Mrs. T.H. Chan Division of Occupational Science and Occupational Therapy, University of Southern California, Los Angeles, CA

**Background:** Oral care is an essential part of pediatric health; when untreated, poor oral health can lead to pain, infection, and difficulty with eating, speaking, and sleeping. However, children with autism spectrum disorder (ASD) exhibit a higher incidence of poor oral health and are at greater risk for developing dental disease. Likewise, they experience significantly more challenges in the access and receipt of dental care. Many of these challenges have been linked to sensory over-responsivity, which is commonly experienced in this population. However, the majority of these studies have utilized parent-report measures to assess the relationship between sensory over-responsivity and oral care challenges, with few studies directly measuring challenges in situ.

**Objectives:** To examine the relationship between sensory sensitivities and behavioral and physiological distress experienced during routine dental cleanings in children with ASD.

**Methods:** As part of a larger randomized control trial, 162 ethnically diverse children with ASD between 6-12 years old received a dental cleaning. Prior to the cleaning, parents completed the Sensory Over-Responsivity Inventory (SensOR) to assess participants' sensory processing. Electrodermal activity, as a measure of physiological stress and anxiety, was collected from the child throughout the entire dental cleaning. To assess behavioral distress, dentists completed the Frankl Scale and Anxiety and Cooperation Scale immediately following the cleaning; researchers used the Children's Dental Behavior Rating Scale (CDBRS) to score behavioral distress from video-recordings at a later date. Multiple mixed effects linear regression models were run with each electrodermal and behavior variable at each dental visit as the dependent variables, crossed with each sensory measure as measured at baseline as independent variables. Additional independent variables in each model were age at sensory assessment, age at dental visit, and first vs. second dental visit. Variables were rank-scored to allow for non-normally distributed data, and standardized so that the beta estimates would represent partial correlation coefficients.

**Results:** Sensory over-responsivity was significantly correlated with behavioral and physiological distress. Specifically, the SensOR Inventory total score was correlated with behavioral distress as measured by the Frankl Scale ( $r = -.19$ ,  $p = .01$ ), the Anxiety and Cooperation Scale ( $r = .20$ ,  $p = .008$ ), and the CDBRS total score ( $r = .17$ ,  $p = .02$ ), as well as physiological distress measured by electrodermal activity ( $r = .21$ ,  $p = .006$ ); significant correlations were also found between behavioral and physiological distress and the individual SensOR Inventory subtests Tactile, Self-care, Sensations, Auditory, Visual, and Olfactory.

**Conclusions:** Sensory over-responsivity is linked to the experience of behavioral and physiological distress in children with ASD during routine dental cleanings. These findings provide insight into the potential for sensory-related interventions to improve dental care for children with ASD.

### **405.108 (Poster)** Relationships between Age and Diagnostic Status on the Presence of Restricted Interests in Toddlers with ASD, Developmental Delay, and No Delay

**M. Frisch<sup>1</sup>, K. L. Coulter<sup>1</sup>, R. P. Thomas<sup>1</sup>, M. Barton<sup>1</sup>, D. L. Robins<sup>2</sup> and D. A. Berger<sup>1</sup>**, (1)Psychological Sciences, University of Connecticut, Storrs, CT, (2)A.J. Drexel Autism Institute, Drexel University, Philadelphia, PA

**Background:** Highly restricted or fixated interests are symptomatic of a diagnosis of autism spectrum disorder (ASD); however, the presence of restricted interests is normative in early childhood (DeLoache et al., 2007). Research suggests that children with ASD display more frequent restricted interests compared to developmentally delayed (DD) and typically developing (TD) peers around 24 months of age, and that these interests differ in nature and intensity in later childhood (Richler et al., 2007; Turner-Brown et al., 2011). Although caregivers more frequently endorse restricted interests in toddlers with ASD compared to those with DD and TD across early childhood (Coulter et al., 2021a), our understanding of the specific relationships between age, diagnosis, and the presence of restricted interests is limited.

**Objectives:** This analysis aims to explore the relationships between age and diagnostic classification (ASD, DD, or TD) on the presence of restricted interests.

**Methods:** Participants were caregivers of 294 toddlers aged 12-36 months ( $M=19.20$ ) who received a developmental/diagnostic evaluation due to a positive screener or pediatrician concern. Of these children, 72 were diagnosed with ASD, 131 were DD, and 91 were TD. A semi-structured interview, the Toddler Autism Symptom Inventory (TASI; Coulter et al., 2021b), was completed with caregivers during the evaluation. Two questions from the TASI were utilized to determine presence of restricted interests in participating toddlers; (a) “Is there anything that your child seems interested in that seems like all he/she wants to do?” and (b) “Does your child enjoy carrying around or playing with items that differ from most children his/her age?”. Participants were coded as either endorsing the presence of restricted interests or not endorsing based on caregiver response to either or both questions.

**Results:** A two-way ANOVA was conducted to examine the relationships between age and diagnostic classification (ASD, DD, or TD) on the presence of restricted interests. Analysis revealed that there was no statistically significant interaction between age and diagnostic classification on the presence of restricted interests,  $F(26, 243) = .626, p = .923$ . Simple main effects analysis showed that diagnostic classification had a statistically significant effect on the presence of restricted interests ( $p < .001$ ) though age did not ( $p = .638$ ).

**Conclusions:** While diagnosis is related to the presence of restricted interests, no interaction between age and diagnostic classification was found. Results suggest that restricted interests are present from a very young age for all diagnostic classifications but are more frequently endorsed in children diagnosed with ASD, regardless of age. This finding does not support the idea that restricted interests emerge or become characteristic of ASD after 24 months of age. Given the normative presence of restricted interests in very early childhood, future analysis should examine longitudinal changes in the intensity and development of restricted interests across early to late toddlerhood.

#### **405.109 (Poster) Sensory Gating in Neurodevelopmental Disorders: A Scoping Review**

**S. E. Schulz<sup>1</sup>, M. Luszczowski<sup>1</sup>, K. E. Hannah<sup>2</sup> and R. A. Stevenson<sup>3</sup>,** (1)Western University, London, ON, Canada, (2)Psychology, University of Western Ontario, London, ON, Canada, (3)University of Western Ontario, London, ON, Canada

---

##### **Background:**

Sensory gating refers to the ability to automatically filter out irrelevant or redundant sensory information from our environment. Without this ability, individuals would be continually overwhelmed with a constant influx of information from their sensory organs including their eyes, ears, nose, and skin, etc. Sensory gating issues have been commonly reported in a number of neurodevelopmental disorders including, not only autism spectrum disorder, but also attention-deficit/hyperactivity disorder, childhood-onset fluency disorder, and tic disorders. The extent to which sensory gating has been studied within and between these neurodevelopmental disorders remains unclear.

##### **Objectives:**

This review aims to explore the current understanding of sensory gating in neurodevelopmental disorders as a possible transdiagnostic mechanism.

##### **Methods:**

We applied methods according to the Joanna Briggs Institute Manual for Evidence Synthesis, following the population, concept, and context, scoping review eligibility criteria. Using a comprehensive search strategy in five relevant research databases (Medline, EMBASE, CINAHL, PsychInfo, and Scopus), we searched for relevant primary research articles that included one of the four neurodevelopmental disorders of interest, such as autism spectrum disorder, and used a measure of sensory gating. Two independent reviewers screened the titles and abstracts, full texts, and completed data extraction.

##### **Results:**

We identified a total of 122 relevant articles and used descriptive analyses to summarize the characteristics and outcomes of all identified studies. Sensory gating was assessed with a variety of measures including prepulse inhibition, habituation, affect-modulated startle, observational measures, and self report. Assessment tools included electromyography, electroencephalography, skin resistance changes, functional near-infrared spectroscopy, respiratory response, and functional magnetic resonance imaging. Overall, the results were very mixed such that study methodologies and participant characteristics impacted the findings in studies of all four clinical groups of interest.

Of the 122 relevant articles found, 49 included ASD as the population of interest and the sample ages spanned the life course. Evidence supports reduced habituation in autistic children and other sensory gating measures were often dependant on key characteristics of the study (e.g. the volume of the startle stimulus or the interstimulus interval) or the samples (e.g. anxiety levels or degree of sensory sensitivity). Overall, we found that the majority of studies supported intact sensory gating in autistic adults. The two areas that are still under contention include habituation and affect-related startle responses. Neurotypicals commonly experience habituation to repeated stimuli and an inhibited startle response following pleasant photos, whereas the startle response of autistic participants was not inhibited in either scenario.

##### **Conclusions:**

Overall, the evidence is inconsistent within and between disorders suggesting there is still much to learn about sensory gating in neurodevelopmental disorders. Within autism, there is evidence to suggest that sensory gating improves into adulthood; however, there appears to be specific conditions and subgroups within the autistic population that could benefit from additional study in this area.

---

**Background:** Exteroceptive and interoceptive sensory processing differences are common in ASD and occur at behavioral, perceptual, and neural levels. These sensory differences may have implications for social, emotional, and occupational outcomes.

**Objectives:** To characterize interoceptive and exteroceptive sensory differences in ASD, their relationship with school performance and social-emotional traits, and their underlying neural mechanisms.

**Methods:** We compared youth aged 8-17 years with ASD to typically developing (TD) youth on sensory processing measures with: school performance ( $N_s = 26$  ASD, 26 TD), social-emotional measures ( $N_s = 35$  ASD, 40 TD), and neural responses to facial expressions ( $N_s = 28$  ASD, 37 TD). Assessments included: self or parent-reported measures of 1. *sensory/interoceptive*: a) The Short Sensory Profile 2 (SSP-2), b) Body Awareness Very Short Form (BPQ-VSF), c) interview of bodily sensation when describing emotional experience (BSE), d) physiological hyperarousal (PH-C) 2. *social-emotional*: a) Alexithymia Questionnaire for Children (AQC), b) Interpersonal Reactivity Index (IRI), and 3. *School performance*: a) Child Behavior Checklist School Competence Scale (CBCL-SCS) variables. During fMRI, children observed videos of facial expressions in the scanner. Parameter estimates were extracted from regions of interest associated with interoception and emotional empathy (anterior insula [AI], anterior cingulate [ACC], amygdala, and pars opercularis [IFGop]). Analyses included: Independent samples t-tests, Pearson correlation, and stepwise and hierarchical multiple linear regression.

**Results:** Compared to TD, the ASD group had increased SSP-2 scores, PH-C, and alexithymia; and decreased CBCL-SCS ( $p$ 's < .05); there were no group differences in interoception (BPQ-VSF or BSE) or emotional empathy (IRI). In the ASD group, an interaction between increased sensory sensitivity and reduced sensory avoidance behaviors explained the greatest amount of variance in CBCL-SCS, even after controlling for age, IQ, and ADHD symptoms. In the TD group, PH-C was positively correlated with personal distress (IRI;  $p = .027$ ) and alexithymia ( $p = .027$ ). In the ASD group, higher BSE correlated with lower personal distress (IRI;  $p = .026$ ) and alexithymia ( $p = .046$ ). However, we found a *negative* relationship between BPQ-VSF and activity in the amygdala, AI, and IFGop in the ASD group, and between the PH-C and the amygdala in the TD group. Conversely, BSE had a positive relationship with AI activity in the ASD group.

**Conclusions:** In youth with ASD, sensory processing strongly impacts school performance, with greater hypersensitivity and fewer avoidance behaviors relating to lower school performance. For the ASD group, while there is no evidence of reduced interoceptive ability (BPQ-VSF) at the group level, reduced awareness of interoceptive information during emotion experience (BSE) was related to greater alexithymia and personal distress. Neural and behavioral data suggests that in the ASD group, BPQ-VSF may index maladaptive symptoms of self-focused interoception more consistent with physiological hyperarousal than with interoceptive accuracy. Conversely, the interview method (BSE) may index interoceptive sensibility that promotes positive outcomes of attention to bodily signals (lower personal distress, lower alexithymia, greater AI activation). Our results point to the need for targeted interventions for children with ASD depending on their level of sensory sensitivity, self-regulation, physiological arousal, and interoception.

#### **405.111 (Poster) Sensory Reactivity Patterns Predict Variation in Restricted and Repetitive Behaviors in Non-Autistic Children**

**S. Soker-Elimaliah<sup>1</sup> and J. B. Wagner<sup>2</sup>,** (1)The Graduate Center, College of Staten Island, City University of New York, New York, NY, (2)Department of Psychology, College of Staten Island, City University of New York, Staten Island, NY

---

**Background:**

Restricted and repetitive behaviors (RRB) are core criteria in ASD diagnosis and can manifest in a variety of ways. Studies have examined the relationship between sensory reactivity and RRB in autistic children and found that hyper-reactivity to sensory input is associated with more RRB (e.g., Boyd et al., 2010) and RRB can be predicted from both hyper- (Schulz & Stevenson, 2019) and hypo-reactivity (Gal et al., 2010). Because sensory reactivity and RRB can be found in the general population, and can have detrimental developmental outcomes including difficulties in adaptive behavior (e.g., Dunn et al., 2016), studies have examined this relationship in non-autistic children, taking the broader autism phenotype (BAP) approach. In non-autistic children, sensory reactivity and RRB were associated (e.g., Feldman et al., 2020), and hyper-reactivity predicted specific RRB subtypes (Schulz & Stevenson, 2019). However, because different sensory reactivity patterns can co-exist in children, it is important to understand how specific sensory pattern combinations might underlie the different RRB subtypes.

**Objectives:**

The current study aims to examine how different sensory reactivity patterns predict variation in RRB subtypes in the BAP.

**Methods:**

The current sample included 52 non-autistic children ( $M_{age} = 6.59$  years,  $SD = 2.50$ , Range: 2.67-11.67). As part of a larger study, parents filled out the Repetitive Behavior Scale-Revised (RBS-R; Bodfish et al., 1999) to assess RRB and the Sensory Experiences Questionnaire (SEQ; Baranek et al., 2006) to measure sensory reactivity patterns. Total RBS-R score and the six subscale scores (stereotyped, self-injurious, compulsive, ritualistic,

sameness, restricted) were calculated as well as SEQ total and sensory response pattern scores (hypo-reactivity, hyper-reactivity, and sensory seeking).

#### Results:

Regression analysis with RBS-R total as the dependent variable and SEQ total as the independent variable showed that RRB were significantly predicted from sensory reactivity ( $F(1,50) = 32.90, p < .001, R^2 = .40$ ). A follow-up regression examined the three sensory response scores as independent variables and results showed that hypo- ( $B = 4.92, p < .001$ ) and hyper-reactivity ( $B = 4.78, p < .001$ ), but not seeking ( $p = .35$ ), significantly predicted RRB. Next, a series of regression analyses examined SEQ total score as a predictor of each of the six RBS-R subscales, and significant models were then followed up with a model using the three sensory response scores as independent variables. Results showed that SEQ total predicted all RBS-R subscales except compulsive. When examining contributions of the sensory response pattern scores, both hypo- and hyper-reactivity predicted stereotyped, ritualistic, and sameness behaviors, and hypo-reactivity and sensory seeking predicted self-injurious and restricted behaviors (see Table 1).

#### Conclusions:

The current study expanded on past work (Gal et al., 2010; Schulz & Stevenson, 2019) and found that different combinations of sensory reactivity patterns predicted different RRB subtypes in non-autistic children, with hypo-reactivity being the most influential sensory pattern (predicting five of the six RRB subtypes), and hyper-reactivity and sensory seeking predicting a smaller number of RRB subtypes. Future work will examine physiological markers that might play a role in mediating the relationship between sensory reactivity and RRB.

#### **405.112 (Poster)** Sensory Symptoms and Internalizing Behaviors in Young Adults and Adolescents with Current ASD, History of ASD, and Typical Development

**H. R. Thomas, M. J. Stabile, R. P. Thomas, D. A. Berger and I. M. Eigsti, Psychological Sciences, University of Connecticut, Storrs, CT**

---

#### Background:

Sensory symptoms are one manifestation of the repetitive or restricted behaviors that are a core diagnostic feature of autism spectrum disorder (ASD). Up to 95% of individuals with ASD exhibit atypical responses to sensory stimuli (Tomcheck & Dunn, 2007), which are typically classified as sensory over-responsivity (SOR), sensory under-responsivity (SUR), or sensory seeking (Miller et al., 2009). Sensory symptoms are thought to have a cascading effect on development across many domains, with particularly strong associations with internalizing behaviors (Green et al., 2012). Studies of individuals with a clear history of ASD who *lose* the ASD diagnosis (LAD) report residual deficits due to internalizing conditions, such as anxiety and depression (Orinstein et al 2015; Fein et al., 2013). However, studies of LAD to date have not probed for the presence of sensory symptoms, and their association with internalizing behaviors.

#### Objectives:

This study measured the presence of sensory symptoms in adolescents and young adults with LAD, current ASD, and typical development (TD) and investigated associations with concurrent internalizing behaviors.

#### Methods:

Data were collected from adolescents and young adults in three groups: LAD [ $n=19$ ;  $M(SD)$  age=23.2(3.2) years]; ASD [ $n=16$ ; 19.9(4.9)]; and TD [ $n=10$ ; 21.9(4.3)]. The Sensory Reactivity in Autism Spectrum (SR-ASD; Elwin et al., 2016) measured total sensory symptoms, SOR, SUR, and sensory seeking. Internalizing behaviors were assessed via parent report with the Achenbach System of Empirically Based Assessment (ASEBA; Achenbach, 2009). Groups did not differ on age or gender. One-way ANOVAs with planned comparisons were conducted to assess diagnostic differences in sensory symptom clusters and internalizing behaviors. Linear regressions probed whether sensory symptoms predicted concurrent internalizing behaviors, above and beyond diagnostic group.

#### Results:

Groups differed in total sensory symptoms and sensory over-responsivity (Table 1). Planned  $t$ -tests revealed significantly more sensory symptoms in all clusters for ASD compared to TD, with large effect sizes (Sensory Total  $d=1.12$ ; SOR  $d=1.03$ ; SUR  $d=0.89$ ; Seeking  $d=0.84$ ). LAD/TD and LAD/ASD group comparisons did not differ. Groups also differed in internalizing behaviors (Table 1); planned comparisons showed that the ASD group exhibited more internalizing behaviors than LAD ( $d=1.21$ ) and TD ( $d=1.68$ ) with large effect sizes; LAD/TD did not differ. Regression analyses indicated that total sensory symptoms, sensory over-responsivity, and sensory seeking predicted concurrent internalizing behaviors while controlling for diagnosis (which did not account for significant additional variance); Table 2.

#### Conclusions:

Sensory symptoms were compared for adolescents and young adults in LAD, ASD, and TD groups. The ASD group exhibited significantly more sensory symptoms than TD; the difference between ASD and LAD groups was not significant, suggesting that participants in the LAD group may still experience subclinical sensory symptoms. The presence of sensory symptoms predicted concurrent severity of internalizing behaviors above and

beyond diagnosis, consistent with findings suggesting that sensory symptoms may contribute to and exacerbate internalizing problems in typical and clinical populations (Istvan, Nevill, & Mazurek, 2020; Green et al., 2012; Ben-Sasson et al., 2009). With data collection underway, future analyses will examine within- and between-group associations of sensory symptoms and internalizing behaviors.

**405.113 (Poster)** The Development and Implementation of an Anonymous Survey to Measure Caregiver Satisfaction with Sensory Interventions for Children with Autism and Related Conditions

**C. F. Layton<sup>1</sup>** and **P. M. Siper<sup>2</sup>**, (1)*The Seaver Autism Center for Research & Treatment, New York, NY*, (2)*Seaver Autism Center for Research and Treatment, Department of Psychiatry, Icahn School of Medicine at Mount Sinai Hospital, New York, NY*

---

**Background:** Sensory reactivity symptoms are present in many individuals with autism spectrum disorder (ASD) and are incorporated into the Diagnostic and Statistical Manual of Mental Disorders, 5<sup>th</sup> Edition (DSM-5) under the Restricted and Repetitive Behaviors domain. The DSM-5 defines sensory symptoms along three dimensions: (1) hyperreactivity, (over-responsiveness), (2) hyporeactivity (under-responsiveness) and (3) sensory seeking, each of which can occur across multiple sensory modalities. Sensory-based interventions are commonly prescribed by occupational therapists and psychologists in the treatment of children with autism and related neurodevelopmental disorders (NDDs). However, there are currently no evidence-based interventions for this population, particularly those with cognitive impairment.

**Objectives:** To examine caregiver satisfaction with various sensory interventions for children with autism and related NDDs.

**Methods:** The most commonly used interventions by sensory domain (visual, auditory, tactile) were identified according to published literature and mainstream sources. A survey was structured to capture sensory preferences based on DSM-5 criteria, with options for characterizing a child with up to two types of sensory symptoms. For each sensory domain, caregivers were asked to select the interventions they had implemented with their child from a list of options. Caregivers were then asked to rate how well the identified interventions worked for their child using a 4-point scale (Never = 1, Sometimes = 2, Usually = 3, Always = 4).

**Results:** Responses for 75 individuals ages 2 to 17 (35 female,  $M_{age} = 9.4$ ) have been collected to date. Of those 75 participants, 46 were reported to have ASD (54% with intellectual disability) and 29 to have a related NDD (22% with intellectual disability). In terms of sensory preferences, caregivers reported the most seeking behaviors (69%), followed by hyperreactivity (49%) and hyporeactivity (20%). Preliminary results indicated that the most-utilized interventions in the visual domain were visual supports (e.g., visual schedules) (27%,  $N=20$ ), sunglasses (17%,  $N=13$ ), and desk partitions (12%,  $N=9$ ). In the auditory domain, the use of noise-cancelling headphones were reported by the greatest number of caregivers (37%,  $N=28$ ), followed by calming/preferred music (27%,  $N=20$ ), and music therapy (23%,  $N=17$ ). In the tactile domain, most caregivers indicated that they used fidget tools with their child (57%,  $N=43$ ), followed by tactile exploration (43%,  $N=32$ ), and massage/touch pressure (41%,  $N=31$ ). Most caregivers reported that the intervention *sometimes* (2) worked for their child for all of the interventions above, except for massage/touch pressure strategies, which most parents reported *usually* (3) worked for their child. Of all of the interventions, the lowest-rated were in the tactile domain, including brushing protocols ( $M=1.72$ ), compression vests ( $M=1.74$ ), and weighted vests ( $M=1.9$ ). The highest-rated were in the auditory domain, including calming or preferred music ( $M=2.85$ ), white noise machines ( $M=2.8$ ), and noise-cancelling headphones ( $M=2.79$ ).

**Conclusions:** Results indicate the caregivers of children with ASD and NDDs utilize a variety of sensory interventions across multiple sensory domains, most of which they perceive as only sometimes working for their child. Future research should evaluate existing sensory interventions in this population using rigorous methodology, such as randomized control trials (RCTs), to validate them as treatment options.

**405.114 (Poster)** The Predictive Relationship between Sensory Reactivity and Depressive Symptoms in Young Autistic Children with Few to No Words.

**T. Rossow<sup>1</sup>**, **K. MacLennan<sup>2</sup>** and **T. Tavassoli<sup>2</sup>**, (1)*Centre for Autism, School of Psychology & Clinical Language Sciences, University of Reading, Reading, United Kingdom*, (2)*Centre for Autism, School of Psychology & Clinical Language Sciences, University of Reading, Reading, United Kingdom*

---

**Background:** Depression, much like other mental health conditions, is common in autism, with autistic individuals much more likely to be diagnosed than their non-autistic peers. Sensory reactivity differences are also commonly experienced by autistic individuals and have been associated with depressive symptoms. However, there is little understanding of the predictive relationship between sensory reactivity and depressive symptoms, or the nature of this relationship in autistic children who speak few to no words.

**Objectives:** This study set out to explore the longitudinal relationship between sensory reactivity and depressive symptoms in young autistic children who speak few to no words over two timepoints.

**Methods:** 33 young autistic children (aged 3-5 at timepoint 1) who spoke few to no words, and who completed Module 1 of the ADOS-2, participated in this study. Parent-report measures of sensory reactivity (SPSI) and depressive symptoms (BASC-3) were given at timepoint 1 and at a 12 month follow up. Correlational analysis and regressions were used to analyse the data.

**Results:** We found positive correlations between depressive symptoms and hyper-reactivity and sensory seeking at both timepoints. We further found a bidirectional predictive relationship between depressive symptoms and sensory seeking.

Conclusions: These results implicate sensory seeking in the development of depressive symptoms in young autistic children who use few to no words. Our findings have important implications for preventative mental health interventions, especially for those with a developmental language delay.

**405.115 (Poster)** The Role of Sensory Processing in Feeding Challenges for Young Autistic Children and Contributions to Family Goals

**K. K. Ausderau<sup>1</sup>** and **B. M. St John<sup>2</sup>**, (1)University of Wisconsin - Madison, Madison, WI, (2)University of Wisconsin-Madison, Madison, WI

---

Background: Feeding challenges effect up to 84% of all autistic children, putting them at high risk of detrimental impacts on their health and development (Leader et al., 2020). In addition, feeding challenges can impact overall family wellbeing and create barriers to child engagement in mealtime. Common autistic feeding challenges include severely limited diet from food selectivity, sensory aversions to food properties, rigid mealtime routines, and difficulty participating in family mealtimes.

Objectives: Examine the role of sensory processing in feeding challenges, mealtime experiences, and functional feeding goals set by caregivers in the context of a caregiver-mediated feeding intervention.

1. Identify the relationship between parent-report sensory features and types of feeding challenges in young autistic children.
2. Characterize how sensory-based feeding concerns relate to child goals and parent concerns.

Methods: 396 families completed a survey related to feeding challenges in autistic children. A subset of those families, n=26 caregiver-child dyads, participated in the Engaged Eaters Program, a six-month caregiver-mediated in-home feeding intervention. Children were between 2 and 7 years, had a diagnosis of autism and caregiver reported feeding challenges. The Sensory Experience Questionnaire 3.0 (SEQ) was used to assess the child's overall sensory processing, the Feeding and Eating in Autism Together (FEAST) was used to assess feeding challenges, and for the families in the Engaged Eaters Program, three goals were collaboratively developed as intervention goals. All goals were developed and scaled using GAS to allow for progress measurement and comparison across families.

Results: Correlations were calculated between FEAST area of feeding challenge (i.e., Sensory, Behavior, Oral Motor, and Health) subscale scores and SEQ 3.0 sensory pattern (i.e., sensory hyperresponsiveness [HYPER], sensory hyporesponsiveness [HYPO], sensory interests, repetitions, and seeking behaviors [SIRS], and enhanced perceptions [EP]) subscale scores. Moderate to large significant correlations were identified between the FEAST Sensory subscale and HYPER ( $r=.507$ ,  $p < .001$ ) and EP ( $r=.302$ ,  $p < .001$ ); Behavior subscale and SIRS ( $r=.500$ ,  $p < .001$ ), HYPO ( $r=.438$ ,  $p < .001$ ), and HYPER ( $r=.404$ ,  $p < .001$ ); and Oral Motor subscale and HYPO ( $r=.337$ ,  $p < .001$ ). A simple linear regression was calculated to predict overall FEAST feeding challenge severity score based on overall SEQ 3.0 severity score. A significant regression was found ( $F(1,398) = 178.172$ ,  $p < .001$ ) with an  $R^2$  of .309. All 26 families had one goal (n=26) focused on expanding their child's repertoire of age-appropriate portion accepted foods. The remaining 52 family goals included the families' primary areas of concerns and were categorized into distinct focus areas (i.e., increased food flexibility, nutrition, oral motor, mealtime routines, self-help skills, and rigid eating behaviors).

Conclusions: Sensory processing plays a clear role in young autistic children's feeding and mealtime challenges. While sensory patterns differentially, contribute to various types of feeding challenges (i.e., OM, Behavior, and Sensory-based). Understanding the underlying contributors to the heterogeneous feeding challenges can help identify appropriate intervention targets to facilitate mealtime participation. In addition, the variety of family priorities and related feeding goals demonstrate that although sensory processing is a critical component of feeding, how it manifests in daily living may be variable.

**405.116 (Poster)** Towards Better Characterization of Circumscribed Interests in Children and Adolescents with Autism

**E. K. Spackman<sup>1</sup>**, **T. W. Frazier<sup>2</sup>**, **A. Y. Hardan<sup>3</sup>** and **M. Uljarevic<sup>4</sup>**, (1)The Melbourne School of Psychological Sciences, University of Melbourne, Parkville, VIC, Australia, (2)Psychology, John Carroll University, Cleveland, OH, (3)Psychiatry & Behavioral Sciences, Stanford University, Stanford, CA, (4)School of Psychological Sciences, University of Melbourne, Stanford, CA, Australia

---

Background: Circumscribed interests (CI) are complex and heterogeneous, encompassing interests that, while typical in topic (e.g., interests in mathematics, arts or TV shows), are intense in terms of focus and/or inflexibility, henceforth labelled restricted interests (RI), and interests that are atypical in topic (e.g., road signs or dates), henceforth labelled unusual interests (UI). Although previous studies have demonstrated the high prevalence of RI and UI in autism, they were limited by sample size and almost exclusively focused on individuals in the normative IQ range, thus limiting the generalizability of findings and insights into the relationship between RI and UI with demographic, cognitive, and clinical variables.

Objectives: This study aimed to investigate prevalence and type of RI and UI as measured by the Dimensional Assessment of Restricted and Repetitive Behaviors (DARB), a novel comprehensive measure of distinct RRB subdomains, in a large, well-characterized sample of children and adolescents with autism that spanned over a broad spectra of cognitive functioning. It further aimed to characterize the pattern of associations between RI and UI with age, sex, IQ, and social and communication impairments (SCI).

Methods: Parents of 1892 children and adolescents with autism ( $M = 10.82$ ;  $SD = 4.14$ ; 420 females) recruited from the Simons Foundation Powering Autism Research for Knowledge (SPARK) database completed the DARB, as a measure of RI and UI and the Social Communication Questionnaire, as a measure of SCI. Data on children's IQ was also collected.

Results: 98.1% (n=1856) of participants demonstrated at least one RI, whilst 85.5% (n=1618) demonstrated at least one UI. The most common RI were interests related to technology, music, and TV shows and movies (endorsed by 81.8%, 80.4% and 78.9% of participants, respectively), whilst the least common RI were interests in psychology (11.3%) and watching sports (19.6%). The most common UI were attachment to a specific object

(53.1%) and fascination with a specific visual aspect of an object (48.1%), whilst the least common were fascination with a specific number (12.4%) and fascination with categorization (16.5%). Two regression models were used to characterize the effects of age, sex, IQ, and SCI on RI and UI scores. The regression model for RI was significant,  $F=13.70$ ,  $p<.001$ , with age ( $\beta=.085$ ,  $p=.001$ ), sex ( $\beta=.072$ ,  $p=.003$ ), IQ ( $\beta=.068$ ,  $p=.008$ ), and SCI as ( $\beta=-.094$ ,  $p<.001$ ) as unique predictors. The regression model for UI was also significant,  $F=7.66$ ,  $p<.001$ , with age ( $\beta=-.067$ ,  $p=.014$ ) and SCI ( $\beta=.123$ ,  $p<.001$ ) as unique predictors.

**Conclusions:** Current findings further emphasise the prevalence and diversity of RI and UI. Interestingly, RI were even more frequent in the current sample than has been reported in previous studies. However, the intensity of preoccupation with these interests is not clear. Importantly, RI and UI showed distinct patterns of relationships with key demographic, cognitive and clinical variables. This may suggest distinct processes underlying RI and UI and demonstrates the need for further research characterising the full range of CI behaviours and their mechanisms.

**405.117 (Poster)** Unsupervised Stratification of Motor Behavior in Autism Isolates a Subtype with Enhanced Motor Noise  
**V. Mandelli<sup>1,2</sup>, I. Landi<sup>3</sup>, S. Busti Ceccarelli<sup>3</sup>, M. Molteni<sup>4</sup>, A. Crippa<sup>4</sup> and M. V. Lombardo<sup>5</sup>,** (1)Center for mind/brain sciences - CIMEC, Centre for Mind Brain Sciences (CIMEC), University of Trento, Italy, Trento, Italy, (2)Center for Neuroscience and Cognitive Systems, Laboratory for Autism and Neurodevelopmental Disorders, Istituto Italiano di Tecnologia, Rovereto, Italy, (3)Scientific Institute, IRCCS Eugenio Medea, Bosisio Parini, Italy, (4)Department of Psychology, University of Milano-Bicocca, Milano, Italy, (5)Center for Neuroscience and Cognitive Systems, Istituto Italiano di Tecnologia, Rovereto, Italy

---

**Background:** Considerable variability exists within the domain of motor development in autism. Motor delays are commonly associated with poorer developmental outcomes and quality of life. Early identification of subtle motor issues could improve phenotypic characterization and planning intervention. At a neurobiological level, many highly penetrant mutations linked to autism also co-occur with substantial motor issues. Many of these genetic causes of autism are also known to dysregulate excitation-inhibition (E:I) imbalance. A downstream consequence of E:I imbalance may be higher levels neural noise in motor cortex that then translate behaviorally into enhanced motor noise, operationalized as enhanced variability in executing actions. The hypothesis examined is whether a subtype exists within autism that shows pronounced motor difficulties on standardized clinical assessments of motor proficiency that also show enhancements in motor noise measured with motor kinematics data

**Objectives:** We aimed to used unsupervised clustering techniques to isolate replicable motor subtypes in autism from simple standardized clinical assessments of motor behavior. Moreover, we looked to fine-grained motor kinematics data to test whether motor subtypes differ in levels of motor noise while executing an upper-limb motor task.

**Methods:**  $n=156$  autistic children aged 3–16-year-old were assessed with the Movement Assessment Battery for Children – 2<sup>nd</sup> edition (MABC-2).  $n=94$  individuals were recruited at a research hospital in Italy (IRCCS Medea), while another  $n=62$  individuals were identified as having MABC-2 data in the National Database for Autism Research (NDAR). To understand whether subtypes could be isolated with unsupervised clustering techniques (e.g., k-means), we use a relative clustering validation framework called *reval* to identify optimal number of clusters and test for reproducibility of clustering solutions in independent data (Landi et al., 2021). Input features to *reval* were standardized scores from the 3 MABC-2 subscales (Manual Dexterity, Aiming and Catching, Balance). A subset of  $n=70$  children recruited at IRCCS Medea performed 10 trials of a *reach-to-drop* task (Forti et al., 2011) while kinematic data were acquired using an optoelectronic system. To measure motor noise, we used a multivariate dynamic time warping (DTW) algorithm to compute the pairwise distances between movement trajectories across the 10 trials in the *reach-to-drop* task. Median distance from DTW was then used to summarize motor noise, with larger distances between trials as indicating high levels of motor noise.

**Results:** *reval* was able to identify 2 motor subtypes as the optimal clustering solution, which achieved a reproducibility accuracy on an unseen test dataset of 89%. These subtypes were highly differentiated by motor noise with the highly impaired motor subtype showing the largest levels of motor noise ( $t=3.2$ ;  $p=0.002$ ; Cohen's  $d=0.77$ ).

**Conclusions:** Autism motor subtypes can be isolated with unsupervised clustering techniques applied to motor profiles present in standardized clinical assessments. Individuals with high levels of motor impairment were those that also showed high levels of motor noise. This result indicates that E:I imbalance may be a particular issue in motor cortex for these individuals. These subtypes may be important for future work on how more personalized early intervention focused on the motor domain may help improve outcomes.

**405.118 (Poster)** Using Both Explicit and Implicit Emotional Responses to Taste Cues for Understanding Taste Preferences Among Autistic Children.

**A. Singh and H. S. Seo, Food Science, University of Arkansas, Fayetteville, AR**

---

**Background:**

Autism spectrum disorder (ASD) is associated with significant sensory challenges that influence feeding behavior, leading to inadequate nutritional balance. In addition to sensory characteristics of food, food evoked emotions have been shown to affect our eating behavior in terms of liking, satiation, sensory characteristics, and the amount of food consumed. Thus, to understand food choice, it is important to examine both sensory and emotional responses of autistic children towards food. Since some autistic children might have difficulties in the expression and understanding of emotions, it is imperative to identify easy methods of emotional measurements.

**Objectives:** The objective of this study was to compare explicit and implicit measurements of emotional responses of autistic children to taste stimuli.

**Methods:** Fifteen autistic children (1 Female; Mean age  $\pm$  SD = 10  $\pm$  2 years) participated in this study. They were given five basic taste solutions: salty (0.44% w/v Sodium Chloride), sweet (7% w/v Sucrose), sour (0.11% w/v Citric Acid), and bitter (0.11% w/v Caffeine and 0.006% w/v Quinine Hydrochloride). The liking and intensity ratings for taste solutions were measured using the 9-point P & K scale ranging from 1 (super bad/ super weak) to 9 (super good/ super strong). To measure implicit taste evoked emotional responses toward the taste solutions, facial expression analysis was used. Explicit emotional responses, a list of 33 emojis were presented in a check-all-that-apply format.

#### Results:

Participants showed a higher liking towards the sucrose solution, as compared to the remaining 4 solutions, with sucrose being the only basic taste that received a liking rating. Interestingly, no difference in the intensity perception was seen between the 5 taste solutions. A biplot of Principle Coordinate Analysis showed that roughly 61% of the variation in the data could be explained by liked vs disliked taste solutions (Figure 1). Sucrose solution was associated with positive valence emojis, whereas caffeine, quinine, and sodium chloride solutions were more associated with negative valence emojis. Correlation analyses showed that frequencies of selecting thirteen different emojis were significantly correlated with the overall liking ratings for all stimuli. On the other hand, the biplot of Principle Component Analysis of the facial expression data showed differences between facial expressions to the taste stimuli (Figure 2). Sucrose solution was associated with “neutral” expression, quinine with “angry” and “disgusted” expression, and sodium chloride with “surprised” expression. The “disgusted” facial expression was negatively correlated ( $P < 0.001$ ) and “neutral” facial expression was positively correlated ( $P < 0.05$ ) with overall liking scores for all stimuli. The “neutral” facial expression was also positively correlated ( $P < 0.05$ ) with overall intensity scores for all stimuli.

**Conclusions:** Both explicit and implicit emotional responses provided an understanding of liking as well as intensity perception of taste stimuli. The results from this study can be useful in developing interventions directed toward emotional regulation during feeding, to reduce food refusal and increase food acceptability.

#### **405.119 (Poster)** The Association between Sensory Domains in Children with Autism Spectrum Disorder

**K. Takach<sup>1</sup>, G. Parra<sup>1</sup>, L. Cornelissen<sup>2</sup> and A. R. Levin<sup>3</sup>,** (1)Boston Children's Hospital, Brookline, MA, (2)Anesthesiology, Boston Children's Hospital, Boston, MA, (3)Neurology, Boston Children's Hospital, Brookline, MA

#### Background:

Sensory processing refers to how the nervous system takes in stimuli from the environment through sensory organs and then processes this information via higher level cognitive functioning. Atypical sensory processing patterns have only recently received greater attention in children with autism spectrum disorder (ASD). Both hyporeactivity and hyperreactivity to different sensations (touch, sound, light, taste, etc.) can occur in ASD.

#### Objectives:

We collect parent-report data on how children with ASD and typically developing (TD) controls respond behaviorally to various sensory domains, which include sensory seeking and avoiding patterns. We hypothesized that sensory seeking and sensory avoiding behavior would be negatively correlated, and that both sensory seeking and avoiding behaviors would be increased in the ASD group.

#### Methods:

We collected data on children 36-47 months of age using the Sensory Profile 2 (SP2). This parent-report survey includes questions about children's behavior in response to various inputs across multiple sensory modalities. The SP2 then calculates scores relating to seeking and avoiding behavior, using variables from every section in the survey. In our study, we split participants into 2 cohorts during recruitment: Typically Developing (TD, n = 6, 5 males, 1 female) and ASD (n = 13, 12 males, 1 female). Recruitment is still active, so these current numbers will increase in the coming months. A Pearson correlation was used to evaluate the association between the avoiding and seeking domains, while an independent-samples t test (uncorrected for multiple comparisons since this was an exploratory analysis) was used to evaluate statistical significance between ASD and TD in each SP2 domain.

#### Results:

There is a positive linear correlation between the Avoiding and Seeking domains in the SP2 for all children, regardless of ASD status ( $r = 0.832$ ,  $p < 0.01$ ; Figure 1). Figure 2 demonstrates that some domains of the SP2 show a statistically significant difference ( $p < 0.05$ ) between ASD and TD participants.

#### Conclusions:

Rather than seeing a dichotomy in which some individuals with ASD demonstrated primarily sensory seeking behaviors and others demonstrated primarily sensory avoiding behaviors, we found that children with strong sensory seeking tendencies also showed strong sensory avoiding tendencies. Certain domains of the SP2 show a marked difference in scores between ASD and TD individuals, suggesting that some sensory processing patterns might be more affected in response to specific stimuli among children with ASD. These findings not only inform our understanding of sensory phenotypes in ASD, but may also guide future steps in using sensory processing as a model for understanding the biology underlying ASD. Specifically, based on our findings we hypothesize that the paradoxical co-existence of sensory hyperreactivity and hyporeactivity seen in ASD

reflects altered “gain control” in ASD (i.e., a tendency for the nervous system to respond to stimuli in an excessively, all-or-nothing manner, rather than modulating itself to allow for more nuanced, graded responses); our future research will aim to test this hypothesis.

**405.120 (Poster)** Autism in Movement: Influence of Motor Development on Other Aspects of Development in Children with and without Autism Spectrum Disorder in New Zealand

**P. Araya-Herrera**, *School of Psychology, The University of Auckland, Auckland, New Zealand*

---

**Background:** Although motor impairments are not a critical diagnostic feature in Autism Spectrum Disorder (ASD), increased clumsiness is typically expected. A gross motor skill (like walking or throwing) is also essential for development. It can evolve into more complex movements that allow the child to engage in other aspects of physical activity and, indeed, to learn by engaging in the world around them. Research has shown that deficits in motor impairments are associated with lower cognitive processing. Motor skills have also been shown to impact social interaction and one's ability to move around their environment, which may influence the child's ability to learn from others and the environment. Furthermore, object exploration supports learning their properties and participating in games with their caregivers. This link facilitates and enriches the experiences of linguistic and social knowledge.

**Objectives:** Increased participation in physical activity has been related to a positive influence on the occurrence of stereotypic behaviour in ASD, social functioning, and health-related outcomes. However, gross motor skills are often necessary to participate in physical activity. Given that people with ASD may be prone to motor deficits, they may also be intensifying their other behavioural excesses and deficiencies. This study aimed to understand how does the gross motor development influence other areas of developmental outcomes in children with and without ASD when controlling mediators such as perinatal health indicators and early sociodemographic in New Zealand.

**Methods:** Sample with and without ASD included 150 participants from the Growing Up in New Zealand project (ASD diagnosis was obtained by parent-report and formal diagnosis at four and a half and eight years), and developmental outcomes were obtained from Data Collection Wave data sets at six weeks, nine months, two years, four and a half years and eight years. Information of prevalence and trajectories was obtained by mother and child questionnaires, child observation and observation instruments to assess motor outcomes of child development. Mediating factors such as ethnicity, maternal education, and socioeconomic status were considered, plus gestational age at birth, body mass index, nutrition, and physical disability. Ethics approval from the Growing Up in New Zealand Data Access Committee (N° IA 21\1014).

**Results:** A decrease in language, cognition and motor alterations were observed in Maori group in children with and without ASD.

**Conclusions:** The lower decrease of motor development in Maori children with and without ASD could be due to protective factors of New Zealand's heritage. Further studies are required in a larger population.

**405.121 (Poster)** Relationships between Motor and Daily Living Skills in Children with Autism Spectrum Disorder (ASD): A SPARK Dataset Analysis

**A. N. Bhat**, *Department of Physical Therapy, University of Delaware, Newark, DE*

---

**Background:** Eighty-seven percent of children with Autism Spectrum Disorder (ASD) from the SPARK study cohort are at risk for motor impairment (Bhat, 2020) and their motor performance correlated with their core social communication impairment, repetitive behavior severity as well as general delays in cognition, language, and functioning (Bhat, 2021). The previous analysis utilized quick parent-report screening tools such as the DCD-Q, SCQ, and RBS-R (Bhat, 2020, 2021).

**Objectives:** This presentation will report new SPARK study data on relations between various domains and subdomains of the Vineland Adaptive Behavioral Scales (VABS-3), a measure of overall and domain-specific adaptive functioning to provide an in-depth examination of adaptive functioning across multiple developmental domains (communication, social, daily living, and motor) and their relations with each other and differences across subgroups based on age, sex, and levels of functioning.

**Methods:** The SPARK study VABS-3 dataset (N=4,257) was examined for associations between multiple developmental domains (social, communication, daily living, and motor) and subdomains (social: play, interpersonal, and coping, communication: receptive, expressive, and written, daily living: community, domestic, and personal, problem behaviors: internalizing, externalizing) of the Vineland Adaptive Behavior Scales, Third Edition (VABS-3). Next, VABS performance for all domains/subdomains will be compared across sex (male, female), age (5-15 years), and functional delay (no delay, some delay, significant delay). Lastly, VABS performance for all domains/subdomains will be compared across domains and whether decline in motor functioning parallels certain other developmental domains.

**Results:** Based on VABS-3 domain scores, 77.9% of children with ASD had low (17.7%) to moderately low (60.2%) motor performance (N=2,644, 4-10 years only). 81.5% of children with ASD between 4 and 16 years had low (34.5%) to moderately low (47.0%) communication performance (N=4,257). 88.1% of children with ASD had low (50.1%) to moderately low (38.0%) social performance (N=4,257). 77.5% of children with ASD had low (35.8%) to moderately low (41.6%) daily living skills performance. In terms of associations between domains, motor VABS standard scores were strongly associated with communication ( $r=0.62$ ), social ( $r=0.61$ ), and daily living ( $r=0.63$ ) standard scores but not the problem behavior domain ( $r=-0.1$ ). Proportion of VABS motor delays across subgroups based on functional delays paralleled proportion of VABS daily living skill delays. Furthermore, age and sex-related differences in VABS performance will be discussed during the presentation.

Conclusions: These findings provide evidence for linkages between motor, social, communication, and daily living skill difficulties in children with ASD. It will be important to facilitate motor exploration in young and older children with ASD to promote cascading effects on other developing systems and to promote functional independence. Taken together, ASD interventions must address not only the social communication and cognitive/behavioral challenges of children with ASD but also their motor function and participation (Kaur & Bhat, 2019; Srinivasan et al., 2015).

## VIRTUAL POSTER SESSION — SENSORY, MOTOR, AND REPETITIVE BEHAVIORS AND INTERESTS

### 505 - Sensory, Motor, and Repetitive Behaviors and Interests --- (V)

#### **505.048** (Virtual Poster) A Comparison of Psychometric and Clinical Properties of Bsiq and ABC-C

J. R. Murray<sup>1</sup>, L. H. Rosenthal<sup>1</sup>, S. Mussarrat<sup>1</sup>, B. Rozumny<sup>1</sup> and E. Hanson<sup>2</sup>, (1)Developmental Medicine, Boston Children's Hospital, Boston, MA, (2)Boston Children's Hospital/Harvard Medical School, Boston, MA

#### Background:

Restricted and repetitive behaviors (RRBs) represent a core diagnostic feature of autism spectrum disorder (ASD) interfering with environmental exploration, development of play skills, and learning and academic performance in children with ASD (Lam & Aman, 2007). There are a number of measures which look at these behaviors including the Social Responsiveness Scale, Second edition (SRS-2, Constantino, 2012), Autism Diagnostic Observation Schedule, Second edition (ADOS-2, Lord et al., 2012) and the Aberrant Behavior Checklist - Community (ABC-C, Marshburn and Aman, 1992). Historically, the trend has been to group many RRB behaviors under one heading. A newer measure, the BSIQ (Hanson et al, 2016), uses a comprehensive listing of individual RRBs.

Previous research explored the correlation between subscales of the ABC-C with Vineland-II (Sparrow et al. 2005) and Child Behavior Checklist (Achenback and Rescorla, 2000, 2001; Kaat et al., 2014). Comparison of psychometric properties of the specific subscales has yet to be explored between BSIQ and ABC-C. ABC-C is a caregiver-filled-out measure of severity of behaviors, with 5 subscales. BSIQ is an investigator-based instrument that uses 13 subscales to assess the type, frequency, and intensity of 74 RRB's.

#### Objectives:

We hypothesize that there is correlation between the RRB subscales of the BSIQ and the ABC-C. We then discuss the relative strengths and potential difficulties with methods of grouping these behaviors.

#### Methods:

Retrospective data on individuals with ASD were used from Boston Children's Hospital Phenotypic and Genetic Factors in ASD study, Autism Consortium, and Simons Variation in Individuals Project. Participants in this study included 108 individuals (75% male) ranging in age between the ages of 28 to 265 months ( $m = 92$ ,  $SD = 55.4$ ). ASD diagnosis was confirmed by cutoff scores on the ADOS-2 and Autism Diagnostic Interview-Revised (Rutter et al., 2003). ABC-C and BSIQ subscales were compared using Spearman's rank correlations test.

#### Results:

Preliminary results suggest the strongest relationship between ABC-C and BSIQ were related to stereotyped behaviors (SB). A relatively strong, positive and significant correlation between ABC-C SB and BSIQ Hand/Finger Mannerisms subscales ( $p=0.66$ ,  $p=7.05 \times 10^{-15}$ ). Similarly, the correlation between ABC-C SB and BSIQ Complex Mannerisms/ was found to be positive and significant ( $p=0.52$ ,  $p=9.61 \times 10^{-9}$ ).

Other relatively strong, positive and significant correlations were found between ABC-C Inappropriate Speech and BSIQ Language-Perseveration ( $p=0.57$ ,  $p=1.79 \times 10^{-10}$ ). Additionally, a positive and significant correlation was found between ABC-C Lethargy/Social Withdrawal and BSIQ Self-Injurious Behavior ( $p=0.42$ ,  $p=4.65 \times 10^{-6}$ ).

#### Conclusions:

This preliminary data analysis supports a plausible relationship between RRB based subsection scores on the BSIQ and ABC-C.

The two measures provide different levels of behavior description. The BSIQ covers a wider breadth of behaviors and provides more comprehensive data, which may have particular merits for use in the research setting. While not as comprehensive for RRBs, the ABC-C provides an overview of a broad range of these and other behaviors, with briefer administration time. This method may increase inaccurate reporting and decrease understanding of the breadth and type of specific behaviors. Future research will focus on parsing out these strengths and concerns.

#### **505.049** (Virtual Poster) A Portrait of the Repetitive Behaviors and Interests of Autistic Children Aged 6 to 12 Years: Parents' Perceptions

J. Desrosiers<sup>1</sup>, V. Courchesne<sup>2</sup>, M. Couture<sup>3</sup>, I. Soulières<sup>4</sup>, G. Thermidor<sup>5</sup>, L. Motttron, M.D.<sup>2</sup> and C. Jacques<sup>5</sup>, (1)University of Montreal, Montreal, QC, Canada, (2)Autism Research Group, CIUSSS du Nord-de-l'Île-de-Montréal, Montréal, QC, Canada, (3)Rehabilitation, Université de Sherbrooke, Sherbrooke, QC, Canada, (4)Department of Psychology, Université du Québec à Montréal, Montréal, QC, Canada, (5)University of

**Background:** Although studies show that repetitive behaviors and intense interests (RBIs) decline through school age in autistic children, very few studies have examined the individual trajectory of these RBIs.

**Objectives:** To document, using a comprehensive list, the nature and frequency/intensity of RBIs in school-age autistic children. To explore if the nature and frequency/intensity of RBIs vary during this period.

**Methods:** Seventy-three french speaking parents of autistic children (6-12 years, 12F: 61M) completed the *Questionnaire on Repetitive Behaviors and Interests School-Aged Autistic Children*, via Lime Survey. The questionnaire included open-ended questions, but here we focused on the frequency/intensity ratings (on a Likert scale) of the 29 themes and objects of interest and the 47 repetitive behaviors included in the questionnaire. Using SPSS software, descriptive analyses were conducted with all the sample and Mann-Whitney U Tests were performed to compare the younger children ( $M = 7.67$  years old,  $SD = 1.00$ , Range 6.08 to 9.92 years) and the older children ( $M = 11.50$  years old,  $SD = 0.88$ , Range = 10.00 to 12.92 years).

**Results:** Four behaviors were observed « very often » by a significant number of parents: *putting object in mouth* (28.77%), *emits vocalizations spontaneously* (28.77%), *repeating words* (26.03%) and *sentences* (24.66%). Interest for three technological tools and one application: *electronic tablet* (46.58%), *YouTube* (41.10%), *video games* (41.10%), *computer* (35.62%) were considered « intense » by the largest number of parents, followed by *listening to music* (17.81%) and *drawing* (16.44%). Mann-Whitney U tests indicated four behaviors that were significantly different in younger and older children: *Facial twitching* was more frequent in older children ( $p < .01$ ), while *putting object in mouth*, *repeating sentences* (echolalia) and *emits sentences spontaneously* were more frequent in younger children (all  $p$ 's  $< .05$ ). None of the interests were reported as significantly more intense in older children, while interests for trains and planes were reported as more intense in younger children (both  $p$ 's  $< .05$ ).

**Conclusions:** Our preliminary results first suggest that technology-oriented interests characterize school-aged children. It will be important to document the properties of the applications that are of interest at this stage of development as well as the developmental trajectory of this common interest in autistic children. Second, our results highlight that the most frequent repetitive behaviors in school age autistic children are mostly related to language, especially in younger children. This latter result needs to be further investigated to better understand the trajectory of these specific repetitive behaviors as well as to better understand the role of language related repetitive behaviors in language development in autism.

#### **505.050 (Virtual Poster) Barriers to an Autistic Identity: How Restricted and Repetitive Behaviors May Contribute to the Underdiagnosis of Females**

**E. L. Cary<sup>1</sup>, A. Rao<sup>2</sup>, E. Matsuba<sup>1</sup>, E. C. Masters<sup>1</sup>, C. MacKenzie<sup>1</sup>, J. Osborne<sup>2</sup> and N. Russo<sup>1</sup>, (1)Department of Psychology, Syracuse University, Syracuse, NY, (2)Syracuse University, Syracuse, NY**

---

**Background:**

Autistic females are frequently underdiagnosed, misdiagnosed, and/or diagnosed later in life. Females require more severe autism symptoms and impairment than males to receive an autism diagnosis and are less likely to get an autism diagnosis even when they have the same number of autistic traits on rating scales. Restrictive and Repetitive Behaviors (RRBs) are increasingly critical for diagnosis and yet are commonly rated lower in females. However, it is unclear whether this reflects genuinely lower levels of these traits, or if female-typical restricted and repetitive behaviors have a different phenotypic presentation that may not register on current quantitative measurement tools.

**Objectives:**

We sought to characterize RRBs in females using a mixed-methods analytical approach. Differences in RRBs across genders were assessed from standard quantitative diagnostic tools and examined through a combined quantitative and inductive qualitative approach.

**Methods:**

Twenty-one autistic females and 21 autistic males matched on chronological age ( $M = 14.5$ ) and Full-Scale IQ ( $M = 103.67$ ) participated in the study. Participants completed the Autism Quotient, Sensory Profile, Autism Diagnostic Observation Schedule 2<sup>nd</sup> Edition, and Autism Diagnostic Interview-Revised. T-tests were used to determine group differences by gender for 1) overall autistic traits using the Autism Quotient (AQ), 2) Sensory features on the Sensory Profile (sum score) 3) each RRB subcategory from the DSM-5 (i.e., stereotyped movements or speech, insistence on sameness, restricted interests, sensory differences) measured by the sum of z-scores for relevant ADOS-2 and ADI-R items. Written comments on the ADOS-2 and ADI-R protocols for items pertaining to each of these RRB categories were qualitatively investigated by forming categories and comparing those between genders.

**Results:**

Quantitative comparisons indicated that there were no gender differences on the Sensory Profile nor AQ. When analyzed by RRB category, the only gender differences were that females scored higher on stereotyped movements and speech on the ADI-R ( $T = 2.58$ ,  $p = .02$ ) and were observed to engage in more sensory behaviors during the ADOS-2 ( $T = 2.35$ ,  $p = .02$ ). Qualitative analyses indicated that both females and males were equally likely to engage in stereotypic behavior, but 38% of females engaged in those behaviors when anxious compared to only 10% of males. Furthermore,

females had more tactile exploration than males (90% vs. 67%), especially tactile exploration of themselves (e.g., feeling their hair or touching their arms; 48% vs. 5%), but also tactile exploration of other people (19% vs. 5%) and objects (62% vs. 43%) as well as sensitivity to materials (33% vs 14%).

#### Conclusions:

Findings highlight differences in RRBs in females that may help enhance diagnostic clarity for. Results add to a growing body of research suggesting that females engage in more sensory behaviors, especially in the tactile domain. Based on the results from this study, the inclusion of sensory behaviors has promising implications for increasing diagnostic sensitivity for autistic females.

#### **505.051** (Virtual Poster) Trauma Mediates the Relation between Autistic Traits and Sensory Sensitivity and Avoiding in Adults

**E. L. Cary<sup>1</sup>**, A. Rodrigues<sup>1</sup>, E. C. Masters<sup>1</sup>, E. Matsuba<sup>1</sup>, C. MacKenzie<sup>1</sup>, J. Osborne<sup>2</sup> and N. Russo<sup>1</sup>, (1)Department of Psychology, Syracuse University, Syracuse, NY, (2)Syracuse University, Syracuse, NY

---

#### Background:

Autistic individuals are more likely than non-autistic individuals to experience trauma in their lifetimes, and frequently report sensory differences. Both autism and traumatic experiences are independently associated with sensory differences. As such the presentation of sensory features in autism might be influenced by the experience of traumatic events. Here we sought to take a preliminary step by looking at the relationship between autistic traits, sensory features, and traumatic experiences in neurotypical individuals.

#### Objectives:

We first assessed the relationship between traumatic experiences, autistic traits, and sensory features in neurotypical individuals using correlation analyses, and then assessed the role of traumatic experiences as a mediator between autistic traits and sensory features.

#### Methods:

Two hundred forty-two participants (126 females, 116 males) ages 18 to 31 ( $M = 24.60$ ,  $SD = 3.58$ ) participated in this online study. Participants completed the Adolescent/Adult Sensory Profile (AASP), Adult Autism Quotient (AQ), and the Adverse Child Experiences Questionnaire (ACE-Q). Pearson correlation coefficients were conducted between autistic traits, measured by the total AQ, sensory features, measured by the four quadrants of the sensory profile, and type of childhood trauma (i.e., abuse, neglect, and household dysfunction). Mediation analyses were completed using PROCESS v3.4 in SPSS and statistical significance was determined at  $p < .05$  if the 95% bias-corrected percentile bootstrapped confidence interval of the indirect effect did not contain zero. Two mediation analyses assessed whether a history of trauma, measured by the total score on the ACEs, mediates the relation between autistic traits, measured by the total score on the AQ, and the sensory sensitivity and avoiding quadrants of the Sensory Profile.

#### Results:

Autistic traits were strongly and positively correlated with the total number of ACEs, and specifically neglect and abuse, but not household dysfunction. Autistic traits were positively correlated with sensory registration, sensory sensitivity, and sensory avoiding, and negatively correlated with sensory seeking. The total number of ACEs, abuse, and neglect were positively correlated with sensory registration, sensory sensitivity, and sensory avoiding but not sensory seeking. Household dysfunction was only positively correlated with sensory sensitivity and sensory avoiding. The relationship between autistic traits and sensory sensitivity and sensory avoiding were both significantly mediated by trauma ( $B = 0.05$ ,  $SE = 0.02$  (95% bias-corrected bootstrapped CI [0.02, 0.1])). Childhood trauma accounted for 8.3% of the relation between autistic traits and sensory sensitivity and sensory avoiding.

#### Conclusions:

Findings suggest that a portion of the relationship between autistic traits and sensory sensitivity and avoiding can be explained by childhood trauma. Findings provide preliminary support for including trauma histories in the conceptualization of sensory features in autism and suggest that future work should assess these relationships within an autistic population.

#### **505.052** (Virtual Poster) Evidence for Specificity of Involvement in Executive Functioning, Behavioral and Attentional Regulation in Tactile Detection Thresholds.

**W. Y. W. Chau<sup>1</sup>**, N. A. Puts<sup>2</sup>, J. L. He<sup>3</sup>, A. Deronda<sup>4</sup>, R. A. Edden<sup>5</sup>, S. H. Mostofsky<sup>6</sup> and E. Wodka<sup>6</sup>, (1)Social, Genetic and Developmental Psychiatry, King's College London, London, United Kingdom, (2)Russell H. Morgan Department of Radiology and Radiological Science, Institute of Psychiatry, Psychology & Neuroscience, King's College London, UK, Baltimore, MD, United Kingdom, (3)King's College London, London, MD, United Kingdom, (4)Center for Neurodevelopmental and Imaging Research, Kennedy Krieger, Baltimore, MD, (5)Russell H. Morgan Department of Radiology and Radiological Science, The Johns Hopkins University School of Medicine, Baltimore, MD, (6)Center for Autism and Related Disorder, Kennedy Krieger Institute, Baltimore, MD

---

**Background:** While commonly exhibited by individuals with autism and now included in the diagnostic criteria for Autism Spectrum Disorder (ASD), sensory differences are not exclusive to ASD and occur in other neurodevelopmental conditions such as Attention Deficit/Hyperactivity Disorder (ADHD). Work from our lab suggests that parent-reported tactile dysfunction in ASD may reflect more global executive (including behavioral and attentional) dysregulation shared by neurodevelopmental conditions. We now seek to establish whether this may be driven by fundamental differences in touch at the perceptual level as these differences are not specific to ASD. Differences in adaptation to tactile thresholds have been linked to altered thalamocortical feedforward inhibition. Understanding whether individuals fall within particular tactile subtypes have different external presentations and executive function performance, independent of clinical diagnosis, could provide important insights into the neurological mechanisms underlying tactile difficulties across disorders.

**Objectives:** To define tactile subtypes based on adaptation to tactile thresholds in typically developing controls (TDC), ASD, and ADHD. We hypothesize that, across diagnoses, those without a typical adaptation response will show more difficulties in behavior, attention and executive functioning with both objective (WISC) and subjective (Conners, BASC) measures.

**Methods:** *Sample:* 413 children aged between 8 to 17 years were recruited. 123 were diagnosed with ASD and 103 were diagnosed with ADHD. The remaining 187 participants were TDC. The following measures were employed to assess attention/behavior regulation and executive function: parent-reported Conners 3<sup>rd</sup> Edition, parent-reported BASC-3, and performance-based WISC-IV/V (working memory, processing speed, full-scale IQ and verbal comprehension indexes). *Psychophysics:* Tactile detection thresholds were measured using a vibrotactile stimulator which delivered stimuli to two fingers. In the static condition, children reported the finger that received a stimulus. In the dynamic condition, children reported the finger which felt a stimulus dynamically increasing from zero amplitude. The difference between static and dynamic thresholds was considered a marker of feedforward inhibition. *Analysis:* Children were grouped into “Typical”, “Neutral” and “Atypical” performance based on their feedforward inhibition thresholds. Participants with changes of more than 25% were considered to have “Typical” performance; those with changes in detection thresholds between -25% and 25% were considered “Neutral”, and those with changes in detection thresholds less than 25% were considered to have “Atypical” performance. One-way ANOVAs (age and sex covaried) were conducted on groups examining attention, behavior and executive function differences.

**Results:** On the BASC-3, participants in the “Atypical” and “Neutral” groups showed more externalizing behaviors and executive function challenges compared to the “Typical” group (both  $p < 0.01$ ), with no differences in internalizing behaviors (both  $p > 0.1$ ). On the Conners 3<sup>rd</sup> Edition, “Atypical” and “Neutral” groups showed more inattention and impulsivity (both  $p < 0.001$ ) compared to the “Typical” group. On WISC-IV/V, “Atypical” and “Neutral” groups showed lowered working memory performance (both  $p < 0.001$ ) compared to the “Typical” group.

**Conclusions:** Our results are consistent with research describing the overlap between attention and sensory dysfunction. Findings suggest that regardless of neurodevelopmental condition, tactile detection differences align with functional measures of executive function, behavioral and attentional regulation.

#### **505.053 (Virtual Poster)** Gender and Age Differences in Sensory Impairments in ASD and ASD+ADHD

**K. Macdonald<sup>1</sup>, M. Santhosh<sup>2</sup>, H. Rea<sup>3</sup>, K. Pelphrey<sup>4</sup> and S. J. Webb<sup>5</sup>,** (1)Child Health, Behavior, and Development, Seattle Children's Research Institute, Seattle, WA, (2)Center for Child Health, Behavior and Development, Seattle Children's Research Institute, Seattle, WA, (3)Center for Human Development and Disability, University of Washington Psychiatry and Behavioral Sciences, Seattle, WA, (4)University of Virginia, Charlottesville, VA, (5)Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA

---

#### **Background:**

Sensory issues are critical features of both ASD and ADHD. Further, gender and age are linked to different presentations of sensory symptoms in both disorders. Research is needed to understand the contribution of co-occurring ADHD symptoms to sensory sensitivities in ASD, as well as gender and developmental differences in these relations.

#### **Objectives:**

To evaluate sex and age differences in severity of sensory impairments in ASD and ASD+ADHD groups.

#### **Methods:**

Participants included ASD individuals ages 6 to 18 years from an NIH-funded study looking at sex differences in ASD. Participants were separated into two groups: the child group included participants  $\leq 11$  years old ( $n=99$ ; ASD=58, 60.3% male); the adolescent group, included participants  $\geq 11$  years ( $n=58$ ; ASD=28, 75% male). All participants met ASD criteria via the ADOS-2 and ADI-R and had an IQ  $\geq 70$  via DAS-II. Co-occurring ADHD symptoms were assessed using the CBCL DSM-oriented subscale for ADHD and the ASD+ADHD group (score  $>63$ ). Parents and participants completed the Sensory Profile (Caregiver and/or Adolescent report). Scores were computed for sensory sensitivity, sensory seeking, and poor registration domains. Lower scores indicated greater sensory impairment. Group differences and gender interactions were analyzed using a series of ANOVAs.

#### **Results:**

In children <11, there was a significant interaction between group and gender ( $F=5.04, p=0.027$ ), such that males with ASD ( $M=36.69, SD=7.5$ ) had greater sensory sensitivity compared to males with ASD+ADHD ( $M=40, SD=9.24$ ) and females with ASD, both with ( $M=39.17, SD=5.94$ ) or without ADHD ( $M=43.74, SD=9.78$ ). There was a significant main effect of gender on poor registration ( $F=4.15, p=0.04$ ), such that males with and without co-occurring ADHD had poorer registration than females with and without ADHD, but no significant interaction or main effect of group. In sensory seeking, there were no significant main or interaction effects.

In Adolescents, there was a main effect of group in sensory sensitivity ( $F=4.64, p=0.036$ ), poor registration ( $F=5.09, p=0.028$ ), and sensory seeking ( $F=14.32, p<0.001$ ). However, there were no significant interactions or main effect by gender.

**Conclusions:** Patterns of the interaction of sex differences and co-occurring ASD+ADHD differed between age groups. Co-occurring ADHD did not exacerbate sensory sensitivities in children with ASD who are younger than 11 years old, but ADHD did affect sensory sensitivities in children with ASD who were older than 11 years old. This difference may reflect the transition from the use of caregiver reports to self-report. However, it may also reflect different

#### **505.054 (Virtual Poster)** Interoceptive Challenges Are Linked to Appetitive and Eating Disorder Traits in Autistic Adults

**R. R. Ritchie<sup>1</sup>, G. L. Wallace<sup>2</sup> and S. L. Chan<sup>2</sup>,** (1)Speech, Language, and Hearing Sciences, The George Washington University, Washington, DC, (2)The George Washington University, Washington, DC

**Background:** Eating behaviors in people with ASD are potentially important contributors to poor health outcomes, including both selective eating and eating in the absence of hunger, yet the mechanisms driving these behaviors are poorly understood. Sensory sensitivities are consistently linked to selective eating in ASD (e.g., Zickgraf et al., 2020), still other factors likely play a role not only in selective eating, but also eating in the absence of hunger. One likely culprit is interoception; the perception of senses from inside the body. Interoceptive abilities are vital in regulating essential bodily functions. Nevertheless, studies to date have not examined associations between interoception and eating behaviors in ASD.

**Objectives:** Examined for the first time, links between interoception and eating behavior among younger adults with ASD.

**Methods:** 254 participants (assigned female at birth; 67%) aged 18-42 years ( $M=31.27, SD=5.63$ ) were recruited online via Simons Powering Autism Research and Knowledge (SPARK; SPARK Consortium, 2018) Research Match. Three questionnaires were completed by participants. Confusion of interoceptive bodily states was assessed using the 20-item Interoception Sensory Questionnaire (ISQ). Appetitive traits were assessed using the 35-item Adult Eating Behavior Questionnaire (AEBQ). Symptomatology of Anorexia Nervosa, Bulimia Nervosa, and Binge-Eating Disorder was assessed using the DSM-5 Eating Disorders Diagnostic Scale (EDDS). Hierarchical linear regressions were run to examine associations between interoception and both appetitive traits (AEBQ) and eating disorder traits (EDDS) after controlling for the influence of age and sex assigned at birth.

**Results:** Analyses revealed that interoception significantly predicts several appetitive traits, including enjoyment of food ( $\Delta R^2=.04, p=.002$ ), satiety responsiveness ( $\Delta R^2=.04, p=.001$ ), and food fussiness ( $\Delta R^2=.03, p=.004$ ), as well as global eating disorder traits ( $\Delta R^2=.02, p<.05$ ). Including dietary restrictions as an additional covariate, resulted in the association between interoception and global eating disorder traits becoming non-significant, while the other three findings remained unchanged.

**Conclusions:** Interoception appears to be a contributing factor to atypical eating patterns in adults with ASD though longitudinal study designs are needed to evaluate more causal pathways. If this link is confirmed, it is possible that developing interventions to address interoception challenges in ASD may cascade to positively impact eating behaviors and health outcomes in this group.

#### **505.055 (Virtual Poster)** Investigation of the Postural Control and Gait of Autistic and Neurotypical Preschool Children

**C. Ong<sup>1</sup>, E. McAdam<sup>1</sup>, M. K. Licari<sup>2</sup>, M. H. Black<sup>1</sup> and S. Morris<sup>3</sup>,** (1)School of Allied Health, Curtin University, Perth, WA, Australia, (2)Telethon Kids Institute, University of Western Australia, Perth, WA, Australia, (3)School of Allied Health, Curtin University, Perth, Australia

**Background:**

Movement difficulties are common in autistic individuals however motor difficulties are not currently identified as a core criterion or specific in the diagnostic criteria for autism. Previous research suggests that up to 75% of autistic children have motor difficulties and 50.9% of Australian autistic individuals are classified as having a severe mobility restriction. Motor differences in autistic children include but are not limited to reduced postural control and atypical gait. Currently information about gait and postural control is very limited for autistic preschool children, despite this being a critical period for motor development. Understanding motor difficulties at an early age is important because these can impact a child's ability to engage and participate in everyday life.

**Objectives:**

This study aimed to compare the postural control and gait of autistic and neurotypical preschool children.

**Methods:**

A case control design compared the postural control and gait of pre-school autistic and neurotypical children. A total of 33 participants consisting of 13 autistic and 20 neurotypical children aged between three to five years of age participated in the study. Standing postural control was recorded using the AccuGait portable force platform while children watched a cartoon they had selected. The force platform provides a measure of centre of pressure (COP) which reflects postural control as the ability to control the centre of mass over the base of support. Gait temporospatial parameters were measured using the GAITRite Walkway System, which provides spatial parameters including step length, stride length and step width, as well as temporal measures including cadence, gait cycle, velocity, step time, and stance time among others. Postural control and gait were also video-recorded with observations undertaken by blinded assessors.

#### Results:

Autistic children had poorer postural control than neurotypical children with 1.5 times larger anterior-posterior sway, 1.4 times larger medio-lateral sway and 2.4 times larger COP trajectory prediction ellipse area than neurotypical children. Observational analysis of postural data showed that autistic children were more categorised as more 'floppy' than neurotypical children ( $p=0.010$ ) and paid less attention to the cartoon ( $p=0.024$ ). They demonstrated more large ( $p=0.002$ ) and wriggly ( $p=0.024$ ) lower limb movements. During gait, autistic children had a higher adjusted ataxia ratio (measure of stride regularity) than neurotypical children, however, no differences between the autistic and neurotypical children were observed for cadence, stride length, step width, double support, or mean normalised velocity. Observational analysis of gait showed autistic children spent more time looking away from the forward position when walking ( $p=0.010$ ).

#### Conclusions:

Autistic children showed differences in postural control and gait compared to neurotypical children. Static postural stability was poorer and video analysis suggested this is due to a combination of hypotonia and difficulty maintaining attention to a task. Gait parameters were similar to those of neurotypical children however the autistic group demonstrated more stride variability and were more distracted during gait. Reduced attention is the most likely contributor to the increased stride variability. Further research on the effect of hypotonia and attention on motor performance and learning in autistic children is recommended.

#### **505.056** (Virtual Poster) Pupil Reveals Auditory over-Responsivity in Children with Autism Spectrum Disorder

**C. Song<sup>1,2</sup>, R. Ma<sup>3</sup>, W. Ni<sup>2,3</sup>, X. Peng<sup>3</sup> and L. Yi<sup>2,3,4</sup>**, (1)School of Psychological and Cognitive Sciences and Beijing Key Laboratory of Behavior and Mental Health, Peking University, Beijing, China, (2)Beijing Key Laboratory of Behavior and Mental Health, Peking University, Beijing, China, (3)School of Psychological and Cognitive Sciences, Peking University, Beijing, China, (4)PKU-IDG/McGovern Institute for Brain Research, Peking University, Beijing, China

**Background:** Sensory over-responsivity is highly prevalent in children with autism spectrum disorder (ASD) and is related with maladaptive behaviors and anxiety (Lane et al., 2015). Research in this field typically relies on parental report questionnaires and autobiography of high functioning individuals (Ben-Sasson et al., 2009; Elwin et al., 2012). A few objective physiological measures utilizing electrodermal activity or heart rate in sensory challenge tasks revealed conflict evidence, with the majority showing either hyper or normal responses to sensory stimuli in ASD (Chang et al., 2012; McCormick et al., 2014). Recently, convenient and contactless pupillometry has been introduced to examine the autonomic response to auditory stimuli in ASD. For example, Top et al (2019) found ASD adults had larger baseline pupil diameter and normal peak pupil diameter change to auditory stimuli, suggesting they endure chronically hyper-arousal in daily life. Habituation rate could impact sensory responsivity and maybe is impaired in ASD (Millin et al., 2018).

**Objectives:** The primary aim of the present study was to measure the responsivity to non-social auditory stimuli in ASD children using pupillometry. We also concerned if slower habituation rate underlies the mechanism of atypical auditory response.

**Methods:** Thirty-seven children with ASD and 40 TD children completed a passive listening task adopted from Top et al (2019). Children were asked to look at a fixation cross at the center of the screen during the experiment while a 300 Hz eye-tracker recorded their pupil diameter throughout the task. Following a silent period which recorded the baseline pupil diameter before the experiment, two blocks of sound were presented, which contained a rather mild sound (2000 Hz sinewave tone) and an aversive sound (2000 Hz sawtooth tone) respectively. In each block the sound was presented 10 times and lasted 2 seconds each time. We used pupil area change as an index of phasic auditory responses. The effect of trial on peak pupil area change was used to depict the habituation rate across each block.

**Results:** No significant difference of the baseline pupil diameter was found between ASD and TD children, suggesting typical baseline arousal in ASD children. Temporal course analysis showed pupil area change was similar in the ASD and TD group at all time points when the mild sound present, while ASD demonstrated more pupil area change than TD children between 0.50-1.93 second from stimuli onset when listening to the aversive sound (Figure 1). The results were confirmed as we extracted the peak pupil area change from the time course individually and found that ASD children had normal phasic response to the mild sound, while responded more to the aversive sound than TD (Figure 2). However, ASD children showed normal habituation to the aversive sound.

**Conclusions:** To conclude, we found typical baseline arousal before the experiment and pupillary over-responsivity to the aversive, but not the mild sound in ASD. Reducing exposure to aversive sensory stimuli is needed to avoid overwhelming feeling and anxiety in ASD children in daily life.

#### **505.057** (Virtual Poster) Reduced Connectivity of Cortical-Cerebellar Networks Is Implicated in Precision Motor Deficits in Individuals with Autism Spectrum Disorder

**Background:** Studies of sensorimotor behaviors offer unique promise for characterizing neurodevelopmental mechanisms associated with ASD as they are precisely quantifiable in both spatial and temporal dimensions, and their underlying neural systems have been well-defined. Sensorimotor issues are present in the majority of individuals with ASD and are associated with core symptoms. However, studies are needed to link sensorimotor phenotypes associated with ASD to specific alterations in brain function.

**Objectives:** Using a rapid visually-guided precision gripping task during functional neuroimaging (fMRI), we examined cortical-cerebellar networks associated with visuomotor control in ASD.

**Methods:** Twenty-five individuals with ASD (10-33 years) and 18 typically developing (TD) controls matched on age and IQ completed a test of precision gripping during fMRI. Participants pressed with their right thumb and forefinger on a force transducer while viewing a green FORCE bar that moved upwards with increased force toward a fixed white TARGET bar. Participants maintained the FORCE bar at the level of the TARGET bar for two seconds, alternating with two second rest periods. Two runs were administered in which target force levels were set at 20% or 60% of each participant's maximum voluntary contraction (MVC). Cortical and cerebellar seeds were analyzed for whole brain connectivity (psychophysiological interaction; PPI) based on previous studies of precision motor tasks.

**Results:** Mean force output was reduced in ASD across both force levels. Relative to controls, individuals with ASD showed more variable initial force output at 60% MVC and less variable initial force output at 20% MVC. Connectivity was similar between groups at 20% MVC. At 60% MVC, individuals with ASD demonstrated decreased force-dependent connectivity between left anterior intraparietal lobule (LaIPL) and right anterior and lateral cerebellum and increased connectivity between LaIPL and right thalamus; the opposite pattern was observed in controls. Force-dependent connectivity of primary motor cortex (M1) and dorsal anterior cingulate cortex (dACC) also was decreased in ASD, but increased in controls. Reduced functional connectivity of LaIPL-right cerebellum was associated with increased symptom severity in ASD participants (Autism Diagnostic Observation Schedule Calibrated Severity Score; ADOS CSS). Dimensional associations between task performance and functional brain activation in visuomotor network regions that showed significant activation during task vs. rest also will be reported.

**Conclusions:** Atypical control of initial force output in ASD suggests reduced integrity of internal action representations that are consolidated and stored within cerebellum and is consistent with previous reports of structural and functional cerebellar abnormalities in ASD. Reduced cerebellar-parietal connectivity in ASD suggests deficits in integrating multimodal sensory feedback may underlie frequently observed deficits in precision motor control in ASD; associations between reduced cerebellar-parietal connectivity and increased symptom severity suggest reduced sensorimotor control may be central to the pathophysiology of ASD. Reduced force-dependent connectivity between M1 and dACC in ASD suggests reduced reliance on error-monitoring processes during visuomotor output, while increased thalamocortical connectivity in ASD suggests individuals may be using alternate strategies (e.g., power grip) for generating precision force. These findings collectively suggest cortical-cerebellar dysfunctions may contribute to precision sensorimotor issues and core clinical symptoms of ASD.

#### **505.058 (Virtual Poster) Sensory Features of the Classroom Affect Task-Behaviour Especially for Autistic Children**

**M. Hanley<sup>1</sup>, E. Jones<sup>2</sup>, J. R. Hirst<sup>2</sup> and D. M. Riby<sup>3</sup>,** (1)South Road, Durham University, Durham, United Kingdom of Great Britain and Northern Ireland, (2)Durham University, Durham, United Kingdom, (3)Department of Psychology, Durham University, Durham, United Kingdom

---

**Background:**

The ability to pay attention and engage in a task is fundamental for learning and participation in the classroom. Typical school classrooms are busy multi-sensory environments in which children must filter out and ignore various sensory inputs (e.g. noise from peers, visual displays on walls) in order to engage and learn. Some children find this very difficult, especially autistic children, many of whom experience significant sensory differences compared to neurotypical children (NT) (Jones et al., 2020).

**Objectives:**

In the current study, the impact of classroom sensory inputs on task behaviour was investigated in children with and without autism. The sensory inputs of interest were classroom noise and classroom visual displays. It was hypothesised that both classroom noise and visual displays would lead to increased off-task behaviour for all children, but to a greater extent for autistic children.

**Methods:**

Twenty-six autistic children (mean age 9.62 years) and 22 NT children (mean age 8.35 years), matched on verbal mental age (using the Wechsler Abbreviated Scale of Intelligence 2), completed reading comprehension tasks in a bespoke mini-classroom. It was possible to manipulate sensory features of the mini-classroom. Participants completed 4 reading comprehension tasks, under different sensory conditions: baseline (no visual/auditory input); auditory (classroom noise played in background); visual (visual displays on walls); and auditory and visual together. The order of conditions was counterbalanced between participants. Using video recordings, behaviour was coded as on or off-task (with sub-categories for fine-grained analyses).

**Results:**

Autistic children spent a significantly greater percentage of time off-task compared to NT peers. However, the pattern of off-task behaviour was the same for the groups in terms of impact of condition – it was greatest for both groups in the visual and auditory-visual conditions, and significantly more off-task behaviour was found in these compared to auditory and baseline conditions. (See Figure 1). Greater off-task behaviour in the visual and auditory-visual conditions was driven by the physical environment, meaning looking at/engaging with visual displays.

#### Conclusions:

This study shows how classroom visual displays can lead to greater off-task behaviour for all children, but particularly for autistic children. Over behaviour measures may not be best suited to understanding the impact of noise on classroom learning and engagement. This study has implications for understanding attention in action for learning in the classroom, as well as classroom design.

#### **505.059** (Virtual Poster) Sensory Profiles in Children with Autism Spectrum Disorder: A Descriptive Study Using the Italian Version of the Sensory Processing Measure-2 (SPM-2)

**A. Narzisi<sup>1</sup>, M. Fabbri-Destro<sup>2</sup>, F. Maugeri<sup>3</sup>, S. Berloff<sup>4</sup>, P. Fantozzi<sup>1</sup>, M. Gulisano<sup>3</sup>, R. Muccio<sup>1</sup>, E. Valente<sup>1</sup>, V. Viglione<sup>1</sup>, R. Rizzo<sup>3</sup>, A. Milone<sup>1</sup>, R. Barone<sup>1</sup> and G. Masi<sup>1</sup>,** (1)IRCCS Stella Maris Foundation, Pisa (Calambrone), Italy, (2)Istituto di Neuroscienze, Consiglio Nazionale delle Ricerche (CNR), Parma, Italy, (3)Child Neurology and Psychiatry Section-Department of Clinical and Experimental Medicine – University of Catania-Catania, Italy, Catania, Italy, (4)IRCCS Stella Maris Foundation, Catania, Italy

**Background:** An increasing body of evidence suggests that subjects with Autism Spectrum Disorders (ASD) exhibit atypical sensory profiles. However, the detailed characteristics of this atypical sensory functioning have not been fully explained. Although unusual sensory features in children with ASD have been reported since Kanner's early descriptions, subsequent literature has not always reached universal conclusions, and large-scale clinical trials are still lacking. Some authors argue that children with ASD show problems at the level of sensory processing but also that the presence of a true disorder would concern only a part of them. The discordant data in the literature may be due to the diversity assessment methods used.

**Objectives:** The main aim is to investigate, through the Sensory Processing Measure-2, the sensory profiles in school-aged children with ASD. To date, the SPM-2 is the only tool adapted with normative data for the Italian population.

**Methods:** The total sample included 86 subjects with ASD aged between 6 and 12 years (mean age = 9.01 years; SD = 2.07; Range: 6-14). All subjects with ASD were native Italian speakers. All children were evaluated through a multi-informant perspective on data collection by using professional observation or interview (ADOS-2; Wechsler Scales and Vineland-II) and parent reports including CBCL 6-18 and the Sensory Processing Measure-2 (SPM-2). Sensory Processing Measure-2 (SPM-2) requires just 15 to 20 minutes; the Home Form (adopted for this study) yield eight parallel standard scores: social participation, vision, hearing, touch, body awareness (proprioception), balance and motion (vestibular function), planning and ideas (praxis), and total sensory systems. Scores for each scale fall into one of three interpretive ranges: typical, some problems or definite dysfunction.

**Results:** A two sensory phenotypes were described: (1) low-functioning (LF) and (2) high-functioning (HF). In subjects with LF, compared to those with HF, there were found significant correlation between SPM-2 (Total and sub-domains scores) and Restricted and Repetitive Behaviours (RRBs) severity score of ADOS-2. Age, adaptive behaviour, internalizing and externalizing problems were not found to differ significantly across the two phenotypes (LF vs HF).

**Conclusions:** Our preliminary study shows a very close link between sensory difficulties and severity in the area of restricted and repetitive behaviors in children with LF. In children with high-functioning ASD, this correlation with RRBs was not found. This finding could be indicative of a high degree of heterogeneity of sensory difficulties in ASD. Creating sensory phenotypes might be a more effective way to analyze the large internal variability. The creation of phenotypes may aid in the development of effective interventions for these difficulties. The sensory difficulties of different phenotypes could be traced to different neurophysiological circuits.

#### **505.060** (Virtual Poster) Slow Updating with Adequate Benefits from Temporal Regularities

**K. Kasten<sup>1</sup> and M. Ahissar<sup>2</sup>,** (1)The Hebrew University, Jerusalem, Israel, (2)Hebrew University, Jerusalem, Israel

**Background:** Mixed results in benefits from temporal regularities and rate of sensorimotor responses led to disputes regarding the nature of difficulties of people with autism in performing such tasks. Breska & Ivry (PNAS, 2018) found reduced benefit in using a single predicted interval. By contrast, administering the same paradigm to adult individuals with a basal-ganglia impairment (Parkinson's disease) they found reduced benefit from a predictive rhythm.

**Objectives:** Given reports of both atypical basal ganglia and cerebellum connectivity in ASD, we now asked whether people with autism manifest similar behavioral difficulties. In addition, by administering a paradigm developed by Breska & Ivry with two conditions we now separated between sensorimotor benefits from different types of temporal regularities, and the updating abilities that have been required in these tasks (verification of target presentation before response)

**Methods:** We recruited 48 participants (24 in each group, age: mean  $\pm$  SEM (years): ASD:  $26.4 \pm 1.4$ , Neurotypical:  $26.5 \pm 0.8$ . Mann-Whitney:  $U=529$ ,  $p=0.33$ . Male/female: 22/2, 16/8, respectively. Matched for spatial reasoning skills). The participants were asked to respond to a visual target (a green square) presented on a screen (by pressing a key) as fast as they can. Each trial consists of two or three red squares, that appear one after

another, followed by a white square and then the target. There were three different block types: 1. “Rhythmic”: the target is presented after a sequence of squares with fixed intervals. 2. “Single-interval”: the interval between the first two squares denotes the interval between the white square and the target. 3. “Random”: the intervals preceding the target are randomly chosen (with the same mean).

We introduced two conditions. In one, every trial ended with a green target (100%), guaranteeing participants' reduced response time as long as they can benefit from the temporal regularity (measured relative to the random condition). In the second, 25% of the trials ended without any target. This condition requires a participant confirmation for the presence of target before pressing, and therefore requires an additional updating with the visual information.

**Results:** Both groups benefitted from the temporal regularities in both conditions, and as expected benefitted more in the 100% condition (Wilcoxon test: ASD:  $p=0.002$ , Neurotypicals:  $p<0.001$ ). The benefit from the two types of regularities was highly correlated in both groups (spearman: ASD:  $0.5112$  ( $p=0.011$ ), control:  $0.667$  ( $p=0.001$ )). We, therefore, averaged, for each participant, the benefit from the two regularity types. In the 100% condition – the groups did not differ, indicating that people with ASD benefit adequately from temporal predictions. However, in the 75% condition, the ASD group showed reduced benefits (mean: ASD-0.14, Neurotypicals-0.17  $p=0.025$ ), indicating that their target present/absent updating was slower than the neurotypicals.

**Conclusions:** our study suggests a specific difficulty in online updating abilities, in line with the “slow updating” hypothesis (Lieder et al., 2019; Vishne et al., 2021), with adequate use of temporal intervals per-se. These findings explain some of the disputes regarding the use of temporal regularities in ASD.

#### **505.061 (Virtual Poster)** Synesthesia Is Consistently Positively Associated with Attention to Detail – a Twin Study

A. Hagström<sup>1</sup>, M. Biasao<sup>2</sup>, L. Wilsson<sup>2</sup>, S. Bolte<sup>3</sup> and J. Neufeld<sup>4</sup>, (1)Karolinska Institutet, Stockholm, Sweden, (2)Center of Neurodevelopmental Disorders at Karolinska Institutet (KIND), Stockholm, Sweden, (3)Center of Neurodevelopmental Disorders (KIND), Centre for Psychiatry Research; Department of Women's and Children's Health, Karolinska Institutet, & Stockholm Health Care Services, Region Stockholm, Stockholm, Sweden, (4)Center of Neurodevelopmental Disorders (KIND), Centre for Psychiatry Research; Department of Women's and Children's Health, Karolinska Institutet, & Stockholm Health Care Services, Region Stockholm, Stockholm, Sweden

**Background:** Synesthesia is a sensory phenomenon where inputs such as noises, letters or weekdays lead automatically to vivid, additional sensations such as color or shape. The phenomenon occurs in ~4% of the population, but is more prevalent in individuals with autism spectrum condition Neufeld et al., 2013, Baron-Cohen et al., 2023). Further, both binary defined synesthesia, the amount of different synesthesia types and the degree of synesthetic consistency are associated with elevated autistic traits (Ward et al. 2017, Burghoorn et al., 2019). Recently, we demonstrated this association for the first time in a twin sample, where familial (genetic and environmental) factors are implicitly controlled for (Neufeld et al., accepted in *Cortex*). More specifically, twins with higher autistic traits in specifically the domain of attention to detail showed a higher synesthetic consistency. However, the sample was small ( $n=65$ ) and consisted preliminary of non-synesthetes with or without neurodevelopmental diagnoses.

**Objectives:** In this study, we aimed to replicate and extend the previous within-pair findings on the link between synaesthesia and autistic traits in an independent, larger twin sample where 23% fulfilled criteria for synesthesia.

**Methods:** The twins completed a standard consistency test assessing color synaesthesia for letter and numbers (grapheme-color synesthesia, GCS) and questionnaires online. Dimensional GCS was defined as the degree of synesthetic color consistency reflected by the test score and binary GCS (fulfilling criteria for being a synesthete) was defined as scoring within the synesthetic range and additionally self-reporting GCS. Autistic traits were assessed using the Autism Spectrum Quotient (AQ), and divided into the two sub-scores “attention to detail” and AQ-other (containing social and communication domains) as suggested by previous research (Hoekstra et al., 2008). 75 individuals were excluded because they failed to follow task instructions correctly or due to missing data. The final sample consisted of  $n=155$  twins (75% female) aged 19 or 20 years, including 39 complete pairs of which 46% were MZ and 12 were discordant for binary synesthesia (= only one twin fulfils criteria for synesthesia).

**Results:** Twins with higher autistic traits in the attention to detail domain showed more consistent grapheme-color associations (= lower scores;  $\beta=-.22$ ,  $SE=.09$ ,  $p=.018$ ) while controlling additionally for touch screen device usage (since touch screen users were overall less consistent in their color choices:  $t=-2.92$ ,  $df=49.12$ ,  $p=.005$ ). In contrast, binary defined GCS was negatively associated with the AQ-other domain ( $\beta=-.15$ ,  $SE=.06$ ,  $p=.010$ ).

**Conclusions:** The results confirm previous findings of a positive association between dimensional synesthesia with specifically the attention to detail domain of autistic traits. In addition, they indicate that higher social/communication-related autistic traits might decrease the likelihood of being identified as a synesthete when controlling for genetic and environmental factors shared by twins and touch screen usage. These latter findings need to be interpreted with caution, due to the small amount of complete synesthesia-discordant pairs. However, they indicate that familial factors might have contributed to the inconsistent findings of previous studies, sometimes indicating a link with the social domain of autistic traits and sometimes not.

#### **505.062 (Virtual Poster)** Differences between ASD and TD in Social and Non-Social Joint Action Performance and Its Predictors

S. Bar Yehuda<sup>1</sup> and N. B. Bauminger-Zively<sup>2</sup>, (1)School of Education, Bar - Ilan University, Ramat - Gan, Israel, (2)School of Education, Bar-Ilan University, Ramat Gan, Israel

Background:

Joint action (JA) is the accomplishment of a shared goal by coordinating a motoric movement with social and non-social partners in time and space, that mandates the successful operation of social-motor capabilities. Though the manifestation of social-motoric difficulties in cognitively able (IQ > 70) youngsters with autism spectrum disorder (CAASD) is common, the differences in JA performance with social and non-social partners between TD and CAASD along development, and the contribution of motor and theory of mind (ToM) abilities to social and non-social JA succession, are underexplored in CAASD.

#### Objectives:

This study examined task (social-JA with a peer / non-social-JA with a computer), group (ASD/TD), and age (early-childhood 6-8, pre-adolescence 8-12, and adolescence 12-16) differences in JA for youngsters with CAASD compared to age-matched controls with typical development (TD). We also examined the prediction of social and non-social JA performance by motor and ToM abilities. Understanding these differences and the effect motor and social-cognition impairments have on JA performance may open future intervention paths focusing on social-motor coordination in youngsters with CAASD.

#### Methods:

Study participants included 84 children and adolescents ages 6-16yrs with CAASD ( $M = 11.11$ yrs,  $IQ = 103.88$ ) and 64 with TD ( $M = 10.73$ yrs,  $IQ = 114.53$ ) in three age-groups. Group differences on age and IQ were non-significant. To evaluate social JA, participants performed four dyadic JA tasks with their peer. Two social JA-mirroring tasks (side-by-side walking, face-to-face movement) and two JA-completion tasks (virtual-football kick-and-catch, walk in a corridor). Dyads were paired by gender, IQ, and chronological age. Participants also performed two non-social JA tasks interacting with a computer: A mirroring task (following a moving triangle with a finger) and a completion task (virtual ping-pong play). JA performance was coded via *Interact* micro-analyses coding system, providing six major coordinated movement scores for each task. In addition, we evaluated the participants motor and ToM abilities via the Individual Motoric Observation Scale (IMOS) and Theory of Mind Inventory (TOMI) parents' questionnaire (Hutchins et al., 2012).

#### Results:

A Generalized Estimating Equations (GEE) analyses yielded significant main effects of task (non-social > social) group (CAASD < TD) and age (early-adolescence and pre-adolescence > early-childhood). The significant Task X Age interaction indicated better JA in the older age-groups in comparison with the youngest age-group in the social mirroring tasks and that adolescents outperformed younger participants in the non-social mirroring task. The significant Task X Group interaction highlighted the advantage of TD participants over ASD participants in the social completion tasks, though not in non-social completion task.

A linear regression analyses indicated the prediction of better JA performance with better motor abilities in social and non-social tasks and with better ToM abilities only in social tasks (see table 1).

#### Conclusions:

Study findings are discussed in light of the connection between social-cognition and motor difficulties in youngsters with CAASD and its possible impact over their peer engagement. Our understanding of the role motor and ToM abilities play in JA, support the development of intervention program to elicit JA abilities in children with CAASD.

#### **505.063** (Virtual Poster) What Is the Developmental Trajectory of Repetitive Behaviors in Autistic Children Aged 6 to 12 Years? - a Parental Perspective

A. Ethier<sup>1</sup>, V. Courchesne<sup>2,3</sup>, M. Couture<sup>4</sup>, I. Soulieres<sup>2,5</sup>, G. Thermidor<sup>6</sup>, L. Mottron, M.D.<sup>2</sup> and C. Jacques<sup>1,2</sup>, (1)University of Quebec in Outaouais, Gatineau, QC, Canada, (2)Autism Research Group, CIUSSS du Nord-de-l'Île-de-Montréal, Montréal, QC, Canada, (3)CAMH : Centre for Addiction and Mental Health, Toronto, Toronto, ON, Canada, (4)Rehabilitation, Université de Sherbrooke, Sherbrooke, QC, Canada, (5)Department of Psychology, Université du Québec à Montréal, Montréal, QC, Canada, (6)University of Montreal Center of Excellence for Pervasive Developmental Disorders (CETEDUM), Montreal, QC, Canada

**Background:** Repetitive behaviors are central in the diagnosis of autism spectrum and are expressed through a wide range of behaviors, from motor stereotypies to an insistence on sameness (American Psychiatric Association, 2013). Several studies have shown that, overall, repetitive behaviors decrease with age (Esbensen et al., 2009). However, some behaviors present at a young age may develop into more complex behaviors over the course of development and current knowledge does not provide information about how these behaviors change in autistic children over time.

**Objectives:** To document the developmental trajectory of repetitive behaviors in autistic children aged 6 to 12 years using a parental perspective and to identify the most prevalent repetitive behaviors in this age range.

**Methods:** 73 parents of autistic children aged between 6.1 to 12.9 years (60 boys: 13 girls) completed the french version of the *Questionnaire on Repetitive Behaviors and Interests in School-Aged Autistic Children* through LimeSurvey. The questionnaire includes a comprehensive list of 47 different repetitive behaviors chosen following an iterative process with expert clinicians. Parents were asked to identify and qualify the repetitive behaviors of their child by answering to multiple-choice and open-ended questions on the frequency and intensity of these behaviors. Descriptive

analyses were conducted to identify the nature and frequency of repetitive behaviors and changes over time in these behaviors were identified through thematic and qualitative analyses.

**Results:** Thirty-nine percent of parents ( $n = 28$ ) reported that their child's behaviors had changed over time. Among these parents, 4 major patterns of change were identified from the thematic analysis: 64% mentioned that the behaviors have evolved over time, either by **becoming more complex** (72%) or by **transforming into other behaviors** (28%). Finally, 29% of parents said that the behaviors had **increased**, while 21% said that they had **decreased** in frequency. Furthermore, the behaviors most frequently reported by these parents were hopping (50%), putting objects in mouth (46%), holding objects in hands (43%), hand flapping, producing vocalizations, words or sentences spontaneously (all reported 39%), repeating words and sentences (echolalia), grouping objects by their perceptual properties, clapping hands and pacing or running (all reported 36%), as well as facial twitching, smelling objects and lining up objects (all reported 32%).

**Conclusions:** Parents' answers suggest that the manifestation of repetitive behaviors evolve with age in autistic children and that there is variability in the developmental trajectory of these behaviors. Clarifying the developmental trajectory of repetitive behaviors may help professionals and clinicians make better prognosis about the evolution of repetitive behaviors. In addition, it may allow the development of assessments based on a better understanding of the transformation of pathognomonic signs in autism. In future research, the understanding of these behaviors and their evolution over time will need to be refined through the addition of direct observation tools with the child.

#### **505.064 (Virtual Poster)** A Multi-Level Investigation of Sensory Sensitivity and Responsivity in Adults with Autism

**L. A. Sapéy-Triomphe<sup>1,2</sup>, J. Dierckx<sup>1</sup>, J. Van Overwalle<sup>1,2</sup>, S. Vettori<sup>3</sup> and J. Wagemans<sup>1,2</sup>, (1)Department of Brain and Cognition, Leuven Brain Institute, KU Leuven, Leuven, Belgium, (2)Leuven Autism Research (LAuRes), KU Leuven, Leuven, Belgium, (3)Institut des Sciences Cognitives - Marc Jeannerod UMR5229, Centre National de la Recherche Scientifique (CNRS) & Université Claude Bernard Lyon 1, Lyon, France**

---

**Background:** Atypical sensory processing is a core symptom of Autism Spectrum Disorder (ASD). Yet, measurements of sensory sensitivity tend to lack of consistency in ASD, which may be due to the (sometimes) unclear notion of sensitivity. Here, we refer to sensory sensitivity as the ability to detect a sensory stimulus, and to sensory responsivity as the intensity of an observable response to a sensory stimulus.

**Objectives:** This study aimed at better characterizing visual sensitivity and responsivity in ASD at three levels: self-reported, behavioral and neural. We also aimed at investigating the relationships between these three levels, and at exploring how atypical sensory processing may contribute to an increased intolerance of uncertainty and anxiety, as these factors were found to account for half of the variance in sensory sensitivity in ASD.

**Methods:** This study involved 25 neurotypical (NT) and 24 autistic adults. The two groups were matched in age, sex ratio and intelligence quotient. At the self-reported level, participants completed questionnaires measuring sensory sensitivity (visual items of the Sensory Perception Quotient – SPQ), sensory responsivity (Sensory OverResponsivity scale – SOR) or both (Glasgow Sensory Questionnaire – GSQ). At the behavioral level, participants took part in a series of tasks measuring sensory sensitivity (i.e., detection thresholds in contrast and spatial frequency of gratings) and responsivity (i.e., contrast, spatial and temporal frequency thresholds at which participants felt uncomfortable). At the neural level, we used Fast Periodic Visual Stimulation (FPVS) and a 64-electrode electroencephalogram (EEG) system as an implicit and objective way to assess detection thresholds in contrast and spatial frequency. Finally, participants completed the short Intolerance of Uncertainty scale (IU) and the State-Trait Anxiety Inventory (STAI).

**Results:** At the self-reported level, the ASD group scored higher than NT on the GSQ and SOR ( $p < .001$ ), while the group difference was marginal on the SPQ ( $p = .057$ ). At the behavioral level, measures of sensory sensitivity and responsivity in contrast and temporal frequency showed no group differences. Yet, the ASD group had higher detection thresholds than NT in spatial frequency ( $p < .01$ ), as well as higher thresholds at which they reported feeling uncomfortable when seeing the grating ( $p < .05$ ). The SOR was correlated with behavioral measures of sensory responsivity, and the GSQ with behavioral measures of sensory sensitivity and responsivity. Contrary to NT, in the ASD group, self-reported and behavioral measures of sensory sensitivity and responsivity were correlated with the IU and STAI, so that higher sensory sensitivity and responsivity were associated with a higher intolerance of uncertainty and more anxiety.

**Conclusions:** In autistic adults, visual sensitivity and responsivity were higher at the self-reported level, and typical or higher, depending on the visual feature, at the behavioral level. Future EEG analyses will determine whether sensory sensitivity is also increased at the neural level in ASD. This multi-level approach sheds light on the mechanisms that underlie sensory issues in ASD, ranging from their difficulties in their daily-lives to peculiarities at the neural level, and to co-occurring issues such as anxiety.

#### **505.065 (Virtual Poster)** Estimating the Relative Prevalence of Early Interest in Written Material in Autism in a Representative Population

**A. Ostrolenk<sup>1,2</sup>, M. Boisvert<sup>3,4</sup>, O. Lemire<sup>3,4</sup>, M. P. Côté<sup>3,4</sup> and L. Mottron, M.D.<sup>5,6</sup>, (1)Department of Psychiatry, Université de Montréal, Montreal, QC, Canada, (2)Autism Research Group, CIUSSS du Nord-de-l'Île-de-Montréal, Montreal, QC, Canada, (3)Department of Psychology, Université de Montréal, Montreal, QC, Canada, (4)Centre de recherche du CIUSSS du Nord-de-l'Île-de-Montréal, Montreal, QC, Canada, (5)Autism Research Group, CIUSSS du Nord-de-l'Île-de-Montréal, Montréal, QC, Canada, (6)Department of Psychiatry and Addictology, Université de Montréal, Montréal, QC, Canada**

---

#### **Background:**

Although the scientific community has not come to an agreement on the defining criteria for hyperlexia, it is commonly described as an **intense and precocious interest in written material** and a **discrepancy in reading skills between advanced decoding and weaker comprehension**. A strong link between autism and hyperlexia has been demonstrated (Ostrolenk et al., 2017), but there are no recent studies assessing the frequency and development of hyperlexic features in a large population of autistic children.

## Objectives:

Our study focuses on the most precocious and specific sign of hyperlexia, early interest in written material. We **documented its frequency and the history of its emergence** in a representative population referred for an autism diagnosis assessment and **compared the results between autistic and non-autistic individuals**. A secondary objective was to collect qualitative and quantitative information on other manifestations of hyperlexia and the parallel development of oral language.

## Methods:

The study participants comprised all children under 7 years of age referred for an autism diagnosis assessment at our autism evaluation clinic from a defined geographic area in northern Montreal. The families were enrolled in two complimentary projects:

- The parents of children assessed at the clinic in 2019 and 2020 who consented to participate in person answered a 45-minute phone questionnaire (PQ) which was developed based on a literature review, a previous pilot questionnaire, and clinicians' opinions. It includes questions about the child's interest in letters and numbers, related behaviours and skills, oral language level, parental attitude regarding written material, and relevant qualitative information. All the parents were contacted shortly after the assessment. The parents of 146 children, of which 84 subsequently received an autism diagnosis, answered the questionnaire ( $M_{age}=55.64$  months;  $SD=12.80$ ; range=29-83). An additional neurotypical control group is currently being recruited for this project.
- The medical files (MF; psychiatrist and psychologist reports) of all the eligible children who were assessed during the same period were anonymously examined using a rating grid investigating the child's interest in letters and numbers, for a total of 446 children, of which 253 received an autism diagnosis. Although the information gathered from MF was less detailed than in the PQ, it allowed us to assess the entire population and to ensure the representativity of our sub-sample.

## Results:

The children's interest in written material was rated using 4 categories (*None < Moderate < Intense < Exclusive*) and yielded similar results in both the direct (PQ) and indirect (MF) investigation: the autistic group showed a superior level of interest than the negative diagnosis group ( $p<0.005$ ). Significantly more autistic children had an *intense* or *exclusive* interest in written material (PQ: 40.48% vs. 20.97%; MF: 23.71% vs. 3.63%). Moreover, the higher the interest, the earlier was its onset.

## Conclusions:

These results indicate that a large proportion of autistic children have an intense interest in written material at the age of diagnosis, confirming the need for more research on hyperlexia and the factors involved in its emergence, as well as its possible uses during diagnostic assessment and intervention.

**505.066** (*Virtual Poster*) Investigating the Relationships between Perceptual Alterations, Sensory Reactivity, Intolerance of Uncertainty and Anxiety in Autistic Children

**H. Powell<sup>1</sup>**, J. L. He<sup>1</sup>, E. Wodka<sup>3</sup>, A. Deronda<sup>3</sup>, R. A. Edden<sup>4</sup>, S. H. Mostofsky<sup>2</sup>, M. J. Meaney<sup>5,6</sup> and N. A. Puts<sup>1</sup>, (1)Institute of Psychiatry, Psychology & Neuroscience, King's College London, London, United Kingdom, (2)Center for Autism and Related Disorder, Kennedy Krieger Institute, Baltimore, MD, (3)Center for Neurodevelopmental and Imaging Research, Kennedy Krieger, Baltimore, MD, (4)Russell H. Morgan Department of Radiology and Radiological Science, The Johns Hopkins University School of Medicine, Baltimore, MD, (5)Department of Psychiatry and Neurology and Neurosurgery, McGill University, Montreal, QC, Canada, (6)Singapore Institute for Clinical Sciences, A\*STAR, Singapore, Singapore

## Background:

Sensory differences and anxiety disorders are common in autism. Previous studies suggest that sensory hyper-reactivity may be associated with anxiety and intolerance of uncertainty (IU) in autistic children. However, those studies predominantly assessed sensory reactivity using questionnaires (i.e., clinical reports), which are often subjective and do not differentiate between sensory difficulties at behavioural and perceptual levels. Psychophysical approaches allow for an objective, quantitative measure of sensory differences at the perceptual level. Determining whether perceptual differences contribute to the manifestation of anxiety, and how this relates to IU, would provide further insight into the nature and impact of sensory difficulties in autism.

## Objectives:

We aimed to: 1) replicate the findings from a previous study (MacLennan et al. 2021), who showed that IU fully mediated the association between sensory reactivity and anxiety, and anxiety fully mediated the association between sensory reactivity and IU; and 2) to investigate how alterations in sensory perception contribute to sensory reactivity, IU and anxiety.

## Methods:

41 autistic children (33 male, 30 with ADHD) were included. Sensory reactivity was assessed using the Sensory Processing Measure (SPM) and a battery of vibrotactile tasks, using a Cortical Metrics stimulator (Figure 1A). Anxiety and IU were assessed using parent-report measures from the

Screen for Child Anxiety Related Disorders (SCARED) and Intolerance of Uncertainty Scale for Children (IUSC), respectively. Pearson's correlations were run between SPM scores, SCARED score, IUSC score, and vibrotactile thresholds. Mediation analyses using bootstrapping were run in R.

#### Results:

Significant positive correlations were found between SPM Touch Score and IU, and between IU and anxiety ( $p \leq 0.04$ ), but not between SPM Touch Score and anxiety ( $p = 0.08$ ). Neither SPM Total Score, nor any other sensory modality, significantly correlated with IU or anxiety (all  $p$ -values  $> 0.05$ ). Of the vibrotactile tasks, only simultaneous frequency discrimination (SFD) threshold (Figure 1B) significantly correlated with SPM Touch Score after Bonferroni's correction ( $p < 0.01$ ; Figure 1C). However, no significant associations were found between SFD threshold and IU or anxiety ( $p \geq 0.10$ ). Mediation analyses showed full mediation between SPM Touch Score and IU through anxiety (Figure 1D;  $p = 0.04$ ). Mediation analysis between SPM Touch Score and anxiety through IU did not meet significance set at 0.05 (Figure 1E;  $p = 0.06$ ), but was similar to findings by MacLennan et al. 2021. No mediation was found between SFD threshold and anxiety through IU (Figure 1F), or between SFD threshold and IU through anxiety ( $p \geq 0.21$ ).

#### Conclusions:

We contribute to previous findings showing full mediation between SPM Touch Score and IU through anxiety, and an association suggestive of mediation between SPM Touch Score and anxiety through IU. While larger samples are needed, our findings suggest that touch processing problems (rather than global sensory reactivity) contribute to the development and maintenance of anxiety and IU. Our findings imply that perceptual alterations contribute to the clinical manifestations of sensory reactivity but are not directly associated with anxiety or IU. This highlights the importance of differentiating sensory difficulties at behavioural and perceptual levels.

#### **505.067** (Virtual Poster) Oromotor Skills in Autism Spectrum Disorder: A Scoping Review

**M. F. Maffei<sup>1</sup>, K. V. Chenausky<sup>2</sup>, H. Tager-Flusberg<sup>3</sup> and J. R. Green<sup>1</sup>,** (1)Speech and Feeding Disorders Lab, MGH Institute of Health Professions, Boston, MA, (2)Neurology, MGH Institute of Health Professions / Harvard Medical School, Boston, MA, (3)Department of Psychological and Brain Sciences, Boston University, Boston, MA

---

#### Background:

The factors that influence language outcomes in autism spectrum disorder (ASD) are not fully understood. A substantive body of research has revealed gross and fine motor impairments among individuals with ASD. These studies have provided compelling evidence for causal linkages between motor disruptions and deficits in expressive language. The vast majority of this work has, however, been focused on general motor skills and not oromotor skills, which are critical to expressive language development. Research on oromotor skills among individuals with ASD has been limited by methodological constraints, contradictory findings, and a relatively small number of studies.

#### Objectives:

The purposes of this scoping review are to summarize and disseminate research findings regarding oromotor skills in ASD and to identify gaps in the existing body of literature. The research questions are: (1) What methods have been used to investigate oromotor functioning among individuals with ASD?, (2) What behaviors have been investigated?, and (3) What do the findings tell us about this topic?

#### Methods:

This scoping review follows the framework outlined by Arksey and O'Malley (2005). After identifying the research questions, we identified studies based on specific criteria (Table 1) via a comprehensive search of relevant databases (Table 2). Two authors independently conducted a title/abstract review of 2,246 manuscripts, dissertations, and book chapters. 396 studies were chosen for full-text review and 74 studies were chosen for final inclusion. Data regarding targeted behaviors, assessment tools, outcome measures, and findings were extracted and analyzed using descriptive statistics.

#### Results:

Analysis approaches included perceptual (73% of studies), instrumental (36%), report/questionnaire (4%), and medical record review (1%), with 15% of studies incorporating multiple approaches. 50% of studies used a published assessment tool. Oromotor functioning was examined in the context of speech abilities (87%), non-speech oromotor abilities (23%), and feeding skills (11%). 86% of studies reported an oromotor abnormality based on comparison to a non-ASD group or the use of standardized norms. Among speech-related oromotor findings, the most common level of analysis was phoneme (52% of speech studies), followed by syllable (40%), word/nonword repetition (37%), and connected/spontaneous speech (20%). While the majority of speech studies examined accuracy (58%), others examined duration (16%), phoneme inventory (13%), rate (13%), and intelligibility (6%). Nonspeech and feeding studies demonstrated a similar variety in methodology, behaviors analyzed, and reported results.

#### Conclusions:

A variety of oromotor abnormalities are present among individuals with ASD, although generalization to the population is limited by methodological constraints of existing literature. The reliance on observational analysis of oromotor and speech behavior, while ecologically valid, exposes studies to rater bias and reliability issues. The variety of assessment paradigms limits cross-study comparisons, as does the reporting of composite scores rather than detailed oromotor characteristics. Small sample sizes and selection bias further complicate generalization. The summarized literature, in conjunction with known associations between oromotor functioning and expressive language skills, motivates future research with implications regarding the efficacy of motor-based therapy approaches, addressing ongoing clinical and scientific issues such as the early detection of ASD, and identifying neurobiological mechanisms influencing communication development.

**505.068 (Virtual Poster)** Sensory and Behavioral Subtypes of Children with Autism Spectrum Disorder

**H. Noda<sup>1,2,3,4</sup>**, D. Enomoto<sup>4</sup>, S. Takahata<sup>5</sup>, M. Ide<sup>3</sup> and R. Iwanaga<sup>1</sup>, (1)Graduate School of Biomedical Sciences, Nagasaki University, Nagasaki, Japan, (2)Japan Society for the Promotion of Science, Tokyo, Japan, (3)Department of Rehabilitation for Brain Functions, Research Institute of National Rehabilitation Center for Persons with Disabilities, Tokorozawa, Saitama, Japan, (4)LITALICO Inc., Tokyo, Japan, (5)Department of Medical and Health Science, Occupational Therapy, Aino University, Osaka, Japan

**Background:** Sensory processing characteristics are exhibited in children with Autism Spectrum Disorder (ASD), and it has been reported to be variable among children with ASD. To understand the patterns of variability in sensory processing characteristics, subtypes based on sensory processing have been reported. These studies suggest that sensory subtypes are formed by sensory severity, sensory modalities, and responsiveness to sensory stimuli. However, information regarding daily difficulties and mental health problems faced by each subtype is lacking.

**Objectives:** The aim of this study was to identify subtypes of sensory processing and behavioral characteristics in children with autism spectrum disorder. We thought that cluster analysis, including mental health and behavioral issues, would help identify sensory subtypes that would be more useful for clinical practices.

**Methods:** Caregivers of children aged 5 to 10 years ( $n = 136$ , 71.3% males, mean = 7.35, SD = 1.93) with ASD participated in this study. All participants were recruited from day-service centers of LITALICO inc. in Japan. All children included in this study were diagnosed with ASD by medical facilities. Sixty-three participants (46.3%) were diagnosed with intellectual disability. The Japanese version of the Short Sensory Profile (SSP-J) and the Strength and Difficulties Questionnaire (SDQ) were used to collect data. Latent profile analysis was used to identify sensory and behavioral subtypes based on z-scores of SSP-J and SDQ. To determine meaningful phenotypes, the Bayesian Information Criteria was used to compare models.

**Results:** Our analyses revealed five distinct subtypes of sensory and behavioral features as follows; (a) typical sensory without behavioral issues (TSB,  $n = 31$ ), (b) moderate hypersensitive taste/smell and conduct problems (MTSC,  $n = 35$ ), (c) mild sensory and social issues (MSS,  $n = 36$ ), (d) severe generalized sensory and severe behavioral issues (GSSB,  $n = 26$ ), and (e) severe sensory seeking and hyperactivity (SSH,  $n = 8$ ). There were no age differences between subtypes ( $F(4,131) = 1.27$ ,  $p = 0.29$ ). Results demonstrated a discrepancy of severity for each component in terms of ASD characteristics; MTSC showed the highest conduct problems (e.g., theft, lies, physical violence), and SSH showed the highest hyperactivity/inattention, even though GSSB had the most severe sensory problems.

**Conclusions:** We concluded that sensory and behavioral features of children with autism spectrum disorder could be classified as five different subtypes. These phenotypes partially replicate previous studies of sensory subtypes and describe their behavioral characteristics. We also found that there are subtypes in which specific sensory and behavioral characteristics co-occur even though sensory and behavioral issues are not strongly correlated in ASD children as a whole (e.g., conduct problems or hyperactivity/inattention). Our study suggests that sensory and behavioral clustering may be helpful to consider individualized approaches for children with ASD.

**505.069 (Virtual Poster)** The Association between Rrbs and Adaptive Functioning

S. Rozenblat<sup>1</sup>, S. Netzer<sup>1</sup>, N. Rudko<sup>1</sup>, A. Shefer<sup>1</sup>, D. A. Zachor<sup>2</sup> and J. Koller<sup>3</sup>, (1)Seymour Fox School of Education, The Hebrew University of Jerusalem, Jerusalem, Israel, (2)The Autism Center/ALUT, Pediatrics, Tel Aviv University / Shamir (Assaf Harofeh) Medical Center, Zerifin, Israel, (3)Seymour Fox School of Education, Hebrew University of Jerusalem, Jerusalem, Israel

**Background:** Studies examining the relationship between autism symptomatology and adaptive functioning show that IQ, age and social-communication symptoms tend to associate with adaptive functioning (Tillman et al, 2019; Frost et al., 2017). In contrast, the relationship between RRBs and adaptive functioning remains unclear, with some research indicating no association, and other work finding a negative correlation between these two constructs (McDonald et al., 2017; Tryob et al., 2016).

The majority of studies examining the association between RRBs and adaptive functioning have used the ADOS or ADI-R to measure RRBs, which provide little nuance regarding the variability in symptom expression. In the current study, we utilized the parent-report Repetitive Behavior Scale-Revised (RBS-R; Bodfish et al., 1999), which divides RRBs into 6 subcategories: stereotypic behavior (SB), self-injurious behavior (SIB), compulsive behavior (CB), ritualistic behavior (RB), sameness behavior (SAB) and restricted behavior (RI).

**Objectives:** To obtain a more nuanced understanding of the relationship between specific subcategories of RRBs and adaptive functioning.

**Methods:** We collected these data within the context of a larger study examining family accommodation among children with autism (Feldman et al., 2019). Participants were 170 children (125 males) at time of diagnosis, who received a gold-standard evaluation including developmental/cognitive

(Mullen, WPPSI, WISC) and autism-specific (ADOS-2) assessments, in addition to the RBS-R and the Vineland Adaptive Behavior Scales 2 (VABS-II; Sparrow et al., 2005). We stratified the sample by age and compared participants age 3-5.11 (N=83) with those age 6-12 (N=87).

Results: A stepwise regression model was used to predict adaptive functioning, as measured by the overall Adaptive Behavior Composite Standard score (ABCS) of the VABS-II, with the six subcategories of the RRBs, as measures by the RBS-R, as predicting variables.

For children 3-5.11 years old, all RRB subcategories significantly and negatively correlated with adaptive functioning ( $p < .01$ ) and the model explaining the most variance in ABCS included IQ, RB, SB and CB as significant predictors. Together they explained 59.23% of variance in ABCS ( $p < .01$ ), such that higher levels of RB, SB and CB predict worse adaptive functioning and higher IQ predicted higher adaptive functioning. For children 6-12 years old, with the exception of RI, all RRB subcategories correlated significantly and negatively with adaptive functioning ( $p < .05$ ). The model explaining the most variance in ABCS included only SIB as a significant predictor, while RI, RB, CB, and SAB were not significant predictors. SIB explained 17.85% of variance in ABCS ( $p < 0.01$ ), such that individuals with higher levels of SIB exhibited decreased adaptive functioning.

Conclusions: This study provides evidence that there is a significant negative relationship between subcategories of RRBs and adaptive behavior, while revealing that certain types of RRBs, specifically RB, SB, CB, and SIB, contribute to the ability to predict adaptive behavior in this population. Results point to differences in the relationship between these variables and age. Future work should focus on possible mediating variables, such as IQ and gender, and should examine these findings in a longitudinal context.

**505.070 (Virtual Poster)** The Shortening of Achilles' Tendon Length in Moderate/High Severity Toe Walkers Is Already Present at a Young Age and Increase with the Age?

**G. Valagussa**<sup>1,2</sup>, **E. Grossi**<sup>2</sup>, **V. Balatti**<sup>2</sup>, **D. Piscitelli**<sup>1,3</sup>, **F. Cantarelli**<sup>4</sup>, **L. Mascetti**<sup>5</sup>, **E. Montrasio**<sup>5</sup>, **M. Mazzucchelli**<sup>6</sup> and **C. Perin**<sup>1</sup>, (1)Program in Physical Therapy, University of Milano-Bicocca, School of Medicine and Surgery, Monza, Italy, (2)Autism Research Unit, Villa Santa Maria Foundation, Tavernerio, Italy, (3)School of Physical and Occupational Therapy, McGill University, Montreal, QC, Canada, (4)Istituto La Casa del Sole, Mantova, Italy, (5)Fondazione Renato Piatti, Milano, Italy, (6)School of Medicine and Surgery, University of Milan-Bicocca, Milano, Italy

Background:

Toe-walking is a phenomenon present in 20-30% of ASD subjects. Using a qualitative structured assessment, we previously described three mutually exclusive clinical functional classes of tip toe behavior (TTB) of increasing severity: during running (TTB1); during walking and running (TTB2); during standing, walking and running (TTB3). In another study, we found a positive relationship between the presence and severity of TTB and the Achilles' tendon shortening. It is not clear if ASD subjects who present TTB manifest the Achilles' tendon shortening at a young age and if this deficit is related to the age of onset.

Objectives:

This cross-sectional study aimed to evaluate: 1) if ASD subjects who present moderate-high TTB severity manifest a deficit in gastrocnemius and soleus muscles (GM and SM) length values (the two muscles that coalesce into Achilles' tendon) at a young age (i.e., before 8 years); 2) if the SM and GM length values decrease with age in moderate-high TTB severity subgroup.

Methods:

The study group consisted in 106 subjects (mean age: 11.27 years – 4.95 SD; 83 males) with autism diagnosed according DSM-5 or ICD-10 criteria. A therapist assessed the presence of TTB during standing, walking, and running using direct observation and an interview of the main caregiver living with the children<sup>2</sup>. Two therapists assessed both the SM and GM length values using a manual goniometer following the methodology previously described<sup>3</sup>. We considered moderate-high severity TTB subjects those belonging to TTB2 and TTB3 subgroups. Therefore, to assess the presence of muscle length deficit at a young age (0-8 years), we compared the GM and SM length values between NON-TTB (n=28) and TTB2+TTB3 (n=9) subgroups using a Mann-Whitney test. To assess if the SM and GM length values decrease with age in moderate-high TTB severity subgroup we performed a Spearman correlation test between age and GM and SM length values in the TTB2+TTB3 subgroup (n=25).

Results: At age of 0-8 years, the mean length value of the **left GM** of NON-TTB subgroup (n = 28) was 18.61° (6.37°SD) vs a value of 9.22° (4.09°SD) TTB2+TTB3 subgroup (n = 9) ( $p < 0.001$ ). The mean length value of the **right GM** of NON-TTB subgroup was 18.32° (4.97°SD) vs a value of 11.33° (4.36°SD) TTB2+TTB3 subgroup ( $p < 0.001$ ). The mean length value of the **left SM** of NON-TTB subgroup was 27.39° (7.57°SD) vs a value of 15.56° (4.5° SD) TTB2+TTB3 subgroup ( $p < 0.001$ ). The mean length value of the **right SM** of NON-TTB subgroup was 26.39° (5.83°SD) vs a value of 18° (2.97° SD) TTB2+TTB3 subgroup ( $p < 0.001$ ). Moreover, we found a significative inverse correlation between age and left GM ( $r = -0.702$ ;  $p < 0.001$ ), right GM ( $r = -0.623$ ;  $p = 0.001$ ), and right SM ( $r = -0.412$ ;  $p = 0.04$ ) of the TTB2+TTB3 subgroup. We found a not significative correlation between age and left SM ( $r = -0.253$ ;  $p = 0.221$ ).

Conclusions: ASD subjects who present moderate-high TTB severity manifest a significant decrease of Achilles' tendon length values at a young age (i.e., before 8 years). We also found the existence of a significative inverse relationship between age and the Achilles' tendon length values.

**505.071 (Virtual Poster)** Visual and Proprioceptive Feedback Mechanisms of Fine and Gross Motor Control in ASD

**Background:** Deficits in sensorimotor integration are highly prevalent in persons with Autism Spectrum Disorders (ASD). Our prior precision gripping studies demonstrate over-reliance on visual feedback for motor control in ASD. Studies of other motor behaviors, including postural control, indicate over-reliance on proprioceptive feedback. These findings suggest that sensorimotor deficits in ASD are not specific to one sensory domain but may reflect deficits integrating multiple sources of feedback during motor control resulting in behavior specific sensory bias.

**Objectives:** Understanding sensory and motor control processes in ASD is important for identifying physiological mechanisms and determining new targets for interventions. To clarify multisensory mechanisms of motor deficits in ASD, we characterized precision force and postural control during conditions of altered visual and proprioceptive feedback.

**Methods:** Participants with ASD (N=19, 9F) and age- (11-25 years) and non-verbal IQ- (ASD: 102±19.6, TD: 112±14.5) matched controls (N=14, 7F) completed precision gripping and postural control tests. For gripping, participants pressed on force sensors with their index finger and thumb to control a moving bar so it reached and stayed stable at the level of a target bar. The spatial resolution of visual feedback was manipulated (low/medium/high). To manipulate proprioceptive feedback of finger posture, 80Hz (ON) or 0Hz (OFF) tendon vibration (TV) was applied at the wrist. For posture, participants stood still on a force platform with feet shoulder width apart for 45s. Visual feedback (lights ON/OFF) was manipulated. TV was applied (ON/OFF) to the Achilles tendons to manipulate the proprioception of ankle posture. Grip force output and postural center of pressure (COP) were analyzed for variability (standard deviation) and regularity (sample entropy and detrended fluctuation analysis, respectively).

**Results:** Force variability was increased in controls with the TV ON relative to OFF, especially at younger ages and was not affected by TV in ASD ( $R^2_{\text{GROUP} \times \text{TV} \times \text{AGE}} = .008$ ,  $t_{151.8} = 2.43$ ,  $p = .016$ ). Force regularity was decreased with the TV ON relative to OFF in ASD only ( $R^2_{\text{GROUP} \times \text{TV}} = .008$ ,  $t_{151.4} = 3.16$ ,  $p = .002$ ). During posture, anterior-posterior COP variability was elevated in both groups with TV ON compared to OFF but trended higher in ASD ( $R^2_{\text{GROUP} \times \text{TV}} = .012$ ,  $t_{65.5} = 1.80$ ,  $p = .077$ ). Medial-lateral COP variability was higher in ASD than controls across conditions ( $R^2_{\text{GROUP}} = .131$ ,  $t_{33.6} = 2.50$ ,  $p = .017$ ). Medial-lateral COP regularity trended lower during TV ON compared to OFF for both groups and decreased with increased age in controls during TV OFF only ( $R^2_{\text{GROUP} \times \text{TV} \times \text{AGE}} = .016$ ,  $t_{68.9} = 1.71$ ,  $p = .091$ ). No other group or group by sensory feedback effects were found.

**Conclusions:** For gripping, disrupting proprioceptive feedback resulted in greater force variability in controls, especially at younger ages, and reduced force regularity in ASD with no effect on variability. For posture, disrupting proprioception led to greater postural variability, especially in ASD, and reduced postural regularity, especially in controls. These findings indicate that controls use multiple sensory inputs to maintain spatial precision of ongoing movements, which improve with age. Persons with ASD show reduced multisensory feedback processing, relying predominantly on vision for gripping and proprioception for posture across age. Our findings help clarify sensory integration deficits that contribute to motor issues in ASD and implicate atypical neurodevelopmental mechanisms.

## Service Delivery/Systems of Care

### PANEL — SERVICE DELIVERY/SYSTEMS OF CARE

#### 201 - How Do We Meet the Challenges to the Delivery of Childhood Autism Diagnostic Services Internationally?

**Panel Chair:** Ian Male, Mid Sussex Child Development Team, Sussex Community NHS Trust, Haywards Heath, United Kingdom

**Discussant:** Kristin Sohl, ECHO Autism Communities, Child Health, Columbia, MO

**201.001 (Panel)** How Can We Improve the Delivery of Childhood Autism Diagnostic Services: Emerging Lessons from Clinician Interviews from Teams Meeting the UK Nice Autism Quality Standard

**I. A. Male<sup>1</sup>, W. Farr<sup>2</sup>, P. M. Wilson<sup>3</sup>, V. J. Abrahamson<sup>4</sup>, S. Wigham<sup>5</sup>, H. Terrell<sup>6</sup>, A. Allard<sup>7</sup>, V. Grahame<sup>8</sup>, L. Kenny<sup>9</sup>, V. Reddy<sup>10</sup> and J. R. Parr<sup>5</sup>**, (1)Mid Sussex Child Development Centre, Sussex Community NHS Trust, Haywards Heath, United Kingdom, (2)Sussex Community NHS Trust, Haywards Heath, United Kingdom, (3)Centre for Health Service Studies, University of Kent, Canterbury, United Kingdom, (4)University of Kent, Canterbury, United Kingdom, (5)Population Health Sciences Institute, Newcastle University, Newcastle upon Tyne, United Kingdom, (6)Research and Development, Sussex Community NHS Foundation Trust, Haywards Heath, United Kingdom, (7)Council for Disabled Children, London, United Kingdom, (8)Cumbria, Northumberland, Tyne and Wear NHS Foundation Trust, Newcastle upon Tyne, United Kingdom, (9)NHS England, London, United Kingdom, (10)Cambridge and Peterborough NHS Foundation Trust, Peterborough, United Kingdom

**Background:** Diagnostic services for children with possible autism are struggling to meet rapidly growing demand across the world where resources are being stretched regardless of setting. The Realist Evaluation of Autism Service Delivery (RE-ASCeD) study was designed to identify and research models that deliver timely, high quality autism diagnostic services (NHS England Long Term Plan (2019)).

**Objectives:**

- To investigate which existing models of Autism diagnostic service delivery offer the timely, cost-effective, high quality and child and family friendly solutions.
- In line with realist thinking, to understand the contexts and mechanisms that underpin their success, or failure.

#### Methods:

6 diagnostic services (2 paediatric, 2 CAMHS, 2 integrated CAMHS / Paediatric) were identified from our national survey completed by 128 services, as being the most compliant with the NICE Quality Standard for autism service delivery, based on self-report, and willingness to participate as a case study site. The sites had all scored well on Care Quality Commission reviews, and reported compliance with NICE quality standard recommendations e.g., ability to consider the child's physical and mental health; offering a personalised plan as part of diagnosis working with family; access to a key worker; and discussion and signposting for psychosocial interventions. We adapted the sampling frame, with input from our Expert Advisory and Parent Groups, from one looking at specific innovative approaches to focus on the broad service delivery types in the UK.

Members of each clinical team, commissioners and referrers (12 at each site) and parents and young people, have, or will be interviewed to explore how the service developed, its strengths and weaknesses, and the factors that have either facilitated or blocked their ability to deliver a high-quality service.

#### Results:

13 professional interviews have been conducted across 4 of the sites. Emerging themes from interviews include:

- **What works well:** use of parent and educational setting questionnaires at referral to inform approach to assessment / early redirection to alternative services; pathway coordinator; skill mix e.g. psychology assistants; tiered assessment responsive to diagnostic complexity, although concern was expressed that "abbreviated" approaches may give insufficient assessment; access to family support from early in pathway, especially with lengthening waiting times; diagnostic reports and future interventions shared with parents, reflecting the child's strengths as well as weaknesses.
- **Challenges:** increasing demand "*the service was developed to see 60 children a year, its about trebled...we see 2 children a week, and get 8 referrals.*" Need to adapt screening and diagnostic tools to better detect girls with autism. Working with multicultural population.
- **Facilitators:** good relationships between team members in non-hierarchical teams; respect for each other's roles; training; access to multidisciplinary team and regular MDT meetings.
- **Blockers:** persuading commissioners of need for greater resourcing; reduction of input from other relevant services.

Conclusions: Emerging data from interviews of professionals delivering or referring to autism diagnostic services point to a number of strategies that can improve quality and timely access. Despite this, it is also evident that significant uplifts in funding and staffing are required to address the consistent increases in demand.

#### 201.002 (Panel) Accuracy of Consultant General Pediatrician Autism Diagnosis Compared to a Multi-Disciplinary Team

**M. Penner<sup>1</sup>, L. Senman<sup>2</sup>, L. Andoni<sup>3</sup>, A. Dupuis<sup>4</sup>, E. Agagnostou<sup>5</sup>, M. Shouldice<sup>6</sup>, S. Kao<sup>7</sup> and J. A. Brian<sup>1</sup>,** (1)Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (2)Autism, Bloorview Research Institute, Toronto, ON, Canada, (3)University of Massachusetts, Boston, MA, (4)Biostatistics, University of Toronto, Dalla Lana School of Public Health, Toronto, ON, Canada, (5)Autism Research Centre, Bloorview Research Institute, Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (6)Hospital for Sick Children, Toronto, ON, Canada, (7)Paediatric Alliance of Ontario, Toronto, ON, Canada

Background: Many existing ASD diagnostic guidelines require that the assessment be conducted by a multi-disciplinary team (MDT), who are often in short supply, leading to lengthy wait times for diagnostic assessment. One potential solution to expand diagnostic capacity is for consultant general pediatricians to perform ASD diagnostic assessments; however, the accuracy of these assessors is not yet known.

Objectives: To determine the accuracy of ASD diagnostic assessments conducted by consultant general pediatricians compared to a MDT.

Methods: This was a prospective cross-sectional study. Pediatricians were eligible if they had not completed subspecialty training in developmental pediatrics. Their patients were eligible if they were less than 5.5 years of age, had been referred with a developmental concern, and did not have an existing ASD diagnosis. The pediatrician and the MDT (a developmental pediatrician, psychologist, and psychometrist) each conducted blinded assessments for the child within two weeks of each other. The MDT assessment included the Autism Diagnostic Interview – Revised (ADI-R), the Autism Diagnostic Observation Scale, 2<sup>nd</sup> edition (ADOS-2) and the Mullen Scales of Early Learning. Patient participants were randomized to either undergo the pediatrician or the MDT assessment first, followed by the other assessment. Both the MDT and the pediatrician recorded a forced decision about whether the child was autistic, as well as their level of certainty on a 5-point Likert scale. Accuracy was measured by calculating sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV).

Results: Seventeen pediatricians (12 women) participated in the study and referred a total of 106 children. Participating pediatricians had been in practice an average of 13 years (range: 1-32). Patient participants (79 boys) had a mean age of 41.9 months (SD 13.3). Fifty-six participants (52.8%) were of non-white race/ethnicity. Seventy-two participants (67.9%) were diagnosed as autistic by the MDT. Sensitivity and specificity of the pediatrician assessments compared to MDT were 0.75 and 0.79, respectively. PPV of the pediatrician assessments was 0.89 and NPV was 0.6. When the MDT and pediatrician agreed the child was autistic, pediatricians indicated feeling Certain/Completely Certain in 80% and the MDT in 96.3% of cases. Among cases with agreement that the child was not autistic, feeling certain occurred in 55.6% of cases for the pediatrician and for the MDT.

When the pediatrician indicated ASD and the MDT did not, the pediatrician and MDT each felt certain in only 28.6% of cases. Finally, among cases in which the MDT indicated ASD and the pediatrician did not, the pediatrician felt certain in 44.4% of cases, whereas the MDT felt certain in 83.3%.

**Conclusions:** Our results show strong agreement between pediatricians who indicate a child has an ASD diagnosis and a subspecialist MDT, with accompanying high feelings of certainty. Agreement was much lower when pediatricians did not feel the child was autistic, which was accompanied by lower feelings of certainty among pediatricians. Our results suggest that consultant general pediatricians can be encouraged to diagnose ASD when they feel certain, and that further education is needed for caution when 'ruling out' ASD.

**201.003 (Panel)** Combination of New Remote Assessment Tool and Echo Autism Program Accelerates Access to Autism Assessment and Diagnosis in Latin America Despite Global Pandemic

**V. Nanclares-Nogues<sup>1</sup>, N. E. Granana<sup>2</sup>, A. Richaudeau<sup>3</sup>, F. Astorino<sup>4</sup> and K. Sohl<sup>5</sup>,** (1)*ECHO Autism Communities, University of Missouri, Columbia, MO, (2)Servicio de Neurología Infantil, Hospital Durand, CABA, Argentina, (3)Hospital Universitario Austral, Buenos Aires, Argentina, (4)Pediatric neurology, Hospital Alassia, Santa FE, Argentina, (5)ECHO Autism Communities, Child Health, Columbia, MO*

---

**Background:** The diagnosis of autism spectrum disorder (ASD) can be difficult, as we rely on developmental history and observable behavior to diagnose. There are great barriers in access to best-practice evaluations for ASD in low-resource countries, ranging from lack of training to few specialists. These barriers were only exacerbated during the COVID-19 pandemic. A group of researchers in Argentina and Chile conducted a pilot study within the validation study of the Brief Observation of Symptoms of Autism (BOSA) instrument developed during the months of confinement due to the pandemic (Lord et al., 2020), piloting the use of the Spanish version of the BOSA for Latin American participants.

**Objectives:** The main objectives were to determine the feasibility of an assessment while maintaining social distance protocols, pilot the use of the Spanish version of the BOSA with a Latin-American population, and, in turn, improve accessibility to diagnosis. In addition, the project sought to train professionals remotely in best-practice care and establish a multicenter network for diagnosis and referral. .

**Methods:** The professionals who participated in the study were part of the ECHO Autism PROTECTEA network. ECHO Autism PROTECTEA "Programa de Orientación Temprana y Concientización en Trastornos del neurodesarrollo y en el Espectro Autista" (Program for Early Detection and Conscientization on Development and Autism Spectrum Disorders) is a network of professionals who work in primary care settings and hospitals that assess individuals with neurodevelopmental differences. These providers participated in the ECHO Autism PROTECTEA teleECHO sessions throughout the 2020 year. Only professionals who met strict criteria were allowed to take part in the pilot study. In addition, all professionals completed the UCLA training on the BOSA, presented at least two BOSA cases during the ECHO Autism: BOSA Supervision teleECHO sessions, and demonstrated reliable administration and coding procedures. The ECHO Autism: BOSA Supervision teleECHO sessions consisted of 6 clinics designed to ensure all professionals involved in the study achieved reliable administration and coding practices prior to the collection of data. The assessment protocol consisted of the BOSA, cognitive assessment (when possible due to COVID restrictions), adaptive behavior assessment, and sociodemographic evaluations.

**Results:** 201 patient cases, 153 males and 48 females, with a median age of 6.3 years. Of the 201 patients, 163 were given the diagnosis of ASD according to BOSA. Cognitive abilities were found to be in the average range for 52% of participants, mild/moderate range in 39%, and 9% of patient cases fell in the severe deficit range. 55% of participants belonged to low and very low socio-economic status, according to the Graffar-Méndez Castellano Scale (Méndez-Castellano, 1986).

**Conclusions:** The study showed that early detection and diagnosis of ASD are feasible in underserved areas, even during a global pandemic. Telehealth technology and social distance protocols were implemented, enabling clinicians to overcome the barriers imposed by the pandemic. Training and supervision of professionals was achieved remotely, with high reliability in use of the BOSA instrument. A multicenter network was created, improving access to diagnosis and early referral to treatment.

**201.004 (Panel)** Validation of the Spanish Version of the Autism Mental Status Exam (AMSE) in Argentina

**S. H. Cukier<sup>1</sup>, A. L. Maglio<sup>2</sup>, J. P. Berman<sup>3</sup>, N. Barrios<sup>4</sup> and D. Grodberg<sup>5</sup>,** (1)*PANAACEA, Buenos Aires, Argentina, (2)Universidad de Buenos Aires, Buenos Aires, Argentina, (3)PANAACEA, Programa Argentino para Niños, Adolescentes y Adultos con Condiciones del Espectro Autista, Buenos Aires, Argentina, (4)Fleni, Capital Federal, ARGENTINA, (5)Mount Sinai School of Medicine, New York, NY*

---

**Background:** Standardized diagnosis of autism spectrum disorders (ASD) is inaccessible to many people in Argentina and other countries in the region. Numerous families, particularly those who live outside the main cities, must travel a great distance (frequently over 100 kilometers) for a diagnostic assessment because there are no standardized assessment tools to support clinical impression in their area of residence. The autism mental status exam (AMSE) is a brief, free-access, clinician-completed instrument that structures the observation and documentation of social, communicative and behavioral signs and symptoms of ASD. AMSE, in its original version in English language, has previously shown high accuracy in identifying autism spectrum disorder (ASD) compared to the autism diagnostic observation schedule (ADOS) in a non-stratified population of high-risk patients suspected of having ASD, and in a sample of high-risk verbally fluent adults using DSM-5 criteria for ASD

**Objectives:** This protocol investigates the sensitivity and specificity of a version of AMSE in the Spanish language in an Argentinian sample of 315 subjects, against DSM-V clinical consensus diagnosis as primary outcome.

**Methods:** The cutoff values were calculated using the ROC (receiver operating characteristic) curve, identifying the sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV). The homogeneity of the items of the version in Spanish of AMSE was determined using Cronbach's alpha.

Results: Findings indicate an optimized sensitivity of 90.71% and a specificity of 92.17% for this sample of 315 patients that consulted spontaneously in seven different psychiatric clinics in five different cities in Argentina. AMSE exhibited fair internal consistency (alpha coefficient of 0.75) and high Inter-rater reliability (96.99%).

Conclusions: AMSE showed to be a reliable diagnostic assessment tool that can support clinical diagnosis of ASD in children and adolescents at risk in Argentina. Because of its high clinical utility, it holds promise as an instrument to be useful in other regions in Latin America, where access to the training and use of main standardized diagnostic tools might be limited.

## PANEL — SERVICE DELIVERY/SYSTEMS OF CARE

### 209 - Novel Models for Improving Healthcare Transition and Adult Healthcare Provision in Individuals with Autism and Related Neurodevelopmental Disabilities (NDD).

**Panel Chair:** Sarah Spence, *Autism Spectrum Center, Department of Neurology, Boston Children's Hospital, Boston, MA*

**209.001 (Panel)** Massachusetts Initiative to Improve Transition to Adult Healthcare for Individuals with Autism and Related Neurodevelopmental Disabilities (NDD)

**S. J. Spence<sup>1</sup>, S. Shanske<sup>2</sup>, L. S. Hunt<sup>3</sup> and J. Polzin<sup>4</sup>,** (1)*Autism Spectrum Center, Department of Neurology, Boston Children's Hospital, Boston, MA,* (2)*Bridges Young Adult Program Department of Social Work, Boston Children's Hospital, Boston, MA,* (3)*Center for Primary Care, Harvard Medical School, Boston, MA,* (4)*Division of Developmental Medicine, Boston Children's Hospital, Boston, MA*

**Background:** Youth with autism and neurodevelopmental disabilities (NDD) face unique challenges with healthcare transition. They may lack access to care and experience poorer health outcomes. Therefore special attention must be paid to this vulnerable population.

**Objectives:** The overall aim of the initiative was to improve the quality of healthcare transition for individuals with autism and related neurodevelopmental disabilities by ensuring that patients have a comprehensive integration from pediatric to adult health care.

**Methods:** A diverse group of stakeholders was recruited to examine drivers for improvement and engage in solution-oriented collaboration. An inter-professional steering committee was established with representation from health care facilities across the state (urban and rural, academic and community based), state agencies, patient and family advocacy groups and payers. Task forces were convened to work on 4 main themes including workforce development, optimizing clinical care, practice management and clinical infrastructure and financing the solution. With the help of a quality improvement consultant, each task force spent a year gathering best practice resources and brainstorming additional recommendations, concluding with a statewide summit in November 2020 with three primary objectives:

1. Identify models for best practice in pediatric to adult care transition for individuals with NDD in Massachusetts.
2. Describe quality improvement strategies to implement changes in practice.
3. Engage in solution-focused collaboration with stakeholders across Massachusetts.

**Results:** Each task force provided deliverables that were made available to the nearly 200 people from across the state who participated in the summit. The summit included: key note addresses (one academic overview and an opening panel with patients, families and providers), task force work overviews, interactive small groups to work on the drivers and change ideas, a number of sessions taking a deeper dive into the task force deliverables and concluding with an exchange of ideas that participants could take back to their own clinical settings.

100% of respondents (n=65) stated that all objectives of the summit were met. 95% rated the summit overall as very good or excellent; 80% reported that the summit was helpful or very helpful in setting transition related goals.

Initiative members, including steering committee and task forces, rated their experience of participation. All respondents (n=27) were neutral to very satisfied and all indicated they felt neutral to very good about the use of their time. 26 out of 27 respondents said that they felt they contributed to overall initiative objectives and 24 of 26 wanted to hear about continued opportunities for engagement.

**Conclusions:** Engaging stakeholders across Massachusetts in efforts to improve transition to adult healthcare for the vulnerable population of people with autism and related NDD yielded positive momentum and a sense of community. We are now engaged in Phase 2 utilizing an innovation collaborative approach from QI methodology, with teams of pediatric providers, adult providers and patient/family partners working together to test change ideas developed in the initiative.

**209.002 (Panel)** Training Neurology Residents to Care for Adults with Autism and Related Neuro Developmental Disabilities

**J. Frueh<sup>1</sup>, S. J. Spence<sup>2</sup>, D. K. Urion<sup>3</sup>, D. Z. Press<sup>4</sup> and J. S. Sanders<sup>4</sup>,** (1)*Department of Neurology, Boston Children's Hospital, Boston, MA,* (2)*Autism Spectrum Center, Department of Neurology, Boston Children's Hospital, Boston, MA,* (3)*Cognitive Neurology Unit, Department of Neurology, Beth Israel Deaconess Hospital, Boston, MA,* (4)*Department of Neurology, University of Colorado, Denver, CO*

**Background:** Many patients with Autism Spectrum Disorder (ASD) and their families feel uncomfortable transitioning from pediatric to adult care settings. Similarly, many neurologists feel uncomfortable caring for this patient population. Insufficient exposure to adults with ASD and other neurodevelopmental disabilities (NDD) during training contributes to provider discomfort in caring for this population, and in turn poses a barrier to

patients receiving optimal care in adulthood. We describe a novel approach to providing care to adults with NDD through a teaching clinic within an adult medical center staffed by trainees and faculty from both pediatric and adult neurology programs.

#### Objectives:

1. Describe the patient population cared for in a resident-developed adult neurodevelopmental disabilities clinic within an adult medical center.
2. Describe an innovative approach to training adult and pediatric neurology residents to care for adults with autism and other neurodevelopmental disabilities.

**Methods:** The adult NDD clinic was created by a neurodevelopmental pediatrics resident in 2018. Working with the cognitive neurology group in an adult academic medical center, the pediatric trainee initially worked with the adult cognitive neurology attendings seeing patients with ASD and related NDD. In 2021, the clinic expanded to include adult neurology residents rotating in cognitive neurology. The adult neurology residents in the adult NDD clinic have supervision from pediatric behavioral neurology attendings who have specific expertise working with this cohort. Data were obtained through retrospective chart review of patients seen in the adult NDD clinic between 2018 and 2021, and of residents rotating through this clinic in 2021.

**Results:** A total of 33 patients were seen by residents in the adult neurodevelopmental disabilities clinic over the observed time course. Mean age of patients was 41.7 years (range 21-73 years). The most common reasons for referral were behavioral concerns (39%), followed by requests for updated diagnostic evaluations (15%). Most frequent diagnoses were intellectual disability (46%), autism spectrum disorder (27%), Trisomy 21 (12%), cerebral palsy (15%) and genetic syndromes (9%). Genetic testing was recommended to 27% of patients, neuropsychological testing to 24%, metabolic testing to 18%, and neuroimaging to 15%. EEG and other studies were ordered in 6%. Sixty-six percent of patients were counseled on lifestyle modifications including behavioral and social strategies as part of their management. About one-third of patients were referred to behavioral or other therapy services, and 21% were referred for community services. A total of 9 trainees (5 child neurology residents, 4 adult neurology residents) were scheduled for half-day rotations in the adult NDD clinic by the end of 2021.

**Conclusions:** This unique clinic model offers an opportunity for both child and adult neurology residents to receive training in the care for adults with autism and related NDDs. The innovative cross training between adult and pediatric neurology providers with expertise in behavioral health is successfully improving access to age-appropriate specialty care for this vulnerable population of patients. Future studies should investigate how this experiential training improve comfort levels of the trainees, and how that can translate to better care for adults with NDD in the future.

**209.003 (Panel) A New Adult Neurodevelopmental Disabilities Clinic: Description of Population and Yield of Genetic Testing in the First Year**  
**J. S. Sanders<sup>1</sup> and M. Mabry<sup>2</sup>,** (1)Department of Neurology, University of Colorado, Denver, CO, (2)University of Colorado School of Medicine, Aurora, CO

---

#### Background:

As patients with NDD transition from pediatric to adult healthcare systems, they often have difficulty finding providers who address their NDD-related needs, including revisiting the etiologic workup of their NDD. In response to this care, a new consultation clinic was established in an adult neurology department to address neurodevelopmental concerns of these adult patients and provide etiologic workup, including genetic testing.

#### Objectives:

1. Characterize the patient population seen in the first year of a newly developed Adult Neurodevelopmental Disabilities (NDD) Clinic.
2. Demonstrate yield of genetic testing in adults with neurodevelopmental disabilities (NDD).

#### Methods:

Data was obtained by a retrospective chart review of all 79 patients seen in the adult Neurodevelopmental Disabilities (NDD) clinic from September 2020 through September 2021.

#### Results:

The average age was 35 years (median 28 years), ranging from 18 to 80 years. Developmental diagnoses included but were not limited to autism spectrum disorder (47%), intellectual disability (44%), Down syndrome (15%), cerebral palsy (8%) and other genetic disorders (27%). Comorbidities addressed included anxiety (in 27% of patients), behavioral concern (22%), seizures (18%), and depression (11%). 21 patients (27%) had previous genetic testing that included Chromosomal Microarray (CMA), Autism Spectrum Disorder/Intellectual Disability Panel (ASD/ID Panel), or Whole Exome/Whole Genome Sequencing (WES/WGS), before the new clinic. New genetic testing was completed in 17 patients (21.5% of the overall cohort). A pathological variant was identified in 6/17 (35%). Diagnoses were established by CMA in 3/11 (27%), ASD/ID panel in 2/5 (40%), and WES in 1/1 (100%).

#### Conclusions:

Our study characterized the diversity of developmental disabilities and comorbidities addressed in a new specialty Adult NDD clinic. Our data also revealed the high yield, and importance of, revisiting etiologic diagnoses in adults with NDDs, as many patients seen in this clinic were provided with genetic diagnoses for the first time as adults.

**209.004 (Panel) Project Echo Autism Adult Healthcare: A Novel Learning Community for Primary Care Providers**

**B. A. Malow<sup>1</sup>, K. Soh<sup>2</sup>, N. C. Cheak-Zamora<sup>3</sup>, J. Shouse<sup>4</sup> and M. O. Mazurek<sup>5</sup>**, (1)*Sleep Disorders Division, Department of Neurology, Vanderbilt University Medical Center, Nashville, TN*, (2)*ECHO Autism Communities, Child Health, Columbia, MO*, (3)*Health Sciences, University of Missouri, Columbia, MO*, (4)*Vanderbilt University Medical Center, Nashville, TN*, (5)*University of Virginia, Charlottesville, VA*

**Background:**

Autistic adults have complex healthcare needs, yet they experience poor healthcare access, experiences and outcomes. This is due in part to shortages of healthcare providers with knowledge and expertise in caring for this population. The Project Extension for Community Healthcare Outcomes (Project ECHO) Autism framework is a novel approach to address this service need. Project ECHO Autism uses secure videoconferencing technology to create a learning community by connecting primary care providers (PCPs) in local communities (“spokes”) to an interdisciplinary team of experts (“hub”). Learning is anchored in the person-family centered model and facilitated through brief evidence-based didactics, case-based learning (during which PCPs present their own cases for discussion and co-management), collaborative mentorship, and guided practice.

**Objectives:**

The objectives are to develop, and pilot test a novel PCP training program using the Project ECHO Autism framework with the goal of increasing high-quality community-based healthcare for adults on the autism spectrum

**Methods:**

Between November 2020 and April 2021, we conducted 12 ECHO Autism sessions (two a month for six months). Each session lasted one hour and consisted of a case presentation and discussion, and a didactic presentation. Before and after each ECHO, the hub team met to discuss elements of the session to maximize participant learning. Three ECHO sessions were randomly chosen to monitor fidelity and were reviewed by an investigator independent of the Hub Team.

ECHO participants completed a series of surveys before and after the 12 sessions, including related to satisfaction and changes they planned to make to their practice.

**Results:**

Of 20 participants entering the ECHO, five were Asian, two were Black, and the remainder White. There were 16 women and 4 men. Average age was 46.5 years. Nine were physicians and eleven were advanced practice providers. Most providers (80%) attended at least 50% of the sessions.

Our “Hub” Team consisted of 8 members (four men and four women), including two neurologists, one of which also had expertise in sleep medicine and was a parent, a psychologist, a psychiatrist, an internal medicine/pediatrics physician, a parent advocate/family navigator, and two self-advocates.

Fidelity was 100% for two sessions and 99% for one session.

Community providers stated a variety of changes they planned to make to their practice, including tools to address the transfer process, using visual tools in their clinic, compiling lists of resources in their area, and identifying specialists experienced with caring for autistic patients. They also stated they would be more aware of patient needs, and implement strategies to help prevent problem behaviors, such as providing headphones to reduce sensory overload.

Providers expressed a high level of satisfaction with the program, including learning best-practice care, connecting with colleagues, and increasing knowledge through case-based learning and didactic presentations.

**Conclusions:**

We developed and piloted a Project ECHO focused on Autism Adult Healthcare, with favorable PCP recruitment and retention, and excellent fidelity. PCP satisfaction was high, and PCPs identified several areas for making changes in their practice.

**ORAL SESSION - 4B — SERVICE DELIVERY/SYSTEMS OF CARE**

**310 - Service Delivery / Systems of Care**

**310.001 (Oral) Diagnostic Accuracy within a Statewide System of ASD Evaluation**

**R. McNally Keehn<sup>1</sup>, B. Enneking<sup>1</sup>, L. R. Hamrick<sup>2</sup>, T. Ryan-Lengacher<sup>1</sup>, G. Kadlaskar<sup>3</sup>, A. Paxton<sup>1</sup>, P. Monahan<sup>4</sup>, N. Swigonski<sup>1</sup>, M. Ciccarelli<sup>1</sup> and B. Keehn<sup>5</sup>,** (1)Pediatrics, Indiana University School of Medicine, Indianapolis, IN, (2)Psychological Sciences, Purdue University, West Lafayette, IN, (3)Department of Psychiatry & Behavioral Sciences, University of California, Davis - M.I.N.D. Institute, Sacramento, CA, (4)Biostatistics, Indiana University School of Medicine, Indianapolis, IN, (5)Speech, Language, and Hearing Sciences, Purdue University, West Lafayette, IN

---

**Background:** The significant gap between the emergence of autism spectrum disorder (ASD) symptoms and diagnosis means that young children are missing opportunities for intervention at the time of optimal impact. Diagnostic delays are exacerbated for children from diverse racial, ethnic, socioeconomic, and geographic groups. As such, developing and testing streamlined community-based methods of ASD diagnosis has been identified as a priority.

**Objectives:** To determine the diagnostic accuracy of a statewide system for early ASD diagnosis in the primary care setting. Specifically, we sought to 1) determine ASD diagnostic agreement between primary care providers (PCP) trained to conduct standardized ASD evaluations and an expert team specializing in early ASD diagnosis, and 2) identify differences in the phenotypic presentation of children accurately and inaccurately diagnosed in the community primary care setting.

**Methods:** Early Autism Evaluation (EAE) Hubs have been established in primary care practices across Indiana. Primary care providers in the EAE Hubs were trained on a standard clinical pathway for ASD evaluation. Since 2012, nearly 4000 toddlers, ages 18-48 months, have been evaluated in the EAE Hubs. In the current study, EAE Hubs refer children for follow-up comprehensive evaluation [including Mullen Scales of Early Learning (MSEL), Vineland Adaptive Behavior Scales (Vineland-3), Autism Diagnostic Observation Schedule (ADOS-2), caregiver DSM-5 ASD interview, and Child Behavior Checklist (CBCL)] by a team specializing in early ASD diagnosis.

**Results:** To date, 55 children (M=2.6 years; SD=0.6; 80% male; 69% White; 18% Latinx) have been evaluated. In 45 cases (82%), there was diagnostic agreement between the EAE Hub PCP and ASD specialist ( $k: 0.61; p < 0.01$ ) indicating a substantial level of agreement. Thirty-one cases were true positives (56% TP; diagnosed by both EAE Hub PCP and ASD expert with ASD), 14 cases were true negatives (26% TN; diagnosed by both EAE Hub PCP and ASD expert with non-ASD) and 10 cases were false negatives (18% FN; EAE Hub PCP diagnosed non-ASD and ASD expert diagnosed ASD). Fifty percent of false negative cases were flagged by the EAE Hub PCP for referral for follow-up specialized ASD evaluation. No false positive cases were identified. Compared to TP cases, FN cases had significantly higher non-verbal (MSEL Visual Reception T Score), expressive language (MSEL Expressive T score), and adaptive abilities (VABS-3 Communication and Daily Living Skills standard scores), and internalizing behaviors (CBCL Internalizing T score); all  $p < 0.05$ .

**Conclusions:** Community-based PCPs trained as part of a statewide system are able to make accurate ASD diagnoses in young children in a significant majority of cases. All diagnostic disagreements to date have been false negative cases. False negative cases appear to have a different phenotypic presentation including higher cognitive, language, and adaptive functioning and increased internalizing behaviors. Findings have implications for further training of PCPs conducting ASD evaluation, specifically with regard to identification of cases requiring referral for specialized evaluation at an ASD diagnostic center. Community-based models of ASD evaluation are a promising method for improving localized, equitable access to diagnostic services, potentially allowing for streamlined entry into interventions.

### **310.002 (Oral) Echo Autism: Mental Health: An Approach to Improved Mental Health Care for Individuals on the Autism Spectrum**

**L. Levinstein<sup>1</sup>, B. B. Maddox<sup>2</sup>, R. Brown<sup>3</sup>, M. Odum<sup>4</sup> and K. Sohl<sup>5</sup>,** (1)University of Missouri - Columbia School of Medicine, Columbia, MO, (2)University of Pennsylvania, Philadelphia, PA, (3)University of Missouri, Columbia, MO, (4)ECHO Autism Communities, University of Missouri, School of Medicine, Columbia, MO, (5)ECHO Autism Communities, Child Health, Columbia, MO

---

**Background:** Autistic individuals struggle with mental health issues, such as anxiety and depression, at alarmingly high rates. Despite the prevalence, mental health concerns are often inadequately addressed or treated in individuals with autism, leading to challenges with social, mental, and physical wellbeing. Modified cognitive-behavioral therapy (CBT), delivered as a component of comprehensive mental healthcare, can reduce anxiety and depression in people with autism, though few clinicians are trained to deliver the care.

**Objectives:** The primary objective of the study is to evaluate the feasibility, acceptability, and efficacy of ECHO Autism: Mental Health with mental health clinicians working with clients on the autism spectrum. Through the program, we hope to advance mental health care for autistic individuals.

**Methods:** ECHO Autism: Mental Health is a virtual learning community that allows a "hub team" of experts to mentor and coach "spoke participants" through videoconferencing technology. This model includes case-based learning, high-yield didactic presentations, and building a network of clinicians who feel confident to serve this vulnerable population. ECHO sessions took place every other week for 1.5 hours per session, across 16 sessions. Participants completed pre/post program surveys asking about demographics, self-efficacy, and perceived barriers to providing care, and semi-structured interviews for open-ended feedback. The interview questions asked about the components of ECHO Autism: Mental Health, barriers to participation, and changes in practice and perception because of the program. All interviews were audio-recorded and transcribed for analysis. We conducted a thematic analysis, a rigorous, systematic approach identify themes from the data.

**Results:** Sixteen mental health clinicians completed the pre/post surveys, and 13 clinicians completed the interviews. Survey results showed statistically significant self-efficacy improvements in all assessed categories ( $p < 0.05$ ). Qualitative findings highlighted positive general feedback, and supported case presentations with hub team recommendations as the most useful component of the program, with many participants utilizing the hub team's recommendations. The supportive interdisciplinary hub team with a family advocate was central to the participants' comfort and learning. One participant stated about ECHO Autism: Mental Health that they "really appreciate the opportunity and the fact that this was done in such a positive professional way. It's one of those things where there was no stupid questions and everyone seemed to feel very free to just, be open to

communicate and provide each other feedback.” All participants stated the program increased their knowledge and/or confidence in treating autistic individuals.

**Conclusions:** Mental health issues, which affect outcomes of physical and social health, are often a challenge for autistic individuals. This study aimed to assess the ECHO Autism model to train more mental health clinicians in CBT techniques specific to autistic individuals. Preliminary results suggest that ECHO Autism: Mental Health is a useful program to increase mental health clinicians’ knowledge and confidence in working with people on the autism spectrum. The study helps to guide revisions for future ECHO Autism: Mental Health cohorts and provide a framework for improving mental health care for autistic individuals.

**310.003** (Oral) Understanding and Improving Education Systems for Children with Autism Spectrum Disorder in South Africa

**S. Pillay<sup>1</sup>, P. J. de Vries<sup>2</sup> and M. Duncan<sup>3</sup>,** (1)Health Sciences, Centre for Autism Research Africa (CARA), Cape Town, South Africa, (2)Centre for Autism Research in Africa, Division of Child & Adolescent Psychiatry, University of Cape Town, Cape Town, South Africa, (3)Occupational Therapy, University of Cape Town, Cape Town, South Africa

---

**Background:**

The prevalence of autism spectrum disorder (ASD) in South Africa is unknown and there is little information on the educational service needs of children with ASD in the country. There are no standardized procedures for identification, diagnosis and management of these children. The Western Cape is one of the better resourced provinces in the country in terms of ASD services yet educational opportunities for children with ASD are limited. We therefore used the Western Cape as a case study to understand education systems for children with ASD in South Africa by examining the ‘hardware’ elements (finances, infrastructure, and resources) and ‘software’ element (ideas and interests, relationships and power, values, and norms) in order to gain whole-systems understanding.

**Objectives:**

The objectives of the study were a) to perform a situational analysis of the needs and resources for children with ASD and their families and b) to examine stakeholder views, perspectives and proposed solutions to meet the educational needs of children with ASD in order to generate contextually appropriate guidelines for improved ASD educational service delivery.

**Methods:**

An exploratory mixed-methods approach was used across two phases. In the first quantitative phase, provincial educational data were used to describe the profile of children with ASD in the formal education system as well as those waiting for educational services. The second qualitative phase used focus groups and interviews to examine the perspectives and recommendations of caregiver, service provider and government stakeholder about ASD services.

**Results:**

The systematic database search for children with ASD in the provincial educational system (serving more than 1 million children), combined with the provincial ‘waiting list’ of those waiting for school placement found very low rates of ASD (<0.1%). The majority of children with ASD (89%) were in special educational placements, and only 10% of children with ASD were in mainstream schools. All children waiting for school placement, were waiting for a place at a special school. Thirty six percent (36%) of the children waiting were of compulsory school-going age and 48% of those waiting received no other ASD intervention while waiting. The key perspective that emerged from the caregiver focus groups was “we wait and we wait”. Here, caregivers expressed their frustrations with current ASD services. Service providers acknowledged the limitations in their capacity to provide services for children with ASD and their families under a theme “we are doing the best we can to bridge the gap” and government stakeholders felt that ASD services were not prioritised due to competing societal demands on government resources under a theme “we are doing damage control”. Synthesis of the findings across the different phases of the study identified six key actions for service improvements.

**Conclusions:**

Findings from this study highlight the urgent need for multi-stakeholder collaboration to develop and implement contextually relevant plans and policies for ASD services for children in South Africa. Better systems for identification of children with ASD, designated early intervention programmes and better inclusion of children with ASD in the education system is recommended.

**310.004** (Oral) Racial Disparities in Autism Service Persist throughout the Pandemic-Induced Transition to Telehealth

**K. D. Riley<sup>1</sup>, N. Ono<sup>2</sup>, K. Keller<sup>3</sup>, E. Neuhaus<sup>4</sup>, J. Mannheim<sup>5</sup>, A. Persons-Geer<sup>6</sup>, H. Willis<sup>6</sup>, J. Skytta<sup>4</sup>, F. Shic<sup>7</sup>, M. Augustine<sup>3</sup>, G. Riley<sup>3</sup>, K. Salum<sup>3</sup> and D. Camenisch<sup>3</sup>,** (1)Seattle Children’s Research Institute University of Washington, Seattle, WA, (2)Seattle Children’s Autism Center, Seattle, WA, (3)Seattle Children’s Hospital, Seattle, WA, (4)Seattle Children’s Research Institute, Seattle, WA, (5)Department of Psychiatry and Behavioral Medicine, Seattle Children’s Autism Center, Seattle, WA, (6)Child Health, Behavior & Development, Seattle Children’s Research Institute, Seattle, WA, (7)Center for Child Health, Behavior and Development, Seattle Children’s Research Institute, Seattle, WA

---

**Background:** Late cancellations, i.e. cancellations within 24 hours of scheduled appointments including no-shows, stress clinical resources and infrastructure, limit optimal care capabilities, and impact patients’ needed care. Previous analysis of a high-throughput metropolitan autism clinic’s

data highlighted several demographic factors associated with increased rates of late cancellations: Black or American Indian race, Medicaid, positive ASD diagnosis, and middle-school age<sup>1</sup>. In March 2020, many in-person appointments transitioned to telehealth due to the COVID-19 pandemic. Although this transition may have represented an opportunity<sup>2</sup> to reduce the disparities in appointments and late cancellations, its impact is yet poorly understood.

**Objectives:** To examine how demographic factors (focused on race/ethnicity) relate to the frequency of telehealth and in-person appointments before and during the COVID-19 pandemic and the likelihood of late cancellations for in-person and telehealth appointments.

**Methods:** Data were obtained from 74,718 scheduled appointments in a high-throughput metropolitan autism clinic between January 2018 and May 2021. “Pre-COVID” is defined as before March 2020 (n=48,526); “during-COVID” is defined as March 2020 onward (n=26,192). Odds ratios were used to examine frequency of visits pre- and during-COVID and frequency of in-person and telehealth visits during-COVID. A generalized linear model was run to explore the probability of encounter-level late cancellations based on race/ethnicity controlling for age, sex, language-other-than-English, ASD/non-ASD diagnosis, new/return visit, and Medicaid insurance usage for three divisions of scheduled appointments: pre-COVID in-person, during-COVID in-person, and during-COVID telehealth. We did not include pre-COVID telehealth appointments in our analyses due to their infrequency.

**Results:** During the pandemic, relative to White families, scheduled appointments increased in frequency for families belonging to more than one race, remained the same for Black families, and decreased for families of all other races (Table 1a). Regardless of race, all telehealth appointments sharply increased in frequency beginning March 2020. Except for Native American families, all non-White families less frequently scheduled telehealth visits compared to White families (Table 1b). Pre-COVID, all non-White families except Asian families late cancelled more frequently than White families (Table 2a). During COVID, in-person visits for all non-white families were late cancelled at comparable rates to White families. However, for telehealth visits, Black, Hispanic, and families of more than one race late cancelled at higher rates compared to White families.

**Conclusions:** Pre-pandemic it was often hypothesized that telehealth could overcome barriers-to-access such as lack of transportation. The converse was observed. Pre-pandemic racial disparities in autism services attainment have persisted through COVID and seem linked to multi-level systemic difficulties in telehealth access involving decreased adoption and increased cancellation of telehealth appointments largely by non-White families. We note that the finding of decreased late cancellations in in-person appointments by minorities during COVID may suggest that increasing the proportion of appointments offered virtually perversely drives minorities to higher fidelity of making in-person visits. It is critical that we continue to explore barriers to appointments for families that late cancel.

## POSTER SESSION — SERVICE DELIVERY/SYSTEMS OF CARE

### 426 - Service Delivery/Systems of Care

**426.098 (Poster)** A Social Network Analysis of Team Coordination to Support Children with ASD in an Inclusive School Setting  
*E. Isralowitz<sup>1</sup>, T. Valente<sup>2</sup> and E. McGhee Hassrick<sup>3</sup>, (1)Chan Division of Occupational Science and Occupational Therapy, University of Southern California, Los Angeles, CA, (2)University of Southern California, Los Angeles, CA, (3)A.J. Drexel Autism Institute, Drexel University A.J. Drexel Autism Institute, Philadelphia, PA*

**Background:** Schools are complex socio-political structures with formal and informal social networks. Evidence-based intervention and resource coordination models frequently target school social networks to improve student outcomes, educational equity, and inclusion. Group collaboration and coordination are crucial to school intervention teams. Special education (SPED) teachers are key players in successful school-based interventions for children with autism (ASD), acting as the primary contact for students, caregivers, and other staff.

**Objectives:** The purpose of this study is to examine the role of teachers in the coordination network of an urban inclusive elementary school and the influence of student support needs on coordination-related group clustering. We hypothesized that (1) SPED teachers would be centrally located in the coordination network and (2) inclusion for students with ASD and higher support needs, indicated by the student’s classroom placement, requires more staff coordination than students needing less support.

**Methods:** A social network survey (Social Dynamics of Intervention; SoDI) was administered to parents of children with ASD (n=17) and school staff (n=32) at three-time points, at Aspire, an inclusive (i.e., all students with ASD were mainstreamed for part of the school day) low-income school. Coordination network data from time point two were analyzed. Participants were asked to identify the individuals they coordinated with for each student’s interventions. Network measures were calculated, and qualitative interview (n=2 teachers) analyses were conducted.

**Results: Network Analysis.** Examination of egocentric (node-level) network centrality indicated that SPED administrators, service coordination staff, and elective teachers had the highest centrality (Figure 1). Parents, general, and SPED teachers were not intermediaries for coordination and had low betweenness scores (Figure 2).

Network-level indicators showed that the network was dense, with 82% of all possible ties present. The network was cohesive with an average path length of 1.91, transitivity of .37, with no isolates and one component. A CONCOR (CONvergence of iterated CORrelations) analysis segmented the coordination network into eight groups with the most influential (Group 1) consisting of two paraprofessionals, and four parents of children with higher-support needs, and SPED administrators, the social worker, and elective teachers as key coordinators in the inclusion of students with ASD (Table 1 and Figure 3). Lesser influential groups, containing the bulk of the teachers, showed low modularity or social mobility.

**Qualitative Interviews.** Teachers reported frequent coordination with other teachers, particularly between general and SPED teachers, and highlighted the benefits and barriers to home-school coordination.

**Conclusions:** Hypothesis 1: Despite evidence supporting the role of teachers as key players in the implementation of school-wide inclusion and intervention initiatives, teachers were absent from the top node-level centrality rankings. The interview results and frequency of teacher connections with one another indicate that coordination among teachers played an important role in interventions and inclusion. The peripheral location of SPED teachers in the network suggests that hierarchical coordination structures informed inclusion processes.

Hypothesis 2: The data confirm coordination of elective teachers, parents, and paraprofessionals supporting students with ASD with higher support needs, suggesting that student characteristics can shape network structure.

**426.099 (Poster) Longitudinal Analysis of Impact of COVID-19 on the Service Patterns and Child/Parent/Family Mental Health in Families Affected By Autism Spectrum Disorder (ASD)**

*A. N. Bhat, Department of Physical Therapy, University of Delaware, Newark, DE*

---

**Background:** Children with ASD receive a multitude of educational, medical, and therapeutic services. At the onset of the COVID-19 pandemic, all of these services came to a complete halt following strict lockdowns. Many services have resumed in a hybrid format using face to face and virtual modes of delivery.

**Objectives:** The present study examines longitudinal data collected in the SPARK study families (N=6,393) on the impact of COVID-19 on service patterns, child/parent/family mental health, and the benefits of online/virtual services (clinic or school-based).

**Methods:** Caregivers of children and adolescents with ASD between 19 months and 18 years completed an online survey inquiring about the impact of COVID-19 pandemic on access to services, parent concerns about the same, impact on child's ASD-related behaviors, child/parent/family mental health, and the benefits/potential benefits of online/future online services. These surveys have been completed across 4-6 time points depending on questions.

**Results:** Preliminary analysis of data from the early part of the pandemic from Spring 2020 revealed that certain demographic (age, income/SES) and child-related factors (repetitive behaviors, language, functional, cognitive, and motor impairments, and child's understanding), as well as parent's past mental health were associated with and predicted service disruptions ( $r=0.15-0.26$ ,  $p<0.001$ ), ASD-related behaviors ( $r=0.16$ ,  $p<0.001$ ), and negative impact on parent mental health ( $r=0.17$ ,  $p<0.001$ ).

**Conclusions:** In conclusion, younger children, children from low-income families, and children with greater impairment severity (more severe repetitive behaviors, language, cognitive, function, language, and motor impairments) were more negatively impacted by the pandemic through service disruptions, increased ASD-related behaviors, negative parent health/family impact, and found online interactions to be less beneficial. A further analysis of child, parent, and demographic factors and their longitudinal impact on service disruptions and other aforementioned issues will be reported during the presentation.

**426.100 (Poster) Academic Performance of College Students with Autism Spectrum Disorder or Attention Deficit Hyperactivity Disorder**

*K. Ryan<sup>1</sup>, T. McFalls<sup>2</sup>, P. Schatz<sup>3</sup>, A. Gatta<sup>2</sup>, M. A. Newell<sup>2</sup>, D. McDevitt<sup>1</sup>, C. Mecke<sup>1</sup> and J. McCleery<sup>3</sup>, (1)Saint Joseph's University, Philadelphia, PA, (2)Kinney Center for Autism Education and Support, Saint Joseph's University, Philadelphia, PA, (3)Psychology, Saint Joseph's University, Philadelphia, PA*

---

**Background:** There is currently extremely limited research on academic progression or academic performance in college students with autism spectrum disorder (ASD), with research on this topic largely limited to self-reported and parent-reported participation and graduation rates (Wei et al., 2014).

**Objectives:** To examine and compare academic progression and academic performance of college students with ASD to college students with Attention Deficit Hyperactivity Disorder (ADHD) and college students from the General Population (GP).

**Methods:** Academic Grade Point Averages (GPAs) of college students with ASD ( $n=46$ ) and individually matched groups of students with ADHD ( $n=46$ ) and students from the GP ( $n=46$ ) were extracted from historical academic records of a small, Catholic university in the greater Philadelphia region. All students were admitted to the University based on standard admissions criteria, with no special consideration. Furthermore, students in the

ADHD and GP groups were matched to the students with ASD individually and at the group level on biological sex, a socioeconomic status indicator (eligibility for federal Pell grant funding), incoming academic year cohort, and school of their major. Finally, all students with ASD or ADHD designated and officially registered their clinical diagnoses with one of the University's official support programs for students with disabilities. Statistical models which included student group (ASD, ADHD, GP) as a between-subjects factor and semester (1 through 8) as a within-subjects factor were conducted to test the hypothesis that students with ASD and/or students with ADHD would exhibit GPAs which differed from GP students at different points in their college academic progression.

**Results:** Results indicate that the mean grade point averages of students with autism (2.91) were statistically indistinguishable from students from either those with ADHD (2.89) or those from the general population (3.09), overall. However, mean grade point averages did differ for both students with ASD and students with ADHD compared with GP students during the first 4 of 8 semesters (ASD=2.845, ADHD=2.875, GP=3.175).

**Conclusions:** These findings indicate that individuals with ASD and those with ADHD who enroll in college are capable of academic achievement equal to the GP, but that the first 2 years of college are significantly more academically challenging for both students with ASD and students with ADHD.

**426.101 (Poster) Autistic Women Evaluate Their Therapies Received**  
*M. L. Bezemer and E. M. Blijd-Hoogewys, INTER-PSY, Groningen, Netherlands*

---

### **Background:**

Autism has for long be missed in many women (Hiller et al., 2014). For, the diagnostic of more camouflaged autism requires additional expertise. The female autism phenotype has been characterized as having higher social motivation, better nonverbal communication, more gender-stereotypical interests, more sensory problems, and higher vulnerability to emotional problems and social camouflage (Bargiela et al., 2016). These are crucial elements to consider not only during diagnostics but also in therapy. Do we therapists do that?

### **Objectives:**

Gaining insight into what kind of therapy is being offered to autistic women and what they claim to benefit from.

### **Methods:**

The Female Autism Network of the Netherlands approached Dutch autistic women through social media and asked them to fill-in a survey on all therapies received, focusing on form of therapies, therapy satisfaction, and adjustment recommendations. All participants ( $N = 150$ ) reported being diagnosed in adulthood ( $M_{\text{age of diagnose}} = 35.82$ ,  $SD = 10.51$ ). Some were mental health care professionals themselves ( $n = 8$ ).

### **Results:**

Of the total group, 90 women (60%) received therapy directly after receiving the ASD diagnosis; 53 women (35%) did not receive direct therapy, though some reported having received some psychoeducation. Reasons for not receiving therapy were no suitable therapy offer, therapy waiting lists, professionals lacking expertise in ASD women, professionals who regarded problems as too mild or expected a more well-defined therapy request.

Almost half ( $n = 70$ ) experienced ill matching therapy offers, often due to a lack of expertise in autistic women. Most autistic women wanted more elaborate and more in-depth psychoeducation, not to simplistic or "that classic ASD story". They mentioned to have learned a lot from reading books and articles, and from peer support. They stated that a therapist needs to be aware of camouflaging behavior, also in therapy session, and should make camouflaging a therapy focus, in combination with attention to self-esteem and identity. Some therapies (e.g., mindfulness and psychotherapy) were experienced as too abstract. Autistic women stressed the need for more concrete language, in-depth questioning and in many cases more practical support. They cautioned for overestimation of their abilities and not to be taken seriously. For more details see Table 1 and 2.

### **Conclusions:**

Except for therapies focusing on energy management, the top-5 of therapies received was not equal to the ones being most valued by autistic women. We advise therapists to pay more attention to sensory management, relaxation strategies, improving social network and peer support. Psychoeducation fell outside the top-5 most valued therapies; autistic women urge psychoeducation to be implemented more individualized.

Autistic women did not seem to profit from emotion-regulation therapies. Possibly, these therapies are not well fitted to them, focusing mainly on behavior strategies and less on recognizing and understanding emotions. Autistic women urge therapist to get more training in the female autism phenotype, matching their communication style and looking further than the mask.

There is no one-size-fits-all conclusion for individual therapies. We had no insight into the quality and content of the therapies supplied. Further research is needed.

**426.102 (Poster)** Building on the Strengths of Autistic Scholars By Addressing Systemic Barriers to Autistic Success in Academia: Year One SIG Results

**A. R. Dallman<sup>1</sup>, D. L. Gassner<sup>2</sup> and P. Dwyer<sup>3</sup>,** (1)Department of Allied Health Sciences, University of North Carolina at Chapel Hill, Chapel Hill, NC, (2)Social Work, Adelphi University, West Hempstead, NY, (3)Department of Psychology, University of California, Davis, Davis, CA

---

**Background:**

Although an increasingly large research literature investigates barriers facing autistic people in undergraduate education, little attention – and no published qualitative or quantitative research studies – have explored the accessibility for autistic people of post-graduate education, academia, and research. However, autistic academics report many barriers and challenges in these domains (Botha, 2021; Dwyer et al., 2021; Jones, 2021). This emphasizes the importance of investigating these barriers, developing theoretical frameworks to describe them, and directing efforts to promote autistic representation, success, and thriving in academia.

**Objectives:**

This submission presents findings from the first of a three-year qualitative study, conducted as an INSAR Special Interest Group, exploring the lived experiences of autistic graduate students in their transition into graduate school, their experiences while in graduate school and their post-graduate experiences after completion of their degrees. The aim of this study is to generate a theory on supports and barriers for autistic researchers as they applied, entered and sought to adjust to their first year of graduate school.

**Methods:**

Stakeholders in the field of autism were invited to participate in one of six (2 groups for autistic researchers, 1 group for faculty who teach autistics, and 3 groups for non-autistic students and postdocs) simultaneously occurring, semi-structured focus group interviews during the 2020 International Society for Autism Research Conference. Focus groups were conducted via Zoom and the main topics of discussion were challenges in post-undergraduate university applications, diagnosis disclosure, activities of daily living during higher education, and supports during college. Data were analyzed using a grounded theory approach and triangulation was applied to synthesize information from the different stakeholders.

**Results:**

A total of 14 autistic researchers, 19 non-autistic students and post-docs, and 4 non-autistic faculty participated in our virtual focus groups. Preliminary coding generated a total of 150 codes that were reduced to 60 focused codes. Our preliminary analyses indicate that autistics have a strong desire to learn in higher education. However, ableist processes built into the college systems such as social requirements, poorly designed classrooms that are often overwhelming for the sensory system of autistics, a lack of external support, and a lack of supportive higher education systems makes the process of obtaining a higher education degree difficult for autistics. In the presentation, we will present finalized analyses and the generated theory.

**Conclusions:**

Based on our findings, ableism presents a clear barrier to autistic people's inclusion in academia and higher education. The culture, expectations, and practices of academia give rise to serious barriers, such as requirements for high degrees of social interaction and lack of clarity in rules. Poorly designed and inaccessible environments also represent a serious challenge to many autistic researchers, as do mental health challenges. Unfortunately, respondents described a dearth of support from programs and institutions. Moreover, the small numbers of openly autistic people in higher education today can prevent autistic colleagues from being an informal source of support or mentorship, exacerbating the challenges faced by autistic people in post-graduate education and academia. Directions for future research will be discussed.

**426.103 (Poster)** COVID-19 Pandemic Influence on Vaccinations and Autism Myth Discussions

**L. V. Gabis<sup>1</sup>, O. Leon Attia<sup>2</sup> and M. Shaham<sup>3</sup>,** (1)Pediatrics, Maccabi health services, Rehovot, Israel, (2)Child development Center, Sheba Medical Center, Tel Hashomer, Israel, (3)Statistics, Haifa University, Haifa, Israel

---

**Background:** Since the declaration of the COVID-19 pandemic in March 2020, extensive efforts have been made to develop and control the infectious virus via the development of vaccinations. As the Covid -19 pandemic began, we began to see a revival in conspiracy theories that have been influencing the beliefs of individuals and instilling a fear based notion in regards to vaccines and their relation to autism. Since the Covid-19 pandemic has been an unpredicted time of uncertainty, discussions have been circulating within social and traditional media as individuals have been falling to conspiracy theories to find some sort of explanation for uncertain times. Importantly, research conducted in the US revealed that vaccination rates dropped initially during the pandemic, as a result of the imposed restrictions, healthcare personnel workload and the concern of exposure to COVID-19 while outside.

**Objectives:**

In order to examine the influence that the COVID-19 pandemic had on current trends in publications, we analyzed semantic networks of vaccine information from formal publications and usage of search engines. In order to decipher the influence of COVID-19 pandemic on public interest we compared publications and search keywords between the years 2019 and 2020.

Even before the first publications of clinical trials with COVID-19 immunizations it was clear to the medical community that vaccine hesitancy may contribute to suboptimal vaccination coverage. Inaction to vaccinate poses a significant risk to the continuation of the pandemic as the public would be unable to acquire herd immunity. All medical associations worldwide initiated campaigns to influence public opinion on vaccine safety, even before the COVID-19 vaccine was distributed.

#### Methods:

Our present study focused on trends in formal publications during a two year period (before and during Corona pandemic) and on search trends made by the general public in various geographic zones.

We constructed semantic networks of vaccine information from Google Scholar engines, searching for articles with keywords “vaccines”, “autism” and the link between the terms. We analyzed trends over two years according to months and geography.

Results: media search of vaccination and autism terms was significantly impacted and followed the different waves of the pandemic. Global trends will be presented according to timeline and location.

Conclusions: The COVID-19 pandemic changed the way vaccine information has been communicated through media which has prompted the medical community to become more active resulting in improved vaccine acceptance

---

#### **426.104 (Poster) Challenges and Opportunities in Building Interdisciplinary Programs Around Autism** **E. Rotheram-Fuller, M. Dixon and N. Scherer, Arizona State University, Tempe, AZ**

---

Background: Children with Autism Spectrum Disorders (ASD) with high-intensity needs often require supports from a range of professionals with unique expertise, but few training programs have opportunities for students to experience and practice cross-disciplinary collaboration.

Objectives: Examine the challenges and opportunities in creating an interdisciplinary program model between autism specialist (AS) and speech and language pathology (SLP) students at the masters level.

Methods: AS and SLP programs worked together to develop an interdisciplinary training model between two colleges and three faculty members. The goal was to incorporate perspectives from two key professional disciplines in the training process around ASD. Four collaborative courses and three semester-long seminars were developed that focused on topics around interdisciplinary collaboration and case consultation. The program development process was documented and barriers in design were addressed.

Results: Over the course of four meetings with three faculty members, the coursework and course sequencing were adapted in both programs to make collaborative activities work for both sets of students. Programs were able to integrate interdisciplinary coursework and seminars without significantly altering their existing course sequence or impacting credentialing competencies. All collaborative activities were moved online to facilitate collaboration, and approvals were needed on program activities from the program faculty and deans of each college. The model developed allows for training of other related professions (e.g., occupational therapy) to be included in the future, to create a truly interdisciplinary model of autism training. Faculty buy-in and program flexibility were key to ensure that interdisciplinary competencies could be incorporated.

Conclusions: Key identified interdisciplinary competencies around children with ASD with high-intensity needs, as well as unique methods to integrate program activities will be discussed. It is feasible to adapt existing programs to include interdisciplinary competencies, however, there must be engagement at the faculty and administration level to ensure prioritization of these competencies and effective coordination.

---

#### **426.105 (Poster) Changes in the Organizational Context of Autism Community-Based Organizations: Effectiveness of a Multi-Faceted Implementation Strategy**

**J. E. Tschida<sup>1</sup>, A. Sridhar<sup>1</sup> and A. Drahota<sup>1,2</sup>, (1)Psychology Department, Michigan State University, East Lansing, MI, (2)Child and Adolescent Services Research Center (CASRC), San Diego, CA**

---

#### Background:

Evidence-based practices (EBPs) for Autism Spectrum Disorder (ASD) lead to improvements in core ASD domains, co-occurring challenges, and quality of life (Steinbrenner et al., 2020). However, within community-based organizations providing services to autistic individuals (ASD-CBOs), EBPs are utilized inconsistently and with low intensity (Brookman-Frazee et al., 2012). Implementation science aims to promote the uptake of EBPs in routine practice and increase understanding of how organizational context may contribute to variable EBP use (Bauer et al., 2015). Organizational capacity to support practice change depends in part on contextual factors such as culture, formal and informal leadership, measurement practices, and available resources (Helfrich et al., 2009). To improve the implementation of EBPs within ASD-CBOs, Drahota and colleagues developed and pilot-tested the ACT SMART Implementation Toolkit, a multi-faceted implementation strategy to guide organizations through EBP adoption and implementation as well as increase organizations' capacity to support practice change (Drahota, Meza, & Martinez, 2014).

#### Objectives:

Assess changes in organizational context within ASD-CBOs following use of the ACT SMART Implementation Toolkit.

## Methods:

Six ASD-CBOs located in Southern California met eligibility criteria and participated in the pilot study. ASD-CBOs provided: Applied Behavior Analysis (ABA;  $n=4$ ), ABA and mental health ( $n=1$ ), and Speech and Language Pathology ( $n=1$ ) services. Supervisors and direct providers at each participating agency (See Table 1) completed an agency assessment, including an adapted version of the Organizational Readiness to Change Assessment, Context Scale (ORCA; Helfrich et al., 2009) at pre- and post-pilot (13 months after pre-pilot assessment). The ORCA Context Scale measures the quality of organizational context to support practice change and includes sub-scales measuring leadership culture, staff culture, leadership behavior, leadership measurement, readiness for change, and organizational resources.

## Results:

Due to the limited sample size of a pilot study, we calculated effect sizes to achieve a more accurate estimate of the magnitude of the effect of the ACT SMART Implementation Toolkit on ORCA Context Scale ratings (Ferguson, 2009). Small to medium effect sizes (Hedge's  $g$ ) were found for both supervisor and direct provider ratings on the ORCA Context Scale and underlying sub-scales. Only the mean for supervisor ratings of organizational resources did not increase from pre-toolkit to post-toolkit (Table 2).

## Conclusions:

Overall, effect sizes indicate that both supervisors and direct providers at ASD-CBOs perceived an increase in organizational leadership culture, staff culture, leadership behavior, leadership measurement, and readiness for change after use of the ACT SMART Implementation Toolkit. These preliminary findings suggest that the toolkit may be an effective strategy for improving ASD-CBOs' organizational capacity to adopt and implement EBPs for youth on the autism spectrum (Moullin et al., 2019). However, supervisors perceived a decrease in organizational resources whereas direct providers perceived an increase in organizational resources after use of the toolkit. This suggests important differences in supervisor and direct provider perspectives and a potential need to further evaluate and adapt the ACT SMART Implementation Toolkit to address resource related barriers to implementing EBPs for autistic individuals.

### **426.106 (Poster)** Childhood Opportunity and Access to Telehealth during the COVID19 Pandemic

**M. E. Villalobos<sup>1</sup>, P. Carbone<sup>2</sup>, A. L. Stuart<sup>3</sup> and A. Ellzey<sup>4</sup>,** (1)Pediatrics, University of Utah, Park City, UT, (2)Univeristy of Utah, Salt Lake City, UT, (3)General Pediatrics, University of Utah, Salt Lake City, UT, (4)University of Utah, salt lake city, UT

Background: Models of care to increase equitable access to autism services in under-resourced communities are needed. The COVID-19 pandemic forced an increase in telehealth, which has great potential for addressing these inequities in autism care; however little to date is known regarding the sociodemographic or environmental factors enhancing or impeding access to telehealth for autism. We examined the impact of neighborhood level resources and conditions on access to autism services.

Objectives: (1) To compare sociodemographic characteristics among families accessing telehealth at a multidisciplinary child development clinic before and during the pandemic. (2) To examine whether any child neighborhood opportunity profiles predicted better access to telehealth using the Childhood Opportunity Index 2.0 (ChOI 2.0).

Methods: We examined medical records of children seen between January 2018- September 2021. For aim 1, children were stratified by telehealth; over 90% of telehealth visits were conducted after February 2020. Binary regression analyses were used to identify associations between sociodemographic profiles of children accessing telehealth. Next, using geoid coding we calculated Childhood Opportunity Index scores for each child. The ChOI is a publicly available surveillance tool that incorporates traditional and novel attributes of neighborhood conditions (education, health/environment, social/economic). Secondary regression analyses examined whether ChOI levels (Very Low, Low, Moderate, High, Very High) predicted accessing telehealth throughout the study period. Post-hoc analyses examined the effect of ChOI levels on differences in age of referral and autism diagnosis across the study sample.

Results: We included 3,500 unique children (1,030 female; 2,469 male) from 12,077 visits. Among all children 1,745 were seen before and 1,755 during the pandemic (See Table 1). Results of the binary logistic regression indicated that there was a significant association between geography (urban and rural), language (English speaking), and insurance type (Commercial), and telehealth access ( $\chi^2(5) = 23.56$ ,  $p < .00$ ). Secondary analyses (See Chart 1 ) further indicated that *Very Low* childhood opportunity levels of education and health and environment predicted increased telehealth access ( $\chi^2(8) = 18.20$ ,  $p < .02$ ). Post-hoc univariate analyses of the ChOI suggested that families in areas with *Very Low* Childhood Opportunity were referred at older ages  $F(8,4039) = 2.2$ ,  $p = .0251$  and less likely to receive an autism diagnosis  $F(4,.149) = 2.94$ ,  $p = .019$ .

Conclusions: Our results suggest that telehealth for autism has strong potential to increase access to care for English speaking families in urban and rural areas and those with commercial type insurance. However, considerations for models of care should be taken for non-English speaking families and those in designated Frontier communities. We also found that while telehealth availability increased access for families in lower opportunity neighborhoods, children in these communities are referred and subsequently diagnosed later. This study is the first to report neighborhood level resources and conditions on access to telehealth autism services. Autism centers should continue to incorporate telehealth models into their existing systems of care and evaluate equitable access using tools such as the ChOI.

### **426.107 (Poster)** Comparing Rates of Health Care Transition across Youth with ASD, Shcn, and Youth with Typical Development

**Background:** Access to health care transition (HCT) services have been included in national surveys for 20 years. Many studies assessing HCT in the National Survey of Children with Special Health Care Needs and the revised National Survey of Children's Health (NSCH) have shown disparities in access to HCT services for youth with autism spectrum disorder (YASD) but these estimates are often varied and don't reflect the needs described by individuals on the spectrum and their caregivers.

**Objectives:** This study aimed to develop and validate a holistic measure of HCT services within the NSCH and utilized this measure to examine access to HCT services among YASD, youth with other special health care needs (YSCHN), and typically developing youth (non-YSHCN).

**Methods:**

*Measurement Development and Psychometric Testing:* We utilized four-years of NSCH data (2016-19, n = 54,434) to examine the model fit of nine HCT questions. The new measure's psychometric properties were assessed by comparing it to theoretically similar and divergent variables including System of Care indicators, unmet needs, youth employment, and access to mental health services, dental treatment, and mentorship.

*Assessing the relationship between condition status and HCT service provision:* We utilized the newly validated dichotomous HCT measure as the dependent variable in a logistic regression model. Using this model, we examined the relationship between the HCT measure and youth's condition status while controlling for demographic and family-related variables.

**Results:**

*Measurement Development and Psychometric Testing:* An exploratory factor analysis and item culling yielded eight items addressing three subscales. A dichotomous and continuous scale was created with subscales including Guidance Toward Independence, Adequate Clinic Visit, and Continuity of Care Discussions. Model fit was excellent with an Eigenvalue of 1.01 and 79% variance explained. Examination of initial reliability and content and criterion validity indicated high reliability and validity for the scale and subscales.

*Assessing the relationship between condition status and HCT service provision:* YASD had the lowest access to HCT services. YSCHN had significantly higher rates of HCT service provision with 27%, followed by non-YSHCN (19%), and YASD (18%, Table 1). Logistic regression analyses indicated that being older, identifying as female, being white or non-Hispanic black, having private insurance, and having a household income at or above 400% of the federal poverty level were strong predictors of HCT service provision.

**Conclusions:** Less than one in five YASD receive HCT services, indicating a significant disparity in access to HCT services. This was the first study to identify this disparity utilizing a validated measure of HCT service provision. This caregiver-report HCT measure assessed providers' use of care plans, promotion of independence, clinic visit quality, and transfer assistance. The low rates of HCT service provision for YASD is a clear indication that the health care system is not assisting YASD, and families move to an adult model of care or helping YASD learn to manage their own health care needs and gain independence.

#### **426.108 (Poster) Content Analysis of the Recommendations from Project Echo Ontario Autism.**

**A. A. Jane<sup>1</sup>, M. Penner<sup>2</sup>, L. Kanigsberg<sup>2</sup>, A. Patel<sup>1</sup>, S. Eldon<sup>1</sup>, J. A. Brian<sup>2</sup> and E. Anagnostou<sup>3</sup>, (1)Queen's University School of Medicine, Kingston, ON, Canada, (2)Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (3)Autism Research Centre, Bloorview Research Institute, Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada**

---

**Background:** The rising prevalence of autism spectrum disorder (ASD) diagnoses in recent decades has caused an increased number of community practitioners to care for this population. However, community practitioners report a lack of knowledge and confidence in treating autistic children, resulting in unmet healthcare needs. The Extension of Community Healthcare Outcomes (ECHO) Autism model aims to address this through case-based and didactic learning to help guide community practitioners in providing comprehensive, best-practice care for ASD screening, diagnosis, and management of co-occurring conditions. Each ECHO session involves a case presentation followed by a list of recommendations generated by community participants and an interdisciplinary 'hub' team. While ECHO Autism has shown to improve physician's abilities to care for children with ASD in their practices, recommendations stemming from ECHO cases have yet to be characterized and may help guide the future care of autistic children.

**Objectives:** To quantify and characterize the common categories within ECHO Autism Ontario case recommendations.

**Methods:** We conducted a content analysis of 422 recommendations stemming from 61 ECHO cases to identify categories of recommendations and their frequencies. Three researchers independently coded recommendations from five ECHO cases, after which an original coding guide was developed. The researchers then independently coded the remaining cases using the coding guide and met regularly with the ECHO lead to modify and consolidate the codes and coding guide. From there, we identified categories and sub-categories from the various codes. Finally, the frequencies of each code and category were calculated.

Results: Fifty-seven codes were included in the final coding guide and were grouped into 8 broad categories. Categories include: 1) diagnosis; 2) concurrent mental and physical health conditions; 3) referrals to allied health providers and other specialists; 4) accessing community resources, such as parent and sibling support groups; 5) providing education and guidance to physicians, patients, and families; 6) management strategies such as nutrition, physical activity, and social skills; and 7) patient and family-centered care. A Covid-19 category was also added as many of the later recommendations were adapted to online service delivery. An analysis of the frequency of codes found that the 1,384 total in-text codes were relatively spread out amongst the various categories. The three highest frequencies of categories were as follows: providing general guidance and education (22%), accessing resources (16%), and referrals (15%).

Conclusions: This is the first time recommendations from ECHO Autism have been characterized and quantified. Our results, particularly the most common category of providing general guidance and education about ASD, show that there is still important work to do with educating clinicians and families about aspects of ASD. Furthermore, findings from this study should inform Pediatrics residency programs about real-world knowledge gaps in ASD care, and may help create more tailored ASD training programs and educational materials for medical trainees and practicing physicians.

**426.109 (Poster)** Developmental-Behavior Extenders Reach Military Families Worldwide

**E. Flake<sup>1</sup>** and **K. Belzer<sup>2</sup>**, (1)Madigan Army Medical Center, Tacoma, WA, (2)Madigan Army Medical Center, Lakewood, WA

---

Background: The prevalence of Autism Spectrum Disorder ASD has been steadily rising over the last 20 years. While treatment services for such children have been expanding, challenges in generating an efficient approach to the timely identification and evaluation of children at risk for ASD. Military Treatment Facility data suggests that primary care clinics on average annually refer ten children out of every 500 children they serve to a sub-specialty clinic to rule out ASD. The time from suspicions of ASD to diagnostic evaluation is often longer than 9-12 months. When combined with the highly mobile nature of this patient population, prolonged wait times for diagnosis often becomes the critical limiting factor in access to services.

Objectives: To evaluate the benefits of the Developmental Extender certification program, a manning-neutral program designed to empower the Patient-Centered Medical Home model to facilitate diagnostic evaluations and connect families to comprehensive therapeutic interventions for children ages 2-5 with autism.

Methods: This program design trains a medical team to diagnose and manage ASD with the hub and spoke Developmental-Behavioral Pediatric Oversight to strategically embedded in clinics with limited access to Developmental Pediatrics services. The PCP team is integrated with and supported by a Regional Developmental Specialist through use of telehealth/telementoring, and site visits.

Results: Since conception, seven military bases with PCP teams function as Developmental Extenders and have performed over 100 evaluations for autism. The average age of diagnosis has been reduced to a current average of is 32 months, 15 months earlier than the national average. The reduction of time to diagnosis went from 28 weeks to 4 weeks. Developmental Extender training has also increased provider confidence in diagnosing and treating autism resulting in a 25% decrease in referrals to specialty evaluations for developmental concerns. The model is being considered for expansion to overseas and other regional hub and spoke sites.

Conclusions: The Developmental Extender model is a promising novel approach to ASD screening, evaluation, and diagnosis that has proven to advance early detection and intervention. A targeted expansion could significantly improve time to service access for young military dependents with special needs.

**426.110 (Poster)** Disparities in Autism Diagnosis and Classroom Placement in Black Students

**B. Ayalew<sup>1</sup>**, **A. Sturm<sup>2</sup>**, **B. A. Boyd<sup>3</sup>** and **C. Kasari<sup>4</sup>**, (1)UCLA Semel Institute for Neuroscience & Human Behavior, Los Angeles, CA, (2)UCLA, Los Angeles, CA, (3)Juniper Gardens Children's Project, University of Kansas, Kansas City, KS, (4)University of California, Los Angeles, Los Angeles, CA

---

Background: Racial disparities in autism diagnosis and educational placement exist, with black children being less likely to receive an autism diagnosis than white children (Mandell et. al., 2009). Black children with disabilities are also more likely to be placed in a separate educational placement regardless of income (Grindal et al., 2019).

Objectives: The objectives of this study were to examine the representation of black students compared to white students served under autism eligibility in public school special education and to explore how the combination of income and race affect educational placement for students with developmental disabilities.

Methods: The data presented uses administrative data from a large southern California school district from the 2018-2019 academic year. Participants included students served under autism, specific learning disability (SLD), intellectual disability (ID), and emotional disturbance (ED) eligibility. Student free or reduced lunch (FRL) eligibility was used as an indicator for household income. Inclusion status (special day class [SDC], general education [GE]) reflected the educational placement where a student spent greater than 50% of their time during the school day. Proportions of black and white students by FRL eligibility and educational placement were tabulated. Black and white students were compared using proportionality measures which were calculated using risk ratios and confidence intervals.

Results: Black students were underrepresented in the autism category compared to white students. Black students made up 8.4% of the district population and 10.5% of students served under autism eligibility and 11.4% of students served under ID eligibility. In contrast, white students made up 10.7% of the district population and 16.2% of students served under autism eligibility and 8% of students served under ID eligibility.

Black students served under autism eligibility, regardless of income, had a significantly higher risk of being in SDC compared to white students. Among students without FRL, black students had a higher risk of being in SDC across all eligibility groups. For students on FRL, black students served under ED, SLD, and autism all also had a higher risk of being in SDC. Additionally among students who received FRL, white students served under SLD eligibility had a higher risk of being in SDC.

Conclusions: Larger proportions of black students served under autism eligibility in special education are not due to differences in income, and exist despite black students making up a smaller percentage of students served under autism eligibility.

**426.111 (Poster)** Examining Perceived Barriers to Engagement and Adaptation of Treatment Delivery for Families of Diverse Racial and Sociocultural Backgrounds Undergoing Participation in an Evidence-Based Parent-Mediated Intervention

**A. Rudrabhatla<sup>1</sup>, N. Brane<sup>2</sup>, E. Greenfield<sup>3</sup>, K. Guerra<sup>2</sup>, N. M. Hendrix<sup>1</sup> and K. Pickard<sup>4</sup>,** (1)Marcus Autism Center, Children's Healthcare of Atlanta and Emory University School of Medicine, Atlanta, GA, (2)Marcus Autism Center, Atlanta, GA, (3)Marcus Autism Center, Emory University School of Medicine, Atlanta, GA, (4)Emory University School of Medicine, Marcus Autism Center, Atlanta, GA

---

**Background:**

Recent meta-analyses have demonstrated the efficacy of parent-mediated interventions (PMIs) for fostering social-communication skills in children with Autism Spectrum Disorder (ASD), and parent responsivity and empowerment (Nevill et al.,2018). Parent engagement is integral to the success of PMIs (Pellecchia et al.,2018;Trembath et al.,2019). However, there remain barriers to parent engagement when PMIs are implemented within historically underserved community settings (Kasari et al.,2015). To date, limited research has examined the structural barriers experienced by families of diverse sociocultural and racially marginalized backgrounds when attempting to engage in PMIs. Further, issues of caregiver engagement may reflect a lack of fit between PMIs and the needs of diverse caregivers and families. Although previous research suggests evidence-based interventions high in sociocultural relevance increase client participation (Castro et al.,2014), it is unclear how PMIs for ASD are adapted during delivery to increase their sociocultural relevance and responsivity.

**Objectives:**

To examine (1) whether perceived barriers to participation differ in families of diverse racial backgrounds, (2) how clinicians deliver and adapt an evidence-based PMI, Project ImPACT, in response to families of diverse racial/sociocultural backgrounds, and (3) the extent to which intervention adaptation predicts perceived therapeutic alliance and program satisfaction for families of diverse racial/sociocultural backgrounds.

**Methods:**

Participants included 16 caregivers of a child with ASD (12-40 months) identifying as African American (n=8), White (n=7) and Biracial/Multiracial (n=1). Following a diagnostic evaluation, children were referred to an outpatient Project ImPACT program at a children's hospital in a major metropolitan area. Participating clinicians included speech language pathologists (n=2) and psychologists (n=2). Prior to participation, caregivers completed questionnaires on sociodemographic information and perceived barriers to treatment participation (Barriers to Treatment Participation Scale (BTPS)). Following treatment, caregivers completed a measure of therapeutic responsivity (Measure of Process of Care-20 (MPOC-20)) and a satisfaction survey. Clinicians delivering Project ImPACT participated in a semi-structured interview. Qualitative data collection employed rapid qualitative methods and thematic analysis. Independent t-tests examined whether perceived barriers differed by racial background.

**Results:**

Data collection is ongoing. However, preliminary data from 16 caregivers and 4 clinicians is reported. African American and White families did not significantly differ in perceived barriers to treatment participation ( $p=.487$ ). Qualitative interviews suggest that clinicians adapt Project ImPACT for socioculturally diverse families to accommodate the language preferences of bilingual families, target goals of priority to families, involve extended family members, and validate family concerns about psychosocial stressors including barriers to accessing care and discrimination/bias. The importance of using collaborative goal-setting to assess family values overall was also highlighted. Overall, clinicians shared that cultural adaptations helped to build rapport and alliance with families.

**Conclusions:**

Preliminary analyses showed no differences in perceived barriers to treatment based on racial background. However, interviews suggest that clinicians adapt Project ImPACT for diverse families to promote family engagement by increasing responsivity to sociocultural values and psychosocial stressors. As data collection is ongoing, future analyses involving a larger sample of diverse participants will examine these trends more closely and whether these adaptations yield positive outcomes for therapeutic alliance and program satisfaction.

**426.112 (Poster)** Social Justice Orientation Moderates the Link between Teacher Attention-Related Concerns and Inclusion Attitudes in Parents of Typically-Developing Children

**A. Rudrabhatla<sup>1</sup>, L. Morgan<sup>2</sup> and M. Siller<sup>3</sup>,** (1)Marcus Autism Center, Children's Healthcare of Atlanta and Emory University School of Medicine, Atlanta, GA, (2)Emory University-Marcus Autism Center, Atlanta, GA, (3)Emory University School of Medicine, Atlanta, GA

---

**Background:**

Federal policy recommendations stipulate that all children with disabilities should have access to inclusive high-quality early childhood education programs (HHS, 2015, 2017). Inclusion programs yield benefits for all children and also allow for increased access to educational environments that support social-communicative skills in children with autism spectrum disorder (ASD; Stahmer et al., 2011). Wide-scale access to inclusion can only become a reality when parents of typically-developing (TD) children value the benefit of such experiences for their children and for society, and eventually select inclusive over non-inclusive alternatives when making decisions about preschool enrollment. While a range of parental concerns (e.g., teachers' ability to divide attention among all children) and values (e.g., social justice attitudes, SJA) have been considered, factors that contribute to the formation of attitudes about inclusion among parents of TD children are poorly understood.

#### Objectives:

To examine factors that predict attitudes about inclusion among parents of TD children, including specific parental concerns and values. Specifically, we predict that parental values (i.e., SJA) moderate the relation between certain parental concerns and attitudes about inclusion.

#### Methods:

Parents of TD children (no Individualized Education Plan, history of early intervention services, developmental concerns) enrolled in Georgia's publicly-funded Pre-K program for 4-year-olds were invited to participate in an online survey. Georgia Pre-K offers two classroom formats: standard (2 teachers, 22 children per class) and inclusion (3 teachers, 18 children per class, incl. 6 children with disability). Surveys were completed by 117 parents. While most parents reported no preference for either classroom format, 14 parents stated that they intentionally sought out an inclusion classroom. Surveys were completed at the beginning of the school year and included measures of inclusion attitudes with a focus on ASD (Attitude Survey toward Inclusive Education-Parent, ASIE-P; Boer et al., 2012), concerns about inclusion (Impact of Inclusion on Typically-Developing Children, IITDC [Risk Subscale], Rafferty & Griffin, 2001; Parental Attitudes Toward Mainstreaming, PATMS [Academics/Teacher Attention Subscale], Green & Stoneman, 1989), and generalized social justice-related values (Social Justice [Attitudes Subscale], SJA; Torres-Harding et al., 2012).

#### Results:

Preliminary analyses comparing parents who intentionally sought out an inclusion class (N=14) and parents who did not (N=103) revealed no significant group differences on any measure ( $p > .05$ ). Pearson correlations between all survey measures are reported in Table 1 and indicate that parental attitudes about inclusion were significantly correlated with general concerns about inclusion ( $r = -.680, p < .001$ ) and teacher attention-related concerns ( $r = .683, p < .001$ ). Finally, we used multiple regression models to test the prediction that SJA moderates the relation between parents' concerns about inclusion (IITDC, PATMS) and attitudes about inclusion (ASIE-P). Results revealed that SJA significantly moderated the relation between PATMS and ASIE-P ( $\beta = .162, p = .026$ , see Figure 1), but not between IITDC and ASIE-P ( $\beta = .002, p = .975$ ).

#### Conclusions:

Analyses highlight the importance of considering both parental concerns about inclusion (particularly concerns about teachers' ability to divide attention among all children) and parental values about social justice (SJA) when aiming to promote positive parental attitudes about inclusion, to address a larger goal of increasing access to inclusion for children with ASD.

#### 426.113 (Poster) Exploring Seasonal Trajectories in Intensity of Intervention Use for Children on the Autism Spectrum

**D. M. Goncalves Fortes<sup>1</sup>, A. Naples<sup>1</sup>, J. M. Wolf<sup>2</sup>, M. Sabatos-DeVito<sup>2</sup>, S. Faja<sup>3</sup>, S. R. Edmunds<sup>4</sup>, K. Chawarska<sup>1</sup>, G. Dawson<sup>4</sup>, R. A. Bernier<sup>5</sup>, S. Jeste<sup>6</sup>, C. A. Nelson<sup>7</sup>, J. Dziura<sup>8</sup>, S. J. Webb<sup>9</sup>, C. Sugar<sup>6</sup>, F. Shic<sup>6</sup> and J. McPartland<sup>10</sup>.** (1)Child Study Center, Yale University School of Medicine, New Haven, CT, (2)Psychiatry and Behavioral Sciences, Duke Center for Autism and Brain Development, Durham, NC, (3)Boston Children's Hospital, Boston, MA, (4)Department of Psychiatry and Behavioral Sciences, Duke Center for Autism and Brain Development, Durham, NC, (5)Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA, (6)University of California, Los Angeles, Los Angeles, CA, (7)Department of Developmental Medicine, Boston Children's Hospital, Boston, MA, (8)Yale University, New Haven, CT, (9)Center for Child Health, Behavior and Development, Seattle Children's Research Institute, Seattle, WA, (10)Child Study Center, Yale Child Study Center, New Haven, CT

**Background:** Autistic individuals have a lifelong need for services across the lifespan (Turcotte et al., 2016), but studies over the last two decades have revealed gaps in service coverage (McIntyre et al., 2017) exacerbated by inequitable access based on race, ethnicity, and socioeconomic status (Smith et al., 2020). Despite this emerging literature, our understanding of intervention use over time is limited by the mostly cross-sectional study designs employed thus far. Studies beginning to examine this question (Siller et al., 2013 & Yingling et al., 2019) have employed geographically restricted samples of parents undergoing advocacy training programs and thus may suffer from limited representativeness.

**Objectives:** (1) To identify mean trajectories in intensity of intervention use for autistic children and (2) to examine the association between said trajectories and child demographic factors (age, race/ethnicity, intellectual ability, autism symptoms, family income, and parental education)

**Methods:** As part of their participation in a multisite longitudinal biomarker study, parents reported the number of hours of intervention their children (N=253, Age(years): M=8.54, SD=1.65) received during a series of five consecutive six-week intervals. The data were log-transformed to correct for skewness and clustered via a longitudinal k-means algorithm. The cluster partition with the lowest Bayesian Information Criteria (BIC) was selected. Variability in seasonal participation was coded by a categorical label describing which seasons were encompassed in the data collection period (e.g. spring-winter-fall). Seasonal trends were further quantified by computing the monthly average change in intervention hours per individual. Per Objective 2, associations between cluster membership with demographic information and clinical characterization are forthcoming.

**Results:** Implementation of k-means clustering yielded a six-cluster solution (Fig.1, BIC= 1371.66, Global Posterior Probability = 0.942): a Moderate-EarlyDip cluster (red, 26.48% of trajectories), Moderate-Stable cluster (yellow, 24.90%), High-Stable cluster (green, 24.11%), Low-Stable cluster (light blue, 11.46%), Moderate-LateDip cluster (dark blue, 10.67%), and a small RapidRise cluster (pink, 2.37%). Observed counts in the seasonal trajectory label per cluster differed from expected counts ( $\chi^2=65.784$ ,  $df=35$ ,  $p=0.001246$ ), with the Moderate-EarlyDip cluster having a higher number of summer-fall trajectories (standardized residual(stdres)=4.01); High-Stable cluster being enriched in fall-winter-spring trajectories (stdres=3.09); and the Moderate-LateDip cluster being enriched in spring-summer (stdres=2.07), and spring-summer-fall (stdres=2.82) trajectories. Monthly changes in intervention hours display a sharp decrease in intervention use during the summer months – particularly June (Fig.2,  $t=-2.98$ ,  $p=0.0038$ ).

**Conclusions:** Clustering the longitudinal trajectories in intensity of intervention use for autistic children yields trends that not only reflect differences in absolute intensity of services received (High, Moderate, Low), but also temporal instability associated with seasonal change (Stable, LateDip, EarlyDip). The decrease in intervention hours during the summer is most likely attributable to an interruption in the school year, and the consequent lapse in school-based service delivery. Since racial differences have been found in reliance on school-based and public services (Siller et al., 2013), our planned exploration of associations between demographics and cluster membership may elucidate differential impacts of this provision lapse. Further research is needed to ascertain the impact of short-term interruptions on behavioral change and educational progress measures.

**426.114 (Poster)** Exploring the Effects of Virtual Mathematics Instructional Tools on the Word Problem Solving Performance of Autistic Elementary School Students

**B. B. Chen<sup>1</sup>**, **G. Yakubova<sup>2</sup>** and **M. Defayette<sup>2</sup>**, (1)University of Maryland College Park, College Park, MD, (2)University of Maryland, College Park, MD

**Background:** Due to the COVID-19 pandemic, many K-12 students in the United States attended school virtually, requiring teachers to alter their teaching methods to virtual formats. Although the use of video modeling (VM) and other behavioral support strategies (e.g., graphic organizers, manipulatives, guided practice) to teach mathematics skills to autistic students is well-supported by the literature, these strategies have not typically been studied in remote, virtual settings.

**Objectives:** The goal of this study was to explore the effects of virtual mathematics instruction and strategies on the word problem-solving performance of three autistic elementary school students.

**Methods:** This exploratory A-B design case study included three autistic students, ages 8-11 years old. Participants included two male students, one of whom also had a secondary diagnosis of ADHD, and one female student, with secondary diagnoses of ADHD, language disorder, and specific learning disability in mathematics. Participating students and their parents attended study sessions virtually, on Zoom. The instructional materials included VM, virtual manipulatives or visual representations, a graphic organizer, guided practice, and corrective feedback. Although parents were present to provide behavioral prompting or technology support, parents did not provide computational help. All students worked on word problem solving on different skills, including multiplication and division, addition and subtraction of mixed fractions, and addition and subtraction with regrouping. Students were evaluated on their independent accuracy of solving word problems, and the number of problem-solving steps that they completed independently per problem. We visually examined data for trend and variability within and between phases.

**Results:** All students demonstrated improved word problem-solving performance from baseline (A) to intervention (B) with the virtual instruction, although to varying extents. Namely, students demonstrated variability in their independent accuracy (calculating the correct final solution), but demonstrated high levels of independent completion of the task analysis steps for the problem-solving process, indicating that additional guidance may be needed for certain steps of the process to result in improved overall independent accuracy. For one student, the use of VM with visual representations, a graphic organizer, three guided practice sessions, and corrective feedback was effective in improving her independent accuracy (mean change= 48%). For the other two students, use of these strategies corresponded with high rates of independent completion of the task analysis steps for problem-solving, but not independent accuracy. Therefore, the VM was replaced with additional opportunities for guided practice to provide explicit instruction on particular steps of the problem-solving process. The use of additional guided practice, coupled with the graphic organizer and corrective feedback, was associated with higher independent accuracy scores (mean change= 58%, 25%).

**Conclusions:** This presentation discusses the findings of one of the early studies that explored the effects of online teaching techniques on autistic students' mathematics accuracy and independent task completion. Each student required different variations of the instructional strategies to improve their independent accuracy of problem-solving based on their individual learning needs. These findings offer implications for future research and practice on individualized mathematics instruction for autistic students in virtual learning environments.

**426.115 (Poster)** Exploring the Impact of Autism-Specific Medicaid Home and Community-Based Waivers: A Scoping Review

**K. J. McLean<sup>1</sup>** and **L. Bishop<sup>2</sup>**, (1)Social Work, University of Wisconsin - Madison, Madison, WI, (2)University of Wisconsin - Madison, Madison, WI

**Background:** Medicaid is intended to provide a broad range of medical and long-term care services to autistic children and adults to support them to live in their homes and communities, rather than institutions. These are also known as home and community-based services (HCBS). Medicaid HCBS waivers are the largest, and often the only, provider of long-term services and supports for people with intellectual and developmental disabilities, including autistic individuals, in the United States. Over the past two decades, many states have developed waivers specifically targeted at supporting autistic children and adults, and their families. Emerging research tests the impact of these autism-specific HCBS waivers on outcomes for autistic individuals and their families; however, this body of work has yet to be synthesized.

**Objectives:** We conducted a scoping review to synthesize what is known about the impact of autism-specific Medicaid HCBS waivers on the lives of autistic people.

**Methods:** In contrast to a systematic review, the intent of a scoping review is to broadly review the literature to examine the extent, range, and nature of research activities and to identify gaps. We systematically searched relevant databases with the guidance of a reference librarian. We comprehensively searched key terms related to autism spectrum disorder, Medicaid, and home and community-based services. These key terms were truncated and broadened to enable comprehensive coverage per guidelines of scoping review methodologies as well as to account for changes in autism spectrum diagnosis language. Studies were included in our review if they: (1) included autistic participants and/or their families; (2) focused on Medicaid HCBS policy; (3) quantitatively tested an aspect of an autism-specific Medicaid HCBS waiver policy on a given outcome.

**Results:** We identified 764 unique studies, of which 6 were eligible for inclusion. All six studies examined the effect of autism-specific HCBS waivers on outcomes for autistic individuals and their families. Three of the studies looked at state-specific autism waivers and their impacts on outcomes for autistic individuals and their families within their state. The remaining three studies used national level data to compare outcomes across states and counties with HCBS waivers targeted at improving outcomes for autistic individuals and their families. No studies utilized causal modeling. Findings indicate that HCBS waivers may improve quality of life for autistic individuals and their families, reduce unmet healthcare needs for autistic people, increase the likelihood that parents will be able to continue working while addressing the care-needs of their autistic children, and reduce racial disparities in access to care.

**Conclusions:** Research on the economic and social impact of HCBS waivers targeted at improving outcomes for autistic individuals is emerging, yet more research is needed to determine causal mechanisms. Key findings of the six studies in this review demonstrate that state-level Medicaid HCBS programs are improving the lives of autistic people and their families. Research that examines the differences between state autism-specific HCBS waivers is now needed to determine which aspects of these programs are working most efficiently and effectively.

Wainer<sup>8</sup> and M. D. Lerner<sup>8</sup>,** (1)Stony Brook University, Stony Brook, NY, (2)Department of Psychology, Stony Brook University, Stony Brook, NY, (3)University of British Columbia, Vancouver, BC, Canada, (4)Child and Adolescent Services Research Center (CASRC), San Diego, CA, (5)Hunter-Bellevue School of Nursing, New York, NY, (6)Department of Psychiatry, Rush University Medical Center, Chicago, IL, (7)Department of Psychology, St. John's University, Queens, NY, (8)Psychology, Stony Brook University, Stony Brook, NY

**Background:** Autistic individuals are more likely to experience adverse childhood experiences (ACEs, e.g., physical and emotional abuse, income insufficiency, divorce) than neurotypical peers (Hoover & Kaufman, 2018). ACEs can have cumulative lifelong effects for autistic individuals (Dodds, 2021), such as worsening autism symptoms (Fuld, 2018), delayed diagnoses, and service access (Berg et al., 2018). Recent research has underscored the importance of explicitly investigating ACE experiences for autistic people to reduce health disparities (Berg et al., 2016; Karpur et al. 2019). Compounding these issues, major racial disparities exist in service access for autistic individuals (Angell et al., 2018). While a recent survey of community-based providers identified patient race as a predictor of trauma-related treatment (Kerns et al., 2020), little research has investigated provider-specific variability in addressing ACEs when serving different racial communities. Even less work has addressed ACEs in autistic young adults, who face risks and challenges in this transition from adolescents to adulthood (Taylor & Gotham, 2016; van Schalkwyk & Volkmar, 2016).

**Objectives:** This study explored variability in ASD provider inquiries of eight individual ACEs based on primary racial group served. We hypothesized that providers primarily serving marginalized racial groups would be more likely to inquire about any of the ACEs than those primarily serving non-marginalized groups.

**Methods:** 148 community-based ASD providers primarily working with young adults completed the Usual Care of Autism Study (UCAS; Wainer et al., 2007). Providers were asked to report primary racial groups served and frequency of ACE inquiries (Table 1). Multivariate regressions analyzed the effect of providers primarily serving different racial groups on likelihood of inquiring about ACEs.

**Results:** Providers who primarily served White autistic young adults reported inquiring less about food scarcity, those who reported primarily serving Asians inquired less about physical or emotional neglect (Figure 1), and those who reported primarily serving Hawaiian or Pacific Islanders inquired less about domestic violence, than those who did not report primarily serving these populations (all  $p < .05$ ; Table 1). Conversely, those who reported primarily serving Black autistic young adults inquired more about physical or emotional neglect, those who reported primarily serving Hispanics inquired more about parent mental illness, and those who reported primarily serving Native Americans inquired more about domestic violence than those who did not serve these populations (all  $p < .05$ ; Table 1).

**Conclusions:** These results suggest provider variability in ACE inquiries based on racial groups of young autistic adults. Autistic individuals face many unique challenges associated with transitioning into adulthood (Taylor & Gotham, 2016) and providers-biases in ACE inquiry (i.e., failing to inquire about ACEs in certain populations) might lead to individuals missing out on services to help address associated mental health concerns. Future work should more directly investigate why these differences may be occurring, determine whether these differences in inquiry are a result of racial biases, and provide more explicit training and education on ACEs in autistic individuals to improve the quality of services.

**426.117 (Poster)** Forward Translation of Who's Caregiver Skills Training (WHO-CST) during COVID-19 Pandemic: A Field Experience from Malaysia

**Background:** Prolonged Malaysia's Movement Control Order mandate benefits children an extra time with primary caregivers from staying at home. With the continuous postponement of hospital appointments, implementing WHO-CST, a program that focuses on training parents to deliver intervention may ensure continuous skills development for autistic children. The Malay language differs from the English language in phonology, grammar, morphology and semantics. Thus, conducting a translation study before implementing the program on a local scale is crucial, considering the significant difference in linguistic and cultural diversity. Besides, in light of the COVID-19, all discussions were conducted virtually.

**Objectives:** To explore challenges in translating the original English module to the local Malay language and solving barriers to implementation.

**Methods:** A group of bilingual interdisciplinary teams (n=65; 82% female; Age<sub>ave</sub> = 31) from the national autism early intervention centre inclusive of occupational therapists, speech therapists, special education teachers and early childhood educators with ≥ 3 years working experience were recruited to translate 623 pages of WHO-CST module to local language. Additional experts (n=10) from medicine, psychology and education with ≥ 10 years working experience in their respective fields were appointed as supervisors. All discussions were made virtually with interactive day workshop and focus group discussion conducted using breakout room and digital workspace apps MURAL.co. The discussion included a linguistic validation comparing Malay translation with the original English by assessing conceptual and content equivalence.

**Results:** As the results of qualitative analysis, three major concerns were raised mainly on (i) translation taxonomy strategies, (ii) cultural filtering and (iii) syntactic problems. All groups reported they were unsure about the words order and grammatical relations. About 6 out of 8 translator groups agree that most illustrations require cultural adaptation and proper characters' names. Furthermore, 3 out of 8 translator groups reported that they had faced challenges when local languages did not have equivalent scientific and technical vocabularies. With in-field experience consulting parents with autism, suggestions were made to use creative translation compared to verbatim, ensuring appropriate adaptation for target users, while language error was suggested to further validate by a language expert. For overall online experience measured using 5-points Likert's scale, out of 32 responses obtained from translators, 50% indicate they were satisfied and find it comfortable navigating online, while 18% feel neutral with the experience.

**Conclusions:** Although the input from the bilingual in-field experts was gained in line with WHO's translation suggestion, there is a need to involve language experts due to the intricacies present in both languages. In the next phase, this research will also gather stakeholders (e.g., the Ministry of Health, Education and the lead advocacy organization) and parents of autistic children to the refined measurement of adaptation outcomes.

#### **426.118 (Poster) Healthcare Disparities Among Autistic, Sexual and Gender Minority Individuals**

**A. Wallisch<sup>1</sup>, B. A. Boyd<sup>1</sup>, J. Hall<sup>2</sup>, N. Kurth<sup>2</sup>, C. Streed<sup>3</sup> and K. Batza<sup>2</sup>,** (1)Juniper Gardens Children's Project, University of Kansas, Kansas City, KS, (2)University of Kansas, Lawrence, KS, (3)Boston University, Boston, MA

---

**Background:**

Longstanding disparities exist in healthcare access and utilization for lesbian, gay, bisexual, transgender, or queer (LGBTQ+) populations. LGBTQ+ individuals often experience healthcare-related barriers due to discrimination and prejudice from practitioners. Similar disparities exist for individuals with disabilities; however, less is known about the healthcare experiences of individuals with these dual identities. The field of autism research increasingly recognizes that disparities exist for groups of autistic individuals, and research has identified disparities for racial and ethnic minorities, females, individuals in rural areas, and individuals with a lower socioeconomic status (for review see Bishop-Fitzpatrick & Kind, 2017). While more autistic individuals identify as LGBTQ+ compared to the general population (De Winter et al., 2017); limited data exist on the health disparities and experiences of autistic individuals identifying with non-binary conceptualizations of sex or gender identity.

**Objectives:**

The objective of this study is to examine the extent to which unmet healthcare needs and health status differ between autistic, LGBTQ+ and autistic, straight, cisgender individuals.

**Methods:**

We conducted a descriptive study with data drawn from the administration of the National Survey on Health and Disability (NSHD) conducted between October 1, 2019 through January 31, 2020. The purpose of the NSHD was to understand the healthcare access and experiences of individuals with disabilities, which yielded a sample of 2,175 individuals, aged 18-64 with a wide variety of disabilities. Our study included participants who reported autism spectrum disorder (ASD) as their primary diagnosis on the NSHD survey, which resulted in a sub-sample of 113 participants. Of the 113 participants, 62 identified as LGBTQ+ and 51 identified as cisgender. We used a MANCOVA to examine group differences in unmet healthcare needs (i.e., physician, prescription drugs, mental health, specialty care, preventative care, dental), refusal of care by these providers, physical health status, mental health status, and the total number of co-occurring disabilities.

**Results:**

Results suggested significant differences between the LGBTQ+ and cisgender group after controlling for gender ( $F(4, 84) = 3.44, p = 0.01$ , Pillai's Trace = 0.14, partial  $\eta^2 = 0.14$ ). Univariate follow-up analyses revealed significant group differences with the LGBTQ+ group reporting significantly more days of poorer physical ( $F(1, 87) = 4.92, p = 0.03$ , partial  $\eta^2 = 0.05$ ) and mental health ( $F(1, 87) = 6.91, p = 0.01$ , partial  $\eta^2 = 0.07$ ), as well as more unmet healthcare needs ( $F(1, 87) = 6.24, p = 0.01$ , partial  $\eta^2 = 0.07$ ). However, there were no significant group differences for the number of occasions healthcare providers refused care ( $F(1, 87) = 0.001, p = 0.98$ , partial  $\eta^2 = 0.00$ ) or the total number of co-occurring diagnoses ( $F(1, 87) = 1.69, p = 0.20$ , partial  $\eta^2 = 0.02$ ).

#### Conclusions:

Novel findings from this study suggest dual identities of LGBTQ+ and autism result in greater disparities in physical and mental health as well as unmet healthcare needs. Since our study compared the health status and healthcare needs of both cisgender autistic individuals and autistic, LGBTQ+ individuals, this means the additive effect of an LGBTQ+ identity magnified these disparities.

#### 426.119 (Poster) Identifying Autism Intervention Components Deliverable By Non-Specialists in Low- and Middle-Income Countries: A Systematic Review

**L. Naithani**<sup>1,2</sup>, **C. Goldie**<sup>3</sup>, **C. Butter**<sup>4</sup>, **A. Kaur**<sup>4</sup>, **S. Lakhera**<sup>4</sup>, **K. Leadbitter**<sup>5</sup> and **G. Divan**<sup>5</sup>, (1)Sangath Society, New Delhi, India, (2)Sangath, New Delhi, India, (3)University of Manchester, Manchester, United Kingdom, (4)Sangath, Delhi, India, (5)Child Development Group, Sangath, New Delhi, India

**Background:** The past decade has seen key advances in developing, evaluating and implementing early intervention programs for autistic children. However, most of these efforts were within the context of high-income countries (HIC). The impact on low- and middle-income countries (LMIC) has been minimal. The care gap seen within these countries remains close to 100%. A key challenge in addressing the care gap concerns the paucity of available specialists to deliver services within LMIC contexts. Task-sharing provides an important potential solution, however globally, the vast majority of the evidence for intervention feasibility, acceptability and effectiveness is based on delivery by specialists. Therefore, making evidence-informed decisions around interventions that are suitable for scaled-up delivery in low-resource settings by non-specialist workers becomes difficult.

**Objectives:** The aim of this paper was to conduct a systematic literature review to identify studies which report intervention delivery by non-specialists within LMIC. With these papers, the process described by Chorpita et al (2005) helped identify common components and shared characteristics that are evidence of a successful delivery by non-specialists in LMIC.

**Methods:** Systematic literature search conducted within four databases (Cochrane Database, APA PsychInfo, Ovid Medline, Embase). Articles included if studies were: (a) in LMIC; (b) of autistic children (age <10); (c) about psycho-social interventions delivered by non-specialists; (d) on child outcomes; and (e) English peer-reviewed full-texts. Our definition of non-specialist centered on the kinds of workers available within LMIC settings (e.g., community health workers, parent champions). Initial search generated 2535 articles. Removing duplicates left 1721 articles. Titles and abstracts were then screened, with 10% double-rated to ensure reliability. Two independent raters screened 50 potential full-text articles. Finally, using Chorpita's model of distillation and matching which is codified within the @Practicewise framework (Chorpita et al. (2009)), elements and techniques were mapped within the identified interventions.

**Results:** Two studies met the inclusion criteria. Rahman et al. (2016), pilot randomized controlled trial (RCT) of a parent-mediated communication-focused intervention (PASS) with autistic children aged 2-9 years, delivered by non-specialist health workers in Rawalpindi (Pakistan) and Goa (India). Divan et al. (2019), pilot RCT of PASS Plus (PASS therapy with additional modules for common comorbidities) delivered to parents of autistic children aged 2-9 years by non-specialists in Kolhapur, India. Using the adapted and expanded @Practicewise framework, we identified eight intervention elements across the two publications: accessibility promotion, activity selection, social communication, language expansion, family engagement, narrative, parent-mediated, problem-solving and play therapy. Additionally, we identified nine common techniques: goal-setting for caregivers, home-work for caregivers, review of homework, record diary, caregiver's praise, psychoeducation, relationship/rapport building, therapist's praise and video-feedback.

**Conclusions:** Our study reveals the acute lack of empirical evidence emphasizing a need for further clinical research in LMIC to provide evidence for task-sharing through non-specialist delivery of autism interventions. Despite the small number of studies, several intervention elements and techniques are highlighted, which non-specialists can be trained in to deliver with good fidelity and acceptability, resulting in positive outcomes. This focus is critical to reduce inequity and achieve universal health coverage within resource-constraint health systems.

#### 426.120 (Poster) Implementation of Telepsychiatry Services in Autism Spectrum Disorder Specialty Clinics: A Nationwide Survey Shows Rapid Implementation to Sustain Access to Mental Health Services during COVID-19 Lockdown

**S. Verma**<sup>1</sup>, **P. Vandana**<sup>2</sup>, **T. Soda**<sup>3</sup>, **K. A. Koth**<sup>4</sup>, **P. Aguayo**<sup>5</sup>, **R. Shaffer**<sup>6</sup>, **J. A. Helling**<sup>7</sup> and **R. A. Muhle**<sup>8</sup>, (1)Psychiatry, San Francisco, San Francisco, CA, (2)Nationwide Children's Hospital, Columbus, OH, (3)Psychiatry, University of Florida, Jacksonville, FL, (4)Medical College of Wisconsin, Milwaukee, WI, (5)Huntsman Mental Health Institute, University of Utah, Salt Lake City, UT, (6)Division of Developmental and Behavioral Pediatrics, Cincinnati Children's Hospital Medical Center, Cincinnati, OH, (7)Psychiatry, University of Missouri Kansas City and Truman Behavioral Health, Kansas City, MO, (8)Psychiatry, Columbia University, New York, NY

#### Background:

Traditional clinical service models, in which patients visit centralized clinical sites for routine care, can decrease access to care if travel to the clinic site is difficult for patients and their families to manage. In addition to possible financial and time-related challenges of travelling to clinics, a special concern for patients diagnosed with autism spectrum disorder (ASD) is the inherent stress of traveling to a new location that may trigger severe

behaviors. Telepsychiatry, in which psychiatric care is provided by videoconference, has been utilized for decades to address these concerns, but in a limited fashion due to state and institutional regulations. In early 2020, however, there was a nationwide shift to telepsychiatry in the wake of the Coronavirus Disease 2019 (COVID-19) pandemic and lockdowns to prevent the spread of SARS-CoV-2.

#### Objectives:

To assess the rate of in-person versus telepsychiatry appointment attendance pre- and post-COVID-19 lockdown.

#### Methods:

We conducted a national, multi-site survey of completed appointments in 2020 compared to a similar time period in 2019. Five outpatient child psychiatry clinics that specialize in the treatment of patients with ASD and/or DD (ASD/DD clinics) provided numbers of scheduled and completed visits for the time period spanning December to June in 2019 and 2020. Visits totals were provided in aggregate for each clinic site, and were approved or exempted by IRB at each institution.

#### Results:

In 2019-2020, only 2 of the sites were performing telepsychiatry visits in the 3 months prior to the COVID-19 lockdown, making up only 1.2% of completed visits at those sites. After the lockdown commenced in March 2020, this rate was immediately inverted, such that telepsychiatry accounted for 99.6% of all completed visits in April 2020, with only a handful of visits completed in person. Outpatient ASD/DD clinics continued this level of telepsychiatry visits thereafter (**Figure 1A**), with an average telepsychiatry completion rate of 87.8% across all clinic sites (**Figure 1B**). Total completed telepsychiatry visits in April – June 2020 surpassed the number of in-person visits completed for the same period in 2019 (3119 in 2019 vs 3218 in 2020).

#### Conclusions:

The COVID-19 lockdown forced the immediate implementation of remote care delivery, and providers and patients have found many advantages to telepsychiatry that support the continued funding of this care model. We now have a wealth of information and experience to better hone telepsychiatry as a model of care. We will discuss the substantial benefits physicians, patients and families have found in using telepsychiatry, as well as concerning factors that must be addressed to improve access to care for this patient population.

**426.121 (Poster)** Incorporating Telehealth Visits in an Interdisciplinary Team Evaluation Approach for Assessing Autism Spectrum Disorder in School-Age Children

*E. Fox<sup>1</sup> and J. Gerdtz<sup>2</sup>, (1)Seattle Children's Autism Center, Seattle, WA, (2)University of Washington LEND, Seattle, WA*

---

**Background:** In 2018, the Seattle Children's Autism Center (SCAC) transitioned to an interdisciplinary team evaluation model for assessing autism spectrum disorder (ASD), in which two providers of different disciplines complete an ASD-focused evaluation in one day (Standard team; Gerdtz et al., 2018). An additional evaluation track (Autism Psych team) was later created to account for a subset of patients (10-18%; Gerdtz et al., 2018, 2019), aged 6 years and older, who are unable to complete their evaluation in the Standard model due to complicating factors. Due to the COVID-19 pandemic, SCAC modified its evaluation models in 2020 to include telehealth visits within the format of these diagnostic tracks.

**Objectives:** To describe outcomes of hybrid (telehealth/in-person) ASD evaluations for children, aged 6-21 years, following the modification in SCAC's evaluation procedures due to the pandemic.

**Methods:** Figures 1 and 2 summarize the evaluation models and referral flow following intake. Data from either chart review or brief provider questionnaire were available for 438 patients who completed a diagnostic intake after SCAC's diagnostic services were resumed. Most patients completed their intake via telehealth (98.2%). Patients ranged in age from 6-21 years ( $M = 10.9$ ,  $SD = 3.5$ ; 62.8% male) and 33.2% reported a non-White racial identity. Fifty-eight percent of patients had Medicaid or did not have insurance, and 5.5% needed an interpreter.

**Results:** Of the 407 patients referred on for team evaluation after intake, 85.7% were referred for a Standard hybrid team (SHT) evaluation, and 14.3% were referred for an Autism Psych hybrid team (PHT) (due to significant psychosocial history, psychiatric/medical comorbidity, and/or complicating intellectual functioning). Diagnostic outcome data could be determined from 292 completed evaluations out of 407 referred. SHTs were able to make a diagnostic decision (yes/no ASD) in 89% of cases; the remaining 11% required additional time to come to a diagnostic conclusion. Reasons included the need for additional testing or records and complex history or symptom presentation. Approximately 74% of patients received an ASD or provisional ASD diagnosis across both tracks. Thirteen patients were asked to return to clinic in 6-12 months for re-evaluation. Patient age was a borderline significant predictor of diagnostic outcome ( $p = .051$ ), in that increased age was associated with a decreased likelihood of ASD diagnosis. Patient sex, race, ethnicity, use of interpreter, and insurance type did not predict diagnostic outcome.

**Conclusions:** Diagnostic evaluations that include telehealth visit(s) appear successful in ruling in/out ASD. Rates of patients needing additional time to make a diagnostic decision are comparable to pre-pandemic levels. Preliminary provider satisfaction data indicate that most SCAC evaluation providers (66.7%) prefer a model that includes a telehealth component. Further study is needed to examine patient family perspectives on the acceptability of this delivery model. Having the option to refer directly to a diagnostically complex team may be helpful in optimizing the length of evaluations to best accommodate those most in need of more in-depth evaluations. Future research will seek to characterize the diagnostically

complex group to help predict complicating factors and improve triage at intake.

**426.122 (Poster)** Optimizing Access to Tailored Autism Integrated Care (ATTAIN) in a Federally Qualified Health Center

**K. Martinez<sup>1,2</sup>, E. Lane<sup>3</sup>, V. Hernandez<sup>4</sup>, E. Lugo<sup>5</sup>, F. Munoz<sup>6</sup>, T. Sahms<sup>7</sup> and N. A. Stadnick<sup>3,6,7</sup>**, (1)Child and Adolescent Services Research Center (CASRC), San Diego, CA, (2)Clinical Psychology, San Diego State University / University of California, San Diego Joint Doctoral Program in Clinical Psychology, San Diego, CA, (3)Child and Adolescent Services Research Center, San Diego, CA, (4)San Ysidro Health Center, San Ysidro, CA, (5)San Ysidro Health Center, San Ysidro, CA, (6)University of California, San Diego, La Jolla, CA, (7)UC San Diego Dissemination and Implementation Science Center, La Jolla, CA

---

**Background:** School-aged children with autism spectrum disorder (ASD) experience high rates of co-occurring mental health (MH) needs (referred to as ASD+). However, this population faces challenges accessing and engaging in specialty MH services (Maddox et al., 2021). To address these challenges, we co-created Access to Tailored Autism Integrated Care (ATTAIN), a customizable model to enhance MH screening and linkage to services for children with ASD at-risk for co-occurring MH conditions. ATTAIN was piloted in two healthcare systems in Southern California (Stadnick et al, under review); providers reported that ATTAIN was feasible and acceptable and shared actionable recommendations for further enhancements. These recommendations were integrated into a refined ATTAIN model that was examined in an optimization pilot in a federally qualified health center (FQHC).

**Objectives:** To examine implementation outcomes and provider perceptions of the adapted ATTAIN model in a 6-week optimization pilot at one FQHC near the US/Mexico border.

**Methods:** To optimize ATTAIN for the FQHC, original implementation strategies were modified to include: (1) a multidisciplinary team of clinic champions, (2) weekly periodic reflections with champion team, (3) virtual training, (4) weekly personalized outreach to provide workflow reminders and technical assistance, and (5) automation of workflow procedures into the electronic health record. Participants in the optimization pilot included 11 providers (4 primary care providers, 6 medical assistants, and 1 care coordinator). Most providers were female (82%) and Latino (64%). ATTAIN adoption rate and post-pilot provider ratings of implementation experiences were analyzed using descriptive statistics. Paired sample t-tests were conducted to examine changes in providers' knowledge and confidence treating children with ASD+ as well as changes in providers' comfort with MH screening, referral, and linkage practices for ASD+ from baseline to post-pilot.

**Results:** ATTAIN adoption (i.e., proportion of ATTAIN-eligible patients with whom provider used ATTAIN) was 100%. Post-pilot, providers rated ATTAIN as feasible ( $M=3.6$  out of 4,  $SD=0.4$ ) and acceptable ( $M=3.7$  out of 4,  $SD=0.5$ ). Providers rated their intentions to continue using ATTAIN as high ( $M=3.0$  out of 4,  $SD=0.3$ ). Providers reported agreement to a "moderate extent" towards the specific components of ATTAIN ( $M=1.8$  out of 4,  $SD=1.1$ ). Significant changes in providers' knowledge of ASD+ ( $t(5)=-6.1$ ,  $p < 0.01$ ) and confidence talking and answering questions about ASD+ ( $t(4)=-3.7$ ,  $p < 0.05$ ) were demonstrated. No changes in comfort identifying co-occurring mental health conditions ( $t(6)=0.2$ ,  $p > 0.05$ ) nor interpreting screening results ( $t(6)=1.0$ ,  $p > 0.05$ ) were observed.

**Conclusions:** Post-pilot ratings indicated favorable perceptions of the feasibility, acceptability, and intentions to continue using ATTAIN. ATTAIN adoption was high in this FQHC setting. Findings demonstrated significant gains in provider knowledge of ASD+ and confidence talking and answering questions about ASD+. Further work is needed to understand the lack of change in providers' comfort identifying ASD+ and interpreting screening results. Next steps include sustainment and scaling of ATTAIN across providers and clinics at the FQHC.

**426.123 (Poster)** Part C Provider- and System-Level Factors Influencing Engagement in Training and Consultation

**N. M. Hendrix<sup>1</sup>, K. Pickard<sup>2</sup>, K. Guerra<sup>3</sup>, E. Kaiser<sup>4</sup>, N. Bond<sup>5</sup>, A. Carney<sup>6</sup> and J. L. Stapel-Wax<sup>5</sup>**, (1)Marcus Autism Center, Emory University School of Medicine, Atlanta, GA, (2)Emory University School of Medicine, Marcus Autism Center, Atlanta, GA, (3)Marcus Autism Center, Atlanta, GA, (4)Children's Healthcare of Atlanta, Atlanta, GA, (5)Pediatrics, Emory University School of Medicine, Atlanta, GA

---

**Background:** Naturalistic developmental and behavioral interventions (NDBIs) are evidence-based interventions for young children with ASD (Schreibman et al., 2015). There has been growing interest in translating NDBIs into community systems to better serve young children with or at risk for autism spectrum disorder (ASD), particularly those who encounter systemic disparities that limit access to specialty care (Jones & Mandell, 2020). Part C Early Intervention (EI) systems play a key role in serving these children and families and are a critical setting in which to study factors impacting the implementation and sustainability of NDBIs.

Although multiple efforts are underway to translate NDBIs into EI systems, little is known yet about the likely complex and varied factors that impact these implementation efforts. This study—which is part of an ongoing contract with a state-level EI system—responds to this gap. Provider- (e.g., Motamedi et al., 2021) and system-level factors (e.g., Herschell et al., 2010; Palinkas et al., 2018) were predicted to contribute to implementation outcomes.

**Objectives:** To identify the extent to which provider factors (i.e., attitudes and years of experience) and system factors (i.e., level of support) impact participation in ongoing NDBI training efforts and implementation outcomes.

**Methods:** Thirty-four interdisciplinary providers enrolled in NDBI training that included one of two specific models. All participants were actively providing services within the EI system to at least one child with an increased likelihood of having ASD. Prior to training, providers completed sociodemographic information including age, discipline, and years of experience supporting young children at risk for having ASD. Providers also completed the *Evidence-Based Practices Attitudes Scale* (EBPAS; Aarons, 2004) and *Organizational Readiness for Change* subscales (ORC; Lehman et al., 2002). Following enrollment, implementation outcomes (e.g., training completion, group consultation attendance, provider fidelity) were

collected. Linear and logistic regression models will be used to predict implementation outcomes from provider experience, attitudes, and reported level of support and resources.

**Results:** Data collection is ongoing. A preliminary logistic regression model was performed to ascertain the effects of selected *EBPAS* and *ORC* subscales on completion of NDBI training and was found to be significant ( $\chi^2(2) = 6.37, p = .041$ ). Specifically, providers with higher *EBPAS* scores related to openness to new practices were more likely to complete training. Preliminary linear regression results for providers who had completed training and could then participate in group consultation revealed that level of supervision support significantly predicted proportion of group consultation sessions attended,  $\beta = 0.03, t(20) = 2.48, p = .02$ . Years of experience did not predict either outcome.

**Conclusions:** This study will contribute insight into factors that may increase the likelihood of EI providers completing NDBI training and participating in group consultation to promote maintenance of these evidence-based practices. Identification of these factors can then shape how implementation efforts respond to system-specific barriers and facilitators, which may increase adoption of evidence-based practices like NDBIs and maximize system capacity to sustain NDBIs over time.

#### **426.124 (Poster) Poorer Self-Reported Healthcare Quality Among Autistic Compared to Non-Autistic Adults**

**E. M. Weir<sup>1</sup>, C. Allison<sup>2</sup> and S. Baron-Cohen<sup>2</sup>, (1)Autism Research Centre, Department of Psychiatry, Autism Research Centre - University of Cambridge, Cambridge, United Kingdom, (2)Autism Research Centre, Department of Psychiatry, University of Cambridge, Cambridge, United Kingdom**

**Background:** Several studies suggest that autistic adults have higher rates of both physical and mental health conditions, and that they have shorter lifespans than others; however, only two studies to date compare the healthcare quality of autistic and non-autistic adults.

**Objectives:** To compare the self-reported healthcare quality of autistic and non-autistic adults in the areas of sensory experience, patient-provider communication, anxiety, access and advocacy, and systemic problems. The study also aimed to consider the self-reported quality of healthcare related to autism specifically, from the patient's perspective.

**Methods:** We administered an anonymous survey via Qualtrics to autistic and non-autistic adults using a 4-point Likert Scale. The final sample included  $n=2,649$  participants, including  $n=1,285$  autistic individuals. The results were binarized to assess whether individuals endorsed or rejected each statement and the research team employed Fisher's exact tests and binomial logistic regression adjusting for age, ethnicity, education-level, and country of residence to provide unadjusted and adjusted estimates of group differences in healthcare experiences, respectively; missingness for covariates only was addressed using five iterations of multiple imputation. To account for multiple testing, a  $p$ -threshold of  $<0.001$  was established for significance.

**Results:** Overwhelmingly, autistic individuals reported lower quality healthcare experiences compared to their non-autistic peers; Table 1 shows the unadjusted and adjusted results below. The only item that did not meet the significance threshold was whether participants had health insurance or were part of a national healthcare program (e.g., NHS, Medicare, Medicaid, etc...). In addition, when discussing autism-specific areas of healthcare, 33.75% of autistic adults did not think that their healthcare provider knew what autism was; 68.83% did not think that their healthcare professional usually tries to make adjustments because of their autism; and 71.54% of autistic adults did not think that their healthcare professional considers their autism when making diagnoses and treatment plans. Full results for these analyses are shown in Figure 1 below.

**Conclusions:**

This study is the largest to date that compares the healthcare experiences of autistic and non-autistic adults. The results suggest that there are sweeping differences in healthcare quality across a wide range of modalities, resulting in poorer self-reported healthcare quality for autistic adults compared to their non-autistic peers. Further, though not comparative, autistic adults perceive their healthcare professionals as having limited knowledge of autism and that the majority do not attempt to make adjustments or considerations for their autism. Future research must focus on practical means of improving healthcare quality for autistic adults to ensure that they are receiving equal access to high quality healthcare.

#### **426.125 (Poster) School Leaders' Perspectives on the Implementation of Evidence-Based Practices for Students with Autism Spectrum Disorder** **I. Taormina<sup>1</sup>, A. Sridhar<sup>2</sup>, M. Rajadhyaksha<sup>3</sup>, S. Moore<sup>1</sup> and G. F. Azad<sup>1</sup>, (1)Psychiatry, Columbia University Medical Center, New York, NY, (2)Psychology Department, Michigan State University, East Lansing, MI, (3)University of California Riverside, Riverside, CA**

**Background:** School leaders are imperative for setting the organizational context (e.g., climate, culture, resources) which may facilitate or hinder the implementation of evidence-based practices (EBPs) in special education settings serving students with autism spectrum disorder (ASD). School leaders may work in an administrative role (e.g., principals, assistant principals) or a practice role (e.g., school psychologists, social workers). School leaders who actively create a supportive organizational context (e.g., using teacher training/coaching as implementation strategies) may positively impact individual implementers (e.g., teachers) and their use of EBPs. However, few studies have examined the perspectives of school leaders on organizational context broadly, and implementation strategies specifically, and its association with EBP implementation in special education settings serving students with ASD.

**Objectives:** The purpose of this mixed methods study was twofold: 1) To examine how leaders perceive the organizational context of their schools; and 2) To examine the most important and feasible implementation strategies for supporting special education teachers use of EBPs for students with ASD.

**Methods:** Participants included 34 school leaders, 59% administrative and 41% practice leaders; 81% were female and identified as either White (86%) or Black (14%). Approximately, 54% worked at public schools serving both general and special education students and 45% worked at nonpublic schools serving only special education students. Semi-structured interviews were conducted to ask participants: 1) The culture/climate of their school and the existing supports for special education teachers; 2) To rate 15 implementation strategies on their feasibility and importance; and 3) To discuss their top three rated strategies. Interviews were coded using a combination of inductive and deductive coding.

**Results:** Qualitative findings indicated that family and student-level factors, as well as organizational-level factors (e.g. programming, staffing) influenced perceived culture and climate. Additionally, school leaders reported a number of supports for the implementation of EBPs by special education teachers including access to resources, professional development, staff meetings, and support from non-teaching staff. Quantitative ratings converged with qualitative findings. More specifically, the top three important implementation strategies were: 1) Providing ongoing consultation/coaching ( $M = 4.82$ ;  $SD = 0.39$ ); 2) Conducting ongoing training ( $M = 4.71$ ,  $SD = .46$ ); and 3) Monitoring the progress of implementation efforts ( $M = 4.64$ ,  $SD = .58$ ). The top three feasible implementation strategies were: 1) Conducting educational meetings ( $M = 3.86$ ,  $SD = 1.08$ ); 2) Changing/altering environment ( $M = 3.82$ ,  $SD = .91$ ); and 3) Providing ongoing consultation/coaching ( $M = 3.77$ ,  $SD = .92$ ). However, importance and feasibility ratings differed by school (i.e., public or non-public) or personnel type (i.e., administrator or practice leader).

**Conclusions:** Our findings are significant because they suggest that school leaders are perceptive of the multiple levels of factors (i.e., student, family, school) that influence culture and climate, as well as the numerous supports necessary for high-quality implementation. Providing ongoing consultation/coaching was rated as the most important and feasible implementation strategy for supporting special education teachers in implementing EBPs for students with ASD.

**426.126 (Poster)** Special Education Services Among Preschool and School-Age Children with Autism with and without Co-Occurring Conditions  
*M. C. Zajic<sup>1</sup> and J. Gudknecht<sup>2</sup>, (1)Health & Behavior Studies, Teachers College, Columbia University, New York, NY, (2)Human Development, Teachers College, Columbia University, New York, NY*

---

**Background:** Children with autism spectrum disorder (ASD) represent 11% (830,000) of students served by the Individuals with Disabilities Education Act and often receive special education services to support preschool and school-age education planning. Existing research highlights wide variability in service utilization, though studies are limited in sample size and treat ASD as homogenous. Students with ASD may have numerous co-occurring conditions that impact academic learning, including intellectual disability (ID), attention-deficit/hyperactivity disorder (ADHD), and/or language disability (LD).

**Objectives:** To examine within a large, national sample of school-age (preschool-12th grade) children with ASD if differences exist in use of special education services relative to the presence of no, one, or multiple co-occurring conditions (ID, ADHD, and LD).

**Methods:** This study uses information collected from parents participating in the Simons Foundation Powering Autism Research initiative, a large database of families with verified ASD diagnoses. The current study includes the following subgroups of children: 1) ASD ( $n=6,554$ ; 74% male; age=9.13[4.32]); 2) ASD+ID ( $n=491$ ; 78% male; age=9.98[5.15]); 3) ASD+ADHD ( $n=5,642$ ; 81% male; age=11.44[3.47]); 4) ASD+LD ( $n=7,790$ ; 79% male; age=7.43[3.99]); 4) ASD+ID+ADHD ( $n=473$ ; 77% male; age=12.10[3.76]); 5) ASD+ID+LD ( $n=3,251$ ; 75% male; age=8.93[4.74]); 6) ASD+ADHD+LD ( $n=3,744$ ; 84% male; age=10.32[3.79]); and 7) ASD+ID+ADHD+LD ( $n=2,021$ ; 78% male; age=11.27[4.07]). All children received special education services for early education, Individualized Education Program (IEP) for autism or other educational reasons, 504 plan, classroom and school supports, and/or targeted skill supports.

**Results:** Chi-square tests examining differences in special education service use by group were statistically significant ( $ps<.001$ ) with small-to-moderate effect sizes (Cramer's  $V$  range=0.05-0.35). Largest effects were identified for preschool services (birth to three=0.31, preschool special education=0.35), IEP/504 services (IEP other=0.27, 504 plan=0.25), and support services (speech=0.36, physical therapy=0.21, social skills=0.20). Post-hoc analyses using standardized adjusted residuals (adj.) highlighted the observed count for the ASD only group fell under the expected count for all 18 services (adj.  $M[SD]=-10.08[7.04]$ ). Notable trends across subgroups included higher usage of IEP (other), classroom support, and targeted support services among co-occurring ID groups; higher 504 plan usage and targeted support in behavior and social skill services among co-occurring ADHD groups; and higher use of preschool and speech support services among co-occurring LD groups. Additional trends across mixed co-occurring groups will be highlighted and discussed based on post-hoc findings from examining standardized adjusted residuals.

**Conclusions:** Findings highlight variable special education services used when contrasting children with ASD with co-occurring conditions. Findings suggest knowing an ASD diagnosis provides limited information about a child's special education services, and accounting for co-occurring conditions can provide additional insights into children's expected special education service usage.

**426.127 (Poster)** The Enduring Predominance of Basic Research in ASD: No Evidence for a Relative Increase in Applied Research Published Since 1979  
*P. Doehring, ASD Roadmap, Chadds Ford, PA*

---

**Background:**

**Background:** It is generally understood that basic research on the characteristics, trajectory, correlates, and possible causes of ASD will eventually translate into applied research seeking to develop assessment and intervention tools, and finally to demonstrate that these can be used effectively in community settings. We have designed a research roadmap that categorizes individual studies to track this progress. We recently reported on the application of this roadmap to articles published between 1979 and 2019 in the Journal of Autism and Developmental Disorders (JADD). We found

that basic research was consistently predominant, comprising about 2/3s of all research publications throughout this period. Despite the tremendous number of research publications, there was no evidence of a shift towards applied research involving interventions delivered in community settings.

**Objectives:** To begin to replicate the publication patterns noted in JADD to other journals over the same time period.

**Methods:** We searched PUBMED for all articles published in 1979, 1989, 1999, 2009, and 2019, with "aut\*" in the title or abstract. We scanned abstracts to select original empirical research focused on autism while excluding case studies, reviews, meta-analyses, research focused on other populations, and research published in JADD. We distinguished between Basic and Applied Research, and between three stages of the latter (Assessment, Intervention, and Other Applied Research). Applied research directly achieves - or documents the achievement of - a specific clinical, behavioral, or educational outcome through services provided to a clinical population. Because of the tremendous increase in research publications over the past two decades, we randomly sampled abstracts published in 2009 and 2019 so as to yield the same number of original research studies retrieved and reviewed in each of these two time periods, relative to the total number of original research studies reviewed for the previous three time periods.

**Results:** Over 7300 abstracts were retrieved, 94% of these from the last two time periods. Our abstract screening yielded 176 original empirical research studies across the first 3 time periods, and so we continued to screen randomly selected abstracts from 2009 and 2019 until we had retrieved 176 original research studies from each (see Figure 1). The distribution of original research across the categories of Basic and Applied research was generally consistent with the patterns noted in our earlier review focused on research published in JADD. An exception is the recent increase in Basic Research. We are now undertaking additional reviews to seek evidence for increases in applied research involving interventions delivered in community settings.

**Conclusions:** Despite an explosion of research over the past two decades, there has been no appreciable shift in the proportion of research seeking to directly improve assessment and intervention. This pattern has now been replicated across the full range of peer-reviewed research publications available in electronic databases - in fact, the emphasis on Basic Research may have increased. The relative lack of applied research, especially involving intervention, has tremendous implications for service delivery and social policy moving forward.

#### **426.128 (Poster)** The Impact of Poverty and Anti-Poverty Program Utilization Among Autistic Adults

**L. Bishop<sup>1</sup>, K. J. McLean<sup>2</sup>, R. A. Charlton<sup>3</sup>, G. A. McQuaid<sup>4</sup>, N. R. Lee<sup>5</sup> and G. L. Wallace<sup>1</sup>,** (1)University of Wisconsin - Madison, Madison, WI, (2)Social Work, University of Wisconsin - Madison, Madison, WI, (3)Psychology, Goldsmiths University of London, London, United Kingdom, (4)The George Washington University, Washington, DC, (5)Department of Psychological and Brain Sciences, Drexel University, Philadelphia, PA

**Background:** Between a quarter and three-fifths of adults with disabilities live in poverty in the US, and autistic adults are likely no exception because of high unemployment and underemployment rates. For autistic adults, poverty may necessitate ongoing utilization of anti-poverty programs that are part of the US social safety net and have potential to improve quality of life (QoL).

**Objectives:** We aimed to describe anti-poverty program utilization and test whether poverty and anti-poverty program utilization were associated with QoL in a large sample of autistic adults.

**Methods:** We recruited 888 autistic adults without intellectual disability (76.9% white; 58.0% female) aged 18-83 (mean=40.47; SD=13.88) via Simons Powering Autism Research for Knowledge Research Match. Autistic adults participated in a broader online study of adult outcomes. Measures assessed: demographic factors, QoL measured via the brief version of the World Health Organization Quality of Life assessment across physical health, psychological health, social relationships, and environmental health domains, as well as an autism-specific QoL measure; binary income below or above 150% of the federal poverty guidelines (standard cut point used for eligibility); and utilization of anti-poverty programs including Medicaid, Social Security Disability Insurance (SSDI), Supplemental Security Income (SSI), and Section 8 housing vouchers. We used five multiple linear regression models to test the association between our dependent variables (QoL domains) and poverty and anti-poverty program utilization, controlling for age, sex, autism symptomatology, and race.

**Results:** Overall, 30.1% of autistic adults in our sample had a household income that was less than 150% of the federal poverty guidelines. 30.6% of our sample utilized Medicaid, 15.0% utilized SSDI, 12.3% utilized SSI, and 6.3% utilized Section 8 housing vouchers. More than half of our sample (55.4%) did not utilize any anti-poverty programs. As expected, autistic adults with income below 150% of the federal poverty guidelines utilized a greater number of anti-poverty programs than autistic adults with incomes above these guidelines. ( $t=13.84$ ,  $p<0.001$ ,  $d=1.07$ ). Having an income above 150% of the federal poverty guidelines was associated with *better* QoL in the domains of physical health ( $b=0.158$ ,  $p<0.001$ ), psychological health ( $b=0.105$ ,  $p<0.001$ ), social relationships ( $b=0.118$ ,  $p<0.01$ ), environmental health ( $b=0.228$ ,  $p<0.001$ ), and autism-specific QoL ( $b=0.204$ ,  $p<0.001$ ). Utilizing Medicaid was associated with *worse* QoL in the domains of physical health ( $b=-0.129$ ,  $p<0.01$ ), environmental health ( $b=-0.148$ ,  $p<0.01$ ), and autism-specific QoL ( $b=-0.162$ ,  $p<0.05$ ). Utilizing SSI, SSDI, and Section 8 housing were not associated with QoL.

**Conclusions:** Findings indicate that both poverty and Medicaid utilization are significantly associated with lower levels of QoL in autistic adults. Our finding that autistic adult Medicaid beneficiaries have worse QoL may reflect that Medicaid beneficiaries are a lower income, be more impacted by co-occurring conditions, and/or have higher support needs than autistic adults who do not utilize Medicaid. Thus, Medicaid beneficiaries may need additional services that can improve their QoL. However, future research is needed to disentangle causal mechanisms underlying the association between service utilization and QoL. Although findings are preliminary and correlational in nature, they suggest reducing poverty among autistic adults has the potential to improve their QoL.

#### **426.129 (Poster)** Understanding Middle Aged and Older Autistic Adults Experiences with Health and Healthcare

**Background:** Physical health problems are highly prevalent in autistic adults, particularly as they age. Although causal mechanisms are not fully understood, it is likely that autistic adults experience their health and access healthcare differently, and these differences may help explain poor health outcomes among middle aged and older autistic adults. However, no qualitative research conducted to date has explored middle aged and older autistic adults' experiences with health or healthcare.

**Objectives:** We conducted a qualitative study that aimed to understand how middle aged and older autistic adults experience health and make decisions about how and if to interface with the healthcare system.

**Methods:** We have conducted a series of one-on-one interviews (N=11) with middle aged and older autistic adults and family members or friends who help them manage their health or healthcare ("emergency contact"). Autistic adults were eligible to participate if they: (1) were age 35+; (2) have an administrative or professional diagnosis of autism spectrum disorder; and (3) were able to communicate in English. Semi-structured interviews probed experiences with health and healthcare across four domains: (1) health habits; (2) health problems; (3) health services; and (4) autism and aging impact. Data were transcribed and analyzed using conventional content analysis. Transcripts were analyzed consecutively, and emerging themes were continually tested against data.

**Results:** Middle aged and older autistic adults and their emergency contacts conceptualized health as the absence of pain, illness, and injury, as well as a lack of sensory changes in their bodies. Autistic adults report utilizing preventive care regularly but struggle with making decisions about when to see a physician for acute pain, illness, or injury because of sensory differences in how they experience health problems and challenges with executive functioning that make seeking preventive care more difficult. A theme that has emerged is that of "independence." Autistic adults strive to be independent in accessing and utilizing health services because independence is one of the primary goals emphasized by autism services. Yet, emergency contacts highlighted the importance for all adults—including autistic adults—of receiving support from loved ones while managing health and healthcare. One emergency contact noted that autistic adults need to know that "if they need certain types of supports, it's a sign of strength to ask for those supports." Participants identified systemic barriers to independence in healthcare, including transportation, physician turnover, and physicians' lack of understanding of autistic adults' communication differences.

**Conclusions:** Results suggest that middle aged and older autistic adults experience sensory differences that impact their experience of health and have difficulty with accessing healthcare for acute health problems because of challenges with executive function. Further, accessing healthcare is an area in which autistic adults want to be fully independent, yet full independence in accessing healthcare is not feasible for most adults, including autistic adults. Social workers working with autistic adults should encourage them identify ways to partner with loved ones to access healthcare while maintaining autonomy in their choices about their bodies and health.

#### **426.130 (Poster)** The Implementation of the Screening Tool for Autism in Toddlers in Part C Early Intervention Systems

*D. M. Tagavi<sup>1</sup>, C. C. Dick<sup>2</sup>, S. M. Attar<sup>1</sup>, L. V. Ibanez<sup>3</sup> and W. L. Stone<sup>2</sup>, (1)University of Washington, Seattle, WA, (2)Psychology, University of Washington, Seattle, WA, (3)UW READi Lab, Seattle, WA*

---

**Background:** Although parents often report developmental concerns about their child by 18 months of age, most children are not diagnosed with ASD or enrolled in ASD-specific services until much later (Baio et al., 2018). To address this problem, the American Academy of Pediatrics published a recommendation for universal screening, which has led to increases in screening in pediatric settings over the last several decades (Murray & Barton, 2021). However, pediatricians may not know where to refer children for ASD-specific assessment if they receive a positive screen or may consider the availability of services before making referrals. Given that children who are identified as having developmental concerns are often referred to receive services in Part C Early Intervention (EI), it is a reasonable setting to perform further ASD screening (Monteiro et al., 2016).

**Objectives:** The current study examines the implementation of the Screening Tool for Autism in Toddlers (STAT), a Level 2 screening measure used to identify children thought to be at risk for ASD, by community EI providers serving toddlers from birth to 3 years. Specifically, we examined the: (a) effectiveness of a 1-day STAT training workshop for increasing EI providers' self-efficacy in ASD screening; (b) key implementation factors related to providers' use of the STAT (i.e., adoption, feasibility, and perceived effectiveness); and (c) barriers and facilitators to STAT implementation.

**Methods:** Participants comprised 69 EI providers (M Age = 43.3 years, 93.7% Female, 92.4% White) who were trained to administer the STAT in their agencies with children for whom they had ASD concerns. An interrupted time-series design was used to examine STAT use, with the STAT training workshops representing the "interruption." Providers answered questions about ASD screening self-efficacy at two baseline timepoints (T1 and T2) and two post-training timepoints (T3, 6 months post-STAT training and T4, 18 months post-STAT training). They reported on their adoption of the STAT and their feasibility and effectiveness of the screener at T3 and T4. At both post-training time points, providers completed open-ended responses regarding barriers and facilitators to STAT use in their practice.

**Results:** Hierarchical linear modeling was used to determine changes in self-efficacy. There was no difference in provider screening self-efficacy levels between the two baseline timepoints. Self-efficacy levels significantly increased from baseline to post-training and providers who reported adopting the STAT had greater increases in self-efficacy post-training than those who did not. Although only half of trained providers reported utilizing the STAT in their everyday practice, those who did adopt it reported it to be feasible and effective. Qualitative analysis of barriers and facilitators to STAT implementation revealed 6 categories of facilitators (i.e., user-friendly, promotes communication with families) and 8 categories of barriers (i.e., certification process, fitting into existing workflow).

**Conclusions:** Results highlight the potential for use of the STAT in EI settings to increase children's access to early evaluation services and, subsequently, to ASD-specific early intervention services. Future research should aim to promote long-term sustainability of screening practices in settings in which children at-risk for social communication concerns are seen frequently.

**426.131 (Poster)** The Role of the COVID-19 Pandemic in Predicting Lack of Needed Health Services for Children with and without ASD  
*S. Brunt and M. O. Mazurek, University of Virginia, Charlottesville, VA*

---

Background:

During the spring of 2020, as the COVID-19 pandemic caused the widespread closure of schools and places of business in the U.S, many healthcare services, including medical, dental, mental, and behavioral health services were restricted or suspended to mitigate the spread of COVID-19. Children with ASD often have unmet healthcare needs as well as barriers to ASD-specific services. Additionally, the negative consequences of the pandemic, such as disruptions in daily routines, increased parental stress, and loss of access to regular specialty services can have a particularly detrimental effect on children with ASD and their families.

Objectives:

The aim of the current study is to examine whether access to and utilization of needed health-related services differ pre- and post-pandemic for children with and without ASD.

Methods:

Data were obtained from the National Survey of Children's Health (NSCH), a parent questionnaire that examines the mental and physical health of children across the U.S. The sample consisted of 37,427 male (51.83%) and 34,783 female (48.17%) children aged 0-17 years. Pre-pandemic respondents (surveyed in 2019) comprised 40.8% of the sample, while 59.2% responded during the pandemic (surveyed between July 2020 and January 2021).

Relevant variables were selected from the questionnaire for use on this project. Current ASD diagnosis and year responding (pandemic vs. non-pandemic year) served as binary predictor variables. Covariates included child age, sex, race, highest level of education completed among parents, and how often the family found it hard to cover basic living expenses, which served as a proxy for income. Multiple logistic regressions were conducted, which included demographic covariates, ASD diagnosis, year, and the interaction between ASD diagnosis and year as predictors of the binary outcome of whether the child was not receiving needed health services (including medical, dental, and mental). Odds ratios are reported in lieu of coefficients for ease of interpretation.

Results:

Children who were older ( $OR=1.04, p<.001$ ), nonwhite ( $OR=1.16, p=.001$ ), and from lower-income families ( $OR=4.49, p<.001$ ) were significantly more likely to lack needed services. Controlling for covariates, children with ASD were over three times as likely to lack necessary services as children without ASD ( $OR=3.24, p<.001$ ), and all children were 1.4 times more likely to lack services during 2020 than 2019 ( $OR=1.39, p<.001$ ). The interaction between ASD diagnosis and year was not significant,  $OR=1.09, p=.58$ .

Conclusions:

Results suggest that, regardless of pandemic interference, children from more marginalized backgrounds (e.g., nonwhite, low-income), are more likely to lack necessary health services. Additionally, the pandemic significantly disrupted services for everyone, regardless of diagnosis or demographic characteristics. Children with ASD were more likely to lack services regardless of pandemic interference. Overall, results point to persisting disparities in access to health-related services as well as a significant disruption in services during the COVID-19 pandemic. Although children with ASD did not experience a disproportionate lack of healthcare services during 2020 compared to children without ASD, more research is needed to determine whether the quality of such services was differentially affected by the pandemic, particularly since many ASD-related services transitioned to virtual or telehealth.

**426.132 (Poster)** The Use of Psychological and Organizational Theories to Predict Implementation of Evidence-Based Practices in School Settings  
*A. M. Hernandez<sup>1</sup>, M. Pullmann<sup>2</sup>, M. L. Hugh<sup>2</sup>, M. Joshi<sup>1</sup> and J. Locke<sup>3</sup>, (1)University of Washington, Seattle, WA, (2)Psychiatry & Behavioral Sciences, University of Washington, Seattle, WA, (3)Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA*

---

Background: The increased prevalence of ASD has impacted public schools, the primary setting where autistic children receive services. Schools are required to provide education in the least restrictive environment; thus, many autistic children are included in general education. There are several evidence-based practices (EBPs) that can be used to purposefully include autistic children. It is unclear which EBPs, if any, general and special education teachers and paraeducators are commonly trained in or whether they use those EBPs to support inclusion. We draw on the Theory of Planned Behavior to examine individual characteristics (attitudes, norms, self-efficacy, intentions) and apply the Exploration, Preparation, Implementation, and Sustainment (EPIS) framework to examine organizational characteristics (implementation climate and leadership) associated with EBP use.

**Objectives:** The purpose of this study is to identify which EBPs educators use to meaningfully include autistic children in general education settings and individual and organizational characteristics that increase EBP use. In this presentation, we will discuss our conceptual model that combines psychological theories of behavior change and organizational theory to guide our study design and each study phase; however, results will only be presented on Study 1 given Studies 2 and 3 are currently underway.

**Methods:** In Study 1, we gathered quantitative and qualitative data to explore which EBPs educators have been trained to and consistently use to support autistic children. We asked participants (n=86 from 73 schools in 40 districts) to complete a modified Autism Treatment Survey about their EBP use (n=21 EBPs) and training and invited participants to a semi-structured interview (n=81) to expand upon their survey responses. Nine themes were developed, and three raters applied the codebook to all transcripts (95% reliability). In Study 2, we will quantitatively measure individual characteristics of educators as well as organizational factors of the school, and in Study 3, we will qualitatively examine mechanisms through which individual and organizational factors facilitate or hinder EBP use in a subset of participants.

**Results:** We collected quantitative data from 27 general education teachers, 31 special education teachers, and 28 paraeducators who support at least one autistic student in a general education setting. Across roles, the most used EBPs to support inclusion were reinforcement (98.8%), modeling (96.4%), visual supports (92.5%), and antecedent-based intervention (86.8%). Video modeling (31.6%), technology-aided instruction and intervention (38.5%), peer-based instruction and intervention (52.4%), and time delay (56.4%) were the least used. Across roles, "District/ESD in-service or workshops" were the most endorsed training type across roles (52.3%) followed by "Teacher Preparation or Educator Certification Program" (51.2%). The least endorsed training types were "Webinars" (15.1%) and "Conferences" (16.3%). Qualitative data highlighted discrepancies between EBP definitions and applied use.

**Conclusions:** The four most frequently used EBPs to include autistic children in general education settings are: reinforcement, modeling, visual supports, and antecedent-based interventions. Implementation theory that describes how multi-level factors simultaneously influence EBP use has yet to be articulated and thoroughly tested.

#### **426.133 (Poster) Trends in English Proficiency Among Autistic English Learners**

**F. A. Castellon<sup>1</sup>, A. Sturm<sup>2</sup>, J. A. Pan<sup>3</sup> and C. Kasari<sup>1</sup>,** (1)University of California, Los Angeles, Los Angeles, CA, (2)UCLA, Los Angeles, CA, (3)Biostatistics, UCLA, Los Angeles, CA

**Background:** There is an ever-increasing rate of immigrant origin children in the United States where at least one parent speaks a language other than English. This has directly resulted in an increased number of English Learners (EL) being served in both general education and special education, including children with autism spectrum disorder (ASD). California statewide reports show that on average, 88% of EL students become reclassified as English proficient by 8th grade but little to none is known about the time to reclassification for students who are both EL and autistic.

**Objectives:** The present study aimed to examine differences in the development of English proficiency among students classified under ASD by (1) identifying changes in English language proficiency, (2) examining the probability of continued EL classification, and (3) identifying student level predictors associated with becoming English language proficient (ELP).

**Methods:** The current study utilized longitudinal special education data collected by the administration of a large urban school district in the US. Students served under a primary eligibility of autism were included for the academic school years from 2011-2012 through 2018-2019. The percentage of students who transitioned from EL to ELP was computed for all students regardless of educational placement. For students who transitioned to English proficient, mean age of classification change was computed along with highest probability transition age. Survival analysis was performed utilizing Kaplan Meier curves and were generated to determine the probability of students remaining classified as EL across time (measured by student age). Finally, a linear regression was conducted to investigate if any student level predictors were correlated with becoming ELP.

**Results:** Of the students with ASD 7532 (77.7% male, 87.3% Hispanic/Latinx,  $M_{age}=5.73$ ,  $M_{observations}=6$ ) were classified as EL sometime between 2011-2019 in grades TK/Kinder-5th. 38.4% classified as EL transitioned to ELP at some point between 2011-2019. The mean age at which students transitioned to ELP was approximately 12.2 (SD= 2.47) years old. Kaplan Meier curves (Figures 1a) revealed that the probability of classification as EL decreased as students aged and had a continuous negative trend. The highest probability age for becoming ELP was 10.8. The student level predictor that was significantly associated with becoming ELP was the classroom placement the year prior to the reclassification of ELP, indicating that students in special day classes became ELP at older ages.

**Conclusions:** The present study revealed the striking number of autistic students classified as EL who are served in a large Southern California urban school district. A minority of ELs with ASD gain English proficiency by middle childhood. Future work is required to identify methods to best support ELs with ASD in schools.

#### **426.134 (Poster) Understanding Differences in Involvement with Community-Based ASD Care Systems between Non-Hispanic and Hispanic Children from Linguistically Diverse Families within a Family Navigation Model**

**A. Lavanderos<sup>1</sup>, A. Miceli<sup>2</sup>, N. Harris<sup>3</sup>, A. S. Weitlauf<sup>4</sup>, E. Davis<sup>2</sup>, M. West<sup>2</sup> and Z. Warren<sup>1</sup>,** (1)Vanderbilt University Medical Center - TRIAD, Nashville, TN, (2)Vanderbilt University Medical Center, Nashville, TN, (3)Vanderbilt Kennedy Center, Vanderbilt University Medical Center, Nashville, TN, (4)Vanderbilt University Medical Center - Treatment and Research Institute for Autism Spectrum Disorder, Nashville, TN

**Background:** Many barriers to diagnostic care exist, especially for children from ethnically and linguistically diverse backgrounds. We created a Family Navigation Network that provides resources to underserved families who have a child with diagnosed or suspected autism spectrum disorder

(ASD). Mindful of care disparities, we focused on reaching Spanish speaking families and tracking their care experiences. We previously found that limited English proficient families received less services than the English speaking families at time of referral. In this work, we further explore these differences in an updated sample by looking at our model through the lens of ethnicity, with a focus on the Hispanic population.

**Objectives:** To identify existing differences in baseline engagement with community-based care systems for families who have a child with diagnosed or suspected ASD, with a specific emphasis on differences for Hispanic families (see Table 2).

**Methods:** Families were referred for Navigation related to diagnosed or suspected ASD. At first point of contact, Navigators logged information into a REDCap database about existing family engagement with 5 community care systems representing best practice for children with developmental risk in our region (see Table 1). Families then received information about community resources, with Spanish speaking families contacted by a bilingual Spanish speaking Navigator. Out of 1054 participating families, 877 identified as non-Hispanic and 177 identified as Hispanic. Of the Hispanic families, 80 identified as English Speaking (ESH) and 97 identified as Spanish Speaking (SSH).

**Results:** As in previous work, Hispanic families were almost twice as likely as non-Hispanic families to not be receiving services at baseline (42.9% vs. 23.1%, respectively). This difference was more subtle across the SSH (45.4%) and ESH (40%) groups. At baseline, ESH families generally received more services than SSH families, with the exception of Part B (school-based services): More Hispanic families received Part B services than non-Hispanic families (see Table 1) and similarly, more SSH families received these services than ESH families (see Table 2). When looking at Part C early intervention services, 71.5% of the non-Hispanic group received services compared to only 47.4% of the Hispanic group. Mean age at point of navigation referral for Hispanic versus non-Hispanic groups was 38.1 and 35.9 months, respectively, and while ESH families were referred at 33.9 months, SSH families were referred almost 7 months later at 41.6 months.

**Conclusions:** We note with concern that the SSH group was referred for navigation at older ages than the ESH group. Similarly, Hispanic families continue to have greater lack of baseline care engagement relative to non-Hispanic families, regardless of primary language spoken. This identifies a need to understand the complex variables across ethnically, racially, and linguistically diverse families that influence service engagement at point of referral. To broaden equal access to care and resources, future research should continue to expand on family navigation and screening tool models inclusive of diverse parenting experiences.

**426.135 (Poster)** The Impacts of the COVID-19 Pandemic on Therapy Utilization Among Racially/Ethnically and Socio-Economically Diverse Children with Autism Spectrum Disorder

**C. W. Gonzales<sup>1</sup>, J. Simonell<sup>1</sup>, C. Rodriguez-Gallegos<sup>1</sup> and J. Tarbox<sup>1,2</sup>, (1)University of Southern California, Los Angeles, CA, (2)FirstSteps for Kids, Los Angeles, CA**

**Background:**

The COVID-19 pandemic and associated restrictions to in-person gathering have raised concerns about disruption to therapeutic services for children with autism spectrum disorder (ASD). Early research on the impacts of the COVID-19 pandemic on children with ASD provides preliminary evidence of ASD related service disruption and worsening behavioral and affective outcomes (Jeste, 2020; Collizzi et al, 2020). Pre-pandemic literature has demonstrated racial and socioeconomic disparities in access to and utilization of ASD related services (Smith, 2020), however little or no research has evaluated these disparities in the context of the COVID-19 pandemic.

**Objectives:**

The current study aims to evaluate disruption to the ASD behavioral health delivery system by describing change in hours of ABA therapy before and through the COVID-19 pandemic and by evaluating if there is differential disruption based on the race/ethnicity and socio-economic status of the child. Additionally, the current study utilizes an extended structure-process-outcome model to interpret the implications of the findings for the quality of the ABA treatment delivery system as a whole and in the context of patient variability and environmental stress.

**Methods:**

Retrospective clinical data on children's demographics and therapy utilization were collected from five ABA clinics throughout California (N=203; 23.6% Asian, 6.4% Black, 21.2% Latinx ethnicity (of any race), 33.5% White, 1% other race/ethnicity, 14.3% not reported). A three-way mixed ANOVA was used in order to evaluate the main effect of time period (Sep-Nov 2019, pre pandemic; Mar-May 2020, early pandemic; Sep-Nov 2020, mid pandemic) on hours of ABA therapy received by children with ASD as well as the moderating effects of child's race and child's primary funding source (private insurance, public insurance, school district).

**Results:**

We found that there was a significant effect of time period on hours of ABA therapy (partial  $\eta^2 = .205$ ) so that there was a reduction in hours between pre COVID-19 and the beginning of COVID-19, with no significant changes in hours of ABA therapy between the beginning of COVID-19 and 6-9 months into the pandemic. Analysis of moderators revealed no significant effect of race or race x payer on the relationship between time period and hours of ABA therapy. There was a significant moderating effect of primary payer on the degree to which time predicted hours of ABA therapy (partial  $\eta^2 = .255$ ) so that children who receive primary funding from school districts experienced a more severe drop in ABA therapy hours during the pandemic compared to children whose treatment is funded by other sources.

## Conclusions:

Findings indicate that ABA services were disrupted at the beginning of the pandemic and did not significantly recover after 6-9 months. A delay of this magnitude carries implications for the long term effects of service disruption, given literature on the negative impacts of delayed start to treatment among children with ASD (Tarbox et al, 2013). These findings also carry implications for how the autism treatment delivery system reacts to world events and how it can be strengthened in anticipation of future crises.

**426.136 (Poster)** Aligning Ecosystems: How Multi-System Brokerage Shapes Autism Interventions for Children on the Autism Spectrum  
**E. McGhee Hassrick<sup>1</sup>, J. Suhrheinrich<sup>2</sup>, P. Schetter<sup>3</sup>, C. Nguyen<sup>4</sup>, M. Melgarejo<sup>2</sup>, Y. Yu<sup>5</sup>, T. Holt<sup>6</sup>, J. Li<sup>6</sup>, J. ---

## Background:

Educational interventions for autistic children are impacted by people situated at different levels of the child's ecosystem. However, coordination of evidence-based interventions (EBIs) across the ecosystem, recommended by decades of research and policy, remains challenging. Professional development (PD) providers play a potentially unique role in the ecosystem supporting the implementation of EBIs for autistic children. Ecological systems theory considers a child's social context as a key mechanism for development and learning across life stages (Bronfenbrenner, 1994; Vygotsky, 1980) and levels of engagement, including the microsystem, mesosystem, exosystem and macrosystem (McGhee Hassrick, 2021; McGhee Hassrick, 2019; Gulsrud, 2021; Shattuck, 2020). This study uses an ecosystem theoretical framework to identify and measure network mechanisms of PD providers participating in a state-wide implementation improvement intervention (CAPTAIN) that impact ecosystem coordination of EBI for autistic children in educational settings

## Objectives:

To investigate the qualitative and quantitative aspects of ecosystem interaction for professional development (PD) providers as they engage in capacity building work, coaching, and training of educational providers of children on the autism spectrum. PD providers self-reported performance as coaches. A performance score was calculated for each PD provider to incorporate both how well they fulfilled their coaching and training requirements as well as how often they used quality training and coaching practices.

## Methods:

High and low performing PD providers were recruited from county-level organizations. PD providers completed a social network survey about their professional support networks and also participated in qualitative, semi-structured interviews about their support networks. Qualitative themes were identified, using a multi-stage coding process in NVIVO. Network data, analysis using R-programming, characterized structural aspects of PD provider ecosystem connections

## Results:

**Qualitative findings** suggested PD providers participated in building and sustaining a *goal-aligned, relational ecosystem*, with a proactive commitment to coordinating the implementation of EBIs across systems. PD providers sought out school, district and county level leaders to secure resources for educators implementing EBIs in their classrooms to build the capacity for change and improvement across the system (Figure 1.1). PD provider reported their own interactions with the child and the child's team of providers and also to exosystem actors provided broader access to resources and support for the child's microsystem team (Figure 1.2). **Social network** results revealed difference between high and low performing PD providers in average network size (HP:15.9/LP:21.4). On average, high performing PD providers reported more connections with microsystem people (HP:13.4/LP:10.4) and exosystem people (HP:9.3/LP:5.9); more ties among microsystem people (HP:27.1/LP:22.5), among exosystem people (HP:27.2/LP:13.3) and between micro/exosystem people (HP:49.3/LP:29.9).

## Conclusions:

Recent research suggests that educational institutional settings are "ghost systems" (Fixen et al 2012) with siloed, disconnected processes at the district, county and state level that interfere with the successful implementation of EBPs for autistic students. Findings from this study suggest that PD providers who work toward building and sustaining a *goal-aligned, relational ecosystem* provide higher quality coaching and support for educators implementing EBPs for autistic students, suggesting network interventions training PD providers how to forge aligned ecosystems.

**426.137 (Poster)** United: Using Collaborative Teaming Strategies and Social Network Theories to Sustain the Implementation of Evidenced-Based Intervention for Children on the Autism Spectrum  
**E. McGhee Hassrick<sup>1</sup>, S. Iadarola<sup>2</sup>, J. Locke<sup>3</sup>, D. S. Mandell<sup>4</sup>, T. Valente<sup>5</sup>, J. Ventimiglia<sup>6</sup>, A. C. Stahmer<sup>7</sup>, B. A. Boyd<sup>8</sup> and C. Kasari<sup>9</sup>, (1)A.J. Drexel Autism Institute, Drexel University A.J. Drexel Autism Institute, Philadelphia, PA, (2)University of Rochester Medical Center, Rochester, NY, (3)Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA, (4)Penn Center for Mental Health, University of Pennsylvania,**

#### Background:

Although evidence-informed autism-specific interventions have increased, most evidence-based interventions (EBIs) are implemented inconsistently or are not widely available to families from historically excluded groups. Those providing community-based intervention (e.g., teachers, agency staff) may feel unsupported in using models that require extensive training and resources. Social network theories prioritize social connections for communication, influence, and behavior changes. Organizational theory suggests that successful implementation is supported by systematic, planned internal “conditions,” including clearly-defined roles, collaborative teams, and transparent expectations. To support creation of critical organizational “conditions,” we integrated social network implementation theories and organizational teaming to develop an intervention to facilitate implementation/ sustainment of EBIs in low-resourced settings: UNITED (Using Novel Implementation Tools for Evidence-based intervention Delivery).

#### Objectives:

Describe how social network and teaming theoretical mechanisms informed UNITED, and how UNITED is designed to impact sustainment of EBI implementation for children with autism spectrum disorder (ASD) from historically excluded communities.

#### Methods:

UNITED integrates two strategies derived from social network and organizational theory: 1) social network analysis (SNA) and 2) collaborative teaming.

1. SNA promotes comprehensive team selection by asking staff at different levels of the organizational hierarchy to identify people with the best expertise, rather than relying solely on formal positional leaders for team selection, potentially overlooking people with key expertise. Potential implementers at a given site rank staff regarding who can best support them in using the intervention effectively. This method of building and supporting a team is one of four key types of SNA interventions. During sustainment, we will use SNA to promote UNITED team strengths and potential gaps by calculating team cohesion, collaboration intensity, and team reach.
2. Collaborative teaming is supported through the strategies such as identifying team structure and roles, development of communication norms and conflict resolution strategies, and development of a clear and operationalized implementation plan. Consultants from the research group assist teams in these collaborative processes.

UNITED is tested via RCT, implemented across three EBIs in community settings. Sites are randomized to UNITED or implementation as usual (IAU; stratified across the three interventions). In accordance with social network and organizational theory, we hypothesize that compared to IAU, sites in UNITED will demonstrate higher team cohesion, greater fidelity to each intervention (our primary outcome), higher sustained implementation, and better child/family outcomes.

#### Results:

We successfully developed the UNITED intervention, including four core modules and supplemental models. For the RCT, we are enrolling community providers in schools and agencies (current n = 75 participants across 18 sites). Data will be presented across the first year of implementation for 1) recruitment and retention; 2) UNITED intervention fidelity; 3) social network size and site implementation climate; and 4) qualitative experiences in UNITED.

#### Conclusions:

Theoretical frameworks provide viable strategies to inform the development of new interventions, such as UNITED, focused on improving implementation outcomes. Evaluating implementation-focused interventions in large-scale trials, in real-world settings, can yield much-needed data to support the use of such interventions to improve equitable delivery of EBI.

**426.138 (Poster)** Using Quality Improvement Science to Standardize ADHD Care in a Pediatric ASD Population in the Autism Care Network  
**D. S. Murray**<sup>1,2</sup>, **J. S. Anixt**<sup>3</sup>, **K. L. Ratliff-Schaub**<sup>4</sup>, **S. Wootton**<sup>5</sup>, **C. Lannon**<sup>6</sup>, **K. Kuhlthau**<sup>7</sup> and **D. Coury**<sup>8</sup>, (1)Science, Autism Speaks, Boston, MA, (2)Developmental & Behavioral Pediatrics/University of Cincinnati, Department of Pediatrics, School of Medicine, Cincinnati Children's Hospital Medical Center, Cincinnati, OH, (3)Division of Developmental & Behavioral Pediatrics, Cincinnati Children's Hospital Medical Center, Cincinnati, OH, (4)Developmental-Behavioral Pediatrics, Prisma Health, Greenville, SC, (5)Anderson Center for Health Systems Excellence, Cincinnati Children's Hospital Medical Center, Cincinnati, OH, (6)Anderson Center for Health Systems Excellence/Department of Pediatrics UC Medical School, Cincinnati Children's Hospital/University of Cincinnati, Cincinnati, OH, (7)Massachusetts General Hospital, Boston, MA, (8)Developmental-Behavioral Pediatrics, Nationwide Children's Hospital, Columbus, OH

---

#### Background:

More than half of children with autism spectrum disorder (ASD) are diagnosed with co-occurring Attention Deficit / Hyperactivity Disorder (ADHD). Although there are published ADHD diagnostic and treatment clinical practice guidelines, the complexity of ADHD management in the setting of ASD is not fully addressed with existing guidelines. The Autism Care Network (ACNet), a learning health network for ASD, is focused on reducing parent-reported challenging behavior, prioritizing three of the most common co-occurring conditions: ADHD, Anxiety, and Irritability. QI methodology was used to improve reliable implementation of an ADHD clinical pathway across multiple centers, with a goal of improving clinical care and accelerating the implementation of best practices.

#### Objectives:

To achieve reliable implementation of a consensus based best-practice clinical pathway for ADHD in children with ASD to improve: a) the identification of ADHD, b) the standardization of care across network centers c) the ability to evaluate impact of pathway implementation on outcomes.

#### Methods:

Network leaders with expertise in ADHD and ASD developed a consensus based best-practice clinical pathway for the identification and treatment of ADHD in children with ASD based on an extensive literature review and previous network research. An improvement lab of six pilot ACNet sites was developed to establish reliable implementation of the ADHD clinical pathway in those centers. A bundle of six markers of reliable pathway implementation at clinical visits were identified, including: use of standardized assessment tools to measure ADHD symptoms (to confirm a new diagnosis and to monitor treatment every six months), assessment of safety concerns, discussion of behavior therapy, discussion or prescription of medication, and, if prescribed medication, assessment of vital signs and side effects. QI methodology including tests of change (PDSA cycles) and data tracking with run charts were used to improve reliability of the bundle care practices. Reliability was calculated on 4 levels <80% chaos, 80%-89% level 1 reliability, >90% level 2 reliability, >99% level 3 reliability (cite). Bi-monthly interval sampling was conducted for eight cycles (N=63-110 encounters/ per cycle). QI support and data sharing were provided at lab meetings with opportunities for sites to share learnings about successful strategies to improve reliability.

Results: At baseline, 0/6 of the ADHD pathway markers were at or above level 1 reliably. Sampling results indicated that 3 markers (discussion or prescription of medication, vital signs, side effects) reached level 1 or level 2 reliability (80-89% or 90-98% reliable, respectively) in cycle #2 and maintained reliability through cycle #8. Clinical improvements were seen in all 6 markers, although 3 markers have not yet achieved level 1 reliability. At the completion of cycle #8, 2 additional markers are approaching level 1 reliability: assessment of safety concerns and discussion of behavior therapy (78-79%). Use of a standardized rating scale for ADHD symptoms is a focus area for current testing (currently achieved at 40% of encounters).

#### Conclusions:

The use of QI methodology and network sharing has supported six ACNet sites to improve reliability of care practices for the diagnosis and treatment of ADHD in the setting of ASD.

#### **426.139 (Poster)** What I Wish You Knew: Insights on Burnout, Inertia, Meltdown, and Shutdown from Autistic Youth

J. Phung<sup>1</sup>, M. Penner<sup>2</sup>, C. Prilot<sup>1</sup> and C. Welch<sup>3</sup>, (1)Bloorview Research Institute, Toronto, ON, Canada, (2)Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (3)University of Toronto, Toronto, ON, Canada

---

Background: Burnout, inertia, meltdown and shutdown (BIMS) have been identified as important parts of daily life for at least some autistic people. This study builds on our earlier work that offered initial academic descriptions of these phenomena, informed by the perspectives of autistic adults.

Objectives: This study aimed to leverage the insights and experiential knowledge of eight autistic children and youth to extend and refine our earlier descriptions of burnout, inertia, and meltdown, with additional study of shutdown. We also aimed to examine how these youth cope with these phenomena and what others around them do that make things better or worse. We did this to glean experiential knowledge for the design of better supports.

Methods: Each participant complete two one-to-one interviews. Collected demographic data indicates that these youth were from families of middle to high socioeconomic status and of Caucasian or European descent. Their ages ranged from eight to eighteen. Five identified as male and three identified as female. The interviews explored their experience with BIMS. To match data generation methods with individual communication strengths of the children and youth, we took a flexible approach to interviews, allowing for augmentative communication systems and use of visual images to support verbal interviews, as needed. We conducted a reflexive, inductive thematic analysis, using an iterative process of coding, collating, reviewing, and mapping themes.

Results: Our analysis indicates that these youth describe BIMS as a complex and multi-faceted experience involving cognitive, emotional, and physical components, which do not entirely fit into any singular clinical model, such as arousal regulation. These multifaceted experiences are often misunderstood, and the associated observable behaviours are often misinterpreted by neurotypical adults. This lack of understanding contributes to inadequate support in managing BIMS in the youths' home and school environments. Of the four BIMS phenomena, these youth identified meltdowns as most common. Additionally, the youth were best able to describe experiences of meltdown and discuss the strategies they find helpful. A limitation to consider is that the descriptions generated are reflective of a sample with limited demographic diversity.

**Conclusions:** By exploring the firsthand experiences of these youths, we have generated new insights into BIMS and developed a more holistic understanding of these phenomena. These youths' descriptions of supportive strategies for BIMS highlight the importance of compassion and collaboration from trusted adults. This new knowledge offers foundational insights for how to better support autistic children and youth in their home and school environments. Further research is required to develop an understanding of BIMS, with particular focus on how it is experienced by children and youth. Future research should leverage the experiential knowledge and insights of autistic children and youth to co-design a support tool(s) for BIMS.

**426.140 (Poster)** When Elementary Students with Autism and Intellectual Disability Are Removed from the General Education Curriculum  
**K. Maurer<sup>1</sup>, F. A. Castellon<sup>2</sup>, A. Sturm<sup>1</sup> and C. Kasari<sup>2</sup>, (1)UCLA, Los Angeles, CA, (2)University of California, Los Angeles, Los Angeles, CA**

---

**Background:** The majority of public school students are provided instruction from the general education (GE) curriculum, aligned with the state's academic standards. However, students who are significantly impacted by intellectual and developmental disabilities may require an alternate curriculum (AC) to address their unique learning goals. Timing of student transition from the GE curriculum to AC is highly variable and may occur as early as preschool. Early placement on AC, however, may adversely impact a student, including reduced access to grade level learning opportunities and engagement with their peers in GE.

**Objectives:** The present study aimed to examine the patterns of AC participation for elementary students receiving special education services under primary Autism Spectrum Disorder (ASD) or Intellectual Disability (ID) eligibility by (1) identifying the number of students on AC compared to GE, (2) examining the patterns of curriculum switching for students between grades preschool-5, and (3) identifying sociodemographic predictors of AC in elementary school (ES) and the moderating influence of eligibility group.

**Methods:** The current study utilized annual longitudinal special education administrative record data from a large urban school district and included students in grades preschool-5 served under a primary eligibility of ASD or ID from the academic years 2011-2012 through 2018-2019. The number of students with at least one observation of AC during ES was tabulated. Patterns of switching from GE curriculum to AC during ES was also tabulated for students in both eligibility groups. To determine sociodemographic predictors (i.e., eligibility group, English language learner status, free or reduced lunch status, ethnicity, gender) of AC during ES, logistic regression was used, where all sociodemographic variables and the interaction between sociodemographic variables and disability were included as predictors in the model.

**Results:** Results revealed 29,410 unique students served under ASD or ID eligibility in ES. Of those students, N=20,406 (69.4%) remained on GE curriculum, N=1,163 (3.9%) transitioned to AC in TK/K, N=1,627 (5.5%) transitioned in 1st grade, N=652 in 2nd grade (2.2%), N=542 in 3rd grade (1.8%), N=283 in 4th grade (.96%), and N=236 in 5th grade (.8%). Eligibility and ethnicity emerged as significant predictors of AC in ES, where the odds of being placed on AC in ES are significantly higher for students served under ID than for students served under ASD. African American and Hispanic students served under ID are significantly more likely than White students served under ASD to be placed on AC in ES.

**Conclusions:** Results reveal the majority of students served under ASD or ID remained on GE throughout elementary. Of those who switched to AC, the majority were likely to do so in TK/K or 1st grade. Eligibility and ethnicity impact placement on AC in ES, but free or reduced lunch, gender, and English learner status showed no impact on AC participation. The study indicates that access to GE curriculum and grade level content is limited for certain populations beginning early in their schooling.

**426.141 (Poster)** Readiness for Change: Implementing Mental Health Interventions for Autistic Youth in Virginia Community Service Boards  
**M. Fok<sup>1</sup>, J. E. Tschida<sup>2</sup>, J. R. Bertollo<sup>3</sup>, A. Sridhar<sup>2</sup>, E. A. DeLucia<sup>3</sup>, A. Drahota<sup>2,4</sup> and A. Scarpa<sup>3</sup>, (1)Department of Psychology, Virginia Tech, Blacksburg, VA, (2)Psychology Department, Michigan State University, East Lansing, MI, (3)Department of Psychology, Virginia Polytechnic Institute and State University, Blacksburg, VA, (4)Child and Adolescent Services Research Center (CASRC), San Diego, CA**

---

**Background:** Autistic youth have elevated service needs due to the chronicity and severity of core ASD symptoms and co-occurring psychological challenges. While mental health evidence-based interventions (MH-EBIs) for autistic youth have been identified, barriers to implementing MH-EBIs in community service agencies exist. Organizational factors (e.g., readiness to change) may interfere with implementation success. Providers may lack proficiency to treat the unique needs of autistic youth, lack specialized training, or perceive autistic youth as particularly challenging to treat. In Virginia, community service board (CSB) organizations provide publicly-funded mental health, developmental, and substance use disorder services for citizens in their communities and are funded and regulated by the Virginia Department of Behavioral Health and Developmental Services. There are 40 CSBs across the five Virginia regions that service all 133 city/county localities.

**Objectives:** We surveyed Virginia CSBs to obtain descriptive data to inform (1) current needs for and (2) barriers to implementing MH-EBI for autistic youth at the organizational- and provider-level.

**Methods:** Twenty-three of the 40 CSB agency leaders responded to recruitment emails and completed REDCap surveys from February-May 2021. They reported their CSB's number of total clients (0-21yrs) and autistic clients (0-21yrs), and the number of providers delivering ASD services (Table 1). Participants reported their CSB's readiness for organizational change using a 4-point (1-5) Likert scale where greater scores reflected greater readiness to implement evidence-based practices (Organizational Readiness to Change Assessment [ORCA] Context Scale; Table 1). The readiness for change subscale of the ORCA Context Scale reflects the extent to which CSB opinion leaders: believe that the current intervention strategies can be improved, encourage and support changes in intervention strategies to improve client care, are willing to try new intervention strategies, and work cooperatively with senior leadership/clinical management to make appropriate changes.

**Results:** Multiple linear regression indicated that number of total clients ( $\beta=0.44, p=.011$ ) and number of autistic clients ( $\beta=-0.23, p=.013$ ) predicted approximately 31% of the variance in a CSB's readiness for change,  $F(2,19)=4.18, p=.031, R^2=.31$ . In hierarchical regression analyses, adding the

number of contracted ASD service providers to the model did not explain significant additional variance in readiness for change,  $\Delta R^2=0.01$ ,  $p=.611$ ; adding the number of ASD service providers within the CSB to the model, instead, also did not explain additional variance,  $\Delta R^2=0.002$ ,  $p=.831$ .

**Conclusions:** Results indicated that CSBs with a greater number of clients overall but with fewer autistic clients were more likely to endorse greater readiness for change and that the number of contracted providers or providers within their CSB that deliver ASD services did not affect readiness to change after accounting for the number of clients. This differing pattern between number of total clients and autistic clients on an organization's readiness to change indicates that there may be elements specific to ASD services (e.g., requirement of specialized training) that impact readiness to implement new MH-EBI for autistic clients. This provides evidence for the need to address organizational factors, such as readiness, to increase MH-EBI implementation in an effort to increase access to quality care for autistic clients.

**426.142 (Poster)** A Mixed-Method Evaluation of the Satisfaction and Acceptability of a Group-Based Parent Coaching Intervention Via Telehealth Based on the Early Start Denver Model

**L. Qu<sup>1</sup>, H. Chen<sup>2</sup>, H. L. Miller<sup>3</sup>, C. Colombi<sup>3</sup> and D. A. Ulrich<sup>1</sup>,** (1)School of Kinesiology, University of Michigan, Ann Arbor, MI, (2)Yangzhou University, Yangzhou, China, (3)Stella Maris Institute, Pisa, MI, Italy

**Background:**

The Early Start Denver Model (ESDM) is considered as an Evidence-based Practice (EBPs) designed for young children with Autism Spectrum Disorder (ASD) aged 1-5, using both developmental and relationship-building frameworks to promote overall development and autism-related outcomes (Rogers & Dawson, 2010). Research demonstrated the efficacy and effectiveness of ESDM both in university and in community settings (Vivanti et al., 2014, Vismara et al., 2009). However, evidence showing the positive outcomes of early intervention studies for children with ASD mainly conducted in university-based efficacy studies in high-income countries, research in low- and middle-income countries is severely limited due to lack of resources and trained professionals (Liao et al., 2021). Additional challenges exist in language and culture when implementing EBPs in the non-English-speaking countries. It is crucial to first examine the satisfaction and acceptability of parents when delivering an EBP in a non-English-speaking country with different language and culture, therefore providing a deeper understanding of the experience or needs of these families and informing future development, adoption and implementation of EBPs in an under-resourced population.

**Objectives:**

This study used a mixed method design to evaluate the experience of parents from China after receiving a 12 weeks group-based parent coaching intervention via Telehealth based on the Early Start Denver Model.

**Methods:**

This mixed method study used the post intervention data from a randomized controlled feasibility trial for a group-based parent coaching intervention in China via Telehealth. The quantitative data collected from satisfaction survey provided descriptive statistics to allow comparisons between intervention arms. The qualitative data collected from focus groups offered a detailed perception from parents with feedback and suggestions based on their 12-week experience of the intervention.

**Results:**

A total of 32 parents in the intervention completed the satisfaction survey and 24 out of them participated the focus group at the post intervention assessment. Parents across intervention groups rated the program favorably with average scores falling on the positive end of the scale in terms of satisfaction(4.6±.5), recommendation(4.6±.5), acceptability(4.4±.5), appropriateness(4.2±.5), feasibility(4.4±.5), and difficulty levels of the program(3.0±.8), etc. Qualitative themes confirmed and expanded the survey scores by adding rich detailed information about the program content and Telehealth delivery.

**Conclusions:**

Findings of this study showed parents in China had an overall positive perceptions about their experience of the group-based parent coaching intervention via Telehealth. The integration of both quantitative and qualitative results provided a nuanced understanding of the satisfaction and acceptability from parents of children with ASD in China. It may suggest the potential of using Telehealth as a service delivery option for the resource-limited countries, and more studies are urgently needed to develop and evaluate the feasibility and effectiveness of the EBPs in resource-limited communities.

**VIRTUAL POSTER SESSION — SERVICE DELIVERY/SYSTEMS OF CARE**

**526 - Service Delivery/Systems of Care --- (V)**

**526.073 (Virtual Poster)** A Scoping Review of Clinical Decision Support System (CDSS) Use in Autism and Other Neurodevelopmental Disorders  
**R. P. Sulek<sup>1</sup>, J. Robertson<sup>1</sup>, A. W. C. Liew<sup>2</sup>, G. Upson<sup>2</sup>, A. J. Whitehouse<sup>2</sup> and D. Trembath<sup>2</sup>,** (1)School of Health Sciences and Social Work, Griffith University, Brisbane, QLD, Australia, (2)School of Information and Communication Technology, Griffith University, Brisbane, QLD, Australia,

**Background:** The provision of clinical supports for all children during the early years can promote optimal developmental outcomes. However, for children with a diagnosis of autism and other neurodevelopmental conditions, a key challenge for clinicians is how to select supports that are most likely to be effective in meeting the therapy aims, from a range of available options. Several factors which contribute to this challenge include; the large number of available supports, the rapidly growing and changing evidence-base, a lack of tools to assist the systematic utilisation of evidence from clinical practice, and the degree of heterogeneity that exists in individual child and family characteristics and preferences around supports. A potential avenue for overcoming some of these challenges is through the application of Clinical Decision Support Systems (CDSS) in a clinical setting to enhance the capacity of health practitioners to make effective decisions when selecting supports for neurodiverse children, including those on the autism spectrum. The extent to which CDSS are currently utilised in this context, however, is relatively unknown.

**Objectives:** We conducted a scoping review of available literature to examine CDSS use for children on the autism spectrum, and with other neurodevelopmental conditions.

**Methods:** The review was conducted according to procedures outlined in the JBI manual for evidence synthesis and the Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping review (PRISMA-Scr) guidelines.

**Results:** Studies identified in online searches (n=287) were screened against eligibility criteria, with six articles meeting all inclusion criteria. All studies described the application of CDSS to support screening and surveillance of young children for neurodevelopmental conditions which included attention deficit hyperactivity disorder, autism, developmental disorders, and language disorders. Five of the included studies described one CDSS, the Child Health Improvement through Computer Automation system (CHICA), modified to include additional neurodevelopmental condition specific screening and surveillance modules. Overall, included studies reported favourable outcomes, with screening rates of children improved compared to control or baseline results, or strong agreement between CDSS screening results and a qualified clinician.

**Conclusions:** The scoping review highlights the seemingly limited application of CDSS in the context of autism and other neurodevelopmental disorders to date. Further, studies rarely reported on the experience of CDSS end users (both clinicians and clients). While CDSS provide a potentially useful addition to clinical practice, by providing ready access to updated to the latest empirical evidence, further research is needed to understand their potential for success within a clinical context if we are to see an increase in the adoption.

**526.074 (Virtual Poster)** Applying the Exploration, Preparation, Implementation, and Sustainment Framework to Adapt and Test an Executive Functioning Intervention for ASD for Mental Health Services

**K. S. Dickson<sup>1</sup>, T. Holt<sup>2</sup> and M. R. Ledoux<sup>3</sup>, (1)Child and Adolescent Services Research Center, San Diego, CA, (2)San Diego State University, San Diego, CA, (3)Graduate School of Education, University of California, Riverside, Riverside, CA**

---

**Background:** Approximately 70% to 80% of autistic individuals meet criteria for at least one-co-occurring psychiatric condition necessitating intervention or support,<sup>1</sup> resulting in the mental health service system playing a critical role caring for autistic youth.<sup>2</sup> Yet, mental health providers report limited autism-specific training and knowledge and instead cite frustration and challenges serving autistic children.<sup>3</sup> Therapists also report lower intention and self-efficacy with respect to using evidence-based mental health interventions for autistic individuals.<sup>3,4</sup> There is a need to apply implementation science theories and methods to improve the uptake and delivery of effective, evidence-based mental health services for autistic youth.

**Objectives:** The current study presents an application of the Exploration, Preparation, Implementation, Sustainment (EPIS; Aarons et al., 2011) framework to systematically adapt and test an evidence-based intervention (EBI) targeting executive functioning in mental health services; a corresponding implementation plan also was developed. EPIS details the influence of key outer (e.g., system, policy) and inner (e.g., organizational, provider) context factors and innovation factors (e.g., fit) on the implementation process.

**Methods:** Data were drawn from a multi-phase study applying EPIS to select and adapt a school-based executive functioning EBI for implementation in community-based mental health settings. The Powell et al., (2012; 2015) taxonomy of implementation strategies was also applied to develop a corresponding implementation plan. Data from an initial needs assessment with mental health therapists (n=43; 83% female; 45% Marriage and Family Therapists) was collected to examine EBI utility and feasibility, using a 5-point Likert scale (1-Strongly Disagree; 5-Strongly Agree). Perspectives regarding necessary adaptations for mental health services as well as EBI implementation determinants were collected to inform necessary adaptations and identify relevant implementation strategies for the proposed implementation plan.

**Results:** Consistent with EPIS, the targeted EBI was selected given its potential to optimally fit organizational constraints and meet both provider training and client clinical needs. This was confirmed by our initial needs assessment findings, with mental health providers rating the EBI as useful (M=3.8, SD=1.5), and a fit with their practice (M=3.3, SD=1.6) and agency (M=3.3, SD=1.5) EBI adaptations primarily centered around further optimizing EBI fit with mental health organizations, providers, clients, and their families. Adaptations included: adjusting the delivery format (group-based to individual), increased psychoeducation materials, addition of parent engagement strategies, and adjusting the length of treatment to accommodate session caps. Top EBI determinants reported included limited resources, skills, time needed to learn and use EBIs, EBI fit, and EBI complexity. In response, a corresponding implementation plan also was developed for the following strategies: use of a community-academic partnership, developing educational materials, promoting intervention adaptability and making training dynamic, including multiple training formats and ongoing supervision and consultation. A pilot test examining the feasibility, utility, and effectiveness of the adapted EBI and implementation plan is underway within community-based mental health settings.

Conclusions: Results indicate the utility of implementation science theories and frameworks to inform the development and adaptation of feasible, context-specific EBIs and implementation plans in service of improving the uptake and delivery of effective mental health services for autistic youth.

**526.075** (Virtual Poster) Clinical Diagnosis and Educational Eligibility: Is There a Match for Latino Children with Autism Spectrum Disorder? *E. Kaplon<sup>1</sup> and N. Reyes<sup>2</sup>, (1)1201 Larimer Street, University of Colorado Denver, Denver, CO, (2)JFK Partners, University of Colorado Anschutz Medical Campus, Aurora, CO*

---

**Background:** The prevalence of autism spectrum disorder (ASD) has increased in the last decade; however, discrepancies in identification and diagnosis in minority children continue to be widespread. Specifically, Latino children are diagnosed with ASD at lower rates than non-Latino peers in both clinical and educational settings. As the proportion of Latino students in schools and communities is expected to continue to grow, it is imperative to examine the experiences of Latino families and children with special needs. However, to the authors' knowledge, previous research has not investigated the intersection of clinical and educational disability evaluation for this group of children and simultaneously considers within-group differences.

**Objectives:** This research seeks to investigate the trends in educational disability identification for Latino children with clinical ASD by answering the following questions: (1) To what extent do Latino children with a diagnosis of ASD also have an ASD educational classification? (2) For children who did not have educational ASD, what educational disability was assigned? (3) Are children older than nine years of age more likely to have both a clinical and educational classification of ASD? (4) Are there differences in the educational disability classifications between Latino children from English Proficient (EP) families compared to families with Limited English Proficiency (LEP)?

**Methods:** This study included 131 medical records of Latino children, who were seen at public hospital in a large city in the western US. The criteria used to select these medical records included: children were Latinos, between the ages of 6 to 12 years, were seen at the hospital between 2015-2019, and had a diagnosis of ASD. The ASD diagnosis was extracted from their psychological reports by the first author and 20% of records were reviewed and compared by second author for accuracy.

**Results:** Of all participants, just 15% of Latino children were identified with educational ASD in schools. An additional 70% were identified with an educational disability other than ASD, with Speech-Language Impairment and Developmental Delay being the most common classifications. When comparing families of differing language proficiencies, children from LEP families were more likely to receive an ASD identification than their EP peers. There were no differences identified based on children's age.

**Conclusions:** These data revealed that Latino children with ASD are not likely to have an educational identification of ASD. That is, most Latino children who meet clinical criteria for a medical diagnosis of ASD receive services under an alternate disability category at school. While children from LEP families were significantly different from peers from EP families, both groups were found to follow similar trends. The reasons for this misidentification are likely to be complex, but it is likely that this misidentification results in having increased and unmet needs in Latino children with ASD. This indicates a need for further training and support of culturally responsive educational ASD evaluations. This research also highlights the need for effective communication between educational and clinical providers, so that each setting's unique evaluation results may be considered in assessment and intervention planning.

**526.076** (Virtual Poster) Critical Autism Theory within Disabilities Studies  
*M. E. Lefebvre, Educational sciences, Université de Montréal, Montréal, QC, Canada*

---

**Background:** Internationally, research in disability sciences on autism revolves mainly around autistic children. When autistic adults are the group of interest, the research methods are chosen often involve those around them, including the family and the intervening staff, but very rarely the autistic people themselves (Elias et al., 2016; Elias et al. White, 2018). Several studies in disability sciences observe the lack of representativeness of the heterogeneity of autism (Wehman et al., 2014; Woods et al., 2018). Several autistic researchers, since 2010, have carried out critical autism studies (CAS)(Woods et al., 2018).

**Objectives:** As part of this presentation, we wish to elaborate on CAS as a research movement still unknown in research through a literature review.

**Methods:** This literature review was carried on articles released since 2010. In fact, CAS emerged from the neurodiversity promoting movement in the UK, created in opposition to the biomedical model that attempts to normalize, reduce and eliminate as many as possible behaviors associated with autism (Kapp et al., 2013). For our descriptive analysis, we considered a total of 13 documents internationally.

**Results:** CAS is distinguished by three characteristics, namely the exploration of power dynamics, the development of discourses challenging the dominant medical model in autism research, and the theoretical and methodological creation of emancipatory approaches. Some authors argue that CAS necessarily calls into question the scientific validity of the diagnosis of autism spectrum disorder (ASD) (APA, 2013) and the need to use labels associated with this diagnosis in order to emphasize the experiences associated with recognizing oneself as an autistic person. Consistent with the extraction of the richness, depth, nuances, and complexity of the experience shared by the autistic participants through ethnographic methodologies (Mason, 2017), CAS are interdisciplinary in order to consider the intersectional nature of the experiences of people with autism, who live with other types of oppression related to gender and sexual orientation, ethnicity, their education, and socioeconomic status. Known through the perspectives of participants, adults with autism challenge stereotypes and stigma associated with being diagnosed with autism (Runswick-Cole et al., 2016; Woods, 2020)

**Conclusions:** CAS are emancipatory spaces for the voice of people with autism through their experiential narratives that they reappropriate, which can positively, through the co-construction of knowledge which positively influence: the results of research, recommendations in terms of services; educational, social, financial, residential, identity, family and professional needs; and policies and laws governing the services offered to adults with autism. In addition, by sharing their experiences, the discourse of adults with autism can shed light on the different oppressions and power dynamics of which they are victims on a daily basis, making it possible to become aware of them and to propose compensatory mechanisms (eg. political, social, financial) in society.

**526.077 (Virtual Poster)** Delivery of Psychotherapy to Autistic Youth: Treatment Approaches, Adaptations and Clinician Knowledge

A. Ibrahim<sup>1</sup>, F. H. Roudbarani<sup>1</sup>, C. Gallant<sup>2</sup>, B. B. Maddox<sup>2</sup> and J. A. Weiss<sup>1</sup>, (1)Psychology, York University, Toronto, ON, Canada, (2)University of Pennsylvania, Philadelphia, PA

---

**Background:** Despite the effectiveness of evidence-based mental health interventions for youth with autism (Weston et al., 2016), many barriers still exist in accessing psychotherapy (Adams & Young, 2020). Some common barriers include therapists' limited knowledge about autism, low levels of competence and confidence, or a lack of intervention adaptations to fit the needs of autistic youth.

**Objectives:** To understand the different treatment approaches and adaptations that mental health clinicians use with youth with mental health problems who are also autistic or have ADHD, and clinicians' perceived helpfulness of these approaches.

**Methods:** 611 publicly funded service providers who deliver psychotherapy to youth in Ontario, Canada, completed an online survey, in partnership with Children's Mental Health Ontario. Of this group, 561 noted providing psychotherapy to autistic clients and clients with ADHD. Participants selected the treatment approaches they use when working with youth with mental health problems with autism or with ADHD separately, from a list of 19 approaches and open-ended options. Participants rated each used treatment approach in terms of its helpfulness on a 10-point Likert scale (1 = *not at all helpful*; 10 = *extremely helpful*). Participants completed the Self-Rated Knowledge of Specific Mental Health Topics, a 6-item self-rated knowledge measure related to mental health topics, using a 5-point Likert scale (1 = *not at all knowledgeable*; 5 = *extremely knowledgeable*). Participants also identified the adaptations they used from a list of 14 adaptations for standard evidence-based interventions (Cooper et al., 2018). Items were counterbalanced with regard to autism and ADHD. We asked about clients with ADHD to be able to compare against service delivery for clients who have another neurodevelopmental diagnosis.

**Results:** Clinicians reported using a broad set of treatment approaches and selected similar treatments for co-occurring mental health conditions in clients with autism or with ADHD. Cognitive behaviour therapy had the highest endorsement for use with both autism (72%) and ADHD (85%), followed by solution-focused therapy (47% for autism and 64% for ADHD), family therapy (49% for autism and 55% for ADHD) and dialectical behavioural therapy (26% for autism and 36% for ADHD). For the majority of treatments, Wilcoxon signed-ranks tests indicated that participants rated the interventions as more helpful for clients with ADHD compared to autism, though in both cases, the average level indicated helpfulness. Paired sample t-tests indicated more total adaptations were used for clients with ADHD compared to autistic clients,  $t(558) = 2.55$   $p = 0.006$ , though it was a small effect size. Spearman's rho demonstrated a positive association between clinicians' average self-perceived knowledge and the number of adaptations used for both clients with autism ( $r_s(558) = 0.33$ ,  $p < 0.001$ ) and ADHD ( $r_s(558) = 0.34$ ,  $p < 0.001$ ).

**Conclusions:** Results indicate that despite mental health clinicians' use of similar treatment approaches for clients with autism or ADHD, many clinicians perceive them to be more helpful for clients with ADHD. Additionally, greater knowledge of how mental health topics can be understood within the context of autism or ADHD was linked to greater use of adaptations across treatments, for both groups.

**526.078 (Virtual Poster)** Enhanced Training Models for Capacity Building in Autism Service Delivery

A. Inge<sup>1</sup>, K. A. Register-Brown<sup>2</sup>, L. Kenworthy<sup>3</sup>, A. C. Armour<sup>4</sup>, N. Nadwodny<sup>5</sup>, Y. Myrick<sup>6</sup>, S. Khurana<sup>6</sup>, C. Morgan<sup>7</sup>, A. Ware<sup>8</sup> and A. Hastings<sup>9</sup>, (1)Center for Autism Spectrum Disorder, Children's National Hospital, Rockville, MD, (2)Center for Autism Spectrum Disorder, Children's National Hospital, Washington, DC, (3)Center for Autism Spectrum Disorders, Children's National Hospital, Washington, DC, (4)Boston Children's Hospital, Boston, MA, (5)DC Autism Parents, Washington, DC, (6)Pediatric Specialists of Virginia, Fairfax, VA, (7)Hearing and Speech Center, Children's National Hospital, Washington, DC, (8)Catholic University, Washington, DC, (9)Children's National Hospital, Washington, DC

---

**Background:** Capacity building in autism-related healthcare service delivery is a critical need. Nationwide and internationally, waitlists at autism specialty clinics have skyrocketed, largely due to the convergence of: 1) improved ASD awareness within communities, 2) referring providers' self-reported lack of training and competence in ASD diagnosis and management (McCormack et al., 2019), and 3) service disruptions and challenges related to the COVID-19 pandemic (Keehn et al., 2021). Physicians commonly report that they graduate into clinical practice without a useful toolkit to document autism diagnosis and initiate management (Fenikile et al., 2015). They therefore are forced to refer even children with unambiguous autistic traits to autism specialty clinics, despite the long wait they know this will entail. To improve provider competence and confidence and reduce specialty autism clinic referrals, enhanced training models are needed that include utilization of multidisciplinary approaches for skill building, ongoing professional mentoring, and community building among providers working with ASD children and families.

**Objectives:** Evaluate the feasibility, acceptability, and benefits of our virtual ECHO (Extension Community Healthcare Outcomes) Autism Clinics as part of an enhanced training model for building autism-related knowledge and competencies among trainees and providers using multidisciplinary approaches.

**Methods:** Consistent with the ECHO Autism model (Mazurek et al., 2018), we used video technology (Zoom platform) to hold virtual "clinics" to provide mentorship and a shared learning forum among autism specialists from six disciplines ("hub") and community providers ("spokes"). Clinics ran in 6-month sessions on a bimonthly basis and consisted of case presentations and discussion, and ASD specific didactics. Research participation was voluntary and consisted of Redcap survey completion at various study time points. Study data collected focused on participant demographics,

self-reported change in ASD-specific knowledge and self-efficacy in autism-related care, as well as overall acceptability/feasibility of the program. No-cost continuing education credits were provided for attendees and incentive pay was offered for participation in research surveys.

**Results:** Data is provided on three cohorts (2 completed, 1 ongoing) who participated in ECHO Autism programming over the course of 15 months. 101 participants (23% trainee, 75% professional, 2% unknown) from a total of nine medical and behavioral health disciplines (see Figure 1) attended at least one clinic. Program evaluation data available in a subset of participants (N=33) indicated 94% improved knowledge and 100% reported improved competency in autism-related care (67% reporting top ratings of improved competency). Race of participants was 3% Asian, 15% Black/African American, 73% White, 6% Other (reported as Middle Eastern), and 3% not reported; ethnicity was 3% Hispanic or Latino, 94% Not Hispanic or Latino, 3% Other. Feasibility/acceptability data was available on some of these participants (N=20) and all reported good satisfaction with the ECHO program as a mode of learning (N=20).

**Conclusions:** We found that our ECHO Autism program is a feasible and acceptable model for building autism-related knowledge and competencies through multidisciplinary mentoring and community building among professionals and trainees.

**526.079 (Virtual Poster)** Exploring the Experiences of Autistic Young Adults and Their Transitions into Employment

**C. Ballantyne<sup>1</sup>, C. B. McCann<sup>1</sup> and C. Wilson<sup>2</sup>,** (1)Department of Psychology, University of the West of Scotland, Paisley, United Kingdom, (2)School of Education, University of Strathclyde, Glasgow, United Kingdom

---

**Background:** Adults with autism spectrum disorder (ASD) are underrepresented in the workplace (National Autistic Society, 2016), and previous research has identified barriers which lead to poor employment outcomes for autistic people including: diagnostic characteristics of autism, personal, environmental, and discrimination related issues (Chiang, et al., 2013; Harmuth et al., 2018; Lindsay, et al., 2019). Research has suggested potential solutions and interventions to these barriers and negative outcomes but there has been little research into the personal experiences of autistic people when entering the world of work.

**Objectives:** This study aimed to explore the experiences of autistic young adults when entering the world of work and identifying if there were differences between those who have had higher education compared with those who have only had secondary school education.

**Methods:** This study used an interpretive qualitative design comprising of one to one semi structured interviews. Inclusion criteria were that participants must be young adults (under 26 years of age) with a diagnosis of ASD who had experience with employment, or who were looking for employment, at the time of the study. 5 participants (3 males, 2 female) volunteered to take part. One to one semi-structured interviews were conducted in private over the virtual medium of video and/or voice calls due to the COVID 19 global pandemic. These virtual interviews were conducted and recorded using either the software 'Microsoft Teams' or 'Webex'.

**Results:** Using thematic analysis three themes emerged from the data. These were: Disclosure, Influences of Education, and The Application Process. The first theme, Disclosure, the autistic young adults were found to be selective on whether, and when, they would disclose their diagnosis to an employer. These choices appeared to be based on both past disclosure experiences as well as each participant's perception of the potential consequences of disclosing. The second theme, Influences of Education, it was found that education had a multifaceted role on the experiences of autistic young adults entering employment. Participants in this study had differing views on the extent that education influenced their career paths. Educational qualifications appeared to have differing significance for each participant. The final theme, The Application Process it was found that, regardless of educational level, participants reported experiencing difficulties. Online applications were identified as a particular issue as participants perceived them as a lengthy process, with differences in application websites resulting in each application meaning starting a new process.

**Conclusions:** The findings of this study have implications for employers in terms of the need to develop autism friendly application and interview processes, how they respond to disclosures of an autism diagnosis, and providing tailored workplace supports. In addition, the need for schools to support autistic young people in preparing for all aspects of the process of securing employment was highlighted. The importance of a combination of qualifications and work experience was identified as essential in leading to positive employment outcomes.

**526.080 (Virtual Poster)** Healthcare Access of Language Minorities with Autism: The Case of English Official Language Minority Language Speakers in Quebec, Canada

**N. Amantayev<sup>1</sup> and A. Nadig<sup>2</sup>,** (1)Communication Sciences and Disorders, McGill University, Montreal, QC, Canada, (2)School of Communication Sciences and Disorders, McGill University, Montreal, QC, Canada

---

**Background:** English and French are both official languages in Canada. Yet, official language minorities (English speakers in Quebec, French speakers in other provinces) face negative health outcomes, including worse subjective health status (1) and more unmet health needs (2). There are critical differences between official and non-official minority language, or immigrant, groups (3), but they share common barriers to healthcare access. Reviews of healthcare access by immigrants in Canada cite language as a primary barrier (4, 5). Qualitative research with Canadian immigrants who have a child with autism have echoed language as a key barrier (6, 7). In US immigrant families who are language minorities, language barriers negatively impact access to autism diagnostic and intervention services (8) as well as the quality of autism services (9).

**Objectives:** Little intersectional data is available on language minorities in Canada with intensive service needs, as is the case for individuals on the autism spectrum. We conducted an online survey examining healthcare and social service access among English (minority language) speakers from Quebec, French (majority language) speakers from Quebec, and English speakers from elsewhere in Canada (majority language speakers) who are autistic adults or someone who cares for a family member with autism.

**Methods:** We analyze responses from 111 participants (51 English - Quebec, 30 French - Quebec, 30 English - rest of Canada, data collection ongoing). Participants self-identified as being autistic, someone who cares for a family member with autism, or both. Surveys were conducted online using LimeSurvey, in either English or French.

Access to primary healthcare was assessed by an adaptation of the Official Language Minority Healthcare Questionnaire (10). Access to specialized autism services was measured by the Family Needs Survey-Revised (11) to evaluate both access (needs met) and unmet needs in multiple healthcare and service domains commonly accessed by people on the autism spectrum.

**Results:** We present the result from a summary question "...How well are your language needs met in obtaining services in your official language of choice (i.e., English)?" Responses were on a likert scale from 1 "clearly not met" to 5 "fully met." Responses are shown in Figure 1. There was a significant effect of language status on language needs being met when obtaining services [ $p = .000$ , English speakers from Quebec ( $M = 3.41$ ,  $SD = 1.31$ ), French speakers from Quebec ( $M = 4.46$ ,  $SD = 1.16$ ), and English speakers from elsewhere in Canada ( $M = 3.90$ ,  $SD = .98$ )]. Post hoc comparisons indicated that satisfaction was lower in English speakers from Quebec than in French speakers from Quebec. Analysis of open-ended responses, and how demographic factors may interact with needs and access, is in progress.

**Conclusions:** This preliminary finding suggests that English official language minorities in Quebec who are autistic, or have a family member with autism, have more difficulty accessing satisfactory services than majority language speakers in the same province. By identifying barriers to access, this project aims to improve services and outcomes for people on the autism spectrum who are language minorities.

**526.081 (Virtual Poster)** Innovation in Access to Early Interventions for ASD in Kenya: Neurodevelopmental Early Intervention Scholarship  
**W. L. Owotoki<sup>1</sup>, M. V. Marques<sup>2</sup>, J. Mathaga<sup>3</sup>, J. Muiruri<sup>3</sup> and P. O. Owotoki<sup>1</sup>,** (1)Vitafluence.ai, Kronberg im Taunus, Germany, (2)Arthur's Dream Autism Trust (ADAT Foundation), Nairobi, Kenya, (3)Kenya Autism Alliance, Nairobi, Kenya

**Background:** Autism spectrum disorder (ASD) is a neurodevelopmental disorder generally characterized by a combination of impairments in social communication and interactions as well as repetitive and restrictive behaviors. According to the CDC, ASD affects 1 in 54 American children, whereas global prevalence is highly variable (1-2% of the population) based on socio-cultural and economic factors. High income countries may contend with long waiting times to diagnosis, while low/middle income countries deal with insufficient access to information, diagnoses and therapies. Here, logistics to therapy centres and finances for therapy are especially cumbersome; all now further exacerbated by the COVID-19 pandemic. Kenya has one healthcare professional for 41666 inhabitants and one healthcare facility for 70922 people - significantly less than the WHO recommended 4.45 healthcare professionals per 1000 people. For neurological conditions, Nairobi, the capital city, has one neurodevelopmental paediatrician for 1.5 million inhabitants. To achieve equality in healthcare and global well-being, barriers to early diagnosis and multi-professional therapy must be removed. Digital health solutions are expected to fill those gaps and shorten the distance between patients and practitioners but may not be affordable for families in financial need.

**Objectives:** To present an innovative solution tackling the financial and logistical gap for children with ASD in need of multi-professional early interventions and offer high quality and affordable therapy to families struggling financially in Kenya through a scholarship and a digital therapeutic platform.

**Methods:** We report on a Neurodevelopmental Early Intervention Scholarship (NEIS). Families were invited to apply for partial financial support to access therapy for their children (0-18 years) with ASD or related neurodevelopmental disorders but not currently receiving therapy. Therapeutic modalities offered face-to-face or via a digital therapeutic platform included occupational, speech and language, music, art and behavioural therapies.

**Results:** NEIS was launched in April 2021 in Kenya running to October 2021. Of 151 applicants, 84 reported an ASD diagnosis while 67 either reported other neurodevelopmental conditions or had not received diagnosis. Of 125 children offered NEIS, 61 (39 with ASD) proceeded to access multidisciplinary therapy face-to-face or via a digital platform. Our data analysis ( $n=39$ ) shows that 82% of the children receiving therapy are boys; 84% of applicants were female guardians; 51% of the carers reported unemployment, unstable work or closed businesses; 28% of the families reported financial issues due to COVID-19. Based on self-reported evidence following consistent therapy, carers and therapists report: reduced tantrums and echolalia; improved attention, speech, reading and counting skills; progress in social interaction; refined motor coordination skills; decreased touch sensibility; and improved autonomy for daily routines.

**Conclusions:** In five months, 61 children have received therapeutic support after financial and logistic needs were met. We report that innovatively minimising the logistical and financial barriers enables carers to focus on their children's therapies, while also ensuring therapy adherence. Carers who have consistently adhered to therapy for their children observed the anecdotal evidence reported above. We can conclude that the NEIS program enabled children living with ASD to receive consistent non-medicinal therapies thus improving their quality of life.

**526.082 (Virtual Poster)** Online Social Support By and for Autistic Adults – Assessing Needs and Interest  
**M. Désormeaux-Moreau<sup>1</sup>, I. Courcy<sup>2</sup> and M. Couture<sup>3</sup>,** (1)École de réadaptation, Université de Sherbrooke, Sherbrooke, QC, Canada, (2)CIUSSS Nord-de-l'Île-de-Montréal, Montréal, QC, Canada, (3)Rehabilitation, Université de Sherbrooke, Sherbrooke, QC, Canada

**Background:** In Quebec, Canada, many autistic adults are neglected by formal support services. Meanwhile, online exchange groups are numerous and initiatives aiming to provide online support by and for autistic adults have been implemented all around the world.

**Objectives:** This research aimed to assess Autistic adults' needs and interest for online social support offered by and for Autistic adults, in order to inform the implementation of such a service.

**Methods:** Participants ( $\geq 18$  years old Autistic, either formally and professionally identified or self-identified) were recruited through social media. A survey was launched using an online questionnaire between July 5 and September 15, 2021. The questionnaire (completion  $\approx 20$  min.) comprised four sections: 1) sociodemographic; 2) actual access and limits to access, source and frequency of use of current social support, either formal or informal; 3) specific area of needs related to social support; and 4) interest in accessing an online platform to provide or receive social support by and for autistic peers. Data analysis relied on descriptive statistical tests.

**Results:** 116 Autistic adults responded to the survey. Participants were between 18 and 64 years of age ( $M = 37$  years old) and most of them have been professionally identified as Autistic (79%). Use of formal social support services was limited due to their inadequacy with participants' needs and preferences (32.0%), their cost (30.9%), and obstacles in their access (47.4%). Meanwhile, most participants expressed receiving informal social support a few times a month (36.4%) or a few times a week (23.2%), either from friends (50.0%), a partner (49.0%) or a family member (34.4%). Participants mentioned needing social support in regards with own life experiences (73.5%), professional or academic life (57.1%), their place and role within society (57.1%), family life and children (48.0%), relationships with friends (45.9%), couple or romantic relationships (41.8%). Finally, among participants, 80.9% were mostly to very favourable to using an online support service that would be offered to Autistic by Autistic, as well as to volunteering to offer such a support (62.2%). Regarding the communication means through which such social support could be offered, participants mentioned they would appreciate an online chat (72.3%), videoconference (51.8%), emails (49.4%), telephone (44.6%) and text messages (43.4%).

**Conclusions:** Findings show even though participants did receive social support from people within their personal social network, various obstacles limit Autistic's access to social support, in addition to not addressing autistic individuals' needs and preferences. Findings also suggest there is a real need for diversifying the social support offered to Autistic individuals. According to this study's participants, an online social support service for and by Autistic adults would receive a very strong support by the community. Moreover, findings do not suggest any challenge in reaching potential users nor in recruiting volunteers.

**526.083 (Virtual Poster)** Parental and Provider Satisfaction with Teletherapy Services for Children with Autism Spectrum Disorder (ASD) during COVID-19 Pandemic.

**K. Sengupta<sup>a</sup>** and **S. Roy<sup>b</sup>**, (1)Ummeed Child Development Center, Mumbai, Maharashtra, INDIA, (2)Developmental Pediatrics, Ummeed Child Development Center, Mumbai, India

**Background:** Teletherapy usage in pre-pandemic times had been limited in LMICs like India, due to varied factors, including provider limitations and end-user scepticism. The COVID-19 pandemic forced providers to increase their telehealth services in lieu of traditional in-person patient encounters.

**Objectives:** The current study's primary objectives are to measure satisfaction among parents of children with autism spectrum disorder (ASD) and providers in urban India seeking and providing teletherapy services.

**Methods:** A multi-centric cross-sectional observational study was conducted at three child development centres in metropolitan Mumbai in January-February 2021. An online survey questionnaire adapted and translated from the Parent and Therapist Satisfaction Questionnaire (Constantinescu, 2012) was used to measure parent satisfaction across seven domains- Perceived Efficiency, Cost-effectiveness, Reliability, Perceived Ease of Use, Usefulness, Quality of interaction and Intention to use. Parents of children with ASD who had participated in a minimum of one telehealth therapy session and multi-disciplinary therapists who had provided a minimum of one teletherapy session and completed the online survey questionnaire were included. Descriptive and analytical analyses were employed to determine the satisfaction level with teletherapy usage among parents and clinical or demographic predictors of satisfaction scores.

**Results:**

A total of 80 caregivers and 38 therapists were considered for data analysis. Demographic data and satisfaction scores were recorded across the seven satisfaction domains, and an overall score was calculated. 93.75% of the respondents to the Parent Questionnaire were mothers, with the mean age of children receiving teletherapy  $5.78 \text{ years} \pm 2.42$ , and 36.25% from outside Mumbai. The overall mean parental satisfaction score was  $3.55 \pm 0.49$  (on a Likert scale of 1-5, with 1=Strongly Disagree and 5=Strongly Agree), with highest scores (3.8) for cost-effectiveness and lowest (3.2) for intention to use. Multivariate regression revealed significant predictors of overall parental satisfaction being non-Mumbai residents ( $p=0.004$ ), and lower/ no fee charged ( $p=0.004$ ) for the session.

Therapists' mean age was  $31.64 \pm 7.98$  years, females (97.37%), with  $7.47 \pm 7.01$  years of experience. Therapists included Occupational therapists (34.21%), Autism interventionists (21.05%), Speech therapists (13.16%) and others (31.58%). The majority (89.47%) had provided in-person services earlier. The therapists' overall mean satisfaction score was 3.32, with the highest (3.84) for cost-effectiveness and lowest for perceived ease of use (2.86). Multiple regression showed that not having provided in-person services before the pandemic had a significant adverse effect on satisfaction scores ( $t = -2.33$ ,  $p=0.026$ ).

**Conclusions:** COVID-19 has forced parents and providers to use telehealth services for ASD. Telehealth services have increased access to therapies for people living in remote areas with limited access to services. In addition, parents were more satisfied when telehealth services were subsidized compared to in-person therapy. On the other hand, therapists' satisfaction levels were comparatively lower, with the ease of use perceived as least satisfactory. While teletherapy has emerged as a feasible solution to increase access to services in under-served areas, conventional in-person services appear to be preferable when accessible. Implications of the findings on how telehealth services can be delivered in the future will be discussed.

**526.084** (Virtual Poster) Predicting Student Success of Autistic Students in Higher Education

**T. C. Bakker<sup>1</sup>**, A. C. Krabbendam<sup>1</sup>, S. Bhulai<sup>2</sup>, M. Meeter<sup>3</sup> and S. Begeer<sup>4</sup>, (1)*Clinical Developmental Psychology, Vrije Universiteit Amsterdam, Amsterdam, Netherlands*, (2)*Mathematics, Vrije Universiteit Amsterdam, Amsterdam, Netherlands*, (3)*Educational and Family Studies, Vrije Universiteit Amsterdam, Amsterdam, Netherlands*, (4)*VU University Amsterdam, Amsterdam, Netherlands*

---

**Background:** Individuals with autism increasingly enroll in universities, but we know little about predictors for success. This study developed predictive models for academic success after one, two, and three bachelor years of autistic students (n = 101) in comparison to students with other health conditions (n = 2,465) and students with no health conditions (n = 25,077).

**Objectives:** Predictive modeling is a machine learning technique to develop models that predict future observations and evaluate their predictive power. Predictive modeling plays a vital role in theory building. It helps to discover new predictive measures and create new hypotheses, find improvements to existing explanatory models, compare competing theories, and quantify the level of predictability by benchmarking predictive accuracy (Shmueli & Koppius, 2011). The number of studies on the application of predictive algorithms in the field of autism is growing (Hyde et al., 2019; Thabtah, 2018; Vabalas et al., 2019), in particular related to diagnostic or physical aspects of autism. However, its use in educational studies on autistic students is virtually absent (Madaus et al., 2020; Morgan, 2018). We studied the feasibility of predictive modeling of academic success of autistic students and the importance of success predictors to improve theory building.

**Methods:** Our sample included 27,643 first-year, full-time students in 54 bachelor programs at a major university in the Netherlands from 2010 to 2016 (M = 19 years of age, 55.0% female) with study measures from the university's student information system. The study population consisted of (1) 101 students with a clinical diagnosis of ASD (0.37%), (2) 2,465 students with other conditions such as ADD/ADHD and dyslexia (8.92%), and (3) 25,077 students with no recorded conditions (90.72%). Propensity score weighting was applied to balance outcomes. We built and trained weighted models that cover a wide range of possibilities in predictive modeling for multi-class outcomes: classification and regression trees, random forest, neural network, boosting, and bagging models.

**Results:** The research showed that autistic students' academic success was predictable and even more accurate than their peers' success predictions. For first-year success, study choice issues were the most important predictors (parallel program and application timing). They had more impact than issues with participation in pre-education and academic performance (age and average grades). Delays at the beginning of their studies predicted delays in their bachelor's program.

**Conclusions:** This innovative methodological approach demonstrates that the student success of autistic students can be predicted. Especially in the second and third years, different predictors should be applied compared to their peers to prevent dropout or study delay of autistic students. Autistic students with non-regular pre-educational study paths are more prone to dropout or study delays. Predictors to identify these risks, age and missingness of average grades in math in secondary education, are easy to register and collect in any student administration and can be used to develop appropriate early warning systems from the start of any study program.

**526.085** (Virtual Poster) Professional Development Programs for Community Professionals Who Support Autistic People: Process and Outcomes

**K. D. Bopp<sup>1</sup>**, S. Hu<sup>2</sup> and P. Mirenda<sup>3</sup>, (1)*Centre for Interdisciplinary Research and Collaboration in Autism, University of BC, Vancouver, BC, Canada*, (2)*Centre for Interdisciplinary Research and Collaboration in Autism, University of BC, Canada, Vancouver, BC, Canada*, (3)*University of British Columbia, Vancouver, BC, Canada*

---

**Background:** There is a need for more professional development to increase inclusion of autistic and neurodivergent individuals in the community. Toward this end, four on-line, self-paced, freely accessible professional development programs were developed and evaluated for the service sectors of human resources/employers; primary care providers/physicians; dental professionals; and childcare providers.

**Objectives:** The goal of the professional development programs is to teach professionals in each field to adjust their practices to better support, accept and include autistic and neurodivergent individuals in their practice.

**Methods:** Autistic individuals and their family members were actively involved in the development and creation of each professional development program. To develop the content for the program Autism and Neurodiversity in the Workplace, for example, a work environment survey was completed by over 170 autistic individuals from across Canada. Autistic individuals were also interviewed on camera and shared their personal experiences and opinions. There are five modules in the workplace program: Understanding autism in the workplace; Benefits of hiring inclusively; Creating a diverse and inclusive workplace and culture; Inclusive recruitment strategies; and Inclusive employment retention strategies. To evaluate the effectiveness of each program, registrants completed a pre and post survey to examine if the program led to increased knowledge and behavioral practice change.

**Results:** To date, results are available for the Autism and Neurodiversity in the Workplace program only. Over 1,700 people have registered for the program, 957 have completed the pre-survey, and between 352 and 550 have completed the post surveys for each of the five modules.

Respondents reported that their ability to support autistic employees increased from 26% to 75%. They also reported that their knowledge in each topic area increased as follows: knowledge on the benefits of hiring inclusively and the strengths of autistic employees increased from 28% to 72%; knowledge on the strategies to create inclusive work environments increased from 27% to 69%; knowledge on strategies to attract, recruit and interview autistic candidates increased from 7% to 73%; and knowledge on the cost and range of accommodation strategies to support onboarding and day-to-day success increased from 10% to 77%. In addition, 94% of respondents reported that they are likely or very likely to incorporate the

strategies learned into their professional work. The program was rated by 97% of respondents as somewhat or very useful to the respondent's work, and 94% of respondents rated the quality of the information as high or very high.

**Conclusions:** The preliminary results reveal that these professional development programs have the potential to significantly increase professionals' understanding and knowledge about how to better support and include autistic individuals in a variety of service sectors. They also reveal that these free online, self-paced programs have the potential to result in practice change.

**526.086 (Virtual Poster)** Testing a Theory of Implementation Leadership and Climate across Autism Evidence-Based Interventions of Varying Complexity

**J. Locke<sup>1</sup>** and **N. Williams<sup>2</sup>**, (1)*Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA*, (2)*Boise State University, Boise, ID*

---

**Background:** Evidence-based practices (EBPs) are infrequently delivered in community settings such as public schools. When they are, fidelity to their essential components often is poor. Diminished fidelity to EBPs reduces their effectiveness. Consequently, identifying factors that influence providers' fidelity to EBPs, and developing implementation strategies that target those factors, holds significant promise to improve the quality and outcomes for autistic youth. Implementation theories have emphasized the importance of first-level leaders who manage or supervise direct service providers. Research suggests first-level leaders (i.e., those who manage providers) can improve the delivery of EBPs through focused implementation leadership behaviors that create an organizational climate for EBP implementation. However, this work has been criticized for poor articulation of boundary conditions that may attenuate leadership and climate's influence.

**Objectives:** This study tests Aarons and Ehrhart's (2014) theory of EBP implementation leadership and climate in schools that serve autistic youth, focusing on how intervention complexity may modify the effects of these antecedents on observed educator fidelity. This study tests the hypothesis that the predictions of EBP implementation leadership and climate theory will hold for observed fidelity to a complex EBP for autism—pivotal response training (PRT)—but not for less complex interventions—discrete trial training (DTT) and visual schedules (VS)—delivered in public schools.

**Methods:** Teachers and staff (n=225) in kindergarten to third-grade autism support classrooms in 65 schools assessed their principals' EBP implementation leadership and school EBP implementation climate prior to the school year. Mid-school year, trained observers rated educator fidelity to all three interventions. Expert raters confirmed PRT was significantly more complex than DTT or VS.

**Results:** For each EBP, a set of simultaneous linear regression models were fit, estimating (a) the association of principal EBP implementation leadership with school EBP implementation climate; and (b) the association of school EBP implementation climate with educator fidelity to one of the three EBPs (i.e., PRT, DTT, or VS) controlling for EBP implementation leadership. Results indicated that principals' increased frequency of EBP implementation leadership predicted higher school EBP implementation climate, which in turn predicted higher educator fidelity to PRT, but not DTT or VS. Comparing principals whose EBP implementation leadership was +/- one standard deviation from the mean, there was a significant indirect association of EBP implementation leadership with PRT fidelity through EBP implementation climate ( $d = 0.49$ , 95% CI = 0.04 to 0.93).

**Conclusions:** Building on research from organizational psychology and management, this study confirms that a theory of implementation leadership and climate explained variation in observed fidelity to a complex EBP (PRT) in public schools. These results answer the call for research testing leadership and climate theory with specific EBPs and clinical populations using observed fidelity. Further, these findings apply these theories within a new population of settings (i.e., schools), leaders (i.e., principals), and providers (i.e., educators) and identified a boundary condition that may modify the association between EBP implementation leadership, climate, and fidelity, namely, the EBP's level of complexity. This study suggests strategies that target EBP implementation leadership and climate may support fidelity to complex behavioral interventions.

**526.087 (Virtual Poster)** Understanding Autistic Parents' Experiences and Relationships with Schools

**A. S. Rabba<sup>1</sup>**, **J. A. Smith<sup>1</sup>**, **G. Hall<sup>1</sup>**, **M. Heyworth<sup>1,2</sup>**, **W. Lawson<sup>1</sup>**, **R. Lilley<sup>1</sup>**, **P. Datta<sup>1</sup>**, **E. Goodall<sup>1</sup>**, **V. Alexander<sup>3</sup>**, **N. Syeda<sup>3</sup>** and **E. Pellicano<sup>1</sup>**, (1)*Macquarie School of Education, Macquarie University, Sydney, NSW, Australia*, (2)*Reframing Autism, Sydney, NSW, Australia*, (3)*Positive Partnerships, Sydney, NSW, Australia*

---

**Background:** Positive partnerships between families and schools can substantially improve engagement with learning as well as success in and out of school. Such family-school partnerships are particularly important for autistic children and young people, who are at increased likelihood for poor academic and mental health outcomes. Despite this knowledge, virtually nothing is known about *autistic parents'* experiences of navigating school for their autistic children and how autistic parents navigate home-school partnerships, and the impact this has on their families and themselves.

**Objectives:** This study therefore aimed to (1) understand autistic parents' views and experiences of interactions with schools for their autistic child(ren), and (2) identify the potential impact of these interactions on themselves and their family.

**Methods:** We adopted a participatory approach where autistic and non-autistic researchers worked together as a team, including an advisory group of four autistic parents with autistic children, who guided the research. We also used a qualitative approach where 30 autistic mothers took part in semi-structured interviews conducted by an autistic researcher to gain a rich understanding of their and their child's experiences of school, of navigating the school system, of their relationships with school staff and community, and the impact this has on them. We are in the process of analysing the data, using reflexive thematic analysis, adopting an inductive approach within an essentialist framework to identify key themes and subthemes.

**Results:** Families with positive home-school partnership experiences spoke of having teachers and school staff who valued autistic parental insight, a school culture that respects diversity and demonstrates acceptance, open, honest, and authentic communication between parents and teachers, and

effective leadership in actioning inclusion and accommodations. Families who recounted negative experiences instead highlighted, teachers and school leadership with limited knowledge about autism, situations in which they and their children did not feel safe at school, imposed generic accommodations that did not reflect individual needs, and broken trust between parents and teachers. These experiences were often highly distressing and had a negative impact on the mental health and wellbeing of the entire family.

Conclusions: Autistic mothers reported wanting to see their autistic children enjoy the same social and curriculum opportunities as non-autistic children; to feel safe and secure at school and be understood and respected for who they are. They also emphasised wanting that for themselves. Our findings suggest that, although there are successful examples of home-school partnerships already, schools need to be more flexible, adaptive, collaborative and caring in their approach to supporting autistic families.

**526.088 (Virtual Poster) Understanding Implementation Readiness in School Systems in California**

Y. Yu<sup>1</sup>, A. C. Stahmer<sup>2</sup>, M. Melgarejo<sup>3</sup>, T. Holt<sup>4</sup>, J. Li<sup>5</sup>, P. Schetter<sup>6</sup>, S. Park<sup>6</sup>, G. S. Young<sup>6</sup> and J. Suhrheinrich<sup>1</sup>, (1)UC Davis MIND institute, Sacramento, CA, (2)UC Davis MIND Institute, University of California, Davis, Sacramento, CA, (3)San Diego State University, San Diego, CA, (4)UC Davis, Sacramento, CA, (5)UC Davis MIND, Sacramento, CA, (6)Psychiatry and Behavioral Sciences, University of California at Davis, MIND Institute, Sacramento, CA

---

Background: Most state systems have limited capacity for scaling up interventions that lead to meaningful improvement in student outcomes (Fixsen et al., 2013). Effectively scaling up Evidence Based Practices (EBP) use for students with autism is challenging, given the distributed leadership and complex organizational structures within special education. Implementation science research has identified mechanisms related to successful implementation including implementation climate, leadership, and attitudes toward EBP. Examining these mechanisms is a critical step in evaluating implementation readiness at various levels of the system. Outcomes may inform selection of implementation strategies to support state-wide scale up.

Objectives: To examine implementation climate, leadership, and attitudes toward EBP across special education structures and providers.

Methods: California school personnel completed the *Implementation Climate Scale (ICS)*, *Implementation Leadership Scale (ILS)*, and the *Evidence-Based Practice Attitude Scale (EPBAS)*. Data were collected at the Special Education Local Plan Area (SELPA), County Office of Education (COE), District and School levels from SELPA directors (n=153), school and district administrators (n=270), specialists (n=373), teachers (n=873), paraprofessionals (n=231) and other direct service providers (n=373). Participants represent 1,379 schools, 473 districts and 132 SELPAs. Participants provided data related to their direct leaders and their school, district, and/or SELPA depending on their role. Multilevel modeling was conducted to characterize implementation readiness across levels of special education structures. Comparisons were made by employment setting (school, district, COE, SELPA) and SELPA type (multi- or single-district).

Results: Overall, implementation climate and leadership scores are low in the education system across levels. For ICS, personnel rate SELPA significantly higher than COE, districts or schools, and COE higher than schools or districts. In terms of ILS, leaders in all settings rated themselves significantly higher than employees rated them. In general, district leaders were rated as having lower implementation leadership by their employees than any of the other settings. School leaders rated themselves significantly lower than the other leaders on most ILS subscales. Attitudes toward EBP were moderate overall, with those working in schools having the poorest ratings (compared to district or SELPA). Specialists/trainers had the highest scores on the EPBAS compared to administrators, teachers and paraprofessionals.

Conclusions: In general, school personnel have moderate attitudes toward the use of EBP for students with ASD. Teachers' self-report of EBP attitudes were similar to those from a California sample over a decade ago (Stahmer & Aarons, 2009), potentially indicating limited change in attitudes over time. Specialists/trainers had the most positive attitudes, which is promising given they are likely to be providing professional development related to ASD EBP. Implementation climate and leadership are low across levels, indicating a need to provide training and support to facilitate effective EBP use and scale up. SELPA personnel rated their

**526.089 (Virtual Poster) Understanding of the Police Caution in the Autistic Population**

S. Anns<sup>1</sup>, S. Lane<sup>1</sup>, R. Cassidy<sup>1</sup>, A. Green<sup>1</sup>, C. Dando<sup>2</sup> and R. Milne<sup>3</sup>, (1)School of Psychology, University of Sussex, Brighton, United Kingdom, (2)Psychology, University of Westminster, London, United Kingdom, (3)Centre of Forensic Interviewing, Institute of Criminal Justice Studies, University of Portsmouth, Portsmouth, United Kingdom

---

**Background:**

Research indicates that some offenders, students and even police officers (Clare et al., 1998; Fenner et al., 2002; Shepherd et al., 1995) do not always fully understand the police caution: a statement of rights given to those suspected of criminal behaviour. Misunderstandings can have significant ramifications: failure to guard against self-incrimination and failure to seek legal advice, for example. Comprehension of the caution in an autistic population is unknown, yet they may experience additional challenges due to atypicalities in information processing, metacognition, working memory, episodic future thinking and compliance (Chandler et al., 2018; Grainger et al., 2014; Kercood, et al., 2014; Lind et al., 2014; Williams et al., 2015)

**Objectives:**

The objective of this study was to investigate understanding of the England and Wales police caution statement in autistic adults compared to typically developed individuals. In doing so we considered i) whether comprehension was impacted by delivery mode (written vs. verbal) and ii) the structure in which it was delivered (as a whole, in full or sentence by sentence).

## Methods:

Seventy-six adults took part in the study. Inclusion criteria was i) resident in the UK, ii) native English speaker, iii) aged over 18 years and iv) with a verbal IQ score of 90 or above (WASI). Group inclusion criteria for the autistic group (n=26) was a T score of <60 on the Social Responsiveness Scale and for the non-autistic group (n=50) >60.

Comprehension of the police caution was assessed across the two adult participant groups (Autistic; Typically developed) using a non-verbal cartoon comprehension test comprising cartoon images depicting 10 true or false scenarios (CCT). There were two conditions, each with two levels: i) Mode of delivery (verbal vs written) and ii) structure of delivery (sentence-by-sentence vs full). Participants participated via Zoom video conferencing platform, which was also used to complete the Pyramids and Palm Trees Test (to check non-verbal lexical semantic ability) followed by the WASI verbal subtests.

## Results:

Preliminary findings revealed that autistic individuals had a significantly poorer understanding of the police caution than non-autistic individuals  $F(1, 72) = 6.67, p = .01, \eta^2 = .09$ . No significant differences emerged in understanding of the police caution as a function of modality but understanding was significantly better when the caution was presented in full rather than sentence-by-sentence across both groups. More data needs to be collected to confirm these latter findings.

## Conclusions:

Interim findings indicate autistic individuals may be vulnerable to misunderstanding the caution and consequently, may require further support such as provision in a written format. Policy makers may wish to consider how they present the police caution to those suspected of criminality to ensure their rights are fully understood.

**526.090** (*Virtual Poster*) "I Wouldn't Discount How Hard We Have Tried" Understanding the Experiences of Chinese Parents of Autistic Children As They Navigate School

**J. A. Smith<sup>1</sup>**, A. S. Rabba<sup>1</sup>, E. Dresens<sup>2</sup>, P. Lee<sup>2</sup>, N. Syeda<sup>2</sup>, G. Hall<sup>1</sup>, M. Heyworth<sup>1,3</sup>, R. Lilley<sup>1</sup>, P. Datta<sup>1</sup>, W. Lawson<sup>1</sup> and E. Pellicano<sup>1</sup>, (1)Macquarie School of Education, Macquarie University, Sydney, NSW, Australia, (2)Positive Partnerships, Sydney, NSW, Australia, (3)Reframing Autism, Sydney, NSW, Australia

Background: Developing effective partnerships between parents and schools is especially important for autistic students since they can benefit from learning supports and consistent approaches across contexts. Yet, parents of autistic children have often reported adversarial relationships with professionals and a lack of two-way partnerships. Minority background families, including Culturally and Linguistically Diverse families, are at greater risk of being marginalised, including in schools. But we know exceedingly little about these families' experiences, and critically of how best to support relationships with schools. The views of Chinese migrant families with autistic children are particularly scarce in Australia, even though Australia is home to more people of Chinese ancestry than any country outside Asia.

Objectives: This research therefore sought to understand in depth Chinese parents' views and experiences of interactions with Australian schools for their autistic child(ren). It also may shed light on how cultural differences and expectations influence home-school partnerships in general.

Methods: We adopted a participatory approach in which autistic and non-autistic researchers worked together as a team, and an advisory group, including five Chinese parents of autistic children, also steered this research. We also adopted a qualitative approach in which 16 Chinese parents (14 mothers, two fathers;  $M_{age} = 43$  years, range = 31 – 56) took part in semi-structured interviews conducted by a Chinese collaborator in Mandarin, Cantonese or English. A separate interpreter provided a simultaneous English translation of Cantonese and Mandarin interviews for transcription purposes. Interview topics included understanding their and their child's experiences of school, navigating the school system, and of their relationships with school staff. We used reflexive thematic analysis to analyse the data.

Results: Most parents had one autistic child (n=13, 81.3%); three families had two autistic children ( $M_{age}=8$ , range 2-17). Most children were in mainstream schools (n=10, 52.6%), with four children in kindergarten (21.1%), and the remainder (n=5, 26.3%) in disability-specific schools or dual schooling (i.e., both mainstream and specialist). We identified five themes, including: (1) Parents were deeply devoted to their children, which included having high expectations of children and schools; (2) Parent and teacher roles were clearly defined and respected; (3) Parents lacked confidence and trust in teachers; (4) Advocacy was difficult for parents due to employment, lack of extended family supports, language barriers, community misunderstanding of autism, and felt stigma; yet, despite all of this, (5) there was a sense of optimism and gratitude for what Australia could offer their children.

Conclusions: Overall, Chinese parents wanted their children to be happy and to lead full lives. Although parents were appreciative of the financial support, acceptance of diversity and provision of holistic education in Australia, parents wanted more transparency from teachers about their children's strengths and challenges and higher expectations for their children. They also wanted to be more involved in their child's schooling. Schools must develop effective ways to be more flexible, open and understanding when working with Chinese parents and their autistic children.

**526.091** (*Virtual Poster*) Usual Care Settings and Differences in Screening and Treatment of Trauma for Autistic Youth

**S. Honovic<sup>1</sup>**, J. A. Gates<sup>1</sup>, K. Walker<sup>1</sup>, C. M. Kerns<sup>2</sup>, A. Drahotá<sup>3</sup>, E. G. Cohn<sup>1</sup>, L. V. Soorya<sup>1</sup>, L. Moskowitz<sup>2</sup>, A. Wainer<sup>2</sup> and M. D. Lerner<sup>2</sup>, (1)Department of Psychology, Stony Brook University, Stony Brook, NY, (2)University of British Columbia, Vancouver, BC, Canada, (3)Child and

**Background:** While potentially traumatic events (PTE) impact about 60% of youth (Kerns et al., 2015), autistic youth are at an even higher risk of experiencing PTEs (Kerns et al., 2020). Further, negative mental health outcomes are associated with PTEs in autistic (Kerns et al., 2020) and non-autistic (Hoover, 2015) populations. Youth with ASD are served in a wide variety of treatment settings by providers from diverse professional disciplines (Kerns et al., 2019), but often have difficulty obtaining trauma-focused treatment (Hoover, 2015; Kerns et al., 2015). Recent work has begun characterizing the landscape of PTE care for autistic youth in usual care (UC) settings, which found that despite an increased risk of PTE, only 10% universally screened and only 5% universally treated PTE (Kerns et al., 2019, 2020). Additionally, Kerns and colleagues (2020) identified that providers from community mental health centers (CMHCs) were more likely to screen and treat PTE than those not working in CMHCs, however, variation of frequencies of screening and treatment across UC settings (i.e., those practicing in different settings) have not been explored. Analyzing which types of UC settings are more likely to address PTE in autistic individuals is essential for understanding the landscape of UC treatment and improving access to care for autistic youth.

**Objectives:** We aimed to build from the results of Kerns et al. (2020) to assess frequency of PTE screening and treatment in multiple different UC settings.

**Methods:** 700 community-based ASD providers from different practice settings participated in the Usual Care for Autism Study (UCAS; Kerns et al., 2020). Providers were asked to disclose practice setting (Table 1) and whether they screen or treat PTEs in ASD youth.  $\chi^2$  tests were used in all analyses.

**Results:** Results revealed differences in PTE screening [ $\chi^2(5, N=700)=43.721, p<.001$ ] and treatment [ $\chi^2(5, N=700)=40.43, p<.001$ ] by UC setting. Providers from four of the six UC settings reported both screening and treating PTEs at least 50% of the time, however CMHC remained the UC site addressing PTEs more than any other setting (Figure 1).

**Conclusions:** This study aimed to further explore variations in PTE screening and treatment by UC setting. While providers from most settings addressed PTEs at least half of the time, CMHCs continued to address PTEs at a higher rate than any other setting. As autistic youth experience PTEs more often than non-autistic youth (Kerns et al., 2020), having providers that are actively addressing these difficulties are important. Notably, autistic youth are most likely to receive services from school-based providers (van Roekel et al., 2010), which, considering these results, indicates that PTEs are less likely to be screened in settings where children are most likely to receive services. As many providers report a lack of training and awareness of PTEs in autistic youth (Brookman-Frazee et al., 2012; Kerns et al., 2020), there is an increased importance for training and development of evidence-based treatments (Kerns et al., 2019). Future work should focus on increasing training and the use of evidence-based treatments for PTEs in UC settings.

## **526.092 (Virtual Poster)** Examining the Balance of Fidelity and Family-Centered Care within a Parent-Mediated Intervention Delivered in a State-Funded Early Intervention System

**K. Pickard<sup>1</sup>, N. M. Hendrix<sup>2</sup>, K. Guerra<sup>3</sup>, E. Kaiser<sup>3</sup>, N. Bond<sup>3</sup> and J. L. Stapel-Wax<sup>4</sup>, (1)Emory University School of Medicine, Marcus Autism Center, Atlanta, GA, (2)Marcus Autism Center, Emory University School of Medicine, Atlanta, GA, (3)Marcus Autism Center, Atlanta, GA, (4)Pediatrics, Emory University School of Medicine, Atlanta, GA**

---

**Background:** Parent-mediated intervention (PMI) is an effective intervention approach for young children with autism spectrum disorder (ASD; Nevill et al., 2018). Although efforts to increase access to PMI are underway, their success has been limited by high attrition when implemented in underserved communities (Kasari et al., 2015). Strategies that have been added to PMI to enhance caregiver engagement have had mixed results (Pellechia et al., 2018) and may reflect an assumption that PMI content itself should engage families and, when not, that engagement must be targeted separately so that fidelity is maintained. The emphasis on maintaining fidelity may restrict how PMI is delivered, at times, placing it at odds with the diverse needs of underserved families. To date, research has yet to evaluate how family needs, values, and preferences are accounted for within PMI delivery.

**Objectives:** The current study examined the delivery of an evidence-based PMI, Project ImPACT (Ingersoll & Dvortcsak, 2019), when delivered within a Part C Early Intervention system. Specific objectives were to examine: 1) providers' fidelity to Project ImPACT; 2) decisions providers weighed in their delivery of Project ImPACT; and 3) perceived impact of these decisions.

**Methods:** Participants were interdisciplinary providers within Georgia's Early Intervention system providing services to children 12-30 months of age with an increased likelihood of having ASD. Providers completed Project ImPACT training and submitted video of each of their Project ImPACT sessions, which were scored for fidelity. After every other session, providers completed an open-ended survey that asked about their intended goals for the Project ImPACT session, how the session played out, the decisions that factored into their delivery of Project ImPACT, and the perceived impact of the decisions. Following participation, providers rated their overarching adaptations to Project ImPACT (Stirman et al., 2019).

**Results:** Preliminary data from 12 of 25 Early Intervention providers indicate improvement in Project ImPACT fidelity towards benchmarks of 80%. Across a random sample of 28 Project ImPACT sessions, providers reported experiencing events that impacted their program delivery. These events occurred in about 40% of sessions and represented acute stressors (e.g., housing eviction, family death), chronic needs (e.g., extended family illness), and stated preferences (e.g., asking for support with feeding or sensory sensitivities). In response to these events, providers indicated pausing Project ImPACT to provide relevant support with the intention of returning to Project ImPACT in subsequent sessions. Providers perceived balancing

fidelity and family-centered care as essential to aligning Project ImPACT with family-centered Early Intervention delivery. Data regarding overarching fidelity and adaptation will be presented.

**Conclusions:** This study provides insight into how providers delivered an evidence-based PMI within a state-funded Early Intervention system and the decisions they weighed in program delivery. Although preliminary data suggest that providers can learn Project ImPACT, findings also highlight the perceived need to deviate from core intervention content to support diverse family needs. These types of family-centered adaptation are not currently accounted for within existing fidelity tools. These results underscore the need to better measure intervention adaptation processes within Early Intervention systems.

**526.093 (Virtual Poster)** A Preliminary Investigation of Code Related Emergent Literacy Skills in Bilingual Children with Autism Spectrum Disorder

**H. S. Mohan<sup>1</sup>** and **S. Tiwari<sup>2</sup>**, (1)Department of speech and hearing, Manipal Academy of higher education, Manipal, India, (2)Department of speech and hearing, Manipal academy of higher education, Manipal, India

---

**Background:**

Emergent literacy skills are the reading and writing experiences of young children before they learn to write and read conventionally, which serve as a foundation for later academic success (Rohde, 2015). Children with Autism Spectrum Disorder (CwASD) have impaired emergent literacy skills due to the challenges faced in areas such as social communication, sensory perception and cognition at younger age. Code related emergent literacy skill predict fluent and accurate reading. Studies suggest that code related skills (alphabet concept and phonological awareness) are non-impaired and meaning related skills (oral language and narration) are impaired in CwASD (Westerveld et al., 2017b). Given the socio-cultural, linguistic, and educational system differences in the Indian context, there is a need to explore emergent literacy skills of bilingual (English language learners) CwASD in India to develop individualized empirical intervention strategies.

**Objectives:** The objectives of the study were

- a) To explore the performance of CwASD on code related emergent literacy measures such as concept about print, alphabet knowledge and phonological awareness
- b) To find an association between code related emergent literacy measures and home literacy environment measures.

**Methods:**

A total of 25 CwASD between the age of 4 to 8 years of age, with mild to moderate autism severity and average or above average intelligence were included in the study. English was the second language and the medium of instruction for all CwASD. Code related emergent literacy measures such as concept about print, alphabet knowledge and phonological awareness were assessed using Tool for Emergent Literacy Assessment (Khurana & Rao, 2011). Home literacy environment was investigated using a questionnaire (Buvaneswari & Padakannaya, 2017) completed by the parents of CwASD.

**Results:**

Mean and standard deviation of all the code related tasks were computed. Performance of CwASD on code related emergent literacy measures were categorised into good, average and poor by computing the 33<sup>rd</sup> and 66<sup>th</sup> percentile scores as shown in Table 1. Most CwASD (n=18) obtained good and average scores on concept about print and alphabet knowledge. A significant positive correlation was observed between home literacy environment and concepts about print concept, alphabet knowledge, and moderate correlation was observed with phonological awareness (Table 2).

**Conclusions:**

Our findings show good and average performance on print concept and alphabet knowledge in bilingual CwASD which is similar to findings from English speaking CwASD (Westerveld et al., 2017b). Association between code related emergent literacy skill and home literacy scores signifies the need to consider home literacy practices such as shared reading, focus on print, and exposure to story book at a younger age. Further, an understanding of performance of CwASD on code and meaning related emergent literacy measures allow us to provide focused early intervention to prevent reading failure. Future research should compare the performance of bilingual typically developing children and CwASD on measures of code and meaning related emergent literacy skills with larger sample size, and compare with age and language matched peers.

**526.094 (Virtual Poster)** Factors Contributing to Employment and Job Satisfaction for Autistic Adults

**B. Schwartzman**, Vanderbilt University, Nashville, TN

---

**Background:** Extant research in the field of employment for autistic adults describes bleak outcomes—high rates of unemployment and underemployment, frequent job changes, challenges adapting to new job settings/routines, lower wages than coworkers, and less time employed than neurotypical peers (Hurlbutt & Chalmers, 2004; Muller, Schuler, Burton, & Yates, 2003). However, research has also elucidated a number of desirable workplace traits that individuals with autism possess such as: attention to detail, reliability, increased productivity, and low absenteeism.

(Baldwin, Costley, & Warren, 2014; Hillier et al., 2007). To better inform employment-related interventions, it is essential to further develop an evidence base which describes successful employment experiences of autistic adults.

**Objectives:** The current study aimed to (1) identify differences between autistic adults who are employed and autistic adults who are unemployed; (2) identify differences between employed autistic adults who are satisfied with their jobs and those who are not.

**Methods:** The current study conducted secondary analyses on a previously collected sample of autistic and non-autistic adults who responded to an online survey (Schwartzman et al., 2015). From this sample, a smaller sample of autistic adults were identified based on survey questions indicating whether they had previously received a formal diagnosis or considered themselves to be autistic (N = 238). Other survey questions assessed personality (IPIP NEO-120), autistic traits (RAADS-R), sensory sensitivities (HSPS), employment status, duration of employment, employment satisfaction, happiness, life satisfaction, level of education, as well as other demographic categories such as age, gender, and ethnicity. Independent samples *t*-tests were utilized to compare differences between employed (N=133) and unemployed (N=105) autistic adults. Within the group of employed autistic adults, two groups were created based on responses to the Job Satisfaction question which was assessed using a 5-point Likert scale. Individuals who indicated they were “Very Satisfied” and “Satisfied” with their jobs were placed in the “Satisfied” group (N=80), while those who indicated “Neither Satisfied nor Dissatisfied,” “Dissatisfied,” or “Very Dissatisfied” were placed in the “Not Satisfied” group (N=53). Independent samples *t*-tests were utilized to compare differences between the “Satisfied” and “Not Satisfied” groups of employed autistic adults.

**Results:** Employed autistic adults reported significantly lower Neuroticism in addition to higher Extraversion, Conscientiousness, happiness, life satisfaction, and level of education than unemployed autistic adults. Further, groups did not significantly differ in reported autistic traits or sensory sensitivities (See Table 1). Autistic adults who were “Satisfied” with their current employment reported significantly lower Neuroticism, higher life satisfaction, and happiness than those “Not Satisfied” (see Table 2). Further, reported autistic traits and sensory sensitivities did not differ between the groups.

**Conclusions:** Current literature on employment of individuals with autism often lumps this diverse population into a homogeneous of individuals who experience employment challenges. While this may be true of a majority of individuals with autism, to better inform future employment-related interventions for those experiencing unemployment and underemployment, it is essential to further develop an evidence base which identifies factors that contribute to successful employment experiences for autistic adults.

**526.095 (Virtual Poster)** Completing Autism Evaluations in an Integrated Pediatric Primary Care Setting.  
**T. Snider, Nationwide Children's Hospital, Columbus, OH**

---

**Background:** The prevalence of Autism Spectrum Disorders (ASD) has continued to increase over the past decade with a current reported prevalence of 1.7% of children in the United States. The frequency of recommended well-child checks (WCCs) and developmental surveillance recommended by the American Academy of Pediatrics (AAP) between the ages of 0-3 years makes the pediatric primary care center a critical and valuable setting to aid in early identification and recognition of children with concerns for a possible ASD. The evidence supporting integration of behavioral health providers in to the primary care center further creates an opportunity to promote early identification of developmental delays as well as access to ASD evaluations resulting in earlier age of diagnosis and successful linking with recommended treatments and therapies. The ability to offer ASD evaluations in the pediatric primary care setting also helps to minimize barriers to care, as the primary care provider (PCP) is often a trusted and familiar setting for families.

**Objectives:** The Integrated Primary Care Autism Spectrum Disorder (IPC ASD) evaluation project was developed with the goals of decreasing the time families wait from first concern to ASD diagnosis **and** improving timely access to evidence-based care and critical early intervention services, particularly for families who identify as racial or ethnic minorities.

**Methods:** In 2020, the average wait time from referral to diagnosis was approximately 15 months at our affiliated autism center. With an average time from diagnosis to treatment of approximately 6 months. The IPC ASD project was piloted in an urban, busy pediatric primary care center, which serves a predominately-underserved and diverse patient population. The target population is children ages 18 months – 5 years who present to their primary care center (PCC), and the PCP identifies concern for a possible ASD based on their clinical judgement, behavioral observations, and results from developmental screeners.

**Results:** Since November 2020, the IPC ASD project has evaluated 70 patients (88% male) from two PCCs. The average age of diagnosis is 34 months (18 – 58 months range), which is over 12 months earlier than the national average. Over 90% of families identified as minority patients (predominately African, Latinx, or African American) with nearly 25% of families identifying English as their second language or as non-English proficient. Compared to treatment as usual, there was over a 160-day reduction in time from referral to diagnosis of ASD. Results revealed an average of 5.5 weeks from diagnosis in the primary care setting to initial treatment appointment at the affiliated autism center (N = 37).

**Conclusions:** The IPC ASD model is a promising approach to ASD evaluation and diagnosis in integrated pediatric primary care setting. Results demonstrate earlier age of diagnosis compared to the national average and more timely access to efficacious behavioral and early intervention services. Perhaps most importantly, results suggest that this model is feasible and acceptable to families from diverse racial and ethnic backgrounds and could help minimize disparities in age of diagnosis and linking with treatment.

**526.096 (Virtual Poster)** ACEs Screening Pilot for Children Clinically Referred for Neurodevelopmental Disorders  
**L. J. Dilly and J. Owen, Marcus Autism Center, Atlanta, GA**

---

**Background:** Children with neurodevelopmental disorders, including Autism Spectrum Disorders (ASD), are at an even greater risk for Adverse Childhood Experiences (ACE) than children in the general population, contributing to the health disparities for this group (Rigles, 2016). Further, children with ASD experiencing more ACEs often demonstrate delays in diagnosis and initiation of therapies (Berg et al., 2012).

Research exists on screening for ACEs within primary pediatric practices to identify needs for trauma treatment and prevention of intergenerational transmission of toxic stress (Gillespie, 2019); however, little is known about screening for ACEs within a clinical setting for children with developmental disabilities.

**Objectives:** The purpose of the study is to pilot an ACEs screening tool within a clinical sample of children referred for evaluation for neurodevelopmental disorders. ACEs rates and possible differences in rates of ACEs amongst gender, race, and insurance sources will be explored.

**Methods:** Retrospective chart reviews were conducted for children referred for neurodevelopmental evaluations at a children's hospital in the Southeastern United States. The families of all children completed the Identified Pediatric ACEs and Related Life Events Screener (PEARLS). Child-level demographic and diagnostic information was gathered.

**Results:** See Table 1 for demographic information. Preliminary results indicate that 64% of children have experienced at least 1 ACE ( $M = 1.41$ ;  $SD = 1.63$ ) and 32% have experienced at least 1 related life event ( $M = .43$ ;  $SD = .43$ ). No differences were found in number of ACEs across sex ( $t(42)$ ,  $= -.446$ ,  $p = .33$ ;  $-1.144$ ), primary diagnosis ( $F(2, 41) = .487$ ,  $p = .62$ ,  $\eta^2 = .023$ ) or White, non-Hispanic and Black non-Hispanic races ( $t(38)$ ,  $= .279$ ,  $p = .78$ ;  $d = 0.088$ ). The number of ACEs and the severity of ASD were also not significantly correlated ( $r = .106$ ;  $p = .246$ ).

Differences in the number of ACEs across insurance types were significant ( $F(2, 41) = 4.468$ ;  $p = 0.018$ ;  $\eta^2 = .179$ ). Post-hoc Tukey HSD Test for multiple comparisons found that the mean value of ACEs was significantly difference between private insurance ( $M = .36$ ;  $SD = .674$ ) and Tricare ( $M = 2.75$ ;  $SD = .957$ ;  $p = .027$ , 95% CI =  $(-4.54, -.24)$ ).

**Conclusions:** Consistent with literature, children referred for a neurodevelopmental evaluation have a high likelihood of having experienced an ACE or Related Life Event. Similar to previous studies, little to no difference in ACEs in children with ASD were found across gender and race; however, differences in insurance coverage were associated with number of ACEs (Berg et al., 2018). In particular, the possible higher levels of ACEs for children autism with military-based insurance deserves further attention. Research has identified that military families with a child with ASD may demonstrate particular challenges (Klin et al., 2015; Davis & Finke, 2015). Further, military families with a child with ASD may be at additional risk for high levels of stress and therefore increased levels of ACEs for their children. Opportunities for targeted family support may be available based on identified ACEs. Limitations include the small sample size.

---

**526.097 (Virtual Poster) Access to Care: Training and Partnership with Primary Care in Colorado**  
**M. Cobian and R. Wilson, Children's Hospital Colorado, Aurora, CO**

---

**Background:** Autism is a prevalent neurodevelopmental disorder identified in 1 out of 54 children nationwide. Symptoms of autism can be detected in children 2 years of age; however, only 44% of children under 36 months have received an autism diagnosis. Earlier diagnosis is crucial because early intervention affords the best prognosis across the lifespan. Primary care providers (PCPs) serve an important role in early identification of developmental delays and symptoms of autism. Therefore, expanding PCPs' knowledge of autism and screening skills can help speed up the time from first concerns about a child's development to screening, diagnosis, and intervention.

**Objectives:** The program ACCESS (Access to Care for Communities through Education, Service and Support) aims to increase access to a timely diagnosis of autism and related neurodevelopmental disabilities for children living in Colorado's rural and underserved communities. This presentation will focus on the program's aim to 1) expand the knowledge, comfort, and skills of PCPs through direct education and training, and 2) support PCPs by providing on-site and telehealth autism evaluations and follow-up visits.

**Methods:** The program ACCESS has partnered with ECHO (Extension for Community Health Outcomes) Colorado, a nonprofit organization dedicated to increasing the management of complex health issues by using technology to bring professionals together to share knowledge, experiences, and viewpoints. Specifically, the Autism ECHO series (10 virtual session didactic training program) trains PCPs on core concepts including the screening, diagnosis, and medical/behavioral management of children with autism and related neurodevelopmental disabilities. An additional training pathway includes Community of Practice Monthly Case Review, a virtual meeting where PCPs share complex cases and consult with developmental specialists including psychologists, developmental behavioral pediatricians, and licensed clinical social workers. Importantly, the ACCESS program bridges the Autism ECHO training with an Outreach Clinic that provides interdisciplinary evaluations with psychologists and developmental behavioral pediatricians, and referrals to a social work team and genetic counselor. A bilingual/bicultural psychologist completes Spanish-language testing in the context of Colorado's large Spanish-speaking population.

**Results:** To this date, the program ACCESS has successfully trained 8 cohorts of PCPs through the ECHO training series. In total, over 100 PCPs across 22 Colorado counties have been involved in the ECHO trainings. Additionally, a total of 2 STAT trainings have been completed as part of the ACCESS program, and this effort trained a total of 30 providers to utilize the STAT in their primary care settings. Finally, the ACCESS program has established Outreach Clinics in primary care clinics across 6 rural and under-served communities in Colorado. A total of 30 autism evaluations have been completed, with 43% of those being Spanish-language evaluations.

**Conclusions:** In summary, the ACCESS Program serves families from rural, underserved, and diverse backgrounds in Colorado who face barriers to a timely ASD diagnosis. This innovative combination of virtual and in-person outreach services underlies a novel approach to care pathways that

increases the capacity of PCPs to manage the identification and care of children with ASD and related neurodevelopmental disabilities within their practices.

**526.098 (Virtual Poster)** Better Together: Using a Coaching Model to Support Teachers' Use of Evidence-Based Practices with Students on the Autism Spectrum

**J. M. Paynter<sup>1</sup>, K. O'Leary<sup>2</sup>, D. Adams<sup>3</sup>, M. Clark<sup>4</sup>, K. Simpson<sup>5</sup>, D. Trembath<sup>6</sup> and M. F. Westerveld<sup>7</sup>,** (1)School of Applied Psychology, Griffith University, Gold Coast, QLD, Australia, (2)Griffith University, Gold Coast, QLD, Australia, (3)Autism Centre of Excellence, Griffith University, Brisbane, Australia, (4)La Trobe University, Melbourne, VIC, Australia, (5)Messines Rd, Griffith University, Brisbane, QLD, Australia, (6)Menzies Health Institute, Griffith University, Australia, (7)School of Allied Health Sciences, Griffith University, Gold Coast, QLD, Australia

---

**Background:** Almost all students on the autism spectrum experience educational restrictions that impact their learning and participation at school (92.3%; Australian Bureau of Statistics, 2018). Teacher delivered evidence-based practices (EBPs) can improve student outcomes; yet, translating these from research to practice can be difficult (e.g., Brock et al., 2020). The need to provide tailored supports, such as coaching, has been highlighted as a potential strategy in international research to bridge this gap (e.g., Ruble et al., 2013). However, there is limited evidence, drawing on the views and experiences of teachers, to guide the development and implementation of such models in general education to inform tailored solutions and build capacity for sustained change.

**Objectives:** Our interdisciplinary team aimed to build capacity of Australian general education teachers to select and implement EBPs via development and evaluation of a coaching model with stakeholder input across each phase.

**Methods:** A mixed methods approach was used across three iterative phases: (1) Qualitative study of 21 teachers to understand needs, barriers, and facilitators to EBP, and attitudes toward coaching; (2) Development and implementation of EBP and coaching training with 35 teachers; (3) Evaluation of the coaching model within four schools. Phase 1 data collection was conducted across three focus groups. Phase 2 involved face-to-face training of teachers (day 1) and senior teachers (day 2) in autism and EBP. Phase 3 focused on implementation of Phase 2 training with online training covering core components that could be shared with others. Schools were randomly assigned to information only (two schools) or coaching support (two schools). Phase 2 and 3 included quantitative measures of self-efficacy to work with students on the spectrum, knowledge/use of EBP, attitudes to EBP, attitudes to coaching, and social validity of training. Measures were completed immediately pre/post training in phase 2 and at 10 weeks follow-up. Measures were completed at school entry to Phase 3, four weeks post-training, and at the end of the school term.

**Results:** Phase 1 analysis identified themes that informed the content and design of the coaching model. In phase 2, results from day 1 participants were used to refine content and targeted recruitment for day 2. Participants from day 1 showed significant increases in confidence working with students on the spectrum ( $t(17)=6.90, p<.001$ ) and in providing peer coaching to other staff ( $t(17)=3.82, p<.001$ ). Day 2 participants demonstrated significant improvements in self-efficacy ( $t(16)=4.12, p=0.001$ ) and coaching investment ( $t(16)=2.14, p=0.048$ ). In Phase 3, trained coaches reported on their own experiences, as did teachers receiving coaching in terms of change to their practice, attitude to coaching, and attitudes to EBPs.

**Conclusions:** Our findings build on evidence from international research, by demonstrating the value of including teacher perspectives in the design and refinement of a coaching model in the Australian context. Future research that investigates fidelity of implementation of EBPs and student outcomes is an important next step to evaluate whether changes in EBP implementation support students on the spectrum to achieve their potential at school.

**526.099 (Virtual Poster)** Evaluating Factors That Influence Provider ASD Referrals in Underserved Primary Care Settings

**T. C. Kalmus<sup>1</sup>, L. V. Ibanez<sup>2</sup> and W. L. Stone<sup>3</sup>,** (1)Psychiatry, The University of Iowa, Iowa City, IA, (2)UW READi Lab, Seattle, WA, (3)Psychology, University of Washington, Seattle, WA

---

**Background:** Early identification and intervention for autism spectrum disorders (ASD) promote best outcomes for the child and their family<sup>1</sup>. Universal ASD screening has been recommended to promote access to referrals for ASD services<sup>2</sup>. Differences in ASD referral rates have been observed across racial boundaries<sup>3</sup> and based on the presence of caregiver or provider concern<sup>4</sup>, but few studies have explored how these factors interact. Further understanding of considerations that catalyze a primary care provider's (PCP) decision regarding different types of referrals may mitigate service access issues and indicate areas to improve provider knowledge.

**Objectives:** To evaluate factors that influence PCP decision-making when referring at-risk toddlers for ASD services via Classification Trees (ctree), which use "nodes" and "splits" to order predictors in a superordinate way related to how much of the variability in outcome they explain.

**Methods:** A four-item checklist inquired about child characteristics (sex, race, ethnicity, familial risk), types of developmental screeners implemented (ASQ, M-CHAT), presence of caregiver and/or provider concern, and types of ASD referrals made during pediatric well-child visits. Sixty-one PCPs completed the checklist for children between 18- and 24-months old. A total of 3,066 checklists were completed across 32 months. Three separate ctree models predicted whether referrals were made for Dx evaluations (Dx), EI services (EI), or any ASD services (Any Referral; Dx, EI, other), respectively. All three ctrees were developed using a training dataset and were evaluated on test/validation dataset using the same 80:20 data split. The predictors considered were child characteristics, screening results, and the presence of caregiver and/or provider concern.

**Results:** The Any Referral ctree had five nodes, two splits, and three levels ( $p = 0.01$ ). The final model included the predictors of ASQ and M-CHAT results and predicted whether a PCP acted with high accuracy, sensitivity, PPV, and moderate specificity and NPV (Table 1). Both PCP and/or caregiver concern were significant predictors but did not explain variability beyond screening results and are not retained in the final ctree; child characteristics were not significant predictors. The two ctrees models conducted for Dx and EI referrals, respectively, did not significantly predict the outcomes.

**Conclusions:** Results indicate that a child failing either screener between 18- and 24-months old was associated with the PCP referring for ASD services. Interestingly, a child failing the ASQ, a generalized developmental screener, was more influential than the child failing the M-CHAT, an ASD-specific screener. Provider and caregiver concern was a potential influencing factor, but PCPs did not act on concern alone. There was no indication that child characteristics, such as race, led PCPs to make certain referral decisions.

Our results also suggest that there is no clear decision-making process for either diagnostic or generalized EI referrals given the current predictors. These predictors did not explain the decision to refer to EI services, yet referral to these services is a recommended guideline for when developmental delay and/or ASD concerns/risk are present. Overall, further investigation is needed to better understand PCP decision-making and explore ways to further systematize the process for referrals beyond current guidelines.

**526.100 (Virtual Poster)** Exploring the Impact of Policy on Access to Early Autism Diagnosis and Other Services in Five States

**O. J. Lindly<sup>1</sup>, A. Chu<sup>2</sup>, P. Fuchu<sup>3</sup>, J. L. Kuhn<sup>4</sup>, D. Abate<sup>5</sup>, E. Feinberg<sup>2</sup> and S. Broder-Fingert<sup>6</sup>,** (1)Health Sciences, Northern Arizona University, Flagstaff, AZ, (2)Boston University School of Public Health, Boston, MA, (3)Boston University School of Medicine, Boston, MA, (4)Pediatrics, Boston Medical Center, Boston, MA, (5)University of Massachusetts, Boston, MA, (6)Boston Medical Center, Boston, MA

---

**Background:** State policy—defined as any rule, regulation, law, or practice—and context more broadly have been shown to impact an array of health outcomes (e.g., childhood obesity, binge drinking). The enactment of certain state laws such as Medicaid Home and Community-Based Services waivers and Autism Insurance Mandates has been linked to improved service delivery for autistic children. Yet little research has examined state policy and context more comprehensively in relation to early autism diagnosis and timely access to other, needed autism-related services. By identifying which policy and contextual factors substantially influence autism-related service access and delivery, it will be possible to advance policy promoting health for autistic individuals and their families across states.

**Objectives:** This study sought to identify policy and other contextual factors across five states participating in a national autism collaborative (Arizona, California, Connecticut, Massachusetts, and Pennsylvania) that impact access to early autism diagnosis and other, needed autism services for children.

**Methods:** We conducted semi-structured interviews by telephone or video conference during 2021 with a purposive sample of 17 experts in autism and/or state policy across Arizona, California, Connecticut, Massachusetts, and Pennsylvania. Snowball sampling was used to determine additional key informants in each state. Interviews were audio recorded and transcribed. Preliminary data were coded using applied thematic analysis.

**Results:**

Eight themes related to policy and contextual factors influencing access to early autism diagnosis and other services across the five states were identified. The following three themes were related to early autism diagnosis: (1) initiatives to promote widespread screening and referral in primary care facilitate early diagnosis; (2) lack of trained and ethnically diverse providers, limited availability of culturally and linguistically appropriate evaluation tools, and poor reimbursement for comprehensive evaluation impede early autism diagnosis; and (3) community autism stigma and family ability (e.g., time, perceived need) to pursue services affect early diagnosis. The following four themes additionally emerged that were related to accessing other, needed autism-related services: (4) needing an autism diagnosis for insurance coverage and/or Medicaid waiver eligibility is a barrier to timely service access; (5) differential financing within states affects the geographic availability of high quality autism services; (6) variable provider training and state licensure requirements impact the quality of autism services families receive; and (7) early intervention enrollment facilitates special education evaluation and access to autism-related services via an individualized education program once children become school aged. The final theme identified pertained to both early autism diagnosis and other, needed service access: (8) state autism agency organization including structure and interagency coordination, as well as the provision of resources influence service access.

**Conclusions:** Policy and contextual factors relevant to workforce, insurance reimbursement, program eligibility, financing, and the organization of service agencies were identified as influencing access to early autism diagnosis and other, needed autism-related services across the five states. Study findings will inform the development of an autism state policy index.

**526.101 (Virtual Poster)** Feasibility and Acceptability of an Integrated Evaluation Program for Autism Spectrum Disorder in a Pediatric Primary Care Clinic

**S. Habayeb<sup>1</sup>, R. Williams<sup>2</sup>, E. Eisenman<sup>1</sup>, A. Hastings<sup>1</sup>, S. Singh<sup>1</sup>, M. Lauer<sup>1</sup>, B. Brown<sup>3</sup>, M. Long<sup>1</sup>, A. Inge<sup>4</sup> and L. Godoy<sup>1</sup>,** (1)Children's National Hospital, Washington, DC, (2)Child Health Advocacy Institute, Children's National Hospital, Washington, DC, (3)University of the District of Columbia, Washington, DC, (4)Center for Autism Spectrum Disorder, Children's National Hospital, Rockville, MD

---

**Background:** Primary care providers (PCPs) are often the first to identify concerns for Autism Spectrum Disorder (ASD) through routine screening in the first two years of life. However, most children do not receive a diagnosis of ASD until after age four. Delays in receiving a diagnosis of ASD disproportionately impact children who are historically disadvantaged based on socioeconomic status or race. To address these issues, leaders in the field have called for the expansion of ASD diagnostic services in primary care by better equipping PCPs to make a diagnosis, particularly when symptoms are clear. However, PCPs alone do not have the ability or capacity to serve as an agent of change in decreasing time to ASD diagnosis. One can therefore look to other clinicians embedded within pediatric medical homes to facilitate increased access to services for children at risk for ASD. It is becoming an increasingly common practice for mental health clinicians, such as psychologists, to be embedded within primary care. Therefore, enabling such providers to provide ASD-specific services offers a promising opportunity to address barriers to accessing services after PCPs identify concerns.

**Objectives:** To evaluate the feasibility, acceptability, and benefits of a program in which embedded psychologists provide ASD diagnostic evaluations in an urban primary care setting.

**Methods:** Children with suspected ASD were referred by their PCPs (pediatricians, nurse practitioners, pediatric residents) or embedded primary care psychologists for an ASD evaluation. Evaluations were conducted by an embedded psychologist with supervision and/or consultation from a psychologist who specializes in ASD. Services were provided in-clinic and via telemedicine due to COVID-19 related disruptions to clinical services. Descriptive data related to sample characteristics were collected and referring providers completed follow-up provider satisfaction questionnaires.

**Results:** Sixty-six families were referred and completed evaluations between October 2019 and October 2021. Sixty-five percent of the evaluations were conducted via telemedicine and thirty-six percent were conducted in person. Mean child age was 34.3 months (SD: 13.9; 59% male). Eighty-two percent of children were Black, 87% of families were insured by Medicaid, and 23% were not primary English speakers. Sixty-eight percent of children received a diagnosis of ASD, 12% had the diagnosis ruled-out, and 20% had the diagnosis deferred, usually due to telemedicine services being insufficient for diagnostic clarification, with follow-up in-person testing recommended. The 17 referring providers who completed questionnaires were overall Satisfied/Very Satisfied with the assessment program (mean satisfaction rating [1-5] = 4.35). Providers ranked the following aspects of the program as “most important”: 1) Accessing evaluations regardless of barriers that may otherwise prevent them accessing this service (e.g., insurance, transportation) and 2) short wait-times for evaluations.

**Conclusions:** Data suggest that an integrated ASD diagnostic clinic in primary care is an acceptable and feasible approach to improve access to ASD evaluations. The program was successful in providing services to families who previously had difficulty accessing care. Expansion of such programs, which increase provider capacity and provide services in the medical home, has the potential to decrease racial and socioeconomic inequities in access to ASD diagnostic services.

**526.102 (Virtual Poster) Feasibility of Screening of Pediatric Neurodevelopmental Patients for Suicide Risk Via Telehealth: A Pilot of the ASQ Instrument Validation Study**

**P. H. Lipkin<sup>1,2,3</sup>, S. Rybczynski<sup>2,4</sup>, A. Thurm<sup>5</sup>, M. R. Ngur<sup>4</sup>, P. C. Ryan<sup>5</sup>, N. J. Lowry<sup>5</sup>, C. Lopez-Arvizu<sup>6,7</sup> and L. M. Horowitz<sup>5</sup>, (1)Neurology and Developmental Medicine, Kennedy Krieger Institute, Baltimore, MD, (2)Pediatrics, Johns Hopkins University School of Medicine, Baltimore, MD, (3)Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD, (4)Kennedy Krieger Institute, Baltimore, MD, (5)Office of the Clinical Director, Intramural Research Program, National Institute of Mental Health, Bethesda, MD, (6)Psychiatric Mental Health Program, Kennedy Krieger Institute, Baltimore, MD, (7)Psychiatry, Johns Hopkins University School of Medicine, Baltimore, MD**

**Background:** Suicide is the second leading cause of death for youth aged 10-24 years (Centers for Disease Control and Prevention, 2019). Previous research has suggested youth with Autism Spectrum Disorder (ASD) and other neurodevelopmental disorders (NDD) are at increased risk for suicide. Screening tools are available to detect suicide risk in youth, identifying patients who require further assessment, but there are no screening tools that have been specifically validated for youth with NDD. In a previous investigation of universal suicide risk screening in an outpatient setting for youth with NDD, 73.3% of patients completed screenings with a 6.8% positivity rate (Rybczynski et al., 2021.) Notably, clinics serving children with ASD had higher rates of positive screenings compared with all other clinic attendees.

**Objectives:** To examine the feasibility of administering a suicide risk screening tool to children with ASD and/or other NDD through telehealth.

**Methods:** As part of a suicide risk screening instrument validation study, ongoing recruitment is occurring across four clinics serving youth with NDD at the Kennedy Krieger Institute. Eligible children ages 8-17 years, English-speaking, and verbally fluent are recruited during intake for medical appointments. Parents/Guardians are asked if they agree to hear about a research study and, if they agree, are contacted by study staff to obtain parental/guardian informed consent and child assent. During a subsequent telehealth research appointment, three measures of suicide risk are completed: First, child participants complete the Ask Suicide-Screening Questions for Youth with Autism and Intellectual Disability (ASQ-AID). This questionnaire includes the five items of the validated tool, the Ask Suicide-Screening Questions (ASQ), as well as an additional 10 candidate items. Second, parents/guardians complete the ASQ-AID, modified for caregiver self-report. Lastly, both are validated against a gold-standard brief clinician interview using the ASQ Brief Suicide Safety Assessment. The clinician is blinded to results of the ASQ-AID. Children who screen positive follow standard clinic safety procedures, including notifying the parent(s) and guiding them through the process of safety planning, and if necessary, scheduling follow-up appointments for the same day or following day.

**Results:** Of 53 eligible patients to date, 32 children were enrolled and screened, with an enrollment rate of 60.4%. Of those 32, 93.8% (n=30) were diagnosed with an NDD including ASD and 71.9% (n=23) with psychiatric disorders. 37.5% (n=12) were positive on any of the three suicide risk tools. 100% of the positive screens were “non-acute” positives and did not require emergency safety precautions. Mental health care providers were contacted for all positive participants. 96.3% of parents and 53.1% of patients were in favor of screening on study evaluation measures.

**Conclusions:** This study has demonstrated the feasibility of administering a suicide risk screening tool to psychiatric and medical pediatric patients with NDD, including ASD, safely over telehealth. Preliminary pilot data reveal a high screen positive rate, which may reflect screening in a sample enriched for psychiatric disorders or possible selection/ascertainment bias, and underscores the need for a validated suicide risk screening instrument for youth with NDD.

**526.103 (Virtual Poster) Implementing Standard of Care Diagnostic Genetic Testing for Autism Spectrum Disorders in Outpatient Psychiatry Clinics**

**M. Goldman<sup>1,2</sup> and D. Moreno De Luca<sup>2,4</sup>, (1)Verrecchia Clinic for Children with Autism and Developmental Disabilities (CADD), E.P. Bradley Hospital, East Providence, RI, (2)Precision Medicine in Autism (PRISMA) Group, Providence, RI, (3)Verrecchia Clinic for Children with Autism &**

#### Background:

Autism spectrum disorders (ASDs) are among the psychiatric conditions with the highest genetic burden, with clinically identifiable pathogenic genetic changes explaining up to 40% of cases. This has led to the recommendation of genetic testing, specifically chromosomal microarray and Fragile X testing, as a key element in the evaluation of people with ASD. However, only a small proportion of patients with this diagnosis receive such tests, highlighting a stark contrast between professional recommendations and clinical practice.

#### Objectives:

We aimed to increase the uptake of diagnostic genetic testing for ASDs. To maximize the generalizability of our efforts to other clinical sites, we focused on implementing genetic testing strategies at the outpatient level of care; at this level, testing is generally covered by medical insurance companies after a preauthorization process.

#### Methods:

Through partnerships with families, advocates, and hospital administration, we developed diverse strategies ranging from low to high levels of support to help clinicians in our system implement genetic testing and to communicate the availability of these services to the ASD community. These included dedicated administrative support for the testing preauthorization process, establishment of hospital-wide agreements with genetic testing companies, educational materials to discuss the process with patients, clinician and trainee education, shift to buccal swab collection, an in-house genetic counseling service to explain and perform genetic testing in families who agreed and deliver the results, and a genomic psychiatry consultation service to provide psychiatry recommendations based on a wide array of abnormal genetics results. Services are available in both English and Spanish. We anchored these interventions on the Consolidated Framework for Implementation Science (CFIR; Figure 1).

#### Results:

Our preliminary data shows that genetic testing at our hospital increased with these strategies. While some psychiatrists started using the available supports to initiate genetic testing themselves, strategies that provided a higher level of support were favored among clinicians. The high demand for these services supported their continued availability and viability. Families received counseling, testing, and psychiatric recommendations in their native language, which was Spanish in over 20% of cases. The yield of pathogenic genetic testing results appears to be in line with previous reports, and families reported a high level of satisfaction and engagement with these services.

#### Conclusions:

Synergistic and diverse implementation strategies for outpatient genetic testing in psychiatry achieve increases in the rate of adoption of these professional recommendations, with high satisfaction reported by ASD families and clinicians alike.

**526.104 (Virtual Poster)** Increasing Understanding of Autism Among University Students Using ‘the Birthday Party’ Psychoeducational Video  
**C. R. Jones, N. Czarnokoza, A. Burunova, K. Warren, J. De Kock, J. Hodges and K. Langley, Wales Autism Research Centre, School of Psychology, Cardiff University, Cardiff, United Kingdom**

---

#### Background:

Understanding of autism in the general population is often limited (Tipton & Blacher, 2004), which can have negative consequences for autistic people and their families (Kinnear et al., 2016). Psychoeducational tools can be an efficient way of educating people about autism (Gillespie-Lynch et al., 2015). However, training packages are seldom evidence-based and empirical testing of their effectiveness is rarely conducted. We evaluated the effectiveness of an 18-minute evidence-based psychoeducational video, The Birthday Party ([www.autismchildsigns.com](http://www.autismchildsigns.com)), in increasing understanding of autism and improving attitudes in undergraduate students. The film includes the 14 most discriminating items (Carrington et al., 2015) from the Diagnostic Interview for Social and Communication Disorders (DISCO; Wing et al., 2002). Autistic community members gave feedback on the film during development. The film highlights five ‘SIGNS’ (Social interaction; Imagination; Gestures; Narrow interests; Sensory responses) of autism and focuses on three autistic children (two boys, one girl) attending a birthday party.

#### Objectives:

To assess the effect of The Birthday Party, a psychoeducational video, on the understanding of autism and attitudes towards autism in undergraduate students.

#### Methods:

In study 1, 71 students (55 female; mean age = 19.15 years, SD = 1.56) were shown either The Birthday Party (N = 36) or an educational film about dyslexia (N = 35). At baseline, groups were matched on previous knowledge of autism (Autism Awareness Survey; Gillespie-Lynch et al., 2015) and previous contact with autistic people (Level of Contact Report; Holmes et al., 1999). Following video presentation, we assessed understanding of autism by presenting participants with ten clinical vignettes that described four autistic children, four children with other childhood disorders, and two with no disorder. Participants had to identify the correct diagnosis for each vignette.

In study 2, we replicated the original design in 136 students (123 female, 2 'other'; mean age = 19 years; SD = 1.92). However, The Birthday Party (N = 38) and dyslexia groups (N = 36) were joined by a third group that read the transcript of The Birthday Party (N = 62). In addition, we measured attitudes to autism following the video/text presentation using an adapted attitude measure (Nevill & White, 2011).

#### Results:

In both studies, participants who watched The Birthday Party video were significantly better at recognising autistic children from clinical descriptions compared to participants who watched the dyslexia video. However, preliminary analysis of Study 2 indicates that those who read The Birthday Party transcript did not significantly differ to those who watched The Birthday Party video. There was no significant difference between groups in their attitudes to autistic children.

#### Conclusions:

Training materials are commonly used to support autism education, but few have an evidence-base or have their effectiveness tested empirically. We established that The Birthday Party has a significant impact on the understanding of autism in undergraduate students, which was replicated across two independent samples. However, the video did not improve attitudes towards autistic children. Future research should investigate the effect of the video, which is available in seven languages, on improving understanding in frontline professionals.

#### **526.105 (Virtual Poster)** Integrating Routine Screening and Identification Strategies into Alabama's Part C/Early Intervention System

**S. E. O'Kelley<sup>a</sup>, A. B. Barber<sup>a</sup>, K. R. Tomeny<sup>a</sup>, M. B. Vick<sup>a</sup>, W. D. Pittard<sup>a</sup>, L. C. Hackney<sup>a</sup>, K. Goff<sup>b</sup>, M. Costo<sup>c</sup> and T. Hilty<sup>a</sup>,** (1)*The University of Alabama at Birmingham, Birmingham, AL, (2)Communicative Disorders, University of Alabama, Tuscaloosa, AL, (3)University of Alabama, Tuscaloosa, AL, (4)Alabama Department of Rehabilitation Services, Tuscaloosa, AL, (5)Alabama's Early Intervention System, Alabama's Department of Rehabilitation Services, Huntsville, AL, (6)Alabama Department of Mental Health, Decatur, AL*

---

**Background:** Children under age 3 with suspected or confirmed Autism Spectrum Disorder (ASD) benefit from a mix of naturalistic and developmental interventions that actively involve their families and address core and associated ASD characteristics as early as possible (Zwaigenbaum et al., 2015). Many children and families receive early intervention (EI) services through federally funded Part C, which mandates that EI is provided to children with developmental delays under age 3. Although autism is a qualifying diagnosis within Alabama's Early Intervention System (AEIS), few children receive this diagnosis prior to age 3, as Alabama children are diagnosed nearly 2 years later than the national average (Baio et al., 2014). This delay limits access to ASD-specific interventions that could be implemented in the AEIS setting (Pickard et al., 2021). Building capacity within community systems to screen and deliver ASD-specific interventions promotes equitable access for families of children with early ASD characteristics (Wallis, 2020).

**Objectives:** The current project describes collaborative partnerships between AEIS and a multidisciplinary statewide team of researchers, clinicians, caregivers, and other stakeholders in developing and implementing an ASD screening pilot within 4 EI programs serving 18 of Alabama's 67 counties. Additional goals include identifying the number of children referred to AEIS who are at-risk for or diagnosed with ASD and investigating score patterns relative to developmental and demographic variables.

**Methods:** The Alabama Advancing Autism Initiative team developed a pilot to integrate the Modified Checklist for Autism in Toddlers- Revised with Follow-Up (M-CHAT-R/F; Robins et al., 2009) at initial eligibility evaluations with referred children between 18 and 30 months of age. Children identified as at-risk were simultaneously referred for comprehensive ASD community evaluation as well as ASD-specific interventions within AEIS. In addition to M-CHAT-R scores and demographics (e.g., sex, age, county, insurance type), participating programs reported caregiver and provider ASD concerns and diagnostic outcomes. Additional data are available regarding the areas of developmental delays observed in each child.

**Results:** M-CHAT-R has been completed regarding 142 children, with 79 (56%) identified as at-risk, of which 54 (68%) families consented to referral for comprehensive ASD assessment. Of the 16 cases for whom diagnostic outcome is available, 13 (81%) received an ASD diagnosis. Preliminary descriptive analyses were conducted on a subset of 125 children. 49 (39%) of these children failed the initial screen, and 31 warranted the Follow-up interview with 26 obtaining failing scores. Parents of 21% of children who failed noted ASD concerns at time of referral. Average age at referral among at-risk children was 21.5 months, one-third were girls, and no differences were found between black and white children. Outcomes are pending for the remainder but are expected within 3 months of referral due to collaborative relationships within the pilot.

**Conclusions:** This pilot has revealed several opportunities for working with state systems of care for young children with ASD and added a structured process and objective measure to empower providers and caregivers to discuss concerns regarding possible ASD to ultimately increase access to ASD-specific intervention within existing state systems.

#### **526.106 (Virtual Poster)** Law Enforcement Officers' Interactions with Individuals with Autism: Commonly Reported Calls and Outcomes

**Background:** Individuals diagnosed with autism are significantly more likely to experience contact with law enforcement officers (LEOs) than others (Curry et al., 1993). Research suggests between 8 – 20% of individuals with autism have experienced LEO contact, with approximately 5% leading to arrest (Rava et al., 2017) and 20% leading to involuntary hospitalization (Gardner & Campbell, 2020). The disproportionate contact with LEOs in this population is often attributed to the core impairments characterized by autism, including deficits with social interactions and communication as well as atypical behaviors (Clark Mogavero, 2018). Although research indicates that autistic individuals interact with LEOs as victims of crime, suspects, elopement, and domestic disputes (Railey et al., 2020), there is little research into the outcomes of these interactions, and characteristics of LEOs and individuals with ASD that may impact the outcomes of these interactions.

**Objectives:** The primary author created a training program for LEOs that prepares officers to respond to calls involving autistic individuals. As part of this training, LEOs reported on the most recent call they responded to that involved an autistic individual. The purpose of the present study was to categorize the (a) most commonly reported calls and (b) level of force used by LEOs during the call.

**Methods:** One-hundred and thirty ( $N = 130$ ) LEOs attended seven separate training sessions. LEOs were 63.1% male with a mean age of 41.02 years ( $SD = 10.4$ ) and 12.98 years of law enforcement experience ( $SD = 9.4$ ). Most LEOs ( $n = 74$ ; 56.9%) reported no prior training in autism despite state mandated annual training effective in 2016. To evaluate LEOs' prior experience with ASD, participants completed a questionnaire that included professional experiences interacting with individuals with ASD including their most recent calls within the last 12 months. LEOs also reported on the circumstances and outcomes of the calls.

**Results:** The most common call ( $n = 47$ ; 36.2%) involved responding to disruptive behavior without aggression (e.g., 'out of control behavior'). The second most common call ( $n = 25$ ; 19.2%) involved responding to suspected abuse or neglect. The third most common call ( $n = 17$ ; 13.1%) involved aggression towards self or others (e.g., 'slapped caregiver,' 'subject was hurting himself'). The most common outcome ( $n = 72$ ; 55.4%) involved providing support to the individual or family (e.g., 'referred to Doctor'). The second most common outcome ( $n = 36$ ; 27.7%) involved use of extreme force (e.g., handcuffed; arrested; involuntary psychiatric hospitalization). The third most common outcome ( $n = 12$ ; 9.2%) involved low level controlling behavior (e.g., 'called parents to take home').

**Conclusions:** More than half of LEOs reported not completing mandatory autism training, despite the state requirement that LEOs complete such training since 2016. Approximately one-third of calls were in response to non-aggressive disruptive behavior. Roughly half of calls were resolved using supportive behaviors, such as LEOs referring families to behavioral health resources and LEOs remaining with families until resolution. Future research should examine the impact of autism specific training on LEOs' use of extreme force.

#### **526.107 (Virtual Poster) Reproductive Health and Obstetrics/Gynecology Health Care Use in Autistic Adults**

J. L. Ames<sup>1</sup>, M. C. Anderson<sup>1</sup>, E. Cronbach<sup>2</sup>, C. Lee<sup>1</sup> and L. A. Croen<sup>3</sup>, (1)Division of Research, Kaiser Permanente Northern California, Oakland, CA, (2)Obstetrics and Gynecology, The Permanente Medical Group, Walnut Creek, CA, (3)Division of Research, Kaiser Permanente Division of Research, Oakland, CA

---

**Background:** Adults with disabilities often have less access to reproductive and sexual health resources than adults without disabilities. Autistic adults may experience additional barriers because of social communication and sensory differences and low provider awareness of autism in adult medicine settings. Furthermore, research suggests autistic adults may be at higher risk of menstrual abnormalities and negative experiences with pain and emotion/behavior regulation related to menstruation than non-autistic adults. Improved access to obstetrics/gynecology (OB/GYN) services may help many autistic adults better manage menstrual conditions and promote their sexual and reproductive health.

**Objectives:** To characterize the utilization of OB/GYN healthcare among autistic adults compared with neurotypical adults.

**Methods:** Our study took place at Kaiser Permanente Northern California (KPNC), a large, integrated healthcare delivery system. Among members aged 18+ who were enrolled in the KPNC health plan from 2017 to 2019 and assigned female sex at birth, we identified two cohorts: autistic adults ( $n=1438$ ) and neurotypical adults ( $n=5752$ ) matched 4:1 on age and KPNC membership length to the autistic cohort. From electronic health records, we extracted information on sociodemographic factors, health conditions, and healthcare utilization during 2017-2019. We compared utilization between groups using chi-squared tests and risk ratios (RR) estimated with modified Poisson regression, adjusting for age, race/ethnicity, health insurance payer, pregnancy during the study period, and frequency of primary care utilization.

**Results:** The prevalence of menstrual disorders (23-25%) was similar across both groups after adjusting for covariates including OB/GYN use; however, some conditions such as polycystic ovary syndrome were more common in the autistic group than in the neurotypical group. In comparison with neurotypical adults, autistic adults were less likely to visit an OB/GYN provider for non-obstetric reasons (59% vs. 73%) and were less likely to receive routine screenings for cervical cancer (47% vs. 72%, among ages 21-65) and breast cancer (75% vs. 84%, among ages 40+) (Table 1). While autistic adults were generally less likely than neurotypical adults to use any form of reversible hormonal contraception overall (38% vs. 51%), they were 3.6 times (95%CI: 2.4, 5.5) as likely to use oral contraception for therapeutic rather than birth control purposes and 1.6 times (95%CI: 1.3, 2.0) as likely to use injectable contraception such as Depo Provera. These disparities between autistic and neurotypical adults in OB/GYN care and cervical cancer screenings were most pronounced during young adulthood (ages 18-30). Some health diagnoses were associated with OB/GYN utilization among autistic adults; for example, epilepsy (RR: 0.76, 95%CI: 0.62, 0.92) and gender dysphoria (RR: 0.64, 95%CI: 0.40, 1.02) were associated with a lower likelihood of cervical cancer screening while anxiety, depression, and ADHD were associated with a higher likelihood of screening.

**Conclusions:** In comparison with neurotypical adults, autistic adults have lower utilization of multiple types of reproductive health care including OB/GYN visits, routine preventive screenings, and use of hormonal contraception. These findings reflect care in an integrated healthcare system with strong outreach programs for preventive care. Thus, these reproductive healthcare disparities may be larger in the broader US population.

**526.108 (Virtual Poster) Service Use Among Asian American Caregivers of Children with Autism**

**I. Kim<sup>1</sup>, S. Dababnah<sup>2</sup> and Y. Xu<sup>3</sup>, (1)School of Social Work, Tulane University, New Orleans, LA, (2)University of Maryland, Baltimore, Baltimore, MD, (3)Department of Health Sciences Education, University of Illinois College of Medicine at Rockford, Rockford, IL**

---

**Background:** With a rapid increase in migrants, Asian Americans (ASA) are the fastest growing racial group in the US. It is projected that ASA will be the largest immigrant group by 2060. Accordingly, ASA with autism are increasing (Biao et al., 2018). Recent studies have documented disparities in service use among racial and ethnic minorities, as well as immigrants (Magana et al., 2013; Shattuck et al., 2009). Other studies found that even higher income racial minorities face barriers in service use (Kim et al., 2020; Dababnah et al., 2019). This demonstrates the needs for understanding service use by specific demographic characteristics.

**Objectives:** The purpose of the study is to describe characteristics of service use among ASA caregivers of children with autism.

**Methods:** We developed a survey that includes items about early intervention, various services, and reasons not to use services. Professional translators translated the survey into four languages: Korean, Japanese, Mandarin, and Vietnamese. Participants were eligible to participate if they 1) lived in Maryland; 2) identified as Asian or ASA; 3) and were a parent or other primary caregiver of a child 18 years or younger with autism. Between October 2019 and July 2020, 42 ASA parents of children with autism completed the survey online and in-person. We used descriptive statistics to summarize our findings.

**Results:** About half of the parents who participated were Chinese (54%); the remaining participants were Korean (26%), Indian (5%), Japanese (5%), Vietnamese (5%), Filipino (2%), or Bangladeshi (2%). Most participants were highly educated (80%), had high incomes (About 80% had \$75,000 household income or more), and born outside of the US (84%). More than half of parents (60%) reported they received early intervention through the Maryland Infants and Toddler program (Part C services). Half of the parents reported that health professionals helped them to find early intervention services, while the remaining parents heard from friends (25%) or searched online (25%). The majority of the parents (81%) reported that their children received therapeutic services starting on average at 39 months (SD=21.5). The most used service was speech therapy (69%), followed by Applied Behavior Analysis (33%), occupational therapy (28.6%), and recreational activities (26.2%). The most commonly cited reason for not using services was that they were not aware of services (15-45%, depending on service). However, for ABA services, being on a waiting list was another equally cited reason (15%).

**Conclusions:** To our knowledge, this is the first quantitative study targeting ASA caregivers of children with autism. Compared to other services, many parents used early intervention and speech therapy. The majority of ASA parents found out about early intervention services through health professionals and friends. For them, the lack of awareness was the biggest barrier in accessing services. Results imply that formal and informal social networks and information about services are significant factors impacting ASA families' service use. Family support programs or parent-focused interventions should tailor their programs to build social networks and create awareness of available community and clinical services.

**526.109 (Virtual Poster) Subjective Satisfaction of Smart School Programs during Lockdown for COVID-19 Pandemics: Comparison between Subjects with Autism Vs Subjects with Other Neuropsychiatric Disorders.**

**E. Grossi, E. Castagna, A. Castelnuovo, E. Caminada, E. R. Castelli, D. Gilardoni, G. Molteni, G. Salardi, E. Zanini, M. Azzaretto and L. Marrano, Autism Research Unit, Villa Santa Maria Foundation, Tavernerio, Italy**

---

**Background:**

COVID-19 pandemic has forced almost all activities as businesses, schools and entire countries to move completely online. For children and adolescents requiring special education like those affected by neuropsychiatric disorders (NPD), a particular effort was needed to ensure good results. A special program called "Smart School" has been developed between April and June 2020 involving 97 subjects with NPD who were unable to access the school in our Institute, providing materials for specialized didactic, educational and rehabilitative activities.

**Objectives:**

The aim of this study is to compare the acceptance and compliance to Smart School programs between subjects with autism vs subjects with other NPD.

**Methods:**

The study group was composed by 28 subjects with autism (DSM-5 diagnosis), age 5-16 years (mean 11); 26 males and by 69 subjects with other NPD, age 4 – 17 years (mean 11); 32 males

The Smart School Project has foreseen the involvement of 20 Primary School Teachers and 5 specialized operators, 1 Chief of Professional Education that coordinates the whole project in all the different steps, 1 Developmental Psychologist 4 Professional Educators (EP) and 1 Neuro-Psychomotor Therapist of Developmental Age

The overall scheme of Smart School program is the following: The teachers (both Primary and Secondary classes) prepare weekly teaching materials for their students and using the Google-Drive platform they insert them in the link generated for each student.

The specialized operators automatically access the links of Google Drive and check weekly the material sent by teachers to compare and integrate it with the educational project. Through We Transfer, the specialized operators send all the material to the families. After sending the material, the families are contacted by the specialized operators assigned to help and support them both in carrying out the activities and in managing their child and any behavioral problems manifested.

After two weeks from the beginning of the online education (April 2020) the index of appreciation and satisfaction expressed by the children was detected through the principal caregiver (mother in 93%) through a 4-point Lickert scale from 1=unsatisfied to 4= very satisfied

#### Results:

The percentages of satisfactory + highly satisfactory judgment expressed by children and adolescents were 64.49% in group with autism and 25.8% in the group with other NPD ( $p < 0.01$ ). The corresponding percentages expressed by the caregiver were 60.8% and 55.3% ( $p = NS$ ) respectively .

#### Conclusions:

Subjects with autism showed a significantly higher appreciation of smart school online program at variance with subjects with other NPD. Caregivers judgments in the two groups were comparable. Lockdown for pandemic as expected seems to affect less the online education acceptance in students with autism despite their known resistance to the change routine context environment, probably because they suffer less from sociality lacking and because their environment at home seems to them more under control.

#### **526.110** (Virtual Poster) Systematic Adaptation of Evidence-Based Resources to Support Adults with ASD in Community Settings

**M. Melgarejo<sup>1</sup>, J. Suhrheinrich<sup>1</sup>, P. Schetter<sup>2</sup> and M. Rettinhouse<sup>3</sup>, (1)San Diego State University, San Diego, CA, (2)UC Davis, Sacramento, CA, (3)Alta Regional Center, Sacramento, CA**

---

#### Background:

The number of adults with autism receiving services through developmental disability (DD) agencies increased by more than 15% from 2009-14, and across the next decade we can expect a 123% increase in the number of individuals with autism transitioning from school-based to adult services (IACC, 2017). These increases have placed growing demand on adult disability service systems including an increased need for staff training on evidence-based practices (EBP) to support adults with autism. The Interagency Autism Coordinating Council (IACC) indicates many challenges faced in working with adults with autism are related to the lack of a well-trained and motivated workforce (IACC, 2017). Further, insufficient use of EBPs is linked to poor pre-service training, lack of supervision, and a low sense that the use of EBP is expected, supported, and rewarded (IACC, 2017). These findings indicate a clear need for professional development to increase staff capacity to use EBPs.

The National Professional Development Center for ASD (NPDC-ASD) developed a model to support increasing the use of EBPs for ASD in public school programs (Cox et al., 2013). The model and resources are associated with increases in overall program quality, use and fidelity of EBP and individual student progress (Odom et al., 2013). Leaders from the California Autism Professional Training and Information Network (CAPTAIN) successfully piloted an adaptation of the NPDC-ASD training model into adult day program contexts.

#### Objectives:

This project used a community-partnered model to evaluate organizational, staff and client needs to inform the adaptation of NPDC-ASD EBP training resources for use within community care facilities serving adults with autism.

#### Methods:

An online survey was sent to community care facility staff and administrators, and parents/caregivers of adults with autism residing in community care facilities. Survey items included demographics and questions about the service context and perceived needs. To expand upon survey data, a focus group was conducted with administrators.

#### Results:

A total of 73 administrators, 13 direct care staff, and 2 parents completed the survey. Staff and administrators identified behavior ( $n=52$ , 22.4%), adaptive skills ( $n=43$ , 18.5%) and mental health ( $n=36$ , 15.5%) as the top areas of client need. Participants reported Antecedent-Based Interventions ( $n=26$ , 19.7%), Reinforcement ( $n=15$ , 11.4%), Prompting ( $n=12$ , 9.1%), Functional Behavior Assessment ( $n=17$ , 12.9%), and Differential Reinforcement ( $n=15$ , 11.4%) as the most helpful EBPs for their facility. The majority of administrators ( $n=25$ , 41.7%) reported that professional development in EBPs for skills teaching and/or behavior management occurs a few times per year.

Focus group findings identified barriers to staff trainings as well as suggestions for adaptations. Administrators primarily emphasized staff knowledge, attitudes, and skills as barriers and suggested trainings should be practical, include an ongoing coaching component to observe the application of knowledge, and be interactive to increase engagement.

#### Conclusions:

Given these results, interactive video training modules were developed for two EBPs and materials including a site assessment checklist were adapted for the service context. The next step in this project is to evaluate the effectiveness of the training modules and coaching model in three community care facilities.

**526.111** (*Virtual Poster*) Talking about Me: An Autistic Take on Autism Terminology and Language  
*S. C. Jones, J. Lowe, C. Gordon and S. Mizzi, Australian Catholic University, Melbourne, VIC, Australia*

---

#### Background:

The public discourse surrounding the use of identity-first or person-first language in relation to autism has become a mainstay debate among autism researchers, health services and the autism community. Kenny (2015) reports identity-first language is preferred by autistic adults and parents/family members who care for autistic people in the UK, whilst person-first language is endorsed by professionals and community members. In relation to nomenclature, Bury et al., (2020) – using a ranked preferences methodology – found the term ‘person on the autism spectrum’ is preferred by autistic Australians.

#### Objectives:

The aim of this study was to understand the Australian autism community’s preferences in relation to autism language and terminology. The perspectives of autistic adults were also compared to the perspectives of family members and carers of autistic people.

#### Methods:

The research team, led by an autistic researcher, designed and implemented an online mixed method survey in consultation with a panel of experts – that is, autistic adults, parents and carers of autistic people. Data were collected in June 2021 and a combination of multiple choice and open-response questions provided an opportunity for participants to share their personal preferences and views on autism terminology and language. The perspectives of 1,666 autistic people were provided by 1,412 participants, including 634 autistic adults and 778 family members and carers of autistic people.

#### Results:

Participants were asked to select their preferred term(s) for autism from the options: autism, ASD, the spectrum, Aspergers, or other (multiple responses allowed). More than two-thirds (71.9%) of autistic respondents selected the term ‘autism’ and only 32.2% selected ‘ASD’. Family/carer participants were less likely than autistic people to select ‘autism’ (63.8%) and more likely to select ‘ASD’ (39.6%). Although ‘Aspergers’ has not been a valid diagnosis since the DSM-5 was released in 2013, 20% of autistic people and 13% of family/carers nominated this as a preferred term. Other preferred terms noted in the open-ended responses included Aspie, ASC (Autism Spectrum Condition), and neurodiverse/neurodivergent; and both groups emphasised the importance on following the lead of the autistic community.

More than half (57.7%) of autistic adults preferred identity-first language, whilst only 11% preferred person-first language; approximately one quarter (27%) had no preference. In contrast, only 27.1% of family members/carers preferred identity-first language, 28.9% preferred person-first language and 36.9% had no preference. In the open-ended comments both groups emphasised the importance of respecting autistic people’s personal preferences in language use.

#### Conclusions:

Autistic adults were five times more likely to indicate a preference for identity-first than person-first language. Conversely, family/carer participants were slightly more likely to indicate a preference for person-first than identity-first language. This divergence may reflect varying perspectives on the extent to which autism is an integral part of the individual. There is a need for further research into these differing perspectives and the extent to which they contribute to, or inhibit, autism acceptance among individuals, families and communities.

**526.112** (*Virtual Poster*) Trends and Variations in Receiving Care from Psychiatric Providers within 30 Days of Psychiatric Emergency Department Visits Among People with Autism Spectrum Disorder  
*G. Liu<sup>1</sup>, L. Kong<sup>1</sup>, D. Ba<sup>1</sup> and M. Murray<sup>2</sup>, (1)Public Health Sciences, Penn State University College of Medicine, Hershey, PA, (2)Department of Psychiatry/Division of Autism Services, Penn State University College of Medicine, Hershey, PA*

---

Background: People with autism spectrum disorder (ASD) are more likely to experience psychiatric crises that require emergency department (ED) visits than those without ASD. It is critical for them to receive psychiatric care soon after these acute episodes. However, little is known on the trends and variations in utilization of service from psychiatric providers after ED visits.

**Objectives:** This study uses a large, national healthcare claims database of a privately insured population in the United States to examine the pattern of psychiatric care received within 30 days of psychiatric ED visits among people with ASD.

**Methods:** Using the 2005-2018 IBM MarketScan® database, we designed a retrospective cohort study to examine the visits to psychiatric providers including psychiatrists and psychiatric nurses within 30 days of the psychiatric ED visits among people with ASD aged under 65. We identified people with ASD as those with  $\geq 1$  inpatient or  $\geq 2$  separate outpatient diagnoses of ASD (ICD-9 code: 299; ICD-10 code: F84). We used the combined information from service place, category and provider to identify ED visits, of which those due to psychiatric reasons were further identified according to the primary/second diagnosis (ICD-9: 290-319; ICD-10: F01-99). For a subject's ED visit to be included in the analysis, a continuous enrollment of  $\geq 1$  year prior to and  $\geq 30$  days after the ED visit was required. Descriptive analyses and multivariable logistic regression are used to examine the trends and variations in receiving care from psychiatric providers in conjunction with other factors.

**Results:** Our study cohort consisted of 56,227 people with ASD, contributing 135,051 psychiatric ED visits from 2006 to 2018. The rates of receiving care from psychiatric providers within 30 days after ED visits (30-Day PsyCare) were generally low overall ( $<35\%$ ), and across all genders, age groups and types of residence (Figure 1). There were significant geographic variations across the states in 30-Day PsyCare (Figure 2). On one hand, states like Iowa, Alaska, and Rhode Island had higher rates above 40%; on the other hand, the rates in Mississippi, Arkansas, Tennessee, and Hawaii were below 20%. Multivariable logistic regression analysis confirmed the findings from the descriptive analysis that there existed significant demographic and geographic variations in the odds of receiving 30-day PsyCare. In particular, living in a rural residence was associated with decreased odds of receiving 30-Day PsyCare than in an urban residence (adjusted Odd Ratio: 0.72; 95% Confidence Interval: 0.67-0.78). Adolescents and young adults were more likely to receive 30-day PsyCare while children aged 12 or younger were the least likely. Other mental health comorbid conditions were strongly associated with 30-day PsyCare (4.96; 4.63-5.37). However, Intellectual disabilities were negatively associated with 30-day PsyCare (0.87; 0.82-0.92), so was history of epilepsy/seizures (0.68; 0.64-0.72).

**Conclusions:** This study documents the consistent trend of low utilization of, and significant geographic/demographic variations in psychiatric care within 30 days of psychiatric ED visits among people with ASD. Further studies are warranted in identifying barriers and points of interventions to improve the post-ED psychiatric care for this vulnerable population.

## Social Cognition and Social Behavior

### PANEL — SOCIAL COGNITION AND SOCIAL BEHAVIOR

#### 214 - Perceptions and Experiences of Social Acceptance and Peer Victimization for Autistic Youth and Adults

**Panel Chair:** **Hannah Morton**, *Binghamton University, Binghamton, NY, Oregon Health & Science University, Portland, OR, Binghamton University, Binghamton, NY, Oregon Health & Science University, Portland, OR*

**Discussant:** **Jonathan Campbell**, *Psychology, Western Carolina University, Cullowhee, NC*

**214.001 (Panel)** Non-Autistic Children Stigmatize Gaze Aversion, but Not Other Autistic-like Behaviors  
**Z. M. Sargent** and **V. K. Jaswal**, *University of Virginia, Charlottesville, VA*

**Background:** Autism is associated with behaviors that are considered atypical, including hand-flapping and decreased levels of eye contact. Non-autistic people quickly form negative impressions of autistic people on the basis of their atypical behaviors, but learning that someone who is behaving in an unusual way is autistic tends to mitigate these negative evaluations. Additionally, young children are sensitive to social norms, and they disapprove of individuals who violate such norms. Thus, it is possible that young children's aversion to norm violations could influence the development of their negative evaluations of autistic people. However, no studies have investigated how specific autistic-like behaviors and perceptions of normativity may influence young non-autistic children's attitudes towards autistic peers.

**Objectives:** The objectives of this study were to investigate whether young (4- to 7-year-old) non-autistic children stigmatize specific behaviors associated with autism, and to what extent diagnostic disclosure would influence their evaluations.

**Methods:** Over Zoom, we presented 112 non-autistic 4- to 7-year-olds (57 female) with six vignettes. Each vignette presented three characters engaging in a normative behavior, and a fourth character engaging in a specific behavior characteristic of autism. Half of the children were told that the autistic-like character had to behave in that way "because she/he is autistic, which means her/his brain is different from other kids'" ("label" condition); half received no such explanation ("no label" condition). After each vignette, we asked children what they would do and whether the autistic-like character could choose how to behave. We also asked whether the normative and autistic-like behaviors were okay, and whether they would like to be friends with the characters.

**Results:** Children usually reported that they would engage in the normative rather than autistic-like behavior themselves. Children in the no-label condition indicated that the autistic-like character could have chosen to engage in the normative behavior, whereas children in the label condition tended to be ambivalent. Crucially, children in both conditions were more accepting of the autistic-like behaviors and characters than would be expected by chance, though they gave higher ratings to the normative behaviors and characters. The only exception to this pattern was gaze aversion:

Children in both conditions disapproved of looking away while a teacher was talking, and they were ambivalent about befriending someone who did so. The disclosure of diagnostic information mitigated evaluations of gaze aversion and the character who engaged in it somewhat.

**Conclusions:** This study suggests that non-autistic children view autistic-like behaviors as non-normative, but that they do not consistently disapprove of these behaviors or individuals who engage in them. However, children did disapprove of gaze aversion, suggesting that norms about eye contact may be especially likely to influence their evaluations of autistic peers. Further work is needed to apply the findings of this study to real-life situations, but one possible implication is that teaching children how eye contact is difficult for some students, and that such students are still paying attention to the teacher, could improve non-autistic students' perceptions of their autistic peers.

**214.002 (Panel)** The Effect of Exposure to Autism and Sense of School Belongingness on Attitudes Towards Bullying and Autism in Schools – a Longitudinal Cohort Study

**A. H. Cook<sup>1</sup> and J. Ogden<sup>2</sup>,** (1)Department of Psychology, Goldsmiths University of London, London, United Kingdom, (2)Psychology, University of Surrey, Guildford, United Kingdom

---

**Background:** In the UK, 40% of autistic children are bullied at school (DfE, 2015). Studies highlight the negative impact of bullying on social, emotional and academic outcomes. Little research explores bystander responses of non-autistic children to different forms of bullying targeted towards autistic peers. It has been suggested that adolescents' attitudes towards bullying and social exclusion are influenced by peer-group and school norms, which can moderate emotions and predict intended behaviours. The opening of new specialist centres for autistic pupils in Southern England (NAS, 2015) offered a unique opportunity to explore the impact of exposure to autism on attitudes of non-autistic children towards the bullying of autistic peers. The role of pupils' sense of school belongingness (SOSB) was also explored. This exists when members of the school community share positive and consistent relationships, and thus provides a proxy measure of school inclusivity.

**Objectives:** The study explored whether non-autistic children's attitudes towards bullying and autism vary according to school type (schools with vs. without a specialist centre), personal exposure to autism and SOSB. It also explored differences in attitudes towards contrasted bullying violations (verbal bullying vs. social exclusion).

**Methods:** Survey data were collected from 302 non-autistic pupils, aged 11-12 (Time 1) and again when they were aged 14-15 (Time 2) from four mainstream schools: two with specialist centres and two without. Participants read vignettes of bullying scenarios depicting either verbal bullying or social exclusion of autistic or neurotypical targets. They then completed measures of their judgements, emotions and intended behaviours in response to the vignette, personal exposure to autism and cognitive attitudes towards autistic people. At Time 2, they also completed a measure of their SOSB.

**Results:** While no differences were found according to school type, a significant interaction showed that the only increase in prosocial judgements occurred in response to social exclusion of autistic targets. Furthermore, a multiple regression analysis indicated that non-autistic pupils' SOSB at Time 2 provided a stronger prediction of attitudes to autism and judgements towards bullying of autistic targets than personal exposure to autism.

**Conclusions:** Findings indicate that non-autistic adolescents' tolerance of social exclusion of autistic peers decreases with age, regardless of school type. This was particularly striking since all other bullying scenarios resulted in lower prosocial responses with age. Verbal bullying – as the most common form of bullying – may be accepted as a social norm and hence be more tolerated in order to preserve group functioning. In contrast, social exclusion of an autistic peer may raise more moral considerations, supporting theories of moral development. Findings also indicate that personal exposure to autism is not as influential for change in cognitive attitudes towards autism and bullying as pupils' SOSB. Positive and consistent relationships may therefore lead to more prosocial attitudes towards neurodivergent peers. These results highlight the importance of developing an inclusive school environment where all pupils feel they belong, in order to reduce bullying and instil greater understanding and acceptance of autistic students and other stigmatised groups alike.

**214.003 (Panel)** Self-Report of Disability-Specific Peer Victimization in Autistic and ADHD Youth: A Pilot Study with Animated Video Stimuli  
**H. E. Morton<sup>1,2</sup>, S. Swinson<sup>1,3</sup>, K. R. Warnell<sup>4</sup>, J. M. Gillis<sup>4</sup> and R. G. Romanczyk<sup>1</sup>,** (1)Binghamton University, Binghamton, NY, (2)Oregon Health & Science University, Portland, OR, (3)Social Work, Columbia University, New York, NY, (4)Department of Psychology, Texas State University, San Marcos, TX

---

**Background:** Autistic and ADHD (Attention-Deficit/Hyperactivity Disorder) youth are more likely to experience peer victimization compared to their neurotypical peers. Most research on this topic, however, is from the perspective of youth who can read prompts and complete written questionnaires. Additionally, autistic/ADHD youth are vulnerable to disability-specific bullying, but existing questionnaires assess bullying using items designed for neurotypical youth. To close these gaps, this study modifies and extends the Assessment of Bullying Experiences (ABE). The ABE is a recently validated, parent-report bullying questionnaire that includes 11 disability-specific victimization behaviors described by autistic youth in prior literature.

**Objectives:** The present study adapts the ABE parent-report questionnaire for youth self-report using both written (ABE-Written) and video-based (ABE-Video) formats.

**Methods:** The ABE-Written was created by revising the third person wording of the ABE parent-report questionnaire. To create the ABE-Video, Vyond Studio Software was used to create 55 brief animated videos (11-17 seconds each) portraying peer victimization behaviors corresponding to items on the written questionnaire. Participants viewed a version of each video that most closely aligned with their own gender and racial identities and then indicated if the scenario had happened to them, how often it had happened, and if this behavior was bullying. Non-bullying videos and impossible scenarios were included as controls. The ABE-Written and ABE-Video were administered online.

**Results: (Study 1)** Pilot findings from 40 undergraduate students (18-23 years old) confirmed that peer victimization videos more likely to be identified as bullying ( $M = 94.7\%$ ,  $SD = 22.4\%$ ) compared to non-bullying or impossible videos ( $M = 12.7\%$ ,  $SD = 33.4\%$ ;  $t(2165) = 49.15$ ,  $p < .001$ ). There was significant intrarater agreement (Intraclass Correlation (ICC)) for undergraduate self-report between the ABE-Written items and the corresponding ABE-Video items for 71% of bullying behaviors, with moderate agreement, on average, between methods ( $M_{ICC} = 52.4\%$ ,  $SD_{ICC} = 24.1\%$ ; range ICC = 0.23 – 1.00).

**Results: (Study 2)** Data collection is underway with autistic and ADHD youth (11-21 years old) via remote Zoom research sessions. To date, 19 youth have completed the ABE in both written and video formats and a sample of 100 adolescents is anticipated by January 2022. Preliminary analyses indicate autistic/ADHD youth are also more likely to identify victimization videos as bullying ( $M = 93.2\%$ ,  $SD = 25.1\%$ ) compared to non-bullying or impossible scenarios ( $M = 10.3\%$ ,  $SD = 30.5\%$ ;  $t(713) = 26.87$ ,  $p < .001$ ). The ABE-Written questionnaire is moderately correlated with the ABE-Video measure ( $r = .42$ ,  $p = .08$ ). Findings from the complete dataset will be presented, including exemplar animations from the ABE-Video digital measure that have high reliability with ABE-Written questionnaire items.

**Conclusions:** The ABE provides unique insight into disability-specific bullying vulnerability in autistic and ADHD youth. The video adaptation shows promise for understanding the peer victimization experiences of nonspeaking youth or those who do not read/write. The bullying behaviors frequently experienced by autistic and ADHD youth, as identified by the ABE, should be incorporated within psychoeducation and acceptance interventions.

**214.004 (Panel)** “Wanting to Belong and Never Quite Making the Mark” a Qualitative Exploration of How Autistic Females Experience Social Rejection

A. Boddy<sup>1</sup> and A. H. Cook<sup>2</sup>, (1)University of Surrey, Guildford, United Kingdom, (2)Department of Psychology, Goldsmiths University of London, London, United Kingdom

---

**Background:** Despite the established link between rejection sensitivity (RS) and internalising symptoms (Bondü et al., 2017), the role of rejection has seldom been explored in relation to the internalising disorders commonly exhibited by autistic women (Kanne et al., 2009). Previous research has suggested that chronic rejection can lead to the development of a rejection-sensitive disposition (Downey et al., 1998) which may function bi-directionally to advance intra- and interpersonal difficulties. It is, therefore, of note that within the autistic community, the term 'Rejection Sensitivity Dysphoria' has been adopted to describe the adverse response to real, perceived, and anticipated rejection. However, this assumed phenomenon has, to date, received little research attention.

**Objectives:** Guided by this community insight and the recent impetus to elevate women's voices in the autistic community (Pellicano et al., 2014), this study sought to advance our understanding of how autistic women experience social rejection throughout their lives. With little research offering an in-depth exploration of responses to rejection amongst this population, this study adopted a do wide scope to address the question: How do women on the autistic spectrum experience social rejection?

**Methods:** Semi-structured interviews were conducted with 10 autistic women aged 19 to 56. Questions captured both the context, experience and response to social rejection at different stages in life; namely childhood, adolescence and adulthood. Accompanying this were questions that sought to elucidate participants overall concern with rejection, response to criticism, as well as any emotional impact of being socially rejected.

**Results:** Thematic analysis offered novel insights into the long-term emotional impact experiences of social rejection. Participants' accounts described the profound impact that formative experiences of social rejection had upon them: serving as a pivotal moment in which an internal sense of 'difference' became actualised. This was to the detriment of participant self-esteem, mental health and trust of others. Themes were highly inter-related, revealing a relationship between experience, response and emotional impact that was, at times, self-perpetuating in nature (Figure 1). Analysis revealed how women's concern with social rejection and desire for acceptance motivated the use of 'risk-mitigating behaviours' including camouflaging, avoidance and withdrawal which, although often protective, equally had the potential to further social isolation and psychological burden.

**Conclusions:** Congruent with the results outlined in this study, the RS model (Downey et al, 1998) proposes that ostracising experiences can sensitise youths to rejection. This can produce a rejection-sensitive disposition characterised by rejection anticipation becoming activated in situations where ostracism is possible. This model has previously been applied to ADHD, and our findings infer its potential applicability to autistic women. Moreover, the study highlights how social and communicative challenges inherent to autism may interact to intensify RS amongst this population. It is concluded that future research should seek to explore the role of RS in mediating the negative internalising outcomes commonly exhibited by autistic women.

## PANEL — SOCIAL COGNITION AND SOCIAL BEHAVIOR

### 216 - Double Empathy Problem: Investigating the Social Interaction Profiles of Autistic People When Interacting within and across Diagnostic Boundaries, and Implications for Theory and Practice

**Panel Chair:** Noah Sasson, *University of Texas at Dallas, Richardson, TX*

**Discussant:** Morton Ann Gernsbacher, *Department of Psychology, University of Wisconsin-Madison, Madison, WI*

**216.001** (Panel) Theorising the Double Empathy Problem: A Retrospective Review  
*D. Milton, Tizard Centre, University of Kent, Canterbury, United Kingdom*

#### Background:

The term the ‘double empathy problem’ was first coined as a practical way to describe to non-academic audiences that the social disjuncture often felt by autistic people was also often felt by non-autistic people in their interactions with autistic people. This way of framing the issue led to an academic article published in 2012, where the concept was situated within broader sociological and social psychological theory, drawing upon personal experience and emerging findings from qualitative studies. Since this work was first published ten years ago, numerous research groups examining social reciprocity between autistic and non-autistic people arrived at similar conclusions. In more recent years this work has been consolidated and has led to discussions regarding the practical implications raised by such a conceptualisation.

#### Objectives:

This presentation retrospectively reviews the theoretical development of the concept of the double empathy problem, its philosophical antecedents, and explores areas for future development of research on the topic.

#### Methods:

A scoping review of relevant literature was used to explore the conceptualisation of the double empathy problem over time and how this continues to be informed by empirical studies.

#### Results:

The issue of the double empathy problem has been theoretically and empirically explored across numerous subject disciplines, with important developments in the fields of psychology, neuroscience and linguistics among others.

#### Conclusions:

Whilst various conceptualisations of the double empathy problem have led to a burgeoning area of research, there is much work needed to fully understand how it operates and manifests in different contexts, particularly regarding wider social dynamics of power within which the double empathy problem resides.

**216.002** (Panel) Autistic Peer-to-Peer Communication Is Effective and Rewarding: Implications for the Social Deficit Model of Autism  
*C. J. Crompton, University of Edinburgh, Edinburgh, United Kingdom*

**Background:** The social deficit model of autism suggests that autistic social deficits underly difficulties in communication with others. Most research to date has focused on autistic deficits on clinical and lab-based social tasks, which in theory underpin difficulties in real-world communication. However, real-world communication requires a complex two-way exchange between interlocutors, relying on reciprocity and mutual understanding, and can be affected by the social context of the interaction.

If social cognition is impaired in autism, real-world communication between two autistic people should be especially challenging, and communication between autistic and non-autistic people should be more successful and easier. However, first-hand reports from some autistic people indicate that this does not align with their experiences. Our research uses experimental quantitative and qualitative methods to examine whether communicating with someone of a different neurotype (i.e. autistic people and non-autistic people interacting together) is more or less successful and rewarding than communicating with someone of the same neurotype (i.e. autistic people interacting together).

**Objectives:** To empirically examine (1) whether there are differences in information transfer accuracy when autistic people communicate with autistic people and non-autistic people (2) whether there are qualitative differences in how autistic people experience spending time with autistic and non-autistic people (3) what the theoretical and practical implications of this work may be.

**Methods:** Three studies will be presented. Study 1 uses a diffusion chain technique; a controlled, experimental form of “telephone” which probes cultural learning between individuals in (a) groups of autistic people (b) groups of non-autistic people (c) mixed groups of autistic and non-autistic

people. Study 2 uses semi-structured interviews to explore and contrast autistic experiences of spending time with autistic and non-autistic family and friends. Study 3 uses qualitative interviews to explore autistic needs and experiences following their diagnosis with a particular focus on autistic peer support.

**Results:** Study 1: Information transfer between groups of autistic people did not significantly differ in quality to information transfer between groups of non-autistic people. Mixed groups autistic and non-autistic people performed significantly more poorly, showing a steeper decline in detail sharing between participants. This indicates that autistic people effectively share information with each other, and information transfer selectively degrades within mixed groups. Study 2: Thematic analysis suggested strong benefits for autistic people creating and maintaining social relationships with other autistic people, with difficulties and exhaustion experienced selectively when interacting with non-autistic people. Participants highlighted a need for autistic-led social opportunities and peer support for autistic adults. Study 3: Autistic participants highlighted the benefits of spending time with other autistic people after receiving a diagnosis in adulthood, and indicated that autistic-specific peer support may be a useful mechanism for post-diagnostic support, offering unique opportunities not available through other support channels.

**Conclusions:** Taken together, these findings provide evidence that autistic peer-to-peer communication is effective and rewarding. They suggest that there may be selective bi-directional difficulties in communication between autistic and non-autistic people, in contrast to the social deficit model of autism. The theoretical and practical implications of this work will be discussed.

#### **216.003 (Panel) Double Empathy in the School Context: Observing Peer Interactions Among Autistic and Non-Autistic Youth**

**Y. L. Chen<sup>1,2</sup>** and **K. P. Koenig<sup>3</sup>**, (1)*Center of Outcomes and Assessment Research, Kessler Foundation, East Hanover, NJ*, (2)*Physical Medicine and Rehabilitation, Rutgers University New Jersey Medical School, Newark, NJ*, (3)*Occupational Therapy, New York University, New York, NY*

---

##### **Background:**

Autistic youth often experience difficulties interacting with peers at school, resulting in greater feelings of loneliness and a higher incidence of bullying than non-autistic youth. As negative peer experiences can adversely affect autistic youth's mental health and quality of life, it is vital to identify factors contributing to autistic peer outcomes in school settings. Previous research on autistic peer interactions has primarily focused on individual factors, such as social-communicative and cognitive characteristics. The Double Empathy Problem (DEP) theory and its supporting research indicate, however, that individual factors may not fully explain autistic social difficulties. Rather, interpersonal similarity in neurotype and social disposition may be more influential on autistic social outcomes.

**Objectives:** To examine the peer interaction profiles of autistic youth when interacting with peers within and across neurotypes in an integrated education setting.

##### **Methods:**

This mixed methods research investigated peer interactions among 17 youth (age 12-14, seven were autistic) in an integrated school club over 5 months. The quantitative study observed and codified the characteristics and reciprocity of social behaviors among autistic and non-autistic youth. Based on the observed peer interactions, we plotted the social networks among the youth and examined the role of neurotype match on peer connections. The qualitative study explored the characteristics of peer interactions within and across neurotypes.

##### **Results:**

Rates of social interactions did not differ between autistic and non-autistic youth. Both autistic and non-autistic youth were more likely to interact with peers within their neurotypes, and this tendency strengthened over time. Social behaviors within neurotype, compared to those across neurotypes, were less likely to be based on functional purposes and more likely to be sharing thoughts, experiences, or items rather than requesting help or objects. Within-neurotype interactions were also more likely to be highly reciprocal than cross-neurotype social behaviors. Unlike typical social networks where individuals tend to interact with those sharing similar social statuses, youth in this study did not show greater connections with those of similar levels of social popularity or activity. Instead, the youth formed more and stronger connections with their same-neurotype peers, as indicated by their social interaction frequencies. Qualitative exploration found that interpersonal similarities in interests and social styles were a central theme in highly reciprocal peer interactions, particularly those among autistic youth. Openness to social profiles that were different from the norms played an important role in cross-neurotype interactions.

##### **Conclusions:**

This preliminary study examined real-world peer interactions in a school setting with equal numbers of autistic and non-autistic youth. Observations of social behaviors and interaction networks revealed better interaction outcomes among youth within than cross neurotypes. The positive outcomes in same-neurotype interactions support the DEP theory and suggest that autistic social difficulties may result from differences in the social expectations and profiles between autistic and non-autistic youth. This hypothesis implies that interventions to support peer engagement in autistic youth may focus on facilitating mutual understanding across neurotypes and promoting a culture of openness to non-normative social styles.

#### **216.004 (Panel) The Effects of Biases Toward Autism on Social Interaction and the Perception of Autistic Abilities**

**D. R. Jones, K. M. DeBrabander and N. J. Sasson**, *University of Texas at Dallas, Richardson, TX*

---

Background:

Non-autistic (NA) people commonly hold biases toward autism. These biases can build exclusionary social environments that contribute to poor personal and professional outcomes for autistic adults.

#### Objectives:

To characterize biases about autism relative to other clinical conditions; to examine whether these biases include underestimating autistic cognitive abilities; and to assess the malleability of biases and their effect on interaction.

#### Methods:

Study 1: A thematic analysis was conducted on open-ended responses from 533 undergraduates on their ideas about diagnostic labels related to either autism, schizophrenia, or an unspecified clinical condition.

Study 2: 977 NA undergraduates predicted the performance of 42 autistic and NA adults on six standardized social cognitive and cognitive tasks after watching them in videos and completed questionnaires assessing their autism knowledge and stigma.

Study 3 (Jones, et al., 2021): 238 NA adults were randomly assigned to: 1) autism acceptance training (AAT); 2) mental health training (MHT), or 3) a control condition. After viewing the training, participants watched thin-slice videos of 40 autistic and NA adults and completed measures assessing their implicit and explicit biases toward autism.

Study 4 (Jones et al., 2021): 39 NA males randomly assigned to AAT or a no-training control condition participated in a 5-min conversation with an unfamiliar autistic partner (n = 39). Participants provided their perceptions of the interaction and their partner.

#### Results:

Study 1: The autism label showed the greatest variability in responses, with the most frequent code (poor social abilities) occurring in just 15% of responses. Responses to schizophrenia and the general clinical condition showed greater cohesion.

Study 2: NA raters were less accurate and underestimated autistic participants' cognitive performance more than NA participants. Underestimation for autistic adults was greater for social cognitive relative to general cognitive tasks. Greater autism knowledge was associated with greater accuracy in ratings of autistic social cognitive abilities but decreased accuracy for ratings of autistic cognitive abilities. For autism stigma, increased stigma was associated with less accuracy for ratings of autistic cognitive abilities and greater accuracy for autistic social cognitive abilities.

Study 3: Participants in the AAT condition were less likely to agree with misconceptions about autism and showed more favorable attitudes toward interactions with autistic people. However, AAT was not associated with reductions in implicit biases toward autism.

Study 4: Both autistic and NA partners reported a greater interest in hanging out with the partner in the future when the NA adult had first completed AAT. Other interaction outcomes, including first impressions and perceptions of the interaction, largely did not differ between training and no-training conditions.

#### Conclusions:

These studies suggest that biases about autism differ compared to other conditions and are associated with negative evaluations of autistic people and misconceptions about autistic abilities, including objectively measured cognitive skills. While interventions targeting autism knowledge and stigma may improve attitudes and reduce biases in the short-term, further evidence is needed to determine the extent of these effects in real-world environments.

## ORAL SESSION - 8A — SOCIAL COGNITION AND SOCIAL BEHAVIOR

### 314 - Innovative Measures of Autistic Social Behavior

#### **314.001** (Oral) Developing an Exploratory Novel Translational Social Habituation Task for Children

**A. Pilkington<sup>1</sup>, J. Koziel<sup>2</sup>, A. N. de Rothschild<sup>2</sup> and E. Loth<sup>3</sup>,** (1)Institute of Psychiatry, Psychology & Neuroscience, King's College London, UK, London, United Kingdom, (2)Department of Forensic and Neurodevelopmental Sciences, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (3)Forensic and Neurodevelopmental Sciences, Institute of Psychiatry, Psychology, and Neuroscience, King's College London, London, United Kingdom

#### Background:

Although difficulties in social communication is a core feature of autism, underpinning processes are multifaceted. These are suggested to range from diminished social reward sensitivity (Klin et al. 2003), to social cognitive processes or anxiety (Chevallier et al. 2012). Therefore, heterogeneity both between autistic people, and in terms of particular neurocognitive atypicalities, has impacted attempts to stratify the condition or to assess the

efficacy of particular therapies. The current study aimed to develop and validate a social novelty task for children by “back-translating” a behavioural assay used in animal models (Bariselli et al. 2018). Social novelty has a well-described neurobiological basis, including oxytocin signalling in dopaminergic neurons in the ventral tegmental area. A recent study showed that both molecular and behavioural responses could be ‘rescued’ by a specific MNK inhibitor that restored oxytocin signalling through resetting of translational regulation (Hörnberg et al. 2020). These findings point to the need for sensitive tests to assess social novelty responses either to specifically enrol a subset of individuals in clinical trials who show this pattern, and/ or to specifically measure the effect of treatments targeting social reward sensitivity.

#### Objectives:

Firstly, to develop a human version of the animal habituation task which creates a meaningful social interaction between the participant and the characters within the task. Second, to validate the task by measuring correlations between social novelty responses and ASD traits reflecting social reward sensitivity on clinical subscales.

#### Methods:

This task is part of the “Time Trekkers”: a behavioural task battery aimed at children aged 6-12. The participant plays quick-fire rounds of rock-paper-scissors with characters from the Trekkers. The first block of 20 trials is always against the same character. The subsequent four blocks are 10 trials, and begin with a choice between this familiar first character and a different character (see Figure 1 below for a schematic visualisation). Key dependent variables are 1) the participant’s first choice, and 2) the number of times a familiar character is chosen (0-4). Parents are asked to complete the SRS and SDQ for the child (results not reported).

To date 19 children aged 6-11 years (10 TD [8 boys], 9 ASD [8 boys]) took part in a pilot study.

#### Results:

Given the current small sample size, only descriptive statistics are reported. Figure 2 shows the pattern of responses for each participant across the four choices. Only the ASD group has 2 participants who choose the familiar character 100% of the time, and has fewer mixed patterns than the TD group. Qualitative feedback from parents indicate this task is well liked, easy to understand, and does elicit a social response from the child; 8 children like this task the most out of the battery.

#### Conclusions:

As a pilot of an exploratory novel task, results and feedback are promising, suggesting a sub-group of autistic individuals who may show a preference for social familiarity. Data collection is ongoing with a target of n=50. We will report on group findings and construct validity.

### **314.002** (Oral) The Social Attribution Task-Revised (SAT-R): Criterion-Oriented Validity and Feasibility of a Brief Spontaneous Theory of Mind Task in Children with Autism Spectrum Disorder

**M. R. Altschuler<sup>a</sup>** and **S. Faja<sup>a</sup>**, (1)*Institute of Child Development & Department of Psychology, University of Minnesota, Minneapolis, MN*, (2)*Boston Children's Hospital, Boston, MA*

---

#### Background:

A primary issue with laboratory-based theory of mind tasks is that they vary in their sensitivity to real-life social demands. To be successful in social situations, it is necessary to spontaneously identify relevant social information. However, only a few studies have examined spontaneous theory of mind by eliciting open-ended narratives, largely due to the time-intensive nature of coding open-ended responses. The Social Attribution Task measures spontaneous theory of mind but requires a significant amount of time for coding and administration. The Problem Solving Index from the Social Attribution Task represents a brief, feasible scale within the larger SAT task that could measure spontaneous theory of mind using quick and straightforward coding, but it has not yet been validated as its own stand-alone task.

#### Objectives:

To establish the feasibility and criterion-oriented validity of a spontaneous theory of mind task that is quick to administer and score but still retains the open-ended nature of eliciting spontaneous narratives about a geometric cartoon with social elements.

#### Methods:

Participants included 55 children between the ages of 7 and 12 years-old with an ASD diagnosis (based on ADOS-2, ADI-R, and DSM-5) and WASI-2 Full Scale IQ of 80 or above. Participants completed the Social Attribution Task (Klin, 2000), which produced open-ended narrative responses about a video of geometric shapes enacting a social scene. The Problem Solving Index was used as a stand-alone measure of spontaneous theory of mind that we propose should comprise the SAT-R (inter-rater reliability, .98). The Salience and Affective Theory of Mind Indices of the SAT were used as laboratory measures of spontaneous theory of mind and required extensive coding time. The Theory of Mind Test (TOM Test; Muris et al., 1999) and false belief video battery (Saxe, 2009) were used as laboratory measures of non-spontaneous theory of mind. The Social

Cognition subscale of the Social Responsiveness Scale (SRS-2) was used as a questionnaire measure of behaviors that require theory of mind in daily life.

#### Results:

The SAT-R was associated with (1) the two laboratory measures of spontaneous theory of mind (Saliency:  $r = .37, p = .01$ ; Affective Theory of Mind:  $r = .46, p < .001$ ); (2) the two laboratory measures of non-spontaneous, traditional theory of mind (TOM Test:  $r = .40, p < .001$ ; Videos:  $r = .35, p = .01$ ); and, (3) the caregiver-questionnaire measure of theory of mind (SRS-2 Social Cognition:  $r = .28, p = .04$ ). Moreover, becoming reliable on and administering the SAT-R was significantly quicker and easier than the full SAT, averaging two minutes per participant to code.

#### Conclusions:

Results demonstrated and feasibility and criterion-oriented validity of a brief spontaneous theory of mind task that is quick to administer and score but still retains the open-ended nature of eliciting spontaneous narratives about a geometric cartoon with social elements. This task provides a feasible and dimensional, lab-based measure of social cognition that more directly simulates the need to engage in ambiguous social problem solving in daily life than do traditional, non-spontaneous theory of mind tasks.

#### **314.003** (Oral) Empathic Accuracy and Empathic Synchrony: Developing a Novel Test with Autistic and Non-Autistic People

**Y. Rum<sup>1</sup>, C. Allison<sup>1</sup>, P. Smith<sup>2</sup>, S. Genzer<sup>3</sup>, O. Golan<sup>4</sup>, A. Perry<sup>3</sup> and S. Baron-Cohen<sup>1</sup>,** (1)Autism Research Centre, Department of Psychiatry, University of Cambridge, Cambridge, United Kingdom, (2)University of Cambridge, Cambridge, United Kingdom, (3)The Hebrew University of Jerusalem, Jerusalem, Israel, (4)Bar-Ilan University, Ramat-Gan, Israel

---

#### Background:

Story-telling can be used as an experimental tool to measure empathic accuracy, i.e., the correspondence between a perceiver and the target of empathy. In this paradigm, an individual (the target) is videotaped, sharing autobiographical memories and is asked to report his/her emotions while story-telling. These reports are then used as a reference when measuring empathic accuracy (when perceivers are asked to infer the target's emotions) or empathic synchrony (when perceivers are asked to report their own emotions while observing the target's stories). Most research based on this paradigm in non-typical populations focuses on empathy deficits in perceivers from neurodivergent populations in relation to neurotypical targets, while the bidirectional nature of empathy is often overlooked. The Double Empathy Theory (Milton, 2012; Milton et al., 2018) challenges the traditional perception of empathy deficits in autism, offering a bidirectional lack of empathy between autistic and non-autistic people. This theory is gaining increased attention from the autism community and autistic researchers, but so far has yielded very little empirical research. Inspired by this theory and because of the need for research tools to investigate empathy towards neurodivergent individuals, we developed the Empathic Accuracy and Empathic Synchrony (EA-ES) set of stimuli as a new tool.

#### Objectives:

To build a new EA-ES set of stimuli, based on autistic and non-autistic targets.

Methods: Autistic ( $n=29$ [1]; 12 females, 15 males, 1 other) and non-autistic ( $n=16$ [2]; 13 females, 3 males) adults participants were video-recorded (using the Zoom platform), sharing emotional autobiographic memories. Each participant shared 3 different stories and then reported their emotions while telling these stories and rated continuously how positive or negative they felt at any moment whilst sharing each story. Participants also completed a demographic survey and questionnaires to measure autism traits (AQ-10), alexithymia (TAS-20), empathy (the EQ-40) and camouflaging of autistic traits (CAT-Q). Table 1 details the participants' characteristics.

[1] Due to the pandemic, testing has been delayed but this sample will be 30 participants

[2] This sample will be 30 participants

#### Results:

This procedure resulted in 135 video clips of targets sharing true stories from their lives (2-6 minutes in length), accompanied by self-reported feelings and emotions of the story-teller. Each story/clip is classified as: 1. conveying positive, negative or mixed emotions according to the targets' reports; 2. referring to a childhood memory, a memory from high-school/early adulthood, or to an event from adulthood; 3. the level of consent by the story-teller for future use of his/her clip. Table 2 details the clips' characteristics. Topics of stories include love stories and marriage, the birth of a child, loss of a close person, stressful social events, stressful events from school/college/university, references to the workplace, special connection to pets and animals.

#### Conclusions:

This invaluable new tool will allow us to examine research questions motivated by the double empathy theory. To accelerate research in the bidirectional nature of empathy, we will make the stimuli available to the research community (depending on each participating target's consent) and

invite researchers interested in collaborations to contact us.

#### Background:

Learning from rewards is a fundamental process with a well-characterised neurobiological basis.<sup>1</sup> Differences in reward processing have been linked to features of autism. Whereas diminished sensitivity to specifically social rewards (people<sup>2</sup>, social-communicative cues<sup>3</sup>) has been posited as a primary difficulty, domain-general differences in reward processing may be related to restricted interests<sup>4</sup> and/or frequently co-occurring ADHD features. Most studies assess reward sensitivity using neuroimaging or eye-tracking. We developed two novel companion sets of behavioural social (SRL) and non-social reward learning (RL) tasks for children (including those with intellectual disability). Given increasing recognition of heterogeneity within autism, as well as cross-condition overlaps, we hypothesise that differences in reward sensitivity may help to identify subgroups.

#### Objectives:

- Design age-appropriate animations to develop and optimise comparable SRL and RL tasks
- Establish task reliability and construct discriminant validity
- Assess if diagnosis, age and/or IQ modulates performance.

#### Methods:

We developed two sets of SRL and RL tasks in an iterative way. The “Magic Boxes” RL and “Come Play with Me” SRL task are intended for pre-schoolers. The “Treasure Chests” and “Royal Feast” tasks were developed for children between 6-11 years. The preschool version was tested in  $n=21$  autistic and  $n=89$  non-autistic children aged 3-5.5 years, and the school version in  $n=6$  autistic and  $n=141$  non-autistic children aged 6-11 years. Tasks varied in difficulty level (100% reinforcement schedule in the preschool version, and in the school-going version 80%-20% probabilistic reinforcement schedules). Tasks were administered during lab visits or at home. Qualitative feedback from parents and testers was collected throughout.

#### Results:

The condition (lab or home) did not significantly affect performance in either version. In non-autistic children, there were no significant differences in accuracy or learning criterion between the RL and SRL on either version. On the preschool version, non-autistic children had significantly higher accuracy scores ( $p=0.02$ ) on the RL but not the SRL task than autistic children. In the school version, no group differences were observed for the RL and SRL tasks. However, the non-autistic children had significantly faster reaction times (RTs) ( $p<0.0001$ ) for the RL task than the SRL task, whereas for autistic children this was not observed. Age had a moderating effect on accuracy and learning criterion in both SRL and RL task in the preschool version. This effect was attenuated for older children, where age was a significant moderator of RTs only. IQ was not significantly correlated to any of the measures in the school-going sample.

#### Conclusions:

We were able to create comparable social and non-social reward learning tasks in preschool- and school-going children as indicated by similar performance levels across versions in non-autistic children. Contrary to the social motivation hypothesis of autism, no significant group differences in social reward learning were found on either version. Validation against social-communication features, restricted interests and ADHD is ongoing.

## POSTER SESSION — SOCIAL COGNITION AND SOCIAL BEHAVIOR

### 406 - Social Cognition and Social Behavior

#### **406.124 (Poster)** Adults with Autism Demonstrate Theory of Mind on a Child-Oriented Word Association Task

*S. West<sup>1</sup>, E. Haebig<sup>2</sup> and C. Cox<sup>1</sup>, (1)Louisiana State University, Baton Rouge, LA, (2)Communication Sciences and Disorders, Louisiana State University, Baton Rouge, LA*

---

**Background:** Theory of Mind (ToM) is the ability to attribute beliefs, interests, and knowledge to others and understand they may be different from our own.<sup>1</sup> Many individuals with autism spectrum disorder (ASD) have impaired ToM, which becomes more disruptive over the lifespan.<sup>2,3</sup> ToM is associated with a range of cognitive mechanisms, but the root cause of ToM deficits in ASD is not well understood.<sup>3,4</sup> Recently, we demonstrated that neurotypical (NT) adults produced shorter, more frequent words with earlier age of acquisition (AoA) during a word association task when instructed to respond as if they are engaging with a toddler. ToM deficits may make adults with ASD less sensitive to this manipulation.

**Objectives:** We investigated whether high-functioning adults with ASD can engage in perspective taking to modify their language in word association tasks.

**Methods:** One hundred neurotypical (NT) adults and 100 adults with ASD were recruited using Prolific and randomly assigned to two versions of a word-association task. Participants were instructed to either respond to cue words with the first three words that came to mind (standard condition) or make three responses as if they were engaging with a toddler (child-oriented condition). All participants responded to the same 60 cue words. We compared responses across groups and conditions on three dependent variables (DVs): age of acquisition (AoA), frequency, and length. Each DV was modeled in a separate repeated-measures ANOVA, with groups, conditions, and response order nested in cue. We expected group by condition interactions for all three DVs, such group differences would be larger in the child-oriented condition, and a strong condition effect in the NT group.

**Results:** The ANOVA analysis of AoA revealed a main effect of condition ( $F(1,236) = 271.89, p < .001$ ), but no group effect or interaction. The analysis of word frequency revealed a significant interaction ( $F(1,236) = 6.33, p = .013$ ) with surprising simple effects: the NT group produced more frequent words than the ASD group in the standard condition ( $F(1,118) = 22.14, p < .001$ ), but frequency did not differ between groups in the child-oriented condition. The effect of condition was significant and in the expected direction for both groups ( $F_{NT}(1,118) = 18.18, p < .001$ ;  $F_{ASD}(1,118) = 52.65, p < .001$ )—larger for the ASD group. The analysis of word length revealed a significant interaction ( $F(1,236) = 19.94, p < .001$ ) with expected simple effects: the NT and ASD groups produced similar length words in the standard condition ( $F(1,118) = 0.76, p = .38$ ) but the NT responses were significantly shorter than ASD responses in the child-oriented condition ( $F(1,118) = 29.98, p < .001$ ). The condition effect was significant for both groups ( $F_{NT}(1,118) = 116.28, p < .001$ ;  $F_{TD}(1,118) = 12.39, p < .001$ ).

**Conclusions:** Both NT and ASD groups shifted their perspective and produce child-oriented responses. Differences between NT and ASD participants varied across DVs. Future work will examine whether the group differences are driven by systematic differences in how the groups represent words and their relations, or a different strategy for completing the task.

#### **406.125 (Poster)** Affect and Autism Spectrum Disorder: Facial Expressivity in Response to Social Uncertainty

*K. Layton<sup>1</sup>, J. Tetreault<sup>1</sup>, D. Morriss Sipsock<sup>2</sup> and S. Sheinkopf<sup>3</sup>, (1)Brown Center for the Study of Children at Risk, Women & Infants Hospital of Rhode Island, Providence, RI, (2)Warren Alpert Medical School, Providence, RI, (3)Brown Center for the Study of Children at Risk, University of Missouri, Providence, RI*

---

**Background:**

Atypical affective expression contributes to core social impairments in Autism Spectrum Disorder (ASD). Prior research, including a recent meta-analysis (Trevisani et al., 2018) reported that spontaneous affective expressions are less frequent and less contextually congruent in individuals with ASD. Other research has demonstrated deficits in autistic individuals' ability to accurately perceive facial expressions or negative emotions. Research studying the intensity of spontaneous affective expression has yielded less consistent findings, but affective intensity can impact the clarity of communication. No recent work has investigated spontaneous facial expressions of autistic individuals during positive social interactions.

**Objectives:**

The present study evaluates differences in spontaneous expressions of facial affect in two groups of young adults with IQ scores in the average range (ASD vs. non-ASD). This study aims to compare group differences in affective presentation during a social interaction task intended to evoke social uncertainty.

**Methods:**

The sample includes pre-recorded videos of participants with ASD ( $n=19$ ; 13 males; Mean IQ: 103, sd: 20) and a non-ASD typically developing (TD) group ( $n=17$ ; 9 males; Mean IQ: 95, sd: 13). Participants were observed during four episodes: (1) Quiet baseline (5 min.); (2) Social engagement (conversation) with a female research assistant (3 min.); (3) Planned ignore (3 min.), and (4) Rejoining conversation (3 min.). Two raters blind to group coded the videos on a scale ranging from -3 (most negative) to +3 (most positive) with 0 representing neutral expressivity. Raters coded the peak absolute value of facial affect during 10 second advancing intervals. Mean intensity was defined as the number of each affect code divided by the total number of intervals in each episode.

**Results:**

The main effect of group was significant ( $p = 0.002$ ); the TD group displayed greater intensity of positive affect ( $M = 0.77$ ,  $SE = 0.10$ ) than the ASD group ( $M = 0.29$ ,  $SE = 0.10$ .) The main effect for episode was significant ( $p < 0.001$ ), with greater positive affect during the Engagement and Rejoin episodes than during the Baseline and Ignore episodes. There was also a significant group X episode interaction ( $F [3, 31] = 7.06$ ,  $p = 0.001$ ), where the mean affect intensity for ASD group was lower than TD during the Engagement and Rejoin episodes, but not different during Baseline or Ignore conditions (see figure).

#### Conclusions:

Both TD and ASD groups modified affective expression in response to a series of standardized social interactions, with reduced positive affect when a previously friendly interactive partner interrupted conversation and ignored them (a planned violation of social norms). However, the ASD group differed in intensity of facial expression and demonstrated less range of affect that was closer to neutral during episodes where the social partner engaged in friendly conversation. These results indicate that verbal, average-IQ individuals with ASD display less intense affective expressions during normative social interactions. Such reduced affective expression may impact social interactions. Measuring range of affect may provide an additional metric in individual impairment, provide possible targets for intervention, and could be a useful treatment outcome measure.

#### **406.126 (Poster)** An 'Autistic Communicative Style'? Exploring Autistic People's Social Communicative Style

**H. Sutherland<sup>1</sup>**, C. J. Crompton<sup>1</sup>, J. Long<sup>2</sup> and S. Fletcher-Watson<sup>1</sup>, (1)University of Edinburgh, Edinburgh, United Kingdom, (2)Scottish Autism, Alloa, United Kingdom, (3)Salvesen Mindroom Research Centre, University of Edinburgh, Edinburgh, United Kingdom

---

#### Background:

There is a wealth of literature on social communication in autism, which primarily focuses on the communication difficulties between autistic and non-autistic people. Recent research, however, has suggested that communication between autistic people is more successful. It is unclear why this might be the case, but these findings suggest that categorising autistic communication as a 'communicative style' rather than a 'deficit' may be appropriate.

Autistic people's perspectives on their natural social communicative behaviours and preferences (and how this differs from or conflicts with non-autistic people's) may provide valuable insights into this 'communicative style', offering novel avenues for research into autistic social communication and guidance for professionals supporting autistic people.

#### Objectives:

To explore autistic people's communicative preferences and natural communication styles, with both other autistic people and non-autistic people. To examine whether autistic people perceive differences between their communication with other autistic people and with non-autistic people, and what those differences are.

#### Methods:

9 autistic adults (4M, 1NB; age mean = 45, range 23-70) took part in an online, asynchronous, text-based focus group. Questions posed to the group focused on five topics: (1) how to signal interest in another person; (2) what feels rude, polite, natural, and unnatural during communication; (3) how communication with other autistic people feels different to communication with non-autistic people; and (4) what makes a social interaction a positive one. An additional free space for participants to address anything else they felt researchers should know about autistic communication was provided.

#### Results:

Thematic analysis of the focus group text is ongoing, with five indicative themes:

- Challenges to communication: a number of factors combine to make social interactions challenging – 'unwritten social rules', sensory issues, communication being energy-costly and potentially dangerous, and the lack of accommodation and communicative flexibility from non-autistic peers.
- Autistic social principles: the autistic social communicative style is characterised by a strong preference for absolute truthfulness, an emphasis on boundaries, routine, and purposeful communication, and a desire to accommodate others.
- Presence: difficulties with attention and staying mentally present during social communication were linked to some evidence of communication being experienced as a 'flow state'.
- The importance of social support: social connections with others is important, though the formats these connections take may be atypical. Of particular importance and comfort is contact with other autistic people, and with non-autistic people who are understanding and accommodative of the autistic social interactive style.
- Intellectualisation: participants had, even prior to the focus group, spent time thinking about how they communicated, and how this might be different to how other people communicate. This included time spent reading academic materials on autism.

Next steps include finalising these themes and member-checking before presentation at INSAR.

## Conclusions:

Several factors influence autistic adults' experiences of social communication: internal experiences, internalised social values, the behaviour of other people involved in the interaction, and the environmental and technical properties of the interaction. These findings offer novel avenues for exploring the features of autistic social communication.

### **406.127 (Poster)** Autistic Traits Modulate the Relation between Self-Perceived and Actual Social Cognitive Ability

**D. Romero Fajardo, N. S. Tucker, L. Sweeney and K. R. Warnell, Department of Psychology, Texas State University, San Marcos, TX**

---

**Background:** In spite of growing literature on the nuances of mentalizing, or theory of mind, in autism (e.g., Livingston et al., 2019), little is known about whether autistic traits influence the relation between one's actual mentalizing ability and one's perception of that ability. One possibility is that higher autistic traits are linked to a decreased awareness of one's skills or even systematic overestimation. Alternatively, those with higher autistic traits may be hyperaware of possible social difficulties, potentially causing underestimates of performance. Effects may also vary with mentalizing ability. Understanding relations between perceived and actual ability has implications for understanding compensatory and camouflaging behaviors.

**Objectives:** We examined whether autistic-like traits influenced the relation between actual performance and self-estimated performance on a face-based mentalizing task.

**Methods:** American participants ( $N=247$ , aged 23-73, mean=39.69,  $N=141$  males) recruited from the general population via MTurk performed the Reading the Mind in the Eyes (Baron-Cohen et al., 2001a), in which they identified mental states from photographs, and then estimated their accuracy on the task. Participants also completed measures of autistic traits (Autism Quotient [AQ]; Baron-Cohen et al., 2001b), social anxiety (Social Interaction Anxiety Scale; Mattick & Clarke, 1998) and social motivation (Mind Reading Motivation; Carpenter et al., 2016).

**Results:** The relation between perceived and actual performance was significantly moderated by autistic traits ( $F(1,243)=6.98, p=.009$ ), even after controlling for social motivation and anxiety ( $p<.01$ ). Moderation was driven by the communication subscale of the AQ ( $F(1,243)=15.31, p<.001$ ; other subscales,  $ps>.15$ ). Follow-up Johnson-Neyman analyses found that the correlation between perceived and actual performance had two inflection points, at AQ-Communication scores of 2 and 5. The Low AQ-Communication group ( $n=67$ ) showed a significant positive correlation between perceived and actual ability, indicating that higher performers did estimate higher scores ( $r=.28, p=.02$ ; **Figure 1**). In contrast, the Middle AQ-Communication group ( $n=116$ ) showed no correlation ( $r=.02, p=.80$ ). The High AQ-Communication group ( $n=64$ ) showed a significant negative correlation such that low performers estimated the highest scores ( $r=-.37, p=.002$ ). For example, the bottom quartile of performers in the Low AQ-Communication group correctly estimated their scores, whereas the bottom quartile in the High AQ-Communication group overestimated by roughly 50 percentage points (**Table 1**). In contrast, when restricting analyses to those scoring above 80% correct, the High AQ-Communication group ( $n=21$ ) underestimated their performance significantly more than the Low AQ-communication group ( $n=36$ ;  $t(55)=2.16, p=.035$ ), despite performing equivalently. Within the High AQ-Communication group, greater social motivation and anxiety related to higher actual performance ( $ps<.001$ ) and a larger underestimation of this performance ( $ps<.06$ ).

**Conclusions:** Individuals vary widely in their capacity to estimate their own social cognitive skills and this capacity is moderated by autistic traits. Specifically, those with higher autistic traits show greater overestimation at levels of low performance and greater underestimation at levels of high performance. Those with high autistic traits and excellent mentalizing showed increased social motivation and social anxiety, suggesting potential mechanisms driving both compensatory skills and low confidence in those skills. Future research should include clinical populations and additional measures of self-perceived and actual abilities across domains.

### **406.128 (Poster)** Children's Autistic Traits and Peer Relationships: Do Non-Verbal IQ and Externalizing Problems Play a Role?

**N. Sari, Erasmus Rotterdam University, Rotterdam, Netherlands**

---

**Background:**

Children with autism have difficulties in understanding relationships, yet little is known about the levels of autistic traits with regard to peer relationships.

**Objectives:**

This study examined the association between autistic traits and peer relationships. Additionally, we examined whether the expected negative association is more pronounced in children with a lower non-verbal IQ and in those who exhibit more externalizing problems.

**Methods:** Data were collected in a large prospective birth cohort of the Generation R Study (Rotterdam, the Netherlands) for which nearly 10,000 pregnant mothers were recruited between 2002 and 2006. Data collection is currently ongoing for early adolescent period. Information on peer relationships was collected with PEERS application, an interactive computerized task ( $M = 7.8$  years). Autistic traits were assessed among general primary school children by using the Social Responsiveness Scale ( $M = 6.1$  years). Information was available for 1,580 children.

**Results:**

Higher levels of autistic traits predicted lower peer acceptance and higher peer rejection. The interaction of autistic traits with externalizing problems (but not with non-verbal IQ or sex) was significant: only among children with low externalizing problems, a higher level of autistic traits predicted less peer acceptance and more peer rejection. Among children exhibiting high externalizing problems, a poor peer acceptance and high level of rejection is seen independently of the level of autistic traits.

#### Conclusions:

We conclude that autistic traits – including traits that do not classify as severe enough for a clinical diagnosis – as well as externalizing problems negatively impact young children's peer relationships. This suggests that children with these traits may benefit from careful monitoring and interventions focused at improving peer relationships.

**406.129 (Poster)** Developing and Maintaining Friendships: The Role of Anxiety, Social Engagement and Mentorship Among Youth with ASD  
**J. E. Pappagianopoulos<sup>1</sup>** and **M. O. Mazurek<sup>2</sup>**, (1)Clinical and School Psychology, University of Virginia, Charlottesville, VA, (2)University of Virginia, Charlottesville, VA

---

**Background:** It is well-established that youth with autism spectrum disorder (ASD) have fewer friends and encounter greater social exclusion in comparison to neurotypical peers. Many individuals with ASD have intrinsic social motivation, yet skill deficits and anxiety may interfere with friendship development. Growing research highlights the benefits of engagement in social and physical activities (e.g., greater feelings of social inclusion and opportunities to authentically practice social skills) and adult mentorship (e.g., decreased social anxiety and increased social connectedness) among youth with ASD. Research is needed to examine whether such constructs (i.e., anxiety, social engagement, and mentorship) relate to friendship success among youth with ASD.

**Objectives:** We investigated the role of social engagement, mentorship, and anxiety on the ability to develop/keep friends among youth with ASD in a population-based sample.

**Methods:** The current study examined nationally distributed data from the 2018-2019 National Survey of Children's Health (NSCH), a caregiver survey. Youth included in this analysis ( $n = 1380$ ) were 6 – 17 years of age ( $M = 12.28$ ). The sample was 79.9% male. Ability to make/keep friends was operationalized as "how much difficulty does this child have making/keeping friends?" ("no difficulty" versus "some/a lot of difficulty"). Comorbid anxiety was defined by whether the caregiver responded that their child "currently has the condition." Social engagement was defined by participation in organized activities outside of school (i.e., clubs or sports). Mentor status was the presence of at least one supportive adult in the school, neighborhood, or community the child can rely on for advice/guidance. Controlling for age, gender, and intellectual disability, binary logistic regression analyses were conducted with social engagement, mentor status, and current anxiety as predictors and difficulty in making friends as the outcome. We examined interactions to assess whether social engagement or mentor status moderated the relationship between co-occurring anxiety and friendships.

**Results:** Hosmer-Lemeshow goodness-of-fit tests showed an acceptable fit for all regression models. Comorbid anxiety was associated with 2.68 times greater odds that the individual encountered difficulty in making friends ( $p=.029$ ), mentor status was associated with .53 times lower odds ( $p=.042$ ) and sports participation was associated with .51 times lower odds ( $p<.001$ ) that the youth had difficulty developing/maintaining peer relationships. Club participation was not a significant predictor and there were no significant interactions.

**Conclusions:** Findings indicate that sports participation and the presence of an adult mentor may protect against social relationship difficulties. It may be helpful to incorporate authentic social experiences and mentorship components into future social skills interventions to enhance feelings of inclusion and skill-building. Results also indicate that anxiety may predict greater friendship difficulties, consistent with prior research highlighting an association between comorbid anxiety and social skill deficits among youth with ASD. More work must be done to better understand how to support individuals with ASD and anxiety in developing and maintaining friendships. Given the study's cross-sectional design, we also need further research to investigate the direction of these effects.

**406.130 (Poster)** Development of a Measure of Positive and Negative Emotions in Autistic Adults

**A. R. Dallman<sup>1</sup>**, **M. Lieb<sup>2</sup>** and **A. Scott<sup>3</sup>**, (1)Department of Allied Health Sciences, University of North Carolina at Chapel Hill, Chapel Hill, NC, (2)Occupational Therapy & Occupational Science, Towson University, Towson, MD, (3)Towson University, Towson, MD

---

**Background:** Recent evidence suggests the underlying etiology and phenomenology of autism results in a fundamentally different autistic experience of emotions than non-autistic peers (Jaysane-Darr, 2020; Jones et al., 2001). In non-autistic perspectives, emotions are often thought of as static constructs (Dallman & Triplett, 2020). However, in autistics, it is likely that emotions are experienced as more complex phenomena (Thomas & Boellstorff, 2017). This might explain, to some extent, why autistic individuals express their emotions in their faces differently, which can make it difficult for non-autistics to identify autistic emotions (Brewer et al., 2016). Autistics also report their emotions differently, more commonly using metaphors to describe how they feel (Thomas & Boellstorff, 2017). Overall, these findings might explain why some measures typically used to characterize emotions among non-autistics fail to capture variability in negative affect among autistics (Dallman et al., 2021). As efforts to develop and evaluate treatments for mood disorders in this population increase, development of measures sensitive to change in response to treatment is an urgent concern.

**Objectives:** The specific aims of this project are to (1) characterize emotional experiences of autistics and (2) develop a self-reported measure of emotional experiences for autistic adults.

**Methods:** Autistic adults ( $n = 24$ ) participated in one of six Zoom focus-group interviews to discuss their emotional experiences. Topics for the interview included experiences of positive emotions, negative emotions, the influence of activity on emotion, and measuring emotions. Interviews were transcribed verbatim and then iteratively coded and analyzed using an interpretative phenomenological analysis framework. Two coders independently coded each transcript and discussed any coding discrepancies until consensus was obtained.

**Results:** A total of 54 codes were generated to describe autistic emotional experiences. Participants described disliking typical emotional words like “happy” or “sad” because these words felt like caricatures of their true emotional experiences. They described emotions using metaphorical and embodied language and problematized current efforts to measure emotions, because they rely on those aforementioned words. These codes were then organized into a thematic framework which was then translated into a self-reported measure of autistic emotion. The measure is a two-part measure of emotions: a clinical interview, and an individualized patient-generated ecological momentary assessment in which the participant’s language from the clinical interview is brought forward to create each individual’s unique measure of emotional experiences.

**Conclusions:** Current measures of emotion may be insufficient at capturing emotional variation among autistics. In this study, we characterized autistic emotion as embodied, metaphorical, and complex. We used that information to develop a novel patient-generated measure of emotion. This measure leverages autistics’ own words, metaphors, and experiences to understand emotional patterns that may be problematic such as long periods of self-described sad feelings or high variability in self-described emotions. Future research will validate this measure in a sample of autistic adults.

**406.131 (Poster)** Diagnostic and Sex-Based Differences in Behavioral Responses to Social Evaluative Threat Among Autistic and Neurotypical Adolescents

**J. M. Schwartzman, R. A. Muscatello and B. A. Corbett, Psychiatry and Behavioral Sciences, Vanderbilt University Medical Center, Nashville, TN**

---

**Background:** Adolescence is a developmental period characterized by social landscapes of increasing complexity and social evaluative threat, which may be challenging for autistic adolescents to navigate given social communication differences. Heightened stress is more prevalent, severe, and chronic in duration in autistic adolescents than their neurotypical peers and has been linked to social difficulties. Though stress may manifest uniquely in females, research on autistic females is limited. To understand stress responses in autism, observational techniques may help to identify behaviors associated with heightened stress/arousal and potential diagnostic- and sex-based differences.

**Objectives:** The primary objective of this study was to examine diagnostic-based differences in behavioral responses to social evaluative threat in 209 well-characterized autistic (ASD) and neurotypical (NT) early adolescents (10:0-13:5 years old). A secondary objective was to investigate sex-based differences in behavioral responses within and between diagnostic groups.

**Methods:** The sample included 118 autistic (85 male, 33 female) and 91 neurotypical (52 male, 39 female) early adolescents enrolled in a longitudinal study of pubertal development in autism (R01-MH111599; PI: Corbett). Data from the first year were analyzed in this study. In a study visit, participants were exposed to the Trier Social Stress Test (TSST-Child version) – a validated, experimentally-induced psychosocial stressor known to reliably activate a stress response during 5-minute speech and math tasks. A behavioral coding paradigm was used to code displacement (e.g., fidgeting, fumbling, grooming, etc.) and continuous (e.g., time spent in silence or talking on/off topic) behaviors during the TSST. As displacement behaviors were not normally distributed, nonparametric Mann-Whitney U tests were employed to examine diagnostic- and sex-based differences. For continuous behaviors that were normally distributed, independent samples t-tests were used to test for diagnostic- and sex-based differences.

**Results:** The NT group displayed significantly more lip presses ( $U = 4207.00, p = .006$ ) and grooming ( $U = 4668.00, p = .03$ ) behaviors during the TSST-Speech than the ASD group, yet distributions for other displacement behaviors were not different between groups. The NT youth spent more time on-topic during TSST-Speech ( $t(204.41) = 3.66, p < .001$ ), while longer periods of silence occurred in the ASD group ( $t(206.20) = -2.76, p = .006$ ). Diagnostic groups did not differ in displacement behaviors during TSST-Math, with the exception of face contact (more frequent in ASD). In TSST-Math, NT youth spent more time engaged in the task ( $t(195.17) = 3.51, p < .001$ ). Between sexes, females exhibited more grooming behaviors compared to males in both tasks, but continuous behaviors did not differ by sex. Within diagnostic groups, autistic females and neurotypical females exhibited more grooming behaviors than their respective male counterparts.

**Conclusions:** Compared to neurotypical peers, autistic youth exhibited fewer behavioral signs of stress in the TSST and were more likely to remain silent, rather than attempt to engage and complete the tasks, amidst social evaluative threat. This may indicate a decreased stress response to social evaluative threat, which has been frequently found in autistic youth evidenced by a blunted cortisol response.

**406.132 (Poster)** Differential Effects of Specific Anxiety Symptoms on Facial Emotion Recognition in Youth with Autism Spectrum Disorder: Examination By Stimulus Type

**E. Fowler-Benton<sup>1</sup>, R. G. McDonald<sup>1</sup>, S. Khawar<sup>1</sup>, N. Yacoub<sup>1</sup>, M. I. Cargill<sup>1</sup>, N. Macapagal<sup>1</sup>, T. Rosen<sup>2</sup>, M. D. Lerner<sup>3</sup> and E. Kang<sup>1</sup>, (1)Department of Psychology, Montclair State University, Montclair, NJ, (2)University of Colorado School of Medicine, JFK Partners, Aurora, CO, (3)Psychology, Stony Brook University, Stony Brook, NY**

---

**Background:** Individuals with autism spectrum disorder (ASD) often have difficulty with facial recognition (FER; Lozier et al., 2014), a key component to understanding social cues (Shanok et al., 2019). In typically-developing (TD) individuals, generalized anxiety (GAD) and social anxiety disorders (SAD) are associated with more accurate FER, owing to increased vigilance and enhanced threat monitoring (Rappaport et al., 2021; Torro-Alves et al., 2016). There is a high prevalence of co-occurring anxiety in ASD (Chang et al., 2012), and cross-sectional studies suggest improved FER with internalizing symptom in ASD (Rosen & Lerner, 2016), while others suggest no relationship (Wong et al., 2012). Yet, no studies have considered specific anxiety symptoms. The heterogeneity in anxiety in ASD calls for understanding the relationship between FER and anxiety subtypes. Findings in ASD also suggest difficulties in recognizing subtler (i.e., low-intensity) emotions (Wallace et al, 2011) and an own-age bias,

reflecting greater FER performance for child compared to adult faces (Hauschild et al., 2020), highlighting the importance of a fine-grained analysis of FER performance by stimulus type.

**Objectives:** This study examined the effects of co-occurring anxiety and FER in ASD youth, by considering specific anxiety symptoms as well as the differences by stimulus type (high- vs. low-intensity emotions; adult vs. child faces). We hypothesized that higher self-reported anxiety, specifically GAD and SAD, will relate to lower FER errors on child faces and high-intensity emotions.

**Methods:** Fifty-five autistic youth ( $M_{age}=11.96$ ,  $SD_{age}=2.99$ , 73% Male,  $IQ \geq 70$ ) participated in this study. They completed an FER task while viewing adult and child faces (DANVA-2; Nowicki & Duke, 2001) and a self-report measure of anxiety (MASC-2; March, 2013). Pearson correlation and multiple linear regressions were conducted to assess whether specific anxiety symptoms uniquely predict FER, depending on the stimulus type.

**Results:** Higher self-reported total anxiety were related to fewer FER errors on adult and child faces ( $r=-.28$  and  $-.32$ , respectively,  $p<.02$ ), as well as high- and low-intensity emotions ( $r=-.35$  and  $-.23$ , respectively,  $p<.05$ ). Specific anxiety symptoms did not uniquely predict FER errors on the high-intensity emotions, or child faces (all  $p>.14$ ). While physical symptoms negatively predicted FER errors, panic and tense-restless symptoms predicted more errors on low-intensity emotions as well as adult faces (see Table 1).

**Conclusions:** Results suggest that co-occurring anxiety in ASD are associated with enhanced FER (i.e., less errors) overall, regardless of stimulus type. However, relations differed by specific anxiety symptoms for subtler emotions and adults faces. Interestingly, physical symptoms predicted enhanced FER, whereas panic and tense-restless symptoms predicted poorer FER performance. These results suggest the differential role specific anxiety symptoms may play in FER, as well as in the well-documented differences in subtler emotions (Wallace et al., 2011) and the own-age bias (Hauschild et al., 2020) in ASD individuals. Our findings provide insight into different pathways of co-occurring anxiety symptoms on FER, which impacts the social deficits of ASD (Bauminger, 2002; Stichter et al., 2010) and may aid in informing future interventions.

#### **406.133 (Poster) Empathy in Autism: A Systematic Review and Meta-Analysis**

**N. Cusson**<sup>1,2</sup>, **A. J. Meilleur**<sup>2,3</sup>, **B. Bernhardt**<sup>4</sup>, **I. Soulieres**<sup>1,2</sup> and **L. Mottron**, **M.D.**<sup>2,5</sup>, (1)Department of Psychology, Université du Québec à Montréal, Montréal, QC, Canada, (2)Autism Research Group, CIUSSS du Nord-de-l'Île-de-Montréal, Montréal, QC, Canada, (3)Department of Psychology, Université du Québec à Montréal, Montréal, QC, Canada, (4)Department of Neurology and Neurosurgery, McGill University, Montréal, QC, Canada, (5)Department of Psychiatry and Addictology, Université de Montréal, Montréal, QC, Canada

**Background:** Empathy can be defined as the ability to understand (cognitive empathy) and to share (affective empathy) another person's emotional state (Gonzalez-Liencre et al., 2013). Empathy deficits are often regarded as a core attribute of autism and are part of the signs deemed relevant to diagnose autism by standardised diagnostic instruments. However, the scientific literature on the subject is mixed, as some studies indicate that autistic individuals have global empathy deficits whereas others suggest that they only have cognitive empathy deficits.

**Objectives:** The objective of this meta-analysis was twofold: 1) to establish whether autistic individuals have an empathy deficit and, if so, in which empathy component and 2) to examine whether the measure chosen to assess empathy has an impact on the studies' results.

**Methods:** This meta-analysis was performed according to the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guideline. A literature search was conducted in four online databases (PubMed, Scopus, PsycNet and Academic Search Complete). 2161 articles were retrieved and 137 met the inclusion criteria. Hedges'  $g$  was computed to assess the difference between the autistic and neurotypical groups' empathy scores. Then, to synthesize the studies' results regarding cognitive and affective empathy, a three-level model was used, whereas for the results of studies measuring empathy as a unidimensional construct, a random-effects model was applied. Finally, separate random-effects meta-analyses were conducted for the three most used empathy measures, namely the Empathy Quotient (EQ), the Reading the Mind in the Eyes Test (RMET) and the Interpersonal Reactivity Index (IRI). Heterogeneity and risk of bias across studies were assessed following each analysis.

**Results:** The results suggest that autistic individuals have significantly less cognitive empathy than neurotypical individuals ( $k=116$ ,  $g=-0.89$ , 95% CI [-0.99; -0.79],  $p<.001$ ), but overall equivalent affective empathy ( $k=71$ ,  $g=-0.19$ , 95% CI [-0.39; 0.01],  $p=.06$ ). Furthermore, when empathy was assessed as a unidimensional construct, autistic individuals had significantly lower scores than neurotypical individuals ( $k=52$ ,  $g=-1.70$ , 95% CI [-1.92; -1.48],  $p<.001$ ). However, the studies' results were greatly influenced by the measure used to assess empathy. Whereas the EQ consistently showed that autistic individuals had lower empathy scores than neurotypical individuals ( $k=30$ ,  $g=-1.72$ , 95% CI [-1.94; -1.50],  $p<.001$ ), the IRI showed a more nuanced picture. For instance, a closer look at the IRI's affective empathy subscales revealed that autistic individuals had significantly lower empathic concern ( $k=29$ ,  $g=-0.63$ , 95% CI [-0.79; -0.47],  $p<.001$ ), but significantly higher personal distress ( $k=22$ ,  $g=0.67$ , 95% CI [0.32; 1.03],  $p<.001$ ) compared to neurotypical individuals.

**Conclusions:** This meta-analysis suggests that autistic individuals do not have a global empathy deficit, but rather have a different empathy profile characterized by difficulties with cognitive empathy and specific affective empathy subcomponents. This underlines the importance of assessing empathy as a multidimensional construct, especially in an autistic sample. Furthermore, these results indicate that empathy deficits in autism are not as pervasive as what current diagnostic instruments imply.

#### **406.134 (Poster) Evidence of Girls with Autism Spectrum Disorder Camouflaging Autistic Traits**

**M. Canihuante**, **J. E. Crank**, **S. Albarran** and **M. Sandbank**, *The University of Texas at Austin, Austin, TX*

**Background:** Early childhood diagnosis of autism spectrum disorder (ASD) can lead to early intervention, which produces better outcomes for autistic individuals. Current diagnostic protocols can delay a diagnosis due to lack of sufficient qualified professionals and lengthy assessments. As a result, an active area of research in autism is how to provide the ability for early and accessible predictive tools to provide accurate diagnoses. We assert that any such tool should reflect documented differences in rate of diagnostic autism between boys and girls and also documented increase in likelihood of a diagnosis, if a family member already has a diagnosis of ASD. One tool approach is to use predictive algorithms based on machine learning (ML). The analysis of one such freely available dataset used in ML, showed that the dataset analyzed using Bayesian methods, did not reflect differences in diagnostic rates between boys and girls and between participants that indicated having at least a family member already diagnosed with ASD.

**Objectives:** The objective of this study to validate that the dataset provides classification of ASD that are consistent with those found in the published literature. In this study, we analyzed a dataset from a phone app-based application, which provides anyone with access to the free phone application with the ability to enter data. The app provides a binary likelihood for autism to the end user. Data from the selected app, ASDTests[1], can be used for machine learning analysis. Our study examined whether the data replicated well to perform a Bayesian analysis, and whether the data approximated documented differences in diagnostic rates between boys and girls and history of ASD in the family.

**Methods:** We used the ASDTests app dataset for for the 4-11 children, which was composed of 292 participants. We used multivariate-logistic regression analysis using Bayesian analysis, using priors for male-female ratio (80-20%) of diagnosis, and priors for having a history of family with ASD (3%). In addition to these two data points, we used the guidance of the author of the app (Thabath, 2019), to use the four most impactful data points.

**Results:** Our analysis showed that while the data replicated well and was suitable for Bayesian logistic regression analysis, when we applied informed priors, the results showed that neither sex nor history of autism in the family had an impact on the likelihood of predicting autism.

**Conclusions:** Access to early intervention for children who may be on the autism spectrum are typically linked to diagnoses. While earlier, more accessible and less time-consuming means to getting an ASD diagnosis could help to bring interventions at an earlier age than it is possible today, models relying on predictive need to reflect what we know about existing diagnosed population differences. In our study, we find that more work of predictive analytics is promising, but as of yet has limitations based on scant freely available datasets.

#### **406.135 (Poster)** Exploring Attention Networks and Social Functioning in Autism Spectrum Disorder

A. Jones<sup>1</sup> and L. Tamm<sup>2</sup>, (1)Cincinnati Children's Hospital Medical Center, Cincinnati, OH, (2)Division of Behavioral Medicine and Clinical Psychology, Cincinnati Children's Hospital Medical Center, Cincinnati, OH

---

**Background:** Attentional deficits within Autism Spectrum Disorder (ASD) are common, and may lead to more global sociocommunicative deficits later in development (Dawson et al., 2004). For example, sociocommunicative deficits in ASD may originate with the inability to disengage and shift attention (Keehn et al., 2013; Oberwelland et al, 1988). The functionally and neuroanatomically distinct alerting, orienting, and conflict networks (Petersen & Posner, 2012) may underlie attentional modulation differences in ASD. Further, deficits in these networks may be associated with social dysfunction in ASD.

**Objectives:** This study explored the relation between attentional network scores and social functioning in children with and without ASD.

**Methods:** Participants included children with ASD without intellectual disability (n=20, 4 females, 13.66% racial minority, age: 10.92±1.2; IQ: 109.52±12.1) and typically developing (TD) children (n=12, 10 females, 28.57% racial minority, age: 10.62±1.1; IQ: 112.69±12.7). Parents completed the Social Responsiveness Scale, Second Edition (SRS-2) Social subscales and Child Behavior Checklist (CBCL) Social Problems subscale. Children completed the Attention Network Test (ANT). Analyses included *t*-tests comparing the groups on social functioning and ANT performance, and Pearson correlations between ANT performance and social functioning by group.

**Results:** Results indicated significant group differences for social functioning, with ASD performing more poorly than TD (Table 1). Both groups performed the ANT accurately. Individuals with ASD had significantly lower orienting scores than TD. Within the ASD group, orienting scores were not significantly associated with social functioning, increased alerting scores were associated with more SRS-2 Awareness problems, and increased conflict scores were associated with more SRS-2 Cognition problems (Table 2). Within the TD group, increased alerting scores were associated with problems across social domains (significant for SRS-2 Motivation and CBCL Social Problems).

**Conclusions:** Consistent with the literature (Keehn et al., 2010; Mutreja et al., 2016), children with ASD benefited less from spatial cuing (lower orienting scores) than TD. However, these orienting deficits were not associated with social functioning. As found by Keehn et al. (2010), higher alerting scores were associated with poorer social functioning. In the ASD group this was specific to the ability to pick up on social cues, but in the TD group this was observed across domains (i.e., ability to pick up on social cues, ability to interpret social cues, expressive social communication, extent of motivation to engage in social behavior, general social challenges). This was somewhat unexpected. Being good at achieving and maintaining sensitivity toward incoming information should be associated with better social performance. However, our results indicate that individuals with poorer social functioning may have an exaggerated alerting effect such that they may be overly receptive to rapid changes in their attention field that may disrupt social processes. Better conflict resolution was associated with poorer ability to interpret social cues in the ASD group. Again, this may be due to individuals with ASD being overly disrupted by conflicting information which affects social processing. Studies

show that substituting social stimuli in the ANT negatively impacts alerting and positively impacts conflict in TD children (Federico et al., 2017). Additional research is warranted.

**406.136 (Poster)** Implicit Social Attribution in Preschool- and School-Aged Children with Autism Spectrum Disorder

**B. Schirmer<sup>1</sup>**, A. Krasno<sup>2</sup>, L. Morgan<sup>3</sup>, M. Siller<sup>4</sup>, L. A. Edwards<sup>5</sup>, W. Jones<sup>5</sup> and A. Klin<sup>5</sup>, (1)Marcus Autism Center, Atlanta, GA, (2)University of California Santa Barbara, Santa Barbara, CA, (3)Emory University-Marcus Autism Center, Atlanta, GA, (4)Emory University School of Medicine, Atlanta, GA, (5)Marcus Autism Center, Children's Healthcare of Atlanta and Emory University School of Medicine, Atlanta, GA

---

**Background:** Previous research has shown that implicit social attribution—or the spontaneous tendency to attribute social meaning to ambiguous displays—is diminished even in individuals with autism spectrum disorder (ASD) who have high verbal skills and “pass” advanced tests of theory of mind skills (Klin, 2000; Burger-Caplan et al., 2016). In the current study we use a passive viewing paradigm to assess implicit social attribution in school-aged children and preschoolers with and without ASD. We showed children scenes from the classic film, *The Red Balloon*, in which a young boy finds a balloon that comes to life. Because the agency of the balloon is dynamic during the film—at times an ordinary balloon, at times an animate character—patterns of social visual engagement across these scenes may be sensitive measures of the tendency to make implicit social attributions. Such measures may be used in monitoring and evaluating outcomes of educational programming and interventions aimed at increasing social functioning in ASD.

**Objectives:** This study aims to develop objective, quantitative measures of implicit social attribution for use in monitoring social functioning and change in children with ASD.

**Methods:** Eye-tracking data were collected while children viewed eight short clips from *The Red Balloon*. In four of the clips, the balloon was inanimate, and in the other four clips, the balloon was an animate character. Data were quantified in terms of percent fixations to regions of interest (ROIs) in animate and inanimate balloon scenes. Two participant groups are presented here: an older cohort of school-aged children with ASD ( $n=60$ ,  $M_{age}(SD)=10.4$  (2.4) years) and their TD peers ( $n=28$ ,  $M_{age}(SD)=9.4$  (2.3) years); and a cohort of preschool-aged children with ASD ( $n=9$ ,  $M_{age}(SD)=4.29$  (1.09) months) and TD peers ( $n=16$ ,  $M_{age}(SD)=4.55$  (1.06) months), currently enrolled in the Marcus Autism Center Preschool Program.

**Results:** In both cohorts, children with and without ASD decreased looking to human characters and increased looking to the balloon in animate, compared to inanimate balloon scenes (all  $p<0.05$ ). Within animate balloon scenes, school-aged TD children looked significantly more to human characters than did children with ASD ( $p<0.001$ ). Preschoolers with and without ASD also differed in their allocation of visual attention to animate balloon scenes ( $p=0.013$ ), although in this age cohort, trends were such that TD children looked less to human characters' faces and bodies and more to the balloon than children with ASD.

**Conclusions:** Our preliminary analyses suggest differences in visual attention to ambiguous social displays, that may change over development, in children with and without ASD. Next steps will quantify finer-grained, time-varying measures of social monitoring between the boy and the balloon in animate vs. inanimate balloon scenes, and associations between these measures and clinical or classroom-based measures of social functioning. The preschool cohort will also be followed longitudinally and assessed for changes over the course of their educational programming.

**406.137 (Poster)** Improving University Students' Attitudes Towards Individuals with Autism

**C. L. Dickter<sup>1</sup>**, J. Burk<sup>2</sup>, K. Burton<sup>1</sup>, A. Allen<sup>1</sup>, M. Blanco<sup>1</sup>, S. Mallipeddi<sup>1</sup>, K. Fergus<sup>1</sup> and K. Carter<sup>1</sup>, (1)College of William and Mary, Williamsburg, VA, (2)William & Mary, Williamsburg, VA

---

Background:

University students with autism may face challenges at university with making and maintaining friendships, despite a desire to do so. One reason for this is that college students with autism experience social exclusion more so than their typically developing (TD) peers who tend to evaluate individuals with autism negatively. While exposure to individuals with autism can improve TD individuals' attitudes towards autism, this contact is not always possible. Investigating ways to improve TD university students' attitudes using simulated interactions may be effective.

Objectives:

Our first goal of this study was to examine whether simulating contact with individuals with autism would improve attitudes towards this group. Labeling people engaging in atypical behavior associated with autism can lead to more positive perceptions, as perceivers have an explanation for these behaviors. Therefore, we examined whether imagining an interaction with someone displaying behavior stereotypically associated with autism and labeled as having autism would affect subsequent attitudes. Our second goal was to test whether this would differ if participants imagined contact with a student of color compared to a White student.

Methods:

TD university students read vignettes in which they imagined interacting with another university student who depicted behaviors associated with ASD (i.e., perseveration) or not and with a label of autism or not. Participants then completed a Feelings Thermometer which measured their attitudes towards individuals with autism. In Study 1 ( $n = 130$ ), participants imagined interacting with a White student. In Study 2 ( $n = 234$ ), participants imagined interacting with either a White or Black student.

## Results:

In Study 1, a 2 (Label: ASD vs. non-ASD) x 2 (Behavior: Perseveration vs. No Perseveration) analysis of covariance (ANCOVA) with prior contact as a covariate was conducted. In Study 2, the same analysis was conducted with the addition of a between-subjects variable representing the race of the person with whom participants imagined contact (Black vs. White). Study 1 revealed a significant Label x Behavior interaction,  $F(1, 111) = 4.53$ ,  $p = .036$ ,  $\eta_p^2 = .039$ , such that there was a significant effect of Behavior for the non-ASD condition but attitudes towards individuals with ASD were higher in those in the Perseveration condition than the No Perseveration condition. In Study 2, as with Study 1, there was a Label x Behavior interaction,  $F(1, 226) = 4.97$ ,  $p = .027$ ,  $\eta_p^2 = .022$ , but no interaction with Race.

## Conclusions:

This research suggests that a short, online exercise can improve TD university students' attitudes towards individuals with ASD, when the person with whom they are imagining the interaction is labeled as having autism and shows behavior consistent with autism. Furthermore, our findings suggest that the race of the person with whom the participant imagines this interaction does not moderate the effect of labeling or behavior. These findings suggest that the imagined contact procedure may be useful for improving attitudes toward individuals who display some behaviors of ASD that may otherwise be viewed in a more negative manner.

### **406.138 (Poster)** Investigating the Role of Emotion Regulation and Physiological Arousal in Anxiety in Children Diagnosed with Autism Spectrum Disorder

**B. Syed<sup>1</sup>, R. Cardy<sup>2</sup>, S. Monga<sup>3</sup>, J. A. Brian<sup>2</sup>, B. Andrade<sup>4</sup>, E. Anagnostou<sup>5</sup> and A. Kushki<sup>1</sup>**, (1)University of Toronto, Toronto, ON, Canada, (2)Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (3)The Hospital for Sick Children, Toronto, ON, Canada, (4)Centre for Addiction and Mental Health, Toronto, ON, Canada, (5)Autism Research Centre, Bloorview Research Institute, Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada

**Background:** Up to 84% of children with ASD experience clinically significant anxiety, which negatively impacts academic achievement, employment outcomes, and physical and mental health. Despite the prevalence and significance of anxiety, very few evidence-based interventions exist. A key challenge to developing such treatments is that the biological, physiological, and emotional factors contributing to anxiety in ASD remain largely unknown. Two mechanisms suggested to underlie anxiety in ASD are physiological arousal and emotion regulation (ER); however, the nature of their contribution remains largely unknown. This knowledge is critically needed to inform targeted treatment approaches for anxiety in ASD populations.

**Objectives:** To examine the role of emotion regulation and physiological arousal in anxiety in ASD.

**Methods:** The study sample consisted of children with ( $n=26$ , 20 male, age:  $11.6 \pm 2.06$ ) and without ASD ( $n=32$ , 17 male, age:  $9.9 \pm 1.73$ ). All children had full-scale IQ greater than 85. The experiment consisted of participants playing video games in between two baseline movie-watching sessions. For short intervals, the video game controls were inverted/unresponsive to elicit frustration. During the protocol, electrocardiogram (ECG) data was collected, and respiratory sinus arrhythmia (RSA) reactivity was computed for each game relative to baseline. ER ability was measured via the Emotion Dysregulation Inventory (EDI), a 64-item parent-reported questionnaire validated in samples of children with ASD, in which a higher score reflects lower ER ability. Anxiety symptoms were characterized using the Screen for Child Anxiety Related Disorders (SCARED), a 41-item parent-report survey. The Social Communication Questionnaire (SCQ), a 40-item parent-report questionnaire, was utilized to measure ASD symptoms. Age, sex, and full-scale IQ (WASI) were included as per significant linear regressions. Structural equation modelling was utilized to examine two potential theoretical models explaining the associations between ASD symptoms, ER ability, RSA reactivity, and anxiety symptoms.

**Results:** Our results revealed a significant positive association between emotion dysregulation and anxiety symptoms in both models ( $p = 0.046$ , Figure 1;  $p = 0.045$ , Figure 2). RSA reactivity did not significantly mediate the relationship between ASD symptoms and emotion dysregulation ( $p < 0.0001$ , Figure 1). However, ASD symptoms mediated the association between RSA reactivity and emotion dysregulation via positive significant associations between RSA reactivity and ASD symptoms ( $p = 0.03$ , Figure 2) as well as between ASD symptoms and emotion dysregulation ( $p < 0.0001$ , Figure 2).

**Conclusions:** Our results confirmed positive associations between emotion dysregulation and anxiety symptoms. Additionally, our results provide preliminary evidence supporting the contribution of emotion dysregulation, ASD-like traits, and physiological arousal to anxiety in ASD.

### **406.139 (Poster)** Lack of Left Gaze Bias to Faces in Adults with High Levels of Autistic Traits

**C. Brittenham<sup>1,2</sup> and J. B. Wagner<sup>3,4</sup>**, (1)Psychology, The Graduate Center, City University of New York, New York, NY, (2)Psychology, College of Staten Island, City University of New York, Staten Island, NY, (3)Department of Psychology, College of Staten Island, City University of New York, Staten Island, NY, (4)Department of Psychology, The Graduate Center, City University of New York, New York, NY

**Background:** Typical face processing is characterized by left gaze bias, defined as increased looking to the left side of the face (e.g., Guo et al., 2011), and thought to relate to greater right hemisphere recruitment in the processing of configural stimuli such as faces. Autistic individuals show differences both in configural processing and face processing (e.g., Behrmann et al., 2006), and have been found to show a lack of left bias (e.g., Dundas et al., 2012). Autistic traits are present in varying degrees in the general population, known as the broader autism phenotype (BAP; e.g. Hurley et al., 2007), but little work has looked at left bias alongside the BAP.

**Objectives:** The current study aimed to examine left gaze bias in face processing in nonautistic individuals with varying levels of autistic traits.

**Methods:** Seventy-eight participants ( $M_{age} = 20.32$  years,  $SD = 4.65$ ) viewed 24 faces from the NimStim database (Tottenham et al., 2009) and 24 houses (control stimuli) for 3 seconds per image. Gaze data were collected with an SMI RED 120 Hz eye-tracker. Areas of interest (AOIs) were drawn on the left and right sides of each image, and net dwell time (NDT) was calculated for the AOIs. A left bias measure was then calculated as NDT Left divided by the sum of NDT Left and NDT Right, and this bias was averaged separately for faces and houses. To capture initial attentional responses, gaze data for each image were extracted in a 500 ms window starting at 350 ms after stimulus onset, with 350 ms reflecting the average onset of participants' initial shift from the pre-image central fixation point. Autistic traits were measured with the Social Responsiveness Scale, Second Edition (SRS-2; Constantino & Gruber, 2012). Left side biases were examined in relation to BAP categorically (participants high vs. low on autistic traits based on SRS-2 cutoff t-score of 59) and continuously.

**Results:** Across the full sample, a one-sample  $t$ -test examined left bias to faces against chance (0.5) and found a significant bias for faces,  $t(77) = 2.76$ ,  $p = .008$ , but no bias for houses ( $p = .582$ ). When examining participants high ( $n = 17$ ) and low ( $n = 61$ ) on autistic traits separately, the left bias held only for the low traits group,  $t(60) = 2.77$ ,  $p = .007$  (Figure 1). Neither group showed a left bias for houses ( $ps > .70$ ; Figure 2). No correlations between left bias and SRS-2 t-scores were found in the full sample or the traits groups ( $ps > .30$ ).

**Conclusions:** In a group of nonautistic participants, we found a left side bias for faces for those with low levels of autistic traits, but no bias for participants with high levels of autistic traits (and neither group showed a left bias for houses). These findings parallel past research which has found a lack of left bias in face processing in autistic adults (e.g., Dundas et al., 2012), showing a similar lack of bias in nonautistic individuals with elevated levels of autistic traits.

Arturi**<sup>2</sup>, **G. Lisi**<sup>2</sup>, **I. Adulti**<sup>6</sup>, **R. Rossi**<sup>6</sup>, **A. Lucaselli**<sup>7</sup>, **A. Rossi**<sup>7</sup>, **C. Niolu**<sup>5,6</sup> and **L. Mazzone**<sup>2,3</sup>, (1)Biomedicine and Prevention, POLICLINICO TOR VERGATA, University of Rome Tor Vergata, Rome, Italy, (2)Child and Adolescence Psychiatry Unit, Policlinico Tor Vergata Hospital, Rome, Italy, (3)Systems Medicine, Division of Child Psychiatry, University of Rome Tor Vergata, Rome, Italy, (4)Biomedicine and Prevention, University of Rome Tor Vergata, Rome, Italy, (5)Systems Medicine, Division of Adult Psychiatry, University of Rome Tor Vergata, Rome, Italy, (6)Adult Psychiatry Unit, Policlinico Tor Vergata Hospital, Rome, Italy, (7)Section of Psychiatry, Department of Biotechnological and Applied Clinical Sciences, University of L'Aquila, L'Aquila, Italy

**Background:**

Perinatal period represents a crucial phase for the neurodevelopment of the foetus and the intra-uterine environment plays a main role in the etiology of Neurodevelopmental Disorders including Autism Spectrum Disorder (ASD), with recent evidence suggesting that the prenatal immune environment may be a particularly promising area for ASD research. In this context, the latest research is attempting to define whether there may be an association between maternal Perinatal Depression (PD), the use of psychotropic medications during pregnancy, and a higher risk of neurodevelopmental disorders in children.

**Objectives:**

A. To evaluate possible long-term effects of maternal PD on the socio-communicative and behavioral phenotype of the offspring with a specific focus on the possible increase of ASD risk.

B. To characterize the clinical phenotype of Offspring of Perinatal Depressed women pharmacologically treated during pregnancy in comparison to Offspring NOT exposed to drug treatment during pregnancy.

**Methods:**

This study has been developed in the context of the SOS MOOD project - a mental health safeguard project aiming to support women during pregnancy and post-partum, and to early detect child warning signals of a derailed development. Women were screened during pregnancy for perinatal depression - categorized as affected (PD) or not (NPD) through the administration of the questionnaire EPDS (Edinburgh Perinatal Depression Scale) - and if necessary were prescribed pharmacological therapy. Offspring of both groups of women (PD and NPD) underwent, at a mean age of 43 months, a standardized neuropsychiatric evaluation of: developmental or cognitive skills, behavioral problems, autism symptoms (Autism Diagnostic Observation Schedule-Second Edition) and parental stress (Parental Stress Index Short Form).

**Results:**

Preliminary results on 59 women (mean age 36 years; 31 PD, 28 NPD) and 59 children (39 males; 20 females; age range 11 months-9 years, mean age 3.5 years) reported no significant difference in the offspring's clinical phenotype (developmental/cognitive, behavioral, autism symptoms) of women with perinatal depression (O-PD) in comparison to children not exposed to maternal perinatal depression (O-NPD) at a mean age of 3.5 years (Fig). However, even if not significantly ( $\chi^2 = 0.790$ ;  $p = 0.674$ ), the group of mothers with PD was characterized by a higher number of children diagnosed - according to the ADOS2- with ASD (6 vs 3) or at risk for ASD (2 vs 1) in comparison to NPD mothers. Interestingly, an increased stress related to parenting emerged within mothers affected by perinatal depression in comparison to women not affected ( $t = 3.8$   $p < 0.001$ ). No

statistically significant difference was found between children of mothers with PD exposed or not exposed to maternal psychopharmacological treatment during pregnancy.

#### Conclusions:

The SOS MOOD project's preliminary results on a limited sample size suggest that maternal perinatal depression, whether pharmacologically treated or not, did not weigh on diagnosis or risk of autism in offspring, and does not significantly impair children's cognitive and behavioral development. The early clinical characterization of children born from mothers affected by perinatal depression represents an important health issue, aimed to support pregnant women diagnosed with PD and for their offspring.

#### **406.141 (Poster)** Mimicry and Social Affiliation with Virtual Partner Are Decreased in Autism

*B. Tuncgenç<sup>1</sup>, C. A. Koch<sup>2</sup>, I. M. Eigsti<sup>3</sup>, S. H. Mostofsky<sup>4</sup> and M. J. Stabile<sup>1</sup>, (1)Psychology, University of Nottingham, Nottingham, MD, United Kingdom, (2)Center for Neurodevelopmental and Imaging Research, Kennedy Krieger Institute, Baltimore, MD, (3)Psychological Sciences, University of Connecticut, Storrs, CT, (4)Center for Autism and Related Disorder, Kennedy Krieger Institute, Baltimore, MD*

---

**Background:** Mimicking other people's mannerisms and gestures occurs spontaneously and contributes to social affiliation and interaction quality. While mimicry of emotional facial expressions is known to be impaired in autism spectrum disorders (ASD), we do not know if non-facial mimicry is also impaired and if so, what this means for autistic individuals' social affiliation.

**Objectives:** In a novel naturalistic interaction setting, this study examined how often children with ASD and neurotypical (NT) peers mimicked a virtual partner's non-facial mannerisms, and how mimicry was associated with self-reported affiliation with the partner. We predicted that: (i) ASD children would mimic their partner's mannerisms less than NT children, and (ii) Mimicry frequency and affiliation would be positively associated in the NT group. We explored whether this association would be different within the ASD group and the association of mimicry with core autism symptoms.

**Methods:** Sixty children (32 ASD, 28 NT) aged 8-12 years participated in a storytelling task, in which they viewed pre-recorded videos of a narrator tell them a story, who scratched her head and arm throughout the task. Using post-hoc frame-by-frame coding, we assessed how often the children scratched their head and arm upon seeing the narrator perform these actions. Subsequently to the storytelling task, the children filled out a questionnaire where they indicated how much they liked the narrator, wanted to play with her again and attributed positive qualities to her, e.g., kindness, friendliness etc. Core autism symptoms were examined using the Autism Diagnostic Observation Schedule (ADOS-2) for children in the ASD group and parent-report of the Social Responsiveness Scale (SRS-2) for all children.

**Results:** Results revealed reduced mimicry,  $p=.001$ ,  $\phi=.38$ , Figure 1A, and less affiliation with the partner,  $p=.01$ ,  $\phi=.33$ , Figure 1B, in ASD relative to NT children. Mimicry was associated with affiliation in the NT,  $r(23)=.64$ ,  $p=.0009$ , but not in the ASD, ( $r(31)=.07$ ,  $p=.72$ , Figure 1C, group. Across groups, mimicry was negatively associated with SRS-2,  $r(53)=-.39$ ,  $p=.004$ , yet this likely reflects the strong clustering of the SRS-2 data based on diagnosis alone; Figure 1D. No significant association was found between mimicry and ADOS-2 scores.

**Conclusions:** This study shows that while autistic children mimic others less, their degree of mimicry is unrelated to their feelings of affiliation. Our findings of reduced mimicry of non-emotional, non-facial gestures in ASD is a novel contribution to the literature and supports the view that basic visual-motor integration deficits, rather than social context, may account for autism-associated differences in motor imitation. Future studies should address how sensorimotor mechanisms are associated with mimicry, affiliation and what, if any, alternative mechanisms for affiliation autistic individuals adopt.

#### **406.142 (Poster)** Nuanced Multimodal Measurement of Pragmatic Communication, Gaze and Accuracy on the Rmet

*E. F. Dillon<sup>1</sup>, C. W. Brune<sup>2</sup>, C. A. Cooper<sup>3</sup>, J. M. Moriuchi<sup>3</sup>, E. V. Ocampo<sup>4</sup>, L. Bush<sup>5</sup>, Z. E. Arnold<sup>4</sup> and L. V. Soorya<sup>1</sup>, (1)Psychiatry, Rush University Medical Center, Chicago, IL, (2)Department of Psychiatry, AARTS Center, Rush University Medical Center, Chicago, IL, (3)AARTS Center, Rush University Medical Center, Chicago, IL, (4)Department of Psychiatry, Rush University Medical Center, Chicago, IL, (5)Northwestern Feinberg School of Medicine, Chicago, IL*

---

**Background:** Children with autism spectrum disorder (ASD) have differences in the way they perceive and understand social stimuli. These differences are reflected on measures of social cognition, including recognizing other's emotions and mental states (ToM, Theory of Mind) and in social behaviors like pragmatic communication. Pragmatic communication skills, which require ToM to successfully relate to a conversation partner are expected to relate to children's social cognitive processes and performance on a ToM task. A measure of social cognition, Reading the Mind in the Eyes Task (RMET, Baron-Cohen et al., 2001) has been used with eye tracking technology to capture cognitive processes. This could be confounded by age, IQ, and diagnosis on accuracy of identifying emotional states (Peñuelas-Calvo et al., 2019). Evidence from family studies of autism suggest that scores on the RMET segregate with social and pragmatic features that may distinguish meaningful autism phenotypes (Losh & Piven, 2007). Measures of gaze patterns and attention can offer more nuanced insight into social cognitive determinants that inform autism phenotypes. The complexity of pragmatic communication skills, variations in ASD presentation, and differences in development and IQ further complicates the relationship.

**Objectives:** To investigate the relationship between RMET, PRS-SA, and IQ in a sample of children with ASD, enrolled in a randomized clinical trial (RCT) of oxytocin augmentation of social cognitive skills training.

**Methods:** 40 children (37 M, 3 F), between the ages of 8 and 11 ( $M=9.25$ ,  $SD=1.10$ ), with confirmed ASD, enrolled in an RCT (NCT02918864) were evaluated at baseline on RMET, and measures of pragmatics, Pragmatic Rating Scale-School Aged (PRS-SA) and the Children's Communication Checklist-2 (CCC-2) and IQ (WAIS-I, WISC-V). A Tobii T60 XL was used for eye-tracking visual patterns and attention. The PRS-SA was coded by trained, reliable clinicians from the Autism Diagnostic Observation Schedule-2. Subjects' baseline data was collapsed across conditions for this analysis. These preliminary analyses focused on correlations between gaze, an observed pragmatics measure, and caregiver report of social language use.

**Results:** Participants' NVIQ positively correlated with accuracy, latency to response, and time spent looking at the image, and negatively correlated with time spent looking at words. Verbal IQ followed the same fixation pattern. Accuracy but not gaze metrics significantly related to Total Pragmatic Impairment on the PRS-SA (Table 1). However, dwell time on image negatively correlated with several CCC-2 subscales, meaning more looking time related to less communicative impairment. These results must be interpreted with caution as NVIQ also related to CCC-2.

**Conclusions:** We found that certain responses on the RMET related to IQ, but IQ was not related to PRS-SA. Specific profiles of social communication impairment may emerge from the PRS-SA and uniquely relate to RMET performance. Further analysis will investigate RMET accuracy and measures of social communication. These relationships may identify bidirectional mechanisms between social communication behaviors, i.e. pragmatic impairment, and social cognitive impairments.

#### **406.143 (Poster)** Parent Report of Nonverbal Joint Attention Symptoms in School Aged Children with ASD

**J. C. Bullen<sup>1</sup>, S. L. Birkeneder<sup>1</sup> and P. Mundy<sup>2</sup>, (1)UC Davis, Davis, CA, (2)University of California at Davis, Davis, CA**

**Background:** Joint attention symptoms are a feature of preschool children with ASD (Mundy, 2018). It is not clear if those symptoms remain present in childhood, especially among verbal children with ASD. The Childhood Joint Attention Rating Scale (C-JARS) is a parent report measure of joint attention developed to examine this issue. The C-JARS is a 60-items parent report measure that provides a 46 item Prosocial Scale Score (PSC) that measure children's verbal and nonverbal spontaneous sharing of a point or reference and experience, a 14 item Asocial Scale Score (ASC) that primarily measures non-verbal problems in sharing attention and experience, and a total Joint Attention Score. Prior research has only examined the total score (Mundy et al., 2017).

**Objectives:** **1)** To examine the test-retest reliability of the ASC and PSC scores. **2)** To determine if a verbal sample of 8-16-year-olds with ASD differ from neurotypical (NT) peers on the nonverbal ASC scale. **3)** To examine the discriminant validity of the ASC for identifying verbal children with ASD versus age matched NT peers. **4)** To test convergent-divergent validity and the hypothesis that C-JARS score will be related to the Social Affect but not Repeated Repetitive Behavior (RRB) dimension score of the Autism Diagnostic Observation Scale-2 (ADOS-2).

**Methods:** Sixty-nine children with ASD ( $M_{FIQ} = 95.32$ ,  $SD = 17.46$ , range = 56-132) and 36 NT children ( $M_{FIQ} = 115.06$ ,  $SD = 13.88$ , range = 88-150) between the ages of 8-16 years old participated at Time 3 of a 30-month longitudinal study. C-JARS data were gathered for across a 15-month interval. See Table 1. Parent report of joint attention abilities was collected with C-JARS. Participants completed Module 3 of the ADOS-2 and the Wechsler Abbreviated Scale of Intelligence-2 full-scale IQ (FIQ) assessment 15 months before C-JARS data were collected.

**Results:** Pearson correlation analyses indicated significant Pearson test-retest reliability for the ASC and PSC scores for ASD ( $r_s = .83$  and  $.79$ ) and NT ( $r_s = .82$  and  $.88$ ) children, respectively. A 2 (Diagnostic Group) ANCOVA controlling for FIQ revealed significant between-group differences on the ASC scale,  $F(1, 105) = 93.61$ ,  $p < .001$ , partial- $\eta^2 = .48$ , wherein the ASD group demonstrated higher nonverbal joint attention symptom scores ( $M = 31.01$ ,  $SD = 8.35$ ) than the NT group ( $M = 12.80$ ,  $SD = 7.75$ ). See Figure 1. Group differences remained after excluding children with ASD and comorbid IDD ( $FIQ < 74$ ),  $F(1, 95) = 102.72$ ,  $p < .001$ , partial- $\eta^2 = .53$ . A discriminate analysis revealed that the ASC score correctly identified 88.4% of the ASD sample and 88.9% of the NT sample. Finally, initial ADOS-2 Social Affect scores predicted parent report C-JARS ASC scores ( $r = .29$ ,  $p = .02$ ) but not RRB did not ( $r = .07$ ,  $p = .60$ ).

**Conclusions:** These data support the hypothesis that parents can provide reliable and meaningful information about childhood nonverbal joint attention development in verbal children with ASD that is related to their objective clinical ratings of social symptoms.

#### **406.144 (Poster)** Quantifying Behavioral Inhibition to Unfamiliar Social and Non-Social Stimuli in Toddlers with ASD

**C. Banarjee<sup>1</sup>, V. Donthireddy<sup>2</sup>, E. Diamond<sup>3</sup>, A. Boxberger<sup>2</sup>, K. All<sup>2</sup>, R. Foster<sup>4</sup>, B. Gordon<sup>2</sup>, E. Brennan-Wydra<sup>2</sup>, A. Vernetti<sup>2</sup>, S. Macari<sup>2</sup> and K. Chawarska<sup>2</sup>, (1)Child Study Center, Child Study Center, Yale School of Medicine, New Haven, CT, (2)Child Study Center, Yale University School of Medicine, New Haven, CT, (3)Yale University, New Haven, CT, (4)Child Study Center, Yale School of Medicine, New Haven, CT**

**Background:** Studies of emotional reactivity to salient novel social and non-social stimuli in toddlers with autism spectrum disorder (ASD) revealed lower intensity of negative emotions and lower physiological reactivity to novel non-social stimuli (e.g., spider toy) than non-ASD peers (Macari et al., 2018, Vernetti et al., 2018), but more intense negative emotionality to novel social stimuli (Macari et al., 2020; Scherr et al., 2017). Physical movement and proximity also indicate a child's appraisal of novel stimuli, with less motor activity, closer proximity to parent, and decreased proximity to the stimuli indicating greater behavioral inhibition (BI) or reticence. Here we examined BI to unfamiliar social (stranger) and non-social (gorilla) stimuli in toddlers with and without ASD.

**Objectives:** (1) To examine BI to novel social and non-social stimuli in 3-year-olds with ASD and typically development (TD) as indexed by overall motor activity, proximity to parent, and proximity to the stimuli. We hypothesized greater BI to the social stimulus alongside lower BI to the non-social stimulus by ASD compared to TD children. (2) To explore associations between BI to novel stimuli and severity of autism symptoms.

## Methods:

3-year-olds (37 ASD, 27 TD) were administered two 3-minute free play tasks in social (unfamiliar adult seated in the corner of the room; Stranger) and non-social (stuffed gorilla propped in the same chair; Gorilla) conditions, adapted from the Laboratory-Temperament Assessment Battery (Lab-TAB; Goldsmith & Rothbart, 1999). Proximity to each novel stimulus was coded offline and we derived: 1) %Time\_In\_Motion (%time spent moving around the room), 2) %Time\_Near\_Parent (%time spent <2 feet from parent), and 3) average distance from stimuli. Group differences were examined using diagnosis (2) by condition (2) linear mixed-effect models followed by planned t-tests. We examined associations between BI measures and autism symptom severity using ADOS calibrated social affect (SA) severity scores.

Results: Toddlers with ASD and TD both exhibited lower levels of motor activity (%Time\_In\_Motion) in the Stranger vs. the Gorilla condition ( $p<0.001, d=-0.57$ ), with no significant effects of diagnosis ( $p=0.35, d=0.09$ ) or interaction ( $p=0.07, d=-0.46$ ). Both groups spent more time near parents (%Time\_Near\_Parent) in the Stranger vs Gorilla condition ( $p<0.001, d=0.84$ , Fig.1A), with no main effects of diagnosis ( $p=0.06, d=0.23$ ) or interaction ( $p=0.83, d=0.05$ ). While children with ASD and TD maintained a similar distance from the gorilla ( $p=0.462, d=0.19$ ), those with ASD maintained closer proximity to the stranger than TDs ( $p=0.011, d=0.65$ , Fig.1B). Within the ASD group, higher ADOS SA severity was associated with less time near parent and lower distance from both the stranger (%Time\_Near\_Parent: $r(35)=-0.453, p=0.005$ , Distance: $r(35)=-0.474, p=0.003$ ) and the gorilla (%Time\_Near\_Parent: $r(35)=-0.396, p=0.015$ , Distance: $r(35)=-0.363, p=0.027$ ).

Conclusions: Contrary to our hypotheses, both groups exhibited more BI in the social compared to the non-social condition, and toddlers with ASD displayed similar BI as TD toddlers when faced with the gorilla. However, children with ASD remained closer to the stranger than TD peers, with increased proximity to both types of novel stimuli and decreased proximity to parent correlated with greater autism severity. Findings reveal a complex picture of young children's appraisal of novel stimuli, which may be affected by the severity of their autism symptoms.

## **406.145 (Poster)** Recognition of Emotions in People with Autistic Traits and Comorbid Anxiety: A Behavioural Study

**M. S. Mann<sup>1</sup>, P. Liu<sup>2</sup>, F. E. Pollick<sup>3</sup> and M. Sutherland<sup>1</sup>,** (1)University of Glasgow, Glasgow, United Kingdom, (2)Sun Yat-Sen University, Guangzhou, China, (3)School of Psychology, University of Glasgow, Glasgow, United Kingdom

Background: Atypical emotion processing has been widely reported in autism spectrum disorder (ASD). The co-occurrence of anxiety with ASD has been frequently reported, but the evidence for anxiety modulating emotion recognition in ASD is still lacking.

Objectives: The current research was therefore designed to explore emotion recognition in individuals with significant autistic traits, considering uni- and multimodal presentations as well as the co-occurrence of anxiety, which is not included in the ASD criteria, but which is frequently associated with ASD.

Methods: Fifty individuals were recruited for the study and were divided into two groups according to their Autism Quotient score based on a criterion of scores 31 and above for the high levels of autistic traits group (HAQ) and 18 and below for the low levels of autistic traits group (LAQ). Half the participants had AQ scores higher than criterion (HAQ) and half the participants had AQ scores lower than criterion (LAQ). Every participant also performed a state trait anxiety inventory (STAI). In a single experimental session, recognition of six basic emotional states (happiness, anger, surprise, sadness, disgust, fear) and one neutral state were assessed using unimodal (face or voice) and multimodal (face-voice) pairs. The face stimuli were short 3 second videos of expressions induced in typical participants and the voice stimuli were obtained from the Montreal Affective Voice dataset. The proportion of correct responses and the response times were recorded.

## Results:

Results suggested that individuals with high levels of autistic traits were able to recognise emotions displayed across different modalities, suggesting a lack of general deficit in emotion perception.

However, the presence of comorbid anxiety appeared to counteract the effects of autistic traits in the recognition of emotions (e.g., fear, surprise, anger), and this effect tended to be different for the LAQ and HAQ groups. More specifically, for the recognition of fear expression, greater anxiety was associated with less probability of correct responses in the HAQ but more probability of correct answers in the LAQs.

As for the reaction times in other emotions, anxiety tended to be significantly associated with longer response latencies in the HAQ group, but shorter response latencies in the LAQ group for the recognition of emotional expressions, for negative emotions (e.g., anger, fear, and sadness), and this effect of anxiety was not restricted to specific modalities.

Conclusions: The research concludes that more needs to be done to investigate the effect of comorbid anxiety in individuals with ASD. It is possible that the cause of the differing results with comorbid anxiety in the HAQ group compared to the LAQ group is likely due to an underlying difference in emotion recognition processing and it is worth investigating further the role of anxieties effect on emotional processing, possibly with a functional MRI study.

## **406.146 (Poster)** Regulatory Strategies, Emotional Expression, and Physiological Responses during a Frustration Eliciting Task in Toddlers with and without ASD

**Background:** Effective regulation of negative emotions is important for well-being in children with and without autism spectrum disorder (ASD) (Mazefsky et al., 2014). When faced with a frustrating task, young children with ASD and typical development (TD) show similar intensity of emotional expression (EE) and physiological responses (Jahromi et al., 2012; Macari et al., 2018; Vernetti et al., 2020). However, toddlers with ASD use fewer constructive emotion-regulation (ER) strategies than TD peers when frustrated (Jahromi et al., 2012; Zantinge et al., 2017), suggesting different developmental patterns of ER (Nuske et al., 2017). Links between specific strategies and emotional and physiological responses to frustrating situations, however, remain poorly understood.

**Objectives:** To examine: 1) whether 3-year-olds with ASD show different patterns of EE-frustration, physiological responses, and ER strategies in response to frustrating events than TD peers, and 2) links between frustration (EE and physiological) and specific ER strategies in toddlers with ASD compared to TD controls.

**Methods:** 125 chronological age-matched toddlers (67ASD, 58TD;  $M_{age}=38.9mo$ ) were given a locked clear box containing attractive toys along with an incorrect key for 60 seconds, an adaptation of the “lockbox” task from the Laboratory Temperament Assessment Battery (LabTAB, Goldsmith&Rothbart, 1999). Intensity of EE-frustration (facial anger, bodily sadness, distress vocalization) and presence of ER strategies (Table 1) were coded offline. Skin conductance level (SCL), an index of physiological arousal, was measured using AffectivaQ-Sensors worn on the ankle. Change in SCL ( $\Delta SCL$ ) between the first 10s and the rest of the task was computed. T-tests assessed group differences in EE and  $\Delta SCL$ , and chi-square analyses assessed group differences in ER strategy use. Differences in EE and  $\Delta SCL$  by ER strategy use and diagnosis were tested using two-way ANOVAs.

**Results:** Toddlers with ASD and TD showed similar intensity of EE-frustration ( $p=0.860, d=0.048$ ) and  $\Delta SCL$  ( $p=0.803, d=0.506$ ) during the task. More toddlers with ASD than TD used physical comfort-seeking ( $X^2(125)=10.559, p=0.001$ ; ASD:29.8%; TD:6.9%) and fewer toddlers with ASD than TD used directed ( $X^2(125)=6.596, p=0.010$ ; ASD:64.2%; TD:93.1%) and undirected social bids ( $X^2(125)=6.723, p=0.010$ ; ASD:76%; TD:93.1%; Figure1a). There were no group differences in use of disengagement or self-soothing strategies (all  $p>0.271$ ). ANOVAs revealed greater EE-frustration in toddlers who used physical comfort-seeking than toddlers who did not ( $p=0.019$ ) and greater  $\Delta SCL$  in toddlers who disengaged ( $p=0.037$ ) and made undirected social bids ( $p=0.023$ ) than those who did not (Figure1b).

**Conclusions:** Three-year-olds with ASD and TD exhibited similar intensity of emotional and physiological responses to a frustrating task. While toddlers with ASD used a range of ER strategies to regulate their frustration, significantly more of them sought physical comfort with their parents and fewer used either directed or undirected social bids compared to TDs, suggesting differences in use of ER. Furthermore, in both groups, physical comfort seeking was associated with greater behavioral expression of frustration, while disengagement and undirected social bids were associated with greater physiological expression of frustration. We established associations between specific regulatory strategies and behavioral and physiological responses to frustration, however to best support ER skills in children with ASD, further work should investigate causal relationships.

#### **406.147 (Poster) Sex Differences in Social-Emotional Insight in Youth with Autism Spectrum Disorder**

**H. M. Mattern<sup>1</sup>, J. Parish-Morris<sup>2</sup>, M. L. Cola<sup>1</sup>, K. G. Tena<sup>1</sup>, A. Knox<sup>1</sup>, A. S. Russell<sup>1</sup>, M. R. Pelella<sup>1</sup>, R. T. Schultz<sup>2</sup> and J. McCleery<sup>4</sup>,** (1)Developmental Psychology, Penn State University, University Park, PA, (2)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (3)The Children's Hospital of Philadelphia Center for Autism Research, Philadelphia, PA, (4)Psychology, Saint Joseph's University, Philadelphia, PA

---

**Background:** Historically, autism spectrum disorder (ASD) has been diagnosed primarily in males, with females accounting for approximately 1 in 4 cases or – in highly verbal subgroups – as few as 1 in 20 cases (Boorse et al., 2019). However, recent research suggests that many girls and women with ASD do not receive a diagnosis until much later in life, which may be due to differences in the way that autism symptoms present in males vs. females. In this study, we examine differences in social-emotional insight between girls and boys with autism spectrum disorder and neurotypical (NT) controls by measuring how they talk about social and emotional topics during semi-structured clinical evaluations. In previous research observing differences in insight of social and emotional topics, an elevated insight has been present in girls compared to boys. This study is observing for if this elevation in girls is still present in the autism population even with deficits in social understanding typical in individuals with autism.

**Objectives:** Assess potential differences in social-emotional insight between children and adolescents with autism spectrum disorder vs. NT controls, with a focus on sex differences.

**Methods:** Sixty-four child and adolescent participants with ASD or NT development were selected from a larger study that included ASD diagnostic assessments, IQ testing and behavioral tasks. All participants were administered the Autism Diagnostic Observation Scale, 2<sup>nd</sup> Edition (ADOS-2), Module 3 or 4, which were recorded for future use with consent and orthographically transcribed. Two reliable coders read each transcript and analyzed insight levels based on four scales measuring: emotion understanding, relationships and relationship roles, perspective taking, and ability to recall past experiences including these topics (Five Levels of Emotional Awareness in Children, Social Cognition and Object Relations Scale, Emotional Investment in Relationships, and Understanding of Social Causality). Four general mixed model 2x2 ANOVAs were conducted to assess diagnostic group differences on each of the four insight scales, with additional ANOVAs were conducted to assess sex differences in the ASD group specifically.

**Results:** Significant sex differences were revealed on two of the four insight scales in the autism group: the social cognition and object relations scale  $F(1,31)=6.03$ ,  $p=.020$ ,  $\eta^2=.17$ , girls ( $M=3.31$ ,  $SD=.63$ ) and boys ( $M=2.60$ ,  $SD=.97$ ) and understanding of social causality scale  $F(1,31)=4.55$ ,  $p=.041$ ,  $\eta^2=.13$ , girls ( $M=3.44$ ,  $SD=.68$ ) and boys ( $M=2.88$ ,  $SD=.81$ ).

**Conclusions:** Elevated insight has previously been observed in NT child and adolescent girls compared to NT child and adolescent boys. Until now, sex differences in social and emotional insight have not been assessed in autism. The current results, while preliminary, provide evidence for sex differences in social-emotional insight in autism, and indicate a need for further research in this area. While not conclusive, our results provide potentially critical insight into the unique challenges and strengths faced by girls with autism and may partially explain why girls are under-diagnosed relative to boys.

**406.148 (Poster)** Sharing Joy during Puppet Shows: Toddlers with Autism Spectrum Disorder Share Positive Affect as Frequently as Typically Developing Controls

**E. Diamond<sup>1</sup>**, K. Alf<sup>2</sup>, B. Gordon<sup>2</sup>, C. Banarjee<sup>3</sup>, R. Foster<sup>4</sup>, A. Boxberger<sup>2</sup>, V. Donthireddy<sup>2</sup>, E. Brennan-Wydra<sup>2</sup>, A. Vernetti<sup>2</sup>, S. Macari<sup>2</sup> and K. Chawarska<sup>2</sup>, (1)Yale University, New Haven, CT, (2)Child Study Center, Yale University School of Medicine, New Haven, CT, (3)Child Study Center, Child Study Center, Yale School of Medicine, New Haven, CT, (4)Child Study Center, Yale School of Medicine, New Haven, CT

**Background:** Shared positive affect (SPA), the coordination of positive affect and gaze towards a social partner, is a key component of early social development (Parlade et al., 2009). Previous research has shown that young children with autism spectrum disorder (ASD) display SPA less frequently than typically developing (TD) peers, though this has only been examined in the context of activities such as an interaction with a caregiver during snack time (Dawson et al., 1990) or during a developmental assessment (Ozonoff et al., 2010). Inconsistent with these results are two studies that examined emotional reactivity in response to standardized tasks aimed specifically to elicit joy. The studies demonstrated that toddlers with ASD display similar intensity of joy as TD toddlers on the behavioral (Macari et al., 2018) and physiological arousal (Vernetti et al., 2020) levels. Here we examine whether in this context toddlers with ASD not only experience joy, but also share it with their parents to the same extent as TD toddlers.

**Objectives:** Determine whether (1) duration of positive affect and (2) rate and duration of SPA differ between toddlers with ASD and TD controls during a standardized joy-eliciting task.

**Methods:** Participants included 75 toddlers, 45 with ASD ( $M_{age}=22.5mo$ ,  $SD=3.08$ , 84% male) and 30 TD ( $M_{age}=21.5mo$ ,  $SD=3.72$ , 57% male). Toddlers viewed a one-minute puppet peek-a-boo show while seated next to a parent, adapted from the Laboratory Temperament Assessment Battery (LabTAB; Goldsmith & Rothbart, 1999). Frequency and duration of toddler attention (e.g., looking at the parent) and affect (positive, negative, neutral) through facial, vocal, and bodily channels were coded without knowledge of diagnoses. The (1) proportion of time the child expressed positive affect (%PositiveAffect: positive affect duration/trial duration), (2) proportion of time the child looked at parent with positive affect (%SPA: SPA duration/trial duration), and (3) SPA occurrences per minute (SPA\_Rate) were computed. Two-sample t-tests assessed group differences in %PositiveAffect, %SPA, and SPA\_Rate.

**Results:** Descriptive statistics and graphical representations are presented in Table 1 and Figure 1, respectively. Diagnostic groups did not differ in %Positive Affect ( $p=.484$ ), %SPA ( $p=.447$ ), or SPA\_Rate ( $p=.261$ ).

**Conclusions:** Although toddlers with ASD shared positive affect slightly less frequently than TD peers, differences were not significant and associated effect sizes were small. The present study extends our prior work (Macari et al., 2018; Vernetti et al., 2020) and suggests that toddlers with ASD not only express similar levels of joy, but also reference their parents while expressing joy as frequently as TD peers. Results of the three studies fail to replicate previous research that measured positive affect during task-oriented interactions with adults. This discrepancy shows that differences in affective responses in ASD are context dependent. The use of playful puppets (Macari et al., 2021) and non-demanding task setup may promote experiencing and sharing joy in toddlers with ASD. Given the role of positive emotions in learning, memory, and social development, such activities could be used to harness shared enjoyment during early intervention programs and in educational settings to create optimal environments for children with ASD to thrive and learn.

**406.149 (Poster)** Social Cognition and Social Anxiety in Neurodevelopmental Disorders

**G. L. Simmons<sup>1</sup>**, T. H. Ollendick<sup>2</sup> and S. W. White<sup>1</sup>, (1)Psychology, The University of Alabama, Tuscaloosa, AL, (2)Virginia Polytechnic Institute and State University, Blacksburg, VA

**Background:** Relative to neurotypical peers, youth with Autism Spectrum Disorder (ASD) present with heightened rates of social anxiety and sociocognitive impairment. Prior work has theorized how these overlapping impairments may interact during adolescent development, and recent studies have explored these overlapping symptom profiles in youth with ASD (Pearcey et al., 2021; Zukerman et al., 2021). However, research has yet to parse out the effects of comorbid symptom profiles on adaptive functioning in youth with ASD. Attention Deficit-Hyperactivity Disorder (ADHD) and ASD are characterized as Neurodevelopmental Disorders (NDs) and often diagnosed together. Youth with ADHD similarly present with both social anxiety and sociocognitive impairments. To date, social anxiety and sociocognitive impairment have not been studied conjointly in order to examine how these impairments may differentially impact adaptive functioning in ASD compared to ADHD.

**Objectives:** We examined the unique effects of sociocognitive impairment and social anxiety on functional impairment in children with ASD. We hypothesized 1) both sociocognitive impairment and social anxiety would explain significant variance in adaptive functioning. We then examined whether differences emerged in the relative influence of social anxiety and sociocognitive impairment on adaptive functioning between youth with

ASD and ADHD. We hypothesized 2) sociocognitive impairment would account for relatively more variance than social anxiety in predicting adaptive functioning in youth with ASD, but not in youth with ADHD.

**Methods:** Participants were referred to a university-affiliated clinic for comprehensive diagnostic assessment services. The present study included caregiver-reported data collected from 34 youth (ages: 7-17 years), half of whom had ASD, and half without ASD but with ADHD. Participants were matched on parent-reported degree of social anxiety, as part of a comprehensive clinical assessment. Participants were primarily male (70.6%) and Caucasian (91.2%), ranging in age from 7 – 17 ( $M = 12.35$ ;  $SD = 2.77$ ). Caregivers completed measures of social anxiety, sociocognitive impairment, and adaptive functioning. Linear regression was used to examine the predictive weight of social anxiety and sociocognitive impairment on adaptive functioning. Effect sizes were calculated for all predictors (Cohen's  $f$ ).

**Results:** In youth with ASD, sociocognitive impairment and social anxiety each significantly predicted adaptive functioning impairment, controlling for FSIQ; in youth with ADHD and not ASD, only sociocognitive impairment significantly predicted adaptive functioning (Table 1). Partial correlations controlling for FSIQ revealed sociocognitive impairment was significantly associated with adaptive functioning impairment in both ASD and ADHD samples (Table 2): social anxiety was significantly associated with adaptive functioning impairment only in youth with ASD.

**Conclusions:** Findings suggest social anxiety compounds functional impairment in youth with ASD, but not those with ADHD who do not have ASD. Future research may explore social anxiety in the context of both understanding patterns of social impairment in ASD and targeted interventions for this population. Moderate to large effect sizes, noted across both samples, emphasize the importance of social cognition in predicting outcome. Findings build on prior work examining social impairments and deficits in adaptive functioning in youth with ASD and ADHD and may inform future mechanism-based treatment research for youth with NDs.

**406.150 (Poster)** Social Motivation Predicts Behavioral Compensation in Autistic Adolescents

**A. Knox<sup>1</sup>, K. G. Tena<sup>1</sup>, A. S. Russell<sup>1</sup>, M. R. Pelella<sup>1</sup>, M. Leuzzi<sup>1</sup>, C. J. Zampella<sup>1</sup>, M. L. Cola<sup>2</sup>, L. S. Cubit<sup>3</sup>, J. Pandey<sup>1</sup>, R. T. Schultz<sup>1</sup> and J. Parish-Morris<sup>1</sup>,** (1)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (2)The Children's Hospital of Philadelphia Center for Autism Research, Philadelphia, PA, (3)Clinical and Social Sciences in Psychology, University of Rochester, Rochester, NY

---

**Background:** According to the extant literature (Hull et al., 2018), camouflaging can be broken up into three categories: masking, compensation, and assimilation, depending on the type of behavior. Examples of masking behaviors include monitoring facial and body language to appear more relaxed and interested during social interactions. Assimilation behaviors include feeling a need to “put on an act” or pretend to be “normal” during social interactions. Camouflaging, compensation, masking, and assimilation have been studied extensively in autistic adults (Cage & Troxell-Whitman, 2019; Hull et al., 2017; Perry et al., 2021). For example, autistic adults have reported social motivations for engaging in camouflaging behaviors such as avoiding negative social experiences, making friends, and fitting in (Bernardin et al., 2021). In contrast, little is known about camouflaging behaviors in autistic adolescents, and even less is known about relationships between parent perceptions of their adolescent children's social motivation and the adolescent's own experiences of social compensation (i.e., actively working to maintain social relationships or interactions). Greater understanding of the relationship between parent-reported social motivation and self-reported social compensation could illuminate novel pathways for intervention aimed supporting autistic adolescent's social goals.

**Objectives:** Examine the relationship between parent-reported social motivation as measured by the Social Responsiveness Scale, 2<sup>nd</sup> Edition (SRS-2; Constantino, 2012) and self-reported social compensation as measured by the Camouflaging Autistic Traits Questionnaire<sup>4</sup> (CAT-Q) in autistic adolescents.

**Methods:** Nineteen autistic adolescents aged 13-17 years (16 male, 3 female) completed the CAT-Q which includes 25 questions related to three categories of camouflaging: compensation (9), masking (8), and assimilation (8). Parents completed the SRS-2, which includes 65 questions across five domains: social awareness, social cognition, social communication, social motivation, and restricted interests/repetitive behaviors.

**Results:** A linear model was used to predict adolescents' self-reported CAT-Q social compensation subscale scores using parent-reported SRS-2 social motivation scores. Results revealed that adolescents who were perceived by parents as having lower social motivation (i.e., higher parent-reported SRS-2 scores) engaged in significantly less self-reported social compensation (i.e., lower CAT-Q scores; estimate  $-.05$ , SE:  $.02$ ,  $t=-2.84$ ,  $p=.02$ ). Conversely, adolescents with greater perceived social motivation (based on parent-report) had higher social compensation scores, indicating greater efforts to support and maintain social interactions. In comparison to the larger adult samples reported in the extant literature<sup>4</sup>, autistic adolescents in our small sample had lower overall CAT-Q scores (adults:  $4.79$  ( $0.99$ ); adolescents: ( $3.61$  ( $0.73$ )), which may reflect differential social and occupational demands and supports experienced by adolescents vs. adults.

**Conclusions:** This preliminary exploration of the relationship between parent-reported social motivation and self-reported social compensation in autistic adolescents revealed that greater motivation to engage with others predicts active compensation to maintain social interaction. Thus, internal social motivation could be one mechanism that drives social compensatory behaviors, such as repeating statements, copying body language, and using learned scripts during conversation. Data collection is on-going, with a sample of 50+ participants anticipated by May 2022. Future analyses with a larger sample will examine whether and how social motivation and social compensation vary by participant sex, age, and cognitive ability.

**406.151 (Poster)** Social Performance - but Not Social Knowledge - Predicts Autism Spectrum Disorder Among Adolescents

**C. E. Freden<sup>1</sup>, K. M. Hauschild<sup>2</sup> and M. D. Lerner<sup>2</sup>,** (1)Stony Brook University, Stony Brook, NY, (2)Psychology, Stony Brook University, Stony Brook, NY

---

**Background:** Social interaction difficulties in autism spectrum disorder (ASD) may arise from either a lack of social knowledge (knowing what to do; Mesibov, 1982), challenges with social performance (inability to reliably enact this knowledge; Lerner, 2013), or both. Recent work has examined how the individual contributions of each may give rise to ASD symptoms (Keifer et al., 2020); however, few studies have examined whether patterns of difference *between* social knowledge and social performance (knowledge-performance discrepancy; Rudolph et al., 1997) may uniquely predict ASD. Furthermore, studies that have examined this difference utilize measures that do not capture consonance across constructs (i.e., social knowledge and performance measures describing the same behaviors; Dissanayake & Macintosh, 2003; Livingston et al., 2018). Thus, utilizing measures and methods that more directly capture the knowledge-performance discrepancy is a crucial aim for refining both the characterization and treatment of ASD.

**Objectives:** 1) To explore the relationship between social knowledge and social performance in ASD via more directly-aligned constructs. 2) To examine whether patterns of knowledge-performance discrepancy predict ASD diagnostic status.

**Methods:** 147 adolescents with and without ASD (Table 1) completed two established measures of social knowledge (Michelson & Wood, 1982; Laugeson & Frankel, 2006) to create a composite score. Adolescents' social performance was evaluated via blinded, double-coded measurement of positive social behavior (all ICC > 0.70; Social Interaction Observation Scale, SIOS; Bauminger, 2002) during an observed semi-structured social interaction with novel peers, as well as by parent-report (Gresham & Elliott, 2008). Moderated logistic regression models (Laird, 2020; Table 1) were run to assess whether patterns of knowledge-performance discrepancy predicted ASD diagnostic status.

**Results:** Adolescents with ASD displayed reduced observed ( $t(145) = 3.01, p < .01$ ) and parent-reported ( $t(145) = 4.41, p < .001$ ) social performance compared to adolescents without ASD. No differences in social knowledge were found between the two groups (Table 1). A main effect of social performance was identified in each moderated logistic regression model, such that observed (Model 1;  $b = -0.07; p < 0.05$ ) and parent-reported (Model 2;  $b = -0.04, p < 0.001$ ) social performance significantly predicted ASD diagnostic status, but the knowledge-performance discrepancy (interaction term) did not (Table 1; Figure 1). No main effects of social knowledge were found.

**Conclusions:** Findings indicate that ASD diagnostic status is best predicted by measures of social performance, rather than by social knowledge or their discrepancy. Indeed, this furthers past work (Lerner & Girard, 2019), indicating that – despite being a common, primary emphasis for intervention (Gates et al., 2017) – challenges in social knowledge do not drive the social interaction difficulties associated with ASD, nor do they enhance what can be learned from an individual's social performance. Thus, future interventions may shift their focus away from didactic methods that aim to improve adolescents' social knowledge and toward the provision of peer interaction opportunities that aim to improve adolescents' social performance through naturalistic practice (Gates et al., 2017).

#### **406.152 (Poster)** Subtypes of Spontaneous Empathic Facial Expression Production in Autistic Adults

**J. Quinde Zlibut<sup>1</sup>** and **C. J. Cascio<sup>2</sup>**, (1)Vanderbilt University, Nashville, TN, (2)Department of Psychiatry and Behavioral Science, Vanderbilt University Medical Center, Nashville, TN

**Background:** It is unclear whether atypical patterns of facial expression production metrics in autism reflect the dynamic and nuanced nature of facial expressions or a true diagnostic difference. Further, the heterogeneity observed across autism symptomatology suggests a need for more adaptive and personalized social skills programs. For example, it would be useful to have a better understanding of the different expressiveness profiles within the autistic population and how they differ from neurotypicals (NTs) to help develop systems that train facial expression production and reception.

**Objectives:** Our primary objective was to explore whether the atypical patterns of facial expression production metrics in autism reflect the dynamic and nuanced nature of facial expressions or a true diagnostic difference

**Methods:** We collected facial expression recordings of 84 adult participants (ages 18-59) while they completed a computerized empathy task. We then derived a set of automated facial expression features from the recordings using the iMotions affect recognition toolkit, and applied an exploratory unsupervised learning approach (K-means clustering) on the feature sets for ASD (n=27) and NT (n=57) participants separately to derive interpretable clusters. Group comparisons were conducted on the two more stable clusters from each analysis (ASD=19, NT=29) using the robust nonparametric Cliff's delta ( $\delta$ ) effect size statistic on the basis of expressiveness and emotive congruence to emotionally charged stimuli.

**Results:** Within the ASD and NT groups, there was a larger and more stable cluster and a smaller, highly variable cluster that differed significantly in mean peak expressiveness scores (ASD clusters:  $\delta = 0.934, p < .001$ ; NT clusters:  $\delta = 0.940, p < .001$ ) and in average emotive congruence (ASD clusters:  $\delta = -0.434, p = 0.035$ ; NT clusters:  $\delta = -0.220, p < .001$ ). The smaller clusters in each group were therefore characterized as having more exaggerated spontaneous facial expressions that were not always congruent with the stimuli's emotional valence. When comparing the two more stable groups, our main finding was that autistic adults show heightened spontaneous facial expressions in response to negative emotional images ( $\delta = -0.009, p = 0.032$ ). The group effect did not extend to positive emotional images, and we did not find evidence for greater incongruous (i.e., inappropriate) facial expressions in autism.

**Conclusions:** These findings point to the highly nuanced and variable nature of facial expression production in autism and neurotypical controls. When we consider the more stable emoters in our group comparisons, these findings build on previous work suggesting valence-specific effects of autism on emotional empathy and suggest the need for intervention programs to focus on social skills in the context of both negative and positive emotions.

#### **406.153 (Poster)** Utilizing Eye Tracking Methodology to Delineate Social Attention Profiles in Fragile X Syndrome and Autism Spectrum Disorder

**Background:** Social attention deficits are a hallmark characteristic within autism spectrum disorder (ASD) and fragile X syndrome (FXS) and have been hypothesized to have cascading effects on emotion recognition (Reisinger et al., 2020; Farzin et al., 2009). Eye tracking methodology has emerged as a potentially reliable, feasible, and sensitive biomarker for examining core phenotypic features of ASD and FXS; however, these findings are mixed with regards to measuring treatment change in clinical trials. Further, delineation of syndrome-specific social attention profiles will expand the current literatures understanding of how these two etiologically distinct, but clinically similar phenotypic profiles of ASD and FXS overlap or differ.

**Objectives:** The present study assesses the utility of an eye tracking paradigm to discriminate between two clinical groups (FXS and ASD) and typically developing controls in their social attention through visual face scanning.

**Methods:** Participants included 24 participants with ASD (91.7% male), 15 participants with FXS (66.7% male), and 39 typically developing (TD) participants (74.4% male) ranging from 6 to 22 years of age ( $M=15.37$ ,  $SD=3.33$ ). Participants completed an eye tracking paradigm with one of two randomized variations of emotional faces as part of a larger study. Stimuli consisted of 12 colored photographs of adult human faces (equal numbers of males and females) from the NimStim Face Stimulus Set, each showing a calm, happy, or fearful facial expression. Eye tracking data were collected using a Tobii T120 infrared binocular eye tracker sampling at a rate of 120 Hz. Areas of interest (AOI) for the eyes (including eyebrows), nose, and mouth, were created on each of the faces and utilized for the present study. Proportion of looking time and latency to first fixation were utilized as the dependent variables.

**Results:** MANOVAs were utilized to examine differences in proportion of time spent looking at the three AOIs for each emotion across groups. For calm faces, the ASD group spent significantly more time looking at the mouth region in comparison the TD group ( $p=0.045$ ). There were no significant differences found between the groups for the AOIs of the fear faces ( $ps>0.05$ ). For the happy faces, the ASD group spent significantly less time looking at the eye region in comparison to the TD group ( $p=0.012$ ). The FXS group was not significantly different in their proportion of looking time for any of the AOIs across of the three emotional faces in comparison to the ASD and TD groups ( $ps>0.05$ ). Similarly, MANOVAs were utilized to examine the differences in latency to first fixation for the three AOIs for each emotional face across groups. No significant group differences were found. ( $ps>0.05$ ). Between group differences for ASD and FXS while controlling for IQ will also be examined.

**Conclusions:** These findings build on the promise of eye tracking as a feasible and reliable biomarker for identifying social attention deficits in ASD and FXS. Detecting differences in emotion recognition explicitly through facial scanning was not as clear and varied by emotion. Specific mechanisms within the eye tracking paradigm may be viable options for assessing treatment-specific outcomes.

**406.154 (Poster) Why Social Motor Synchrony Matters: The Implications of Social Motor Synchrony on Adaptive Behavior of Children with ASD**  
**M. Sabag<sup>1</sup>, J. Yarmolovsky<sup>2</sup>, N. B. Bauminger-Zviely<sup>3</sup> and R. Geva<sup>4</sup>**, (1)Psychology, Bar-Ilan University, Ramat Gan, Israel, (2)Gonda Brain Science Center, Bar-Ilan University, Ramat Gan, Israel, (3)School of Education, Bar-Ilan University, Ramat Gan, Israel, (4)Psychology Department, Bar-Ilan University, Ramat-Gan, Israel

---

**Background:** Social motor synchrony is a universal phenomenon that occurs in various social settings, but its role in shaping adaptive capacities in other domains is still undocumented. Furthermore, the developmental trajectory of social motor synchrony is understudied, with research focusing on early childhood and adulthood, overlooking the development path throughout childhood. Preliminary leads suggest that Autism Spectrum Disorders (ASD) exhibit social motor dis-synchrony, however it is unclear if this is a delayed development or pervasive deficit. As children with ASD experience deficits in multiple domains of adaptive behavior, we set out to explore if social motor synchrony in children with ASD promotes adaptive behavior.

**Objectives:** To assess typical and atypical development of social motor synchrony and explore its effect on adaptive behavior, postulating that children with ASD will show deficits in social motor synchrony and adaptive behavior, and that the ASD deficit in adaptive behavior will be moderated by social motor synchrony.

**Methods:** 62 children (ASD=39), ages 8.15-17.08 ( $M=12.28\pm2.65$ ) divided into mid-childhood (8-11 years-old) and late childhood (12-17 years-old) participated in the study. Children were paired to same age and diagnostic group dyads, and preformed a social turn taking task in two structured conditions: simultaneous drumming, where follower joins into the leader's rhythm at same time, and mirroring leader's rhythm upon completion of their turn. Prior to the experiment parents filled out the adaptive behavior assessment scale (ABAS-II). Children were screened for IQ (WISC-IV<sub>HEB</sub>).

**Results:** Validity checks: Task main effect was significant ( $p=.012$ ), yielding higher synchrony while mirroring compared to drumming simultaneously, supporting that as expected motor synchrony with no lag is a less complex capacity than mirroring (Fig. 1.). The developmental hypothesis was also supported ( $p=.018$ ), with late childhood group demonstrating higher social synchrony compared to mid-childhood, in line with a developmental trajectory (Fig. 1). An expected diagnosis effect was found for adaptive behavior, with ASD scoring lower than typically developing children ( $p<.001$ ).

**Hypotheses testing:** Social motor synchronizing tasks' performance was affected by group ( $p=.008$ ), with ASD demonstrating overall diminished synchrony (Fig. 1). There was no interaction effect of diagnosis and age ( $p=.834$ ) suggesting a pervasive deficit in ASD that does not seem to wane with age. Finally, to assess the impact of social motor synchronization on adaptive behavior in both populations two moderation models were

conducted. Only social motor synchrony, but not mirroring, moderated the effect of group on adaptive behavior ( $p=.031$  and  $p=.672$  respectively). Exploration of the moderation effect using Johnson-Newman technique revealed a significant ASD deficiency in adaptive behavior when social motor synchrony is lower than  $r_c=.64$ , demonstrating the importance of social motor synchrony as a scaffold for the development of adaptive behavior in ASD (Fig. 2).

**Conclusions:** The results suggest social motor synchrony as an important social construct that underlines adaptation, one of the most prominent and pervasive deficits in ASD.

**406.155 (Poster)** Examining Conversational and Prosodic Abilities of Adolescents with ASD through Computerized Acoustic Analysis

H. Shaham<sup>1</sup>, M. Eni<sup>2</sup>, S. J. Rabin<sup>1</sup>, E. Zadok<sup>1</sup>, I. Gordon<sup>1</sup>, I. Dinstein<sup>1</sup> and O. Golan<sup>1</sup>, (1)Department of Psychology, Bar-Ilan University, Ramat-Gan, Israel, (2)National Autism Research Center of Israel, Ben Gurion University, Beer Sheva, Israel, (3)Cognitive and Brain Sciences Department, Ben-Gurion University of the Negev, Beer Sheva, Israel

---

**Background:** Adolescents with ASD experience various social communication difficulties, including difficulties engaging in reciprocal conversations and difficulties appropriately using prosody to express themselves. However, their assessment has relied mostly on behavioral coding, which is time-consuming, resource-intensive, and prone to reliability issues. The use of computerized acoustic analysis (CAA) to evaluate conversational and prosodic abilities in ecological social interaction contexts can shed light on adolescents' social communication skills in a swift, objective, and ecological manner.

**Objectives:** to use CAA to 1. characterize conversational and prosodic abilities of adolescents with ASD, compared to their typically developing (TD) peers; 2. test if conversational and prosodic abilities of adolescents with ASD improve following social skills training.

**Methods:** To test the first question, we compared 60 male adolescents with ASD to 32 TD male adolescents on the contextual assessment of social skills (CASS; Ratto et al., 2011). To test the second question, we compared 34 male adolescents with ASD who participated in the PEERS® social skills intervention to 35 ASD waitlist controls. Participants took the CASS with different unfamiliar confederates before and after a 16-weeks intervention/wait period. All interactions were recorded, videotaped, and analyzed through CAA, and by human coding of behaviors. The CAA consisted of manual labeling of speakers, which was processed by inhouse software developed in Matlab, its outputs being acoustic features (e.g., pitch and energy of the speaker in each segment) as well as turn-taking quantification (i.e., subject responding to the confederate within 2 seconds).

**Results:** CAA in ASD-TD comparison revealed differences in conversational and in prosodic abilities. In conversational abilities, adolescents with ASD had longer, and less consistent turn-taking time compared to their TD peers. In prosodic abilities, compared to their TD peers, adolescents with ASD expressed less variability in pitch and stressful emotional state, and used higher and less consistent volume.

Furthermore, positive associations were found between conversational abilities as measured by CAA to social skills as measured by human coding of behaviors, while only specific prosodic abilities were associated.

CAA analyses for the intervention trial indicated that following the PEERS® intervention, adolescents improved their conversational abilities, including the number of speech segments they had in the conversation. They also showed intervention-related improvements in prosodic abilities such as voice quality, emotional state, and volume variability used during conversation. These indicate that the adolescents took a more active part in the conversations, and as such, support the well-documented effectiveness of PEERS®. Positive associations were found between the improvement in social skills as measured by human coding of behaviors and the improvement in the variability of the conversational rate of the adolescents as measured by CAA.

**Conclusions:** Our results support previous findings relating to conversational and prosodic deficits in individuals with ASD and extend the understanding of these differences to the age group of adolescence. The use of CAA for the purpose of evaluating improvement following an intervention has been scarcely used (Cabibihan et al., 2017). In the present study we have shown how using this objective method can complement behavioral coding.

**406.156 (Poster)** Associations between Intervention Hours and Attention to Faces in ASD: An Exploratory Analysis from the Autism Biomarkers Consortium for Clinical Trials

H. Willis<sup>1</sup>, F. Shic<sup>2</sup>, S. Faja<sup>3</sup>, S. R. Edmunds<sup>4</sup>, M. Sabatos-DeVito<sup>5</sup>, A. Naples<sup>6</sup>, R. A. Bernier<sup>7</sup>, K. J. Webb<sup>16</sup> and J. McPartland<sup>17</sup>, (1)Child Health, Behavior & Development, Seattle Children's Research Institute, Seattle, WA, (2)Center for Child Health, Behavior and Development, Seattle Children's Research Institute, Seattle, WA, (3)Boston Children's Hospital, Boston, MA, (4)Psychiatry and Behavioral Sciences, Duke Center for Autism and Brain Development, Durham, NC, (5)Child Study Center, Yale University School of Medicine, New Haven, CT, (6)Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA, (7)Department of Psychiatry and Behavioral Sciences, Duke Center for Autism and Brain Development, Durham, NC, (8)University of California, Los Angeles, Los Angeles, CA, (9)University of Washington, Seattle, WA, (10)Department of Developmental Medicine, Boston Children's Hospital, Boston, MA, (11)Yale University, New Haven, CT, (12)UCLA, Los Angeles, CA, (13)Child Study Center, Yale Child Study Center, New Haven, CT

---

**Background:** Research has identified associations between social attention, as qualified by eye gaze patterns during dyadic bid eye-tracking (ET) paradigms, and validated clinical outcome measures used to assess social communication.<sup>1</sup> With evidence implicating ET as a potential biomarker for social communication,<sup>1</sup> researchers have traditionally been interested in examining how ET measures associate with controlled exposures to specific interventions targeting social skill development.<sup>2,3</sup> However, there is little work examining how changes in ET measures may reflect effects of naturally occurring intervention use.

**Objectives:** To investigate how interventions used with children with ASD might be associated with an ET-derived outcome measure, the Oculomotor Index of Gaze to Human Faces (OMI).<sup>4</sup>

**Methods:** Data were acquired from the Autism Biomarkers Consortium for Clinical Trials. The sample included 280 participants (M=215, F=65) aged 6-11 years with ASD. ET data was collected at three timepoints (T1: baseline, T2: 6 weeks, T3: 6 months). OMI was calculated per timepoint by averaging percent of valid looking at faces during Activity Monitoring, Social Interaction and Static Social Scenes ET paradigms.<sup>4</sup> Change in OMI from T1 to T3 ( $\Delta$ OMI) was calculated controlling for effects of T1 OMI, age, and IQ. Intervention data were collected per timepoint through caregiver interview and total hours of intervention between T3 and T1 minus six weeks were estimated. Interventions that were used by at least 5% of the sample were included in analyses (12 specific and 3 aggregate interventions). Intervention hours were transformed by  $\log(x+1)$  before being passed through Lasso variable selection for predicting  $\Delta$ OMI. Linear regression modeled lasso selected variables as predictors of  $\Delta$ OMI.

**Results:** Lasso retained 4 intervention variables: cognitive behavioral therapy, parent training, supportive therapy, and the aggregate of evidence-based practice (EBP) interventions. Entering these into a linear regression identified EBP (standardized  $\beta = .146$ ,  $p=.022$ ) and supportive therapy ( $\beta = .125$ ,  $p=.045$ ) as significant but weak predictors of  $\Delta$ OMI. The overall fit of the model was relatively weak ( $R=.204$ ) (Table 1).

**Conclusions:** The results of this analysis suggest that interventions qualifying as evidence-based practices<sup>5</sup> and supportive therapy may be associated with changes in OMI over time, even when controlling for IQ, age, and OMI at baseline. However, as a data-driven machine learning approach, this work requires additional validation and verification. Looking at the composition of the EBP intervention aggregate (Table 2), the more frequently-used interventions, targeting social skills specifically, might logically associate with increased attention to faces. Future analyses could investigate each component to further define the effect of EBP outlined by the regression model. Targeting efforts to contextualize the supportive therapy variable might also broaden our interpretation of this model. The heterogeneity of ASD elicits a wide array of individual challenges; better understanding the nature of supplemental therapies that impact face looking may provide insight into general treatment factors impacting social attention.

**406.157 (Poster)** Cluster Analysis of Social Competence Profiles of Autistic Children, Using the Parent Report Version of the Multidimensional Social Competence Scale (MSCS)

**V. Mount<sup>1</sup> and G. Iarocci<sup>2</sup>,** (1)Psychology Department, Simon Fraser University, Burnaby, BC, Canada, (2)Psychology, Simon Fraser University, Burnaby, BC, Canada

**Background:** There is marked variability in the presentation of core diagnostic features across autistic individuals, which poses a significant obstacle for research design and interpretability, as well as for understanding clinical outcomes. Subtyping methods such as Cluster Analysis (CA) can be used to divide large autistic populations into smaller, more homogeneous subgroups according to their scores on select variables. Social Competence (SC; an individual's ability to effectively integrate and adapt social skills to fit a given social context) is a promising variable for identifying autistic subtypes within the domain of social impairment.

**Objectives:** To extract dimensionally-homogenous SC-based subgroups from a sample of autistic youth.

**Methods:** Participants were 91 autistic youth (16 females) aged 6-14 (mean = 9.78, SD = 1.85) with a minimum IQ of 71 points, from the lower mainland region of British Columbia. Within this sample, 44.00% self-identified as Asian, 38.50% as "Canadian", 3.30% as European, 2.20% as African American, and 11.00% self-identified as "Multicultural".

Two K-means Cluster Analyses (CA) were conducted on the participant's Multidimensional Social Competence Scale (MSCS) profiles, requesting three- and four-cluster solutions. One-way Analysis of Variance (ANOVA) procedures were then conducted to determine the variance in each MSCS domain that was accounted for by individual clusters, and to determine if clusters differed significantly from one another with respect to each MSCS variable. Clusters were interpreted by examining the average MSCS domain scores for each cluster.

In order to assess cluster differences beyond the variability that was observed in MSCS profiles, additional one-way ANOVAs were conducted for both CA solutions, with Social Responsiveness Scale, 2<sup>nd</sup> Edition (SRS-2) scores, IQ and age as the respective dependent variables. Chi-square analyses were also conducted for each CA solution, with gender as the dependent variable. Variability in SRS-2 scores was examined to determine if the clusters differed significantly on an alternative measure of social functioning. IQ, age, and gender were examined across clusters to inquire into the influence of these variables on distinguishing SC profile clusters.

**Results:** For both K-means CAs, all 7 MSCS domains contributed meaningfully to cluster determinations. The 3-cluster solution resulted in an overall high-scoring cluster, a moderate-scoring cluster with the lowest levels of social motivation, and a low-scoring cluster with the lowest verbal conversation skills and emotional regulation scores. The 4-cluster solution resulted in two higher-scoring clusters that differed from each-other on the verbal conversation skills, nonverbal sending skills, and emotional regulation skills domains, and two lower-scoring clusters, that differed from each-other on the verbal conversation skills and emotion regulation domains. In follow-up analyses, SRS-2 scales varied significantly across the 3- and 4-cluster solutions, whereas age and IQ scores did not vary significantly across clusters, and no significant association was found between gender and cluster membership.

**Conclusions:** Results show that heterogeneous autistic populations can be divided into more homogeneous subgroups based on similarities in social competence profiles. The continued conceptualization of more homogeneous autistic subgroups may advance the development of individualized interventions, and further our understanding of between-group differences within autism.

**406.158 (Poster)** Evaluating Effects of Caregiver Anxiety and Emotion Regulation on Child Emotional Functioning in Autism Spectrum Disorder  
*N. Cristallo<sup>1</sup>, A. Constantine<sup>2</sup>, S. H. Kim<sup>1</sup> and D. Swain<sup>3</sup>, (1)Psychiatry, Center for Autism and the Developing Brain, White Plains, NY, (2)Weill Cornell Medicine, White Plains, NY, (3)Virginia Polytechnic Institute and State University, Blacksburg, VA*

---

**Background:** Children with ASD present increased difficulty in emotion regulation (ER), the ability to evaluate and react to emotional stimuli, which can lead to negative social and academic outcomes (Mazefsky et al., 2013). Parents play a critical role in the development of child ER. In neurotypical populations, parent factors, such as ER strategies and anxiety, have been shown to impact parenting behaviors and ER development in children (Bariola et al., 2011). However, limited research exists in the field of ASD examining the influence of parent factors on early child development of ER.

**Objectives:**

1. Evaluate the effects of parent anxiety and ER on ER in toddlers with ASD.
2. Explore changes in parent anxiety and ER as well as child ER over a 6-month period of time.
3. Examine influence of baseline parent factors on changes in child ER.

**Methods:** Participants included 42 toddlers with ASD ( $M_{age}=30.81$  months,  $SD_{age}=8.81$ ) and their caregivers ( $M_{age}=38.98$  years  $SD=6.24$ ). Parents completed self-report measures of ER (cognitive reappraisal and expressive suppression from Emotion Regulation Questionnaire) and anxiety (Beck Anxiety Inventory) and parent report measures of child executive function abilities related to ER (Shift, Inhibition, Emotional Control subscales from the BRIEF-Preschool Version). A subset of families ( $n=13$ ) completed all measures 6-months later. Three regressions predicting child ER were run with three parent predictor variables: parent anxiety, cognitive reappraisal and suppression. There were no significant correlations between child non-verbal IQ/age and any child ER outcome measure and thus, these child factors were not included as covariates in the regressions. Paired-sample t-tests were run to examine changes in parent and child ER over 6-months. Finally, correlations between baseline parent ER and anxiety and child change scores were examined.

**Results:** When predicting child inhibitory control, parent anxiety ( $\beta=.38, p=.02$ ) and cognitive reappraisal ( $\beta=-.34, p=.024$ ) were significant predictors, such that higher parent anxiety and lower use of cognitive reappraisal were associated with increased difficulties in child inhibitory control. Parent anxiety was a significant predictor for child emotional control ( $\beta=.39, p=.01$ ), such that higher parent anxiety corresponded with higher child emotional difficulties. For the subset of families with two timepoints, no significant changes were noted in regard to parent or child factors. Higher use of emotion suppression at baseline was significantly correlated with increases in child inhibitory challenges over time ( $r^2=.56, p=.038$ ).

**Conclusions:** In the current study, parent anxiety and use of adaptive ER strategies played a key role in their child's ability to modulate emotions, behavior, and responses. Thus, incorporating parent factors when studying child ER development in ASD is important. Exploratory analyses revealed high stability in parent and child ER over a 6-month period of early childhood although this was based on a smaller sample. Additionally, findings within a subset showed that parent maladaptive ER use could influence child ER development. Results should be replicated with larger, more diverse samples to further explore the impact of additional parent and child factors, such as depression and stress on child ER strategies.

**406.159 (Poster)** Investigating Sex Differences in Friendship Quality and Loneliness in Autistic and Neurotypical Children  
*N. Libster<sup>1</sup>, A. Knox<sup>2</sup>, C. Lord<sup>3</sup>, D. Geschwind<sup>1</sup>, J. Parish-Morris<sup>2</sup> and C. Kasari<sup>1</sup>, (1)University of California, Los Angeles, Los Angeles, CA, (2)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (3)UCLA Semel Institute for Neuroscience and Human Behavior, Los Angeles, CA*

---

**Background:** Compared to neurotypical children, autistic children are less accepted by their peers and have fewer reciprocal friendships (Chamberlain et al., 2007). However, autistic boys report qualitatively different friendships than autistic girls, who have been reported to have similar friendship quality to neurotypical girls and boys (Head et al., 2014; Sedgewick et al., 2019). Autistic boys are also less likely than neurotypical boys to define friendship in terms of companionship, affection, and intimacy (Bauminger & Kasari, 2000). Autistic boys report higher degrees of loneliness than neurotypical boys (Bauminger & Kasari, 2000) – but few if any studies have examined sex differences in loneliness among autistic children.

**Objectives:** Examine differences in self-reported friendship quality and loneliness in autistic boys and girls compared to neurotypical boys and girls.

**Methods:** The current mixed-methods study was a secondary analysis of transcribed clinical evaluations from 58 autistic children (29 girls) matched to 42 neurotypical children (21 girls) on age ( $M=10.19$ , range: 6-15y) and IQ ( $M=105.07$ ). As part of the ADOS-2 (Module 3; Lord et al., 2012), children were asked to describe their relationships with friends, define what a friend is, and answer the question “Do you ever feel lonely?”. Logistic regression analyses examined whether definitions of friendship and perceived loneliness differed by diagnosis and sex. Thematic analyses were conducted to identify themes related to friendship quality and loneliness.

**Results:** Autistic boys and girls were as likely as neurotypical boys and girls to define friendship in terms of character, companionship, and dependability. The odds of incorporating character increased by 2.37 for girls compared to boys ( $p=.04$ ), but there were no sex differences for companionship and dependability. Only 7% of children (mostly neurotypical girls) incorporated intimacy in their definitions. Meanwhile, 8% of autistic children and 2% of neurotypical children (girls and boys) were unclear when asked if they had friends. Furthermore, 12% of autistic children (girls and boys) reported having friends but did not play or spend time with them, and 3% of autistic children (girls) reported being bullied by their friends. Autistic boys and girls were also as likely as neurotypical boys and girls to feel lonely at times. However, 17% of autistic children (girls and boys) reported that they were often lonely because they had few friends.

**Conclusions:** This study revealed that autistic boys and girls provided similar definitions of friendship compared to neurotypical boys and girls. However, a thematic analysis revealed that autistic children had qualitatively different friendships than their neurotypical peers. Autistic boys and girls were as likely as neurotypical boys and girls to feel lonely at times, but it is important to note that the loneliness measure on the ADOS does not address degree of loneliness – rather, participants are asked if they ever feel lonely. A thematic analysis revealed that autistic boys and girls experienced greater loneliness compared to their neurotypical peers. Qualitative methods therefore suggest that the friendship and loneliness experiences of autistic children differ from those of neurotypical children but may not differ greatly by sex.

#### **406.160 (Poster) Sex Differences in Peer Conflict in Autistic and Neurotypical Children**

**N. Libster<sup>1</sup>, A. Knox<sup>2</sup>, C. Lord<sup>3</sup>, D. Geschwind<sup>1</sup>, J. Parish-Morris<sup>2</sup> and C. Kasari<sup>1</sup>,** (1)University of California, Los Angeles, Los Angeles, CA, (2)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (3)UCLA Semel Institute for Neuroscience and Human Behavior, Los Angeles, CA

**Background:** Autistic adolescents experience higher rates of peer conflict, specifically overt conflict, than neurotypical adolescents. While adolescent boys – both autistic and neurotypical – report more overt conflict than girls, autistic girls report higher rates of overall peer conflict and relational conflict than autistic boys and neurotypical girls and boys (Sedgewick et al., 2019). Meanwhile, few if any studies have examined sex differences in peer conflict among school-aged autistic children. School-aged autistic boys experience higher rates of peer conflict than neurotypical boys (Maiano et al., 2016), but it is unclear whether school-aged autistic girls also experience more conflict with their peers. Autistic boys tend to be isolated or rejected by their peers, while school-aged autistic girls tend to be overlooked or ignored (Dean et al., 2017). Although autistic girls are more motivated than autistic boys to interact with peers, putting them at higher risk for peer conflict, school-aged autistic girls may have difficulty recognizing subtle forms of aggression.

**Objectives:** Examine differences in self-reported peer conflict in autistic boys and girls compared to neurotypical boys and girls.

**Methods:** The current mixed-methods study was a secondary analysis of transcribed clinical evaluations from 58 autistic children (29 girls) matched to 42 neurotypical children (21 girls) on age ( $M=10.19$ , range: 6-15y) and IQ ( $M=105.07$ ). As part of the ADOS-2 (Module 3; Lord et al., 2012), children were asked if they ever had problems getting along with peers at school and if they had ever been teased or bullied. Transcripts were coded for problems with peers and bullying victimization, and logistic regression tested whether reported problems differed by sex and/or diagnosis. Thematic analyses were conducted to identify themes related to personal experiences of victimization.

**Results:** Autistic boys and girls were as likely as neurotypical boys and girls to experience problems with peers. However, the odds of having been bullied increased by 4.87 for autistic children compared to neurotypical children ( $p=.002$ ). There were no sex differences in bullying victimization among autistic and neurotypical children. Thematic analyses revealed that autistic children were more likely than neurotypical children to experience verbal and physical aggression but were as likely to experience relational aggression. Among autistic children, causes of peer conflict included trouble with interaction (boys), difficulty with flexibility (girls), and peers initiating conflict (girls). Both autistic and neurotypical boys and girls further attributed peer conflict to their personalities or to being “different.”

**Conclusions:** Autistic boys and girls were as likely to report experiencing problems with peers as neurotypical boys and girls. However, autistic children were more likely to have been overtly bullied compared to neurotypical children. A possible explanation for this discrepancy is that autistic children have difficulty perceiving subtle problems with peers, which can be less perceptible than being bullied. Similarly, they may have greater difficulty perceiving relational conflict compared to overt conflict, such as verbal and physical aggression. While there were no sex differences in the types of aggression experienced by autistic boys and girls, boys and girls reported different underlying causes of peer conflict.

#### **406.161 (Poster) Effects of Creative Movement Interventions on Praxis, Imitation, and Interpersonal Synchrony Skills in Children with ASD**

**K. Lombardi<sup>1</sup>, W. C. Su<sup>2</sup>, C. Cleffi<sup>3</sup>, J. Dolan<sup>1</sup>, S. Williams<sup>1</sup>, N. Amonkar<sup>4</sup>, S. Srinivasan<sup>5</sup> and A. N. Bhat<sup>6</sup>,** (1)University of Delaware, Newark, DE, (2)Physical Therapy, University of Delaware, Newark, DE, (3)Physical therapy, University of Delaware, Newark, DE, (4)University of Connecticut, Storrs, CT, (5)Kinesiology, University of Connecticut, Storrs, CT, (6)Department of Physical Therapy, University of Delaware, Newark, DE

**Background:** Children with Autism Spectrum Disorder (ASD) have primary impairments in social communication skills and comorbid deficits in imitation and interpersonal synchrony (IPS). In the past, our research group reported greater improvements in imitation and IPS performance in children with ASD after receiving rhythmic and yoga-based interventions compared to a fine motor-based (FM), standard of care intervention.

**Objectives:** In the current study, we combined music, dance, and yoga activities to develop a Creative Movement (CM) intervention and compare its effects to that of an FM intervention.

**Methods:** Thirty children with ASD between 5 and 14 years were recruited and randomly assigned to the CM or FM groups. Both groups received 16 training sessions (2 sessions/week), over 8 weeks. The CM group engaged in whole-body movements using music, dance, and yoga to promote IPS, imitation, coordination, and balance; whereas the FM group engaged in tabletop activities such as reading, building, and art-craft to promote social interactions and fine-motor skills. Two tests were administered before and after the intervention: a) The postural praxis and bilateral motor coordination subtests of Sensory Integration and Praxis Tests (SIPT-PP and SIPT-BMC)4 and b) IPS performance during drumming actions. We also assessed their task-specific performance during the yoga task and the amount of time in sync/out of sync with the trainer/caregiver during an early and a late training session.

**Results:** Our preliminary data from 21 children with ASD (13 in CM and 8 in FM) suggests positive findings that differ between the CM and FM groups. The CM group showed reduced SIPT-PP directness errors (Mean $\pm$ SE Error #): Pre = 10.58 $\pm$ 0.75, Post = 7.18 $\pm$ 4.09;  $p < 0.01$ ) and SIPT-BMC temporal errors after intervention (# of errors, Pre = 11.92 $\pm$ 3.44, Post = 6.31 $\pm$ 1.65;  $p < 0.05$ ); while the FM group only showed reduced SIPT-BMC temporal errors, post-intervention (# of errors, Pre = 11.25 $\pm$ 1.92, Post = 3.13 $\pm$ 1.17;  $p < 0.05$ ). In terms of task-specific tests, there was a trend for increased imitation accuracy during yoga poses (# of error, Pre = 13.15 $\pm$ 1.68, Post = 10.85 $\pm$ 1.55;  $p = 0.07$ ), and less time spent out of synchrony with the trainer/caregiver during the late compared to the early training session (mean duration in minutes (mean $\pm$ SE): Early session = 28.17 $\pm$ 7.35; Late session: 21.10 $\pm$ 5.40,  $p = 0.09$ ).

**Conclusions:** The CM intervention developed in this study has positive effects on imitation and IPS, therefore, could be used to promote synchrony/imitation skills in children with ASD which may increase social connections with peers and caregivers.

**406.162 (Poster)** "Social Pain Is Feeling Unwanted, When Nobody Wants You Around": Perceptions of Social Pain Among Adults with Autism. **M. Levi<sup>1</sup>, N. Schreuer<sup>2</sup>, Y. Granovsky<sup>3</sup>, I. Weissman-Fogel<sup>4</sup>, T. Bar-Shalita<sup>5</sup>, T. Hoffman<sup>4</sup> and E. Gal<sup>6</sup>,** (1)Occupational therapy, University of Haifa, Haifa, Israel, (2)Occupational Therapy, University of Haifa, Haifa, Israel, (3)Department of Neurology, Rambam Health Care Campus and the Laboratory of Clinical Neurophysiology, Faculty of Medicine, Technion, Haifa Israel, Haifa, Israel, (4)University of Haifa, Haifa, Israel, (5)Occupational Therapy, Tel Aviv University, Tel Aviv, Israel, (6)Department of Occupational Therapy, University of Haifa, Haifa, Israel

**Background:** The DSM-5 definition of Autism includes the existence of deficits in social interaction as a core feature. One manifestation of this diagnostic criterion is the absence of interest in peers. Another Autism diagnostic criterion is repetitive and restricted behaviors and interests, including abnormal reactions to sensory input, such as indifference to physical pain.

While physical pain has been widely investigated, research addressing emotional pain, particularly social pain in Autism, is scarce. However, there is a growing body of literature concerning social pain, its neural mechanism, and its behavioral expression. It is often assumed that autistic people do not experience social pain. It has long been questioned whether, and how they experience social pain and the answer to this question is still vague. Research in neurotypical population examines social pain, as it manifests in various emotions, while in autistic people, research is limited and focuses mainly on aspects of empathy. Such research suggests that while autistic people can empathize with another's physical pain, they have significant deficits in sharing representations of emotions. There is currently no research that relates to all aspects of the term "social pain" among autistic people.

Insight into the inner world of autistic people regarding social pain may promote a better understanding of their experience, which in turn may facilitate better integration into society and an enhanced quality of life.

**Objectives:** This study aims to shed light on how autistic people experience and perceive social pain and will explore the implications of social pain on their lives.

**Methods:** Using a phenomenological approach, 15 autistic adults participated in face-to-face in-depth interviews. The audio-taped interviews were transcribed verbatim and analyzed using thematic analysis to develop themes inductively.

**Results:** Three themes emerged relating to the experience of social pain: (1) Communication challenges as the source of social pain, i.e., difficulties in understanding others, difficulties in expressing oneself, and a sense of rejection by others; (2) The experience of social pain throughout the lifespan (anguish of social rejection, and sense of loneliness/ isolation) and (3) Responses and coping strategies with social pain.

**Conclusions:** While previous studies suggest that autistic people do not face social pain, the current results, based on first-hand accounts, demonstrate that, in fact, social pain is a significant challenge in their lives, markedly affecting participation and wellbeing. Interviews echo that the sense of isolation and feelings of solitude experienced by the participants are not based on their free choice but rather a byproduct of difficulties with social interaction and rejection by others. Moreover, interviews revealed examples of strategies autistic people use to cope with the social obstacles they face.

The results highlight the crucial need to listen to the point of view of autistic people, especially when it comes to subjective experiences such as pain. They also clarified the need to develop and improve intervention programs, which would assist them in dealing with their social pain.

**406.163 (Poster)** Social Engagement in Children with ASD in Inclusive Urban Classrooms

**Background:** There has been an increase of students with special needs that are served under the Individuals with Disabilities Education Act (2004) who are enrolled in general education (Hussar et al., 2020). This shift in inclusion for students with disabilities, including students with autism spectrum disorders (ASD), provides more opportunities for students with ASD to be educated with their typically-developing (TD) peers and increases the opportunities for social interaction. However, it is unclear whether the shift in more inclusionary practices in schools has impacted social engagement between students with ASD and their peers over time.

**Objectives:** This study is a secondary cross-sectional data analysis of three cohorts of elementary students with ASD who were fully included in urban schools. The study examined baseline data of social engagement between students with ASD and their peers.

**Methods:**

The study included 141 participants from three cohorts of students with ASD (2003-2007; 2008-2011; 2011-2014) from the Greater Los Angeles area. Participants were elementary students with ASD (ages 5-12) who were fully included in general education. Across cohorts of students, students' IQ ranged from 87 to 102. Students from ethnic minority backgrounds ranged from 53% to 85% across cohorts.

The Autism Diagnostic Observation Schedule (ADOS; Lord, et al., 2001) is a semi-structured, standardized assessment designed to assess the clinical presentation of ASD or other pervasive developmental disorders.

Playground Observation of Peer Engagement (POPE; Kasari et al., 2005) is a 15-minute observation of children's social engagement with peers during recess or lunchtime. Data was collected in one-minute intervals for 15 minutes. Each minute, independent blind observers coded for engagement states (e.g., solitary, proximity, onlooking, parallel, parallel aware, joint engagement, and games). Reliability was estimated with Kappa statistic and averaged .91.

**Results:** ANCOVAs were conducted to examine how engaged the children were on the playground. Generally, engagement was less than 50% of time observed. There were no differences among the cohorts in the percentage of time children spent isolated (33.66%, 28.11%, 29.24%), ( $F(2, 124) = 0.484, p = 0.617$ ) or engaged (40.92%, 43.09%, 52.56%) with their peers,  $F(2, 124) = 1.803, p = 0.169$ .

**Conclusions:** The study demonstrated that over the three cohorts of students spanning a decade, there were no significant differences in children's joint engagement with their peers in school. However, the data did show a positive trend of improvement in joint engagement from the first cohort (2003-2007) to the third cohort (2007-2014) of students. There was a 10% increase in time spent in joint engagement. Although this increase is not statistically significant, it is promising that there was a positive trend in joint engagement between students with ASD and their peers, perhaps with the increase of inclusionary practices. Future studies should examine the inclusionary practices implemented in schools and whether they impact joint engagement in students with ASD and their peers.

#### **406.164 (Poster) The Impact of Stress in Experimental Measures of Gaze Perception in Adults with ASD**

**A. Saitovitch<sup>1</sup>, A. Vinçon-Leite<sup>2</sup>, L. Fillon<sup>3</sup>, J. Boisgontier<sup>4</sup>, A. Philippe<sup>4</sup>, H. Lemaitre<sup>3</sup>, N. Boddaert<sup>3</sup> and M. Zilbovicius<sup>3</sup>, (1)INSERM, Paris, France, (2)INSERM U1000, Paris, France, (3)Institut Imagine / INSERM U1299, Paris, France, (4)Institut Imagine / UMR 1163, Paris, France**

---

**Background:**

In a previous research project, we investigated the effect of repetitive transcranial magnetic stimulation (rTMS) on social perception in typically developing individuals and in individuals with autism spectrum disorders (ASD). We used eye-tracking to measure looking behavior to the eyes during visualization of social movies at 3 time points after both active TMS and sham stimulation applied to the superior temporal sulcus. In healthy volunteers, results showed a significant decrease in the number of fixations to the eyes of characters after active inhibitory TMS (cTBS), but not after sham condition (Saitovitch et al. 2016). In the ASD group, we observed no significant effects of active excitatory TMS (iTBS). Strikingly, we observed a great variation of gaze pattern after sham condition, contrary to results from typically developing individuals (Figure 1).

**Objectives:**

In this study we aimed to better understand the impact of experimental conditions on gaze perception in individuals with ASD. For that purpose, we measured gaze pattern to the eyes during successive visualizations of the same stimuli set as the TMS protocol, but without any intervention.

**Methods:**

Seven male adults with ASD (mean age =  $27.2 \pm 2.9$ ), who have participated in the previous TMS study, were included in this study. All participants watched the same stimuli set, displaying scenes with characters engaged in social interactions, seven successive times. Eye-tracking data was processed with Tobii-Studio® software and number of fixations to the eyes were calculated for each visualization and for each participant. We used a linear regression analysis with repeated measures to investigate whether the number of fixations to the eyes would be impacted by the consecutive visualizations.

## Results:

We observed no statistically significant variations on the number of fixations to the eyes over the successive visualizations ( $F_{1,6} = 0.09$ ;  $p = 0.76$ ), indicating within-subject stability in gaze pattern across time in individuals with ASD.

## Conclusions:

Contrary to the behavior they presented in the previous TMS study, participants showed a great stability of gaze pattern to the eyes (Figure 2). These results suggest that, without any intervention, gaze behavior towards socially relevant stimuli is stable over time in individuals with ASD, as was previously described in typically developing individuals (Saitovitch et al., 2019). This strongly suggest that stress brought up in the experimental conditions of research protocols, even if they are minimum, can have a major impact on the data. Therefore, this should be acknowledged and taken into account when designing and interpreting results from research, particularly in protocols that inherently present a stressful environment, such as fMRI or TMS protocols.

## VIRTUAL POSTER SESSION — SOCIAL COGNITION AND SOCIAL BEHAVIOR

### 506 - Social Cognition and Social Behavior --- (V)

**506.072** (*Virtual Poster*) Alexithymia, Emotional Intelligence and Adjustment to College in Students with and without Autistic Traits  
*D. Davidson<sup>1</sup> and D. Morales<sup>2</sup>, (1)Psychology, Loyola University Chicago, Chicago, IL, (2)Loyola University Chicago, Chicago, IL*

## Background:

Alexithymia is a personality construct characterized by difficulties in describing emotions in oneself and in others (Bagby et al., 1994). Alexithymia may be inversely related to emotional intelligence (EI), or the clusters of traits that comprise emotion knowledge. In fact, alexithymia may underlie difficulties with socio-emotional functioning in autism spectrum disorder (ASD; Bird & Cook, 2013), although existing research is limited.

## Objectives:

Research questions were: (1) Do adults with autistic traits present higher levels of alexithymia and lower levels of EI than neurotypical adults? (2) Does alexithymia or autistic traits better predict EI? and (3) What predictive roles do alexithymia, autism symptomatology and EI play in adjustment to college?

## Methods:

Following IRB approval, 144 college students participated. Students with autistic traits ( $n = 57$ ;  $M_{age} = 19;10$ , range 18;04 – 25;02) and without autistic traits ( $n = 87$ ;  $M_{age} = 19;08$ , range 18;10 – 22;07) were determined using T-scores from the Social Responsiveness Scale (SRS-2). The SRS-2 is a robust instrument for detecting the presence and severity of social impairment and restrictive/repetitive behaviors associated with autism (Constantino & Gruber, 2012). As shown in Table 1, students did not differ on gender (72% female), race (65% Caucasian), year in school (first, second), or GPA ( $M = 3.3$ ). Measures included the Toronto Alexithymia Scale (TAS-20; Bagby et al., 1994), the Trait Emotional Intelligence Test (TEI-SF; Petrides, 2009), and the Student Adaptation to College Questionnaire (SACQ; Baker & Stryk, 2017). The SACQ was used to assess academic adjustment (beliefs about adequacy of academic efforts), social adjustment (successful social integration), and personal-emotional adjustment (psychological and physical well-being).

## Results:

**Research Question 1:** Students with autistic traits displayed significantly higher levels of alexithymia ( $M = 58.0$ ;  $SD = 8.61$ ) than those without autistic traits ( $M = 40.74$ ;  $SD = 9.73$ ),  $t(142) = -11.03$ ,  $p < .001$ . They also scored lower on EI,  $t(142) = 8.46$ ,  $p < .001$ . **Research Question 2:** With alexithymia and autistic traits as predictors of EI, the overall model and both predictors were significant (see Table 2). **Research Question 3:** With alexithymia, autistic traits and EI as predictors, the overall models were significant for social and personal-emotional adjustment (Table 2). However, only EI was a significant predictor in these models (Table 2). The overall model was not significant for academic adjustment,  $F(3, 134) = 0.25$ ,  $p = .863$ .

## Conclusions:

College students with autistic traits showed greater alexithymia and lower EI than those without autistic traits. However, *both* alexithymia and autistic traits were significant predictors of EI. Additionally, alexithymia and autistic traits were not significant predictors of social or personal-emotional adjustment in college beyond the significant, predictive role of EI. These findings suggest that the cluster of traits comprising emotion understanding (EI) may be particularly important for successful socio-emotional functioning and adjustment in college. Wider implications of these findings include the need to understand how these co-occurring aspects of emotion processing in ASD affect socio-emotional functioning.

**506.073 (Virtual Poster)** Amount and Timing of Attention to the Eyes Are Differentially Associated with White Matter Maturation

A. L. Ford<sup>1</sup>, X. Dai<sup>2</sup>, L. Li<sup>3</sup>, Z. M. Ammar<sup>4</sup>, W. Jones<sup>4</sup>, A. Klin<sup>4</sup> and S. Shultz<sup>1</sup>, (1)Neuroscience Program, Emory University, Atlanta, GA, (2)Iowa State University, Ames, IA, (3)Marcus Autism Center, Children's Healthcare of Atlanta, Emory University, Atlanta, GA, (4)Marcus Autism Center, Children's Healthcare of Atlanta and Emory University School of Medicine, Atlanta, GA

---

**Background:** Attention to eyes—a critical skill that guides typical socialization—is already in decline by the second month of life in infants later diagnosed with Autism Spectrum Disorder (ASD). In contrast, typically developing (TD) children *increase* their attention to eyes throughout infancy and specialize their attention patterns *to look to social stimuli at the right time (i.e., relative salience)*, establishing a foundation for continued social visual engagement and brain specialization. The neural systems associated with these basic mechanisms of social adaptive action are currently unknown, even in typical development. Identifying associations between trajectories of social visual engagement and trajectories of brain maturation in typical infancy is an important step towards understanding how deviations from these trajectories may contribute to the emergence of social disability in ASD.

**Objectives:** To identify associations between trajectories of white matter microstructure and trajectories of eye-looking and relative salience from 0-6 months in TD infants.

**Methods:** Diffusion MRI and eye-tracking data were collected prospectively and longitudinally in the same infants ( $n=71$ , 29 female) at 3 and 6 pseudorandom time points, respectively, between birth and 6 months. All participants were full-term, healthy infants with no family history of ASD or developmental delay and no known medical or genetic conditions. Atlas-based tractography was used to delineate 11 major white matter (WM) tracts including the pyramidal tract (PT) and corpus callosum splenium (CCs). Fractional anisotropy (FA) values were generated for each tract to index maturation. Eye-tracking data were collected while infants viewed scenes of actress caregivers engaging in naturalistic interaction and percentage of time spent fixating on the eyes was calculated. Relative salience values were computed to measure how similarly infants watched these scenes relative to an age-matched reference sample. Growth curves were fit using functional principal component analysis and Functional Linear Regression tested associations between longitudinal trajectories.

**Results:** Functional linear regression revealed a robust association ( $R^2 = .06, p < .02$ ) between growth curves of FA in the PT and total amount of eye-looking, such that higher FA in the PT contributes to greater eye-looking from 80-120 days (Fig. 1). Parametric multivariate analyses between features of variance from trajectories of FA in the CCs and relative salience reveal higher FA in the CCs is associated with greater relative salience values ( $R^2 = .06, p < .04$ ), meaning infants who learn to attend to social stimuli at the right time faster than other infants also have a more mature CCs (Fig. 2). No other relationships were observed between measures and WM tracts.

**Conclusions:** This study demonstrates critical associations between trajectories of WM microstructure and social visual engagement in the first months of life. Eye-looking and relative salience are associated with the maturation of the PT and CCs, tracts involved in sensorimotor development and efficient goal-direct orienting, respectively. These findings suggest that developing sensorimotor and visual networks may be particularly responsive to experiential input involving the eyes of social partners and suggest a process by which early divergence from normative experience may lead to and/or result from atypical patterns of white matter development in ASD.

**506.074 (Virtual Poster)** Are Developmental Trajectories from Toddlerhood to Adolescence in ASD Related to Social Relationship Competence?

R. Saban-Bezalet<sup>1</sup>, E. Ben-Itzhak<sup>2</sup> and D. A. Zachor<sup>3</sup>, (1)Communication disorders, Ariel university, Ariel, Israel, (2)Bruckner Center for Research in Autism, Communication Disorder, Ariel University, Ariel, Israel, (3)The Autism Center/ALUT, Pediatrics, Tel Aviv University / Shamir (Assaf Harofeh) Medical Center, Zerifin, Israel

---

**Background:** The ability to establish social relationships evolves early in life and becomes increasingly important with age, especially during early adolescence. Evidence shows that social relationships impact children's development, well-being, and adaptive development in adulthood. Considering the known social difficulties of children and adolescents with autism spectrum disorder (ASD), they may be particularly at risk for experiencing challenges in establishing crucial social relationships. However, to date, there is a paucity in follow-up studies assessing the relationship between developmental trajectories and outcomes in social relationships among those with ASD.

**Objectives:** The current study examines the relationship between developmental trajectories, including cognitive ability, autism severity, and adaptive skills, and social relationship competence of adolescents with ASD.

**Methods:** Our follow-up study included 43 adolescents (5 females) with a mean age of 13:06 years ( $SD = 2:0$ ) who were diagnosed with ASD during toddlerhood. Participants underwent comprehensive assessment of cognitive ability, adaptive skills [Vineland Adaptive Behavior Scales-VABS], and autism severity [Autism Diagnostic Observation Scales (ADOS (calibrated severity score (CSS))] during toddlerhood (T1) and adolescence (T2). We generated a social relationship competence construct score based on three variables: 1. adolescent self-report and identification of friendship(s), 2. parental report regarding whether their child has a friend, and 3. adolescent social insight (based on ADOS Module 3 "Insight into Typical Social Situation and Relationships" item). Participants with a self-declared friend, whose parents report them having a friend, and who evidence insight into social relationships including their own role, were included in the higher social relationship competence (HSRC,  $n = 19$ ) group. Participants who did not fulfil all these criteria were included in the lower social relationship competence (LSRC,  $n = 25$ ) group.

**Results:** To examine change in cognitive ability, ASD symptom severity, and adaptive behavior skills from T1 to T2, a series of 2X2 (2 groups X 2 times) ANOVAs with repeated measures were performed.

For the ADOS social affect CSS, a significant Time X Group interaction was noted. Only the LSRC group showed an increase from T1 ( $M = 6.59$ ,  $SD = 2.30$ ) to T2 ( $M = 8.08$ ,  $SD = 2.23$ ) ( $p < .05$ ) in symptom severity. For VABS subdomains, a significant Time X Group interaction was found. Examining each subdomain separately, Time X Group interactions were significant for VABS socialization and daily living skills subdomains. In both measures, the HSRC group showed an increase from T1 ( $M = 71.70$ ,  $SD = 7.53$ ;  $M = 69.05$ ,  $SD = 5.71$ , respectively) to T2 ( $M = 93.18$ ,  $SD = 14.28$ ;  $M = 91.18$ ,  $SD = 14.81$ , respectively). No significant Time effect or Time X Group interaction was found for IQ, ADOS Restricted and Repetitive Behaviors CSS, and VABS communication scores.

**Conclusions:** This long-term follow-up study's findings suggest that a portion of toddlers diagnosed with ASD can develop social relationships during adolescence. Better trajectories over the years for social-communication autism severity, and social and daily living adaptive skills are important for achieving better outcomes in social relationships and should be the focus of interventions.

**506.075 (Virtual Poster)** Assessing Contribution of Pragmatic Impairments and Executive Dysfunction to Theory of Mind Deficits in School-Aged Children with High-Functioning Autism

Z. Y. Wu<sup>1</sup> and F. M. Tsao<sup>2</sup>, (1)National Taiwan University, Taipei, Taiwan, (2)Psychology, National Taiwan University, Taipei, Taiwan

---

**Background:**

Impairments in theory of mind (ToM) and executive function (EF) explained core behavioral symptoms of autism. Impairment of EF subcomponents, e.g., cognitive flexibility, inhibition and planning, accounts for ToM deficits in autism (Demetriou et al., 2019). Individuals with high-functioning autism (HFA) also impaired in pragmatic skills, from recognizing emotions of words (i.e., emotional prosody perception) to narratives. Advanced ToM tasks were categorized with two factors, social reasoning (e.g., eyes task) and transgression recognition (e.g., faux pas task) (Osterhaus et al., 2016). Few studies investigated relative contribution of EF and pragmatic skills to factors of advanced ToM in school-aged children with HFA.

**Objectives:**

To investigate whether subcomponents of EF and pragmatic skills would account for higher-order ToM deficits in HFA children.

**Methods:**

*Participants.* HFA ( $n=73$ , mean age=10.11 years) and TD ( $n=65$ , mean age=10.03 years) in Taiwan. Inclusion criteria of HFA: CAST (Childhood Autism Spectrum Test) score  $\geq 15$  and FSIQ of WISC-IV  $> 85$ .

*Tasks and Measures*

*Pragmatic skills.* Children's Communication Checklist-2 (CCC-2) assessed social communication and pragmatic skills in children.

*Emotional prosody perception.* Children judged emotion of each word, varied with emotional prosody (angry, sad, happy, and neutral).

*Advanced ToM task.* (1).Reading the Mind in the Eyes Task (*Eyes task*). Children matched mental state of a person with one of four mental state words, based on only an image of their eyes. (2). *Faux Pas Task*. Children listened to a story, then determined whether they detected the faux pas in the story.

*Executive Function*

*Tower of London (TOL)* task assessed the ability of spatial planning. *Wisconsin Card Sorting Task (WCST)* assessed cognitive flexibility.

**Results:**

*HFA vs. TD group.* Compared with TD group, HFA group showed significant impairments (one-way ANOVA,  $p < .01$ ) in advanced ToM tasks, cognitive flexibility, planning, and emotional prosody perception.

*Pragmatic skills, EF and advanced ToM.* Hierarchical liner regression models were conducted for each child group (Table 1). Verbal or non-verbal IQ and age were control variables (Model 1). EF subcomponents with additional contribution on  $R^2$  were included in Model 2. CCC-2 scores were added to final model (Model 3).

*HFA group.* On social reasoning, WCST significant contributed to eye task, after controlling verbal IQ and age. Regarding to recognize transgression, stereotyped restricted language (SRL) of CCC-2 was weighted more than verbal IQ to faux pas task. Both social communication ability (SCA) of CCC-2 and WCST score predicted variances of emotional prosody perception.

*TD group.* Compared with HFA group, results (Table 1) showed that language skills predicted variances of eyes task and faux pas task. However, WCST did not account for variances in advanced ToM tasks. Spatial ability (PRI of WISC) accounted for variance of emotional prosody perception.

## Conclusions:

Among EF subcomponents, cognitive flexibility weighted more than pragmatic skills to social reasoning but not detecting social transgression in HFA group. Pragmatic skills were weighted more than cognitive flexibility to recognize transgression during social interactions in HFA group. In brief, pragmatic skill and cognitive flexibility account for different dimensions (social reasoning and transgression) of ToM impairments in HFA children.

### **506.076** (Virtual Poster) Associations of Emotion Dysregulation and Heart Rate Variability in Adolescents with and without Autism Spectrum Disorder

**H. T. Chiu<sup>1,2</sup>, F. N. Y. Ching<sup>1,2</sup>, I. Ip<sup>1,2</sup> and S. W. H. Wong<sup>1,2</sup>**, (1)Department of Educational Psychology, The Chinese University of Hong Kong, Hong Kong, Hong Kong, (2)Laboratory for Brain and Education, The Chinese University of Hong Kong, Hong Kong, Hong Kong

---

**Background:** Although not a defining feature of the disorder, emotion regulation (ER) deficits are increasingly seen as a risk factor linked to the problematic behavioral and affective problems observed in individuals with autism spectrum disorder (ASD). Heart rate variability (HRV), which refers to the variation in heart beats, is a physiological indicator of autonomic flexibility. Past studies in combined samples of children and adults with and without ASD have separately shown that HRV is associated with ASD symptomatology (Cai et al., 2019), anxiety (Guy et al., 2014), internalizing and externalizing symptoms (Neuhaus et al. 2014). Nevertheless, it remains unclear whether HRV is linked to levels of emotion dysregulation, particularly in samples of adolescents with and without ASD.

**Objectives:** To investigate whether emotion dysregulation in adolescents with and without ASD is associated with HRV.

**Methods:** Fifteen adolescents with ASD (male = 66.7%,  $M_{age} = 16.60$ ,  $SD = 2.32$ ) and thirty-five without ASD (male = 25.7%,  $M_{age} = 16.34$ ,  $SD = 1.28$ ) completed a 6-minute resting electrocardiogram (ECG) in the laboratory. HRV indices were derived from the ECG, including, standard deviation of the NN interval (SDNN), root mean square of successive interbeat intervals (RMSSD), percentage of number of interbeat intervals that differ in more than 50ms (pNN50) and high frequency component of HRV (HF).

All participants completed the Autism Quotient (AQ), while participants' caregiver or parents completed the 30-item Emotion Dysregulation Inventory (EDI), an informant-report questionnaire that measured emotional distress and problems with ER. Each participant was scored on the two EDI sub-scales measuring Reactivity (rapidly escalating, intense negative affect) and Dysphoria (sadness and anhedonia). All scales were administered in Chinese.

**Results:** Independent samples *t*-tests indicated that ASD adolescents scored significantly higher on scores of Reactivity and Dysphoria, compared to adolescents without ASD. Furthermore, ASD adolescents showed lower RMSSD than adolescents without ASD. Correlational analyses in the combined sample of participants revealed significant associations between HRV indices and the EDI. Specifically, Reactivity showed negative correlations with RMSSD and pNN50. Dysphoria was not associated with any of the HRV indices.

**Conclusions:** The findings indicate that ASD adolescents experience greater emotion dysregulation and show lower autonomic flexibility than their typically developing peers. More importantly, the finding that lower HRV was significantly related to higher levels of emotion dysregulation, lends support to HRV as a biomarker of ER. This study suggests that disruptions in ANS functioning may underlie emotion dysregulation in adolescents with ASD. Future research will be required to examine the potential for interventions that improve autonomic balance in ASD populations.

### **506.077** (Virtual Poster) Development of Helping Behavior in Children at Elevated Likelihood for Autism Spectrum Disorder

**E. Demurie, S. Boterberg, E. Bruyneel, C. Bontinck, P. Warreyn and H. Roeyers**, Department of Experimental-Clinical and Health Psychology, Ghent University, Ghent, Belgium

---

**Background:** According to the social motivation hypothesis of autism spectrum disorder (ASD), decreased social motivation may result in less attention to and thus fewer experiences with social sources of information, negatively influencing the development of social cognition and social-communicative abilities (Chevallier et al., 2012). Given the etiological nature of this reduction in social motivation, we expect this difference to be detectable early in life. As younger siblings of children with ASD have a 10 to 20 times higher chance of developing ASD themselves (Szatmari et al., 2004), the current study focused on intrinsically socially motivated behavior of elevated likelihood (EL) siblings, by administering helping tasks.

**Objectives:** The current study aims to answer the following research questions:

1. Is there a difference in helping behavior between EL children and children at typical likelihood (TL) for ASD?
2. Is helping behavior associated with social-communicative abilities?

**Methods:** Fifty EL siblings and 41 TL siblings (i.e., siblings of typically developing children), participating in a prospective study design, were tested in six helping tasks (Warneken & Tomasello, 2006) at 14, 24 and 36 months of age. In the **experimental condition** (3 tasks) the researcher accidentally encountered a problem that he/she could not solve himself/herself without the child's help. In the **control condition** (3 tasks, counterbalanced) a similar situation was created intentionally by the researcher and thus no help was needed. All sessions were videotaped and coded with regard to helping behavior and eye contact. Autism Diagnostic Observation Schedule-2 (ADOS-2; Lord et al., 2013) and Mullen Scales of Early Learning (MSEL; Mullen, 1995) were administered.

**Results:** All participants at all ages helped more frequently in the experimental compared to the control condition, which suggests that the experimental manipulation was successful. Second, EL siblings helped less in the experimental condition than TL siblings at the ages of 14 and 24, but not at 36 months. Furthermore, at 24 months TL siblings, but not EL siblings, made more eye contact with both researcher and parent in the control condition compared to the experimental condition. Finally, within the total sample, more frequent helping behavior at 14 months was associated with lower ADOS-2 Social Affect and total scores at both 14 and 36 months, but not with MSEL scores. At 24 months, only a cross-sectional association with ADOS-2 scores was found. Within the EL group, outcome status was related to helping behavior at 14 months: EL siblings with later ASD characteristics (BAP or ASD outcome at 36 months) helped less than EL siblings without later ASD characteristics.

**Conclusions:** Children at EL for ASD seem to experience a delay in the development of helping behavior, which might be indicative of lower levels of (pro)social motivation. Moreover, the difference in helping behavior at the age of 14 months is predictive of later ASD symptomatology. Finally, at the age of 24 months we found evidence for less social referencing in the ambiguous control conditions in the EL group, as TL siblings checked more often with the parent and researcher during this awkward social situation.

**506.078 (Virtual Poster)** Interpersonal Contexts Predict Interaction Reciprocity: How Autistic, Non-Autistic, and Mixed-Neurotype Peer Interactions Unfold in an Inclusive School Environment

**Y. L. Chen<sup>1</sup>** and **K. P. Koenig<sup>2</sup>**, (1)Center of Outcomes and Assessment Research, Kessler Foundation, East Hanover, NJ, (2)Occupational Therapy, New York University, New York, NY

Background:

Youth on the autism spectrum learning in inclusive education commonly experience difficulties in peer interactions and relationships, associated with a higher level of loneliness and bullying victimization rate among these students than their non-autistic peers. Previous studies on peer interactions of youth on the spectrum primarily investigated individual factors (e.g., social-communicative or cognitive traits), presenting a knowledge gap in the effects of interpersonal contexts on social outcomes. However, the Double Empathy Problem Theory emphasizes the role of interpersonal alignment in social expectations and interests on social outcomes, which is supported by other theoretical and empirical evidence.

Objectives:

This study aimed to investigate the effects of interpersonal contexts on the reciprocity and progress of real-world peer interactions in inclusive education. We defined interactive contexts as the neurotype composition among students participating in an interaction.

Methods:

This mixed-methods study investigated peer interactions among 12 students (six on the spectrum, age 12-14) over eight 45-min club sessions across 5 months, codifying a total of 1,174 social behaviors in 188 peer interaction series. For each interaction, we coded the interpersonal context (autistic, non-autistic, or mixed-neurotype dyad/group), interaction reciprocity (the total number of social turns in the interaction), and the characteristics of each social behavior. We further categorized interactions as *functional* or *relational* (the former reflected an instrumental purpose, e.g., seeking help, while the latter included all other initiations), based on the purpose of the initial social behavior. For all social turns following the initial social behaviors, we categorized each behavior as *extending*, *relevant*, or *tangential* depending on whether it expands or is relevant or tangential to the prior social behavior.

Results:

Regardless of the initiation purpose, autistic interactions showed the highest average and variance in reciprocity ( $M=7.22$ ,  $SD=7.57$ ), followed by non-autistic students ( $M=5.47$ ,  $SD=4.28$ ) and mixed-neurotypes ( $M=5.00$ ,  $SD=3.85$ ) dyads/groups. Figure-1 reveals the distinct reciprocity distributions of interactions by interpersonal contexts, initiation types, and initiator neurotypes. Poisson regression shows that autistic interactions had significantly higher reciprocity than non-autistic interactions (estimate=0.25,  $SE=0.07$ ,  $p<.001$ ), and relational interactions had higher reciprocity than functional interactions (estimate=0.40,  $SE=0.07$ ,  $p<.001$ ).

Figure-2 plots the characteristic of social behaviors against the sequence of social turns, illustrating the progress of peer interactions by interpersonal context and interaction purpose. Compared with non-autistic interactions, autistic interactions demonstrated a similar mixture of relevant and extending responses as well as increased tangential turns. Such tangential turns, however, did not interrupt the progress of autistic interactions, which reciprocated further than non-autistic and mixed-neurotype interactions. Mixed-neurotype interactions showed earlier instances of tangential responses than other interpersonal contexts. To explain these findings, an ongoing qualitative analysis of interactions across interpersonal contexts will be presented.

Conclusions:

This study provided preliminary findings on the effects of interpersonal contexts on interaction reciprocity and progress. Within-neurotype interactions showed higher reciprocity than cross-neurotype ones, which aligned with the Double Empathy Problem Theory. Findings on the progress of autistic interactions demonstrated the unique characteristics of autistic sociality.

**506.079 (Virtual Poster)** Investigation of Autism Spectrum Disorder Diagnosis and Social Anxiety Symptoms As Predictors of Visual Attention to Faces and Eyes

**C. J. Franke<sup>1</sup>, J. M. Wolf<sup>1</sup>, A. Naples<sup>1</sup>, M. E. Johnson<sup>2</sup>, G. T. Han<sup>1,3</sup> and J. McPartland<sup>4</sup>,** (1)Child Study Center, Yale University School of Medicine, New Haven, CT, (2)Child Study Center, Child Study Center, Yale University, New Haven, CT, (3)Yale Child Study Center, New Haven, CT, (4)Child Study Center, Yale Child Study Center, New Haven, CT

---

**Background:** Up to 34% of adolescents with autism spectrum disorder (ASD) have co-occurring social anxiety (SA; Kreiser & White, 2014), but this association has not been fully explored (Spain et al., 2018). Eye-tracking (ET) provides an objective measurement of social attention that could clarify relationships between ASD and SA characteristics. In previous studies, individuals with ASD and individuals with SA both looked less at eyes than typically developing (TD) individuals; however, ASD participants also looked less at faces, while participants with SA showed an early attentional bias towards negative faces compared to neutral stimuli (Hessels et al., 2018; Chita-Tegmark, 2016; Günther et al., 2021).

**Objectives:** The current study investigated predictors of percent looking time (%looking, measured by ET) at different facial regions of interest (ROIs). It was predicted that (1) higher SA scores and (2) ASD diagnosis would each predict less %looking at eyes. Additionally, exploratory analyses were conducted to look for interaction effects among diagnostic group, SA score, and stimulus valence on %looking at ROIs.

**Methods:** Fifty-four children with ASD (22.22% female;  $M=13.27\pm2.94$  years) and 35 TD children (54.29% female;  $M=12.45\pm2.61$  years) completed the Multidimensional Anxiety Scale for Children—Child Version (MASC-C). The Social Anxiety (SA) subscale was used for the current analyses. Eye-tracking data were collected during a gaze-contingent emotional faces paradigm, in which neutral faces became happy or fearful after participants directed their gaze to the eyes. ROIs were created for the face, eyes, nose, and mouth, and %looking at each ROI for each emotional face was averaged across trials for each participant and logit transformed. Multiple linear regressions were performed to examine whether ASD group, SA score, and/or stimulus valence predicted %looking at ROIs.

**Results:** Emotional valence did not predict %looking for any ROI ( $ps>.05$ ). Regression models with ASD group and SA score as predictors were significant for faces ( $F(3,164)=13.08, p<.001, R^2=17.83\%$ ) and eyes ( $F(3,164)=3.23, p=.024, R^2=3.86\%$ ). Children with ASD looked less at faces than TD children ( $\beta=0.04, t=4.12, p<.001$ ) but not less at eyes ( $p>.05$ ). Children with higher SA scores looked less at eyes ( $\beta=-.050, t=-2.74, p=.007$ ) than those with lower SA scores. Additionally, there was a significant diagnostic-group-by-SA-score interaction for %looking at faces; ASD participants with higher SA scores looked more at faces than ASD participants with lower SA scores, a pattern not seen in the TD group ( $\beta=-.002, t=-2.04, p=.043$ ).

**Conclusions:** Partially replicating previous findings, results indicated distinct contributions of SA and ASD characteristics to visual attention. Though children with ASD looked less at faces overall, their levels of eye fixation did not differ from TD children; however, higher levels of SA predicted less looking at eyes. Furthermore, children with ASD looked more at faces when they had higher SA scores, which could indicate either increased social motivation or increased hypervigilance to faces compared to children with ASD who have lower SA levels. These findings suggest that it is important to consider both ASD and SA when studying face gaze in children.

**506.080 (Virtual Poster)** Links between Perceived Dissimilarity, Loneliness and Internalizing Symptoms in Autistic Children and Adolescents  
**P. Munshell<sup>1</sup>, D. Alkire<sup>2</sup>, H. A. Yarger<sup>3</sup> and E. Redcay<sup>3</sup>,** (1)Department of Psychology, University of Maryland at College Park, College Park, MD, (2)Neuroscience and Cognitive Science Program, University of Maryland, College Park, MD, (3)Department of Psychology, University of Maryland, College Park, MD

---

**Background:** Loneliness, or the lack of desired social relationships, increases during adolescence as children experience greater social needs as well as increased risk of social isolation or rejection (Whitehouse et al., 2008). The relation between loneliness and other psychological variables in autistic children is not fully understood. Prior research in autistic children has found that higher levels of internalizing symptoms relate to increased loneliness (Deckers et al., 2017; White & Roberson-Nay, 2008; Whitehouse et al., 2008). However, less is known about how loneliness in autistic children is affected by their perceptions of themselves in relation to others. Perceiving oneself as similar to others predicts feelings of connectedness in relationships (Montoya et al., 2008; Murray et al., 2002; Pinel et al., 2006). Conversely, perceiving oneself as dissimilar to others—as autistic individuals may be especially likely to do—may lead to difficulty in forming high-quality social connections, in turn leading to increased loneliness.

**Objectives:** This study explores relations between loneliness and 1) self- and parent-reported internalizing symptoms and 2) perceived dissimilarity in autistic and neurotypical children aged 8–14 years.

**Methods:** 31 autistic children (ages 8–14,  $mean_{age} = 10.73$ ,  $n_{female} = 9$ ) with a confirmed diagnosis of autism participated in this study. A group of 31 neurotypical children (ages 8–14,  $mean_{age} = 10.73$ ,  $n_{female} = 9$ ) were matched on age and gender. All children had an IQ of at least 80. For internalizing symptoms, children and parents each completed the Screen for Child Anxiety Related Emotional Disorders (Birmaher et al., 1995, 1997), and parents also completed the internalizing subscale of the Child Behavior Checklist (CBCL; Achenbach & Rescorla, 2001). In addition, children answered six original questions about perceived dissimilarity and three original questions about loneliness developed by the researchers. Separate multiple linear regression analyses were run for each group. Each model controlled for participant age and gender and included self- and parent-reported anxiety (SCARED total scores), parent-reported internalizing (CBCL), and perceived dissimilarity as predictors of loneliness. We hypothesized that in both groups, internalizing symptoms and perceived dissimilarity would positively predict loneliness.

**Results:** The autistic group showed significantly higher self- and parent-reported internalizing symptoms, as well as significantly higher perceived dissimilarity than the neurotypical group. Self-reported loneliness did not significantly differ between the autistic and neurotypical groups. In the

autistic group, perceived dissimilarity was the only significant predictor of loneliness ( $p < 0.01$ ), whereas in the neurotypical group, parent-reported anxiety was the only significant predictor ( $p < 0.05$ ).

**Conclusions:** Results of the study expand upon prior research that levels of internalizing symptoms are significantly higher in autistic children when compared to neurotypical children but failed to replicate studies that show a relation between internalizing symptoms and loneliness in autistic children, instead highlighting perceived dissimilarity as a correlate of loneliness. Furthermore, parent-reported anxiety and not perceived dissimilarity predicted loneliness in the neurotypical group; thus, predictors of loneliness may differ between autistic and non-autistic children. Future research should continue to investigate measures of perceived dissimilarity as a predictor of increased loneliness among autistic child and adolescent populations.

**506.081 (Virtual Poster) Loneliness in Autistic Children: In Relation to School Recess Time**

**Y. T. Tsou<sup>1</sup>, M. Nasri<sup>1</sup>, L. van Klaveren<sup>1</sup>, E. M. Blijd-Hoogewys<sup>2</sup>, M. Baratchi<sup>3</sup>, A. Koutamanis<sup>4</sup>, K. Liu<sup>1</sup> and C. Rieffe<sup>1,5,6</sup>,** (1)Institute of Psychology, Leiden University, Leiden, Netherlands, (2)INTER-PSY, Groningen, Netherlands, (3)Leiden Institute of Advanced Computer Science (LIACS), Leiden University, Leiden, Netherlands, (4)Faculty of Architecture & the Built Environment, Delft University of Technology, Delft, Netherlands, (5)Faculty of Electrical Engineering, Mathematics and Computer Science, University of Twente, Enschede, Netherlands, (6)Institute of Education, University College London, London, United Kingdom

---

**Background:**

Loneliness is the cognitive awareness of the deficiency in one's interpersonal relationships (Asher & Paquette, 2003). Previous research using self-reports showed that the feeling of loneliness becomes more pronounced when autistic children enter adolescence, experiencing an elevated level of loneliness compared to their non-autistic peers (Bauminger & Kasari, 2001; Bottema-Beutel et al., 2019; Deckers et al., 2017).

School recess time is when children can have child-led, unstructured activities and interactions, which makes it a crucial part of school life for children to develop interpersonal relationships. While observational studies have revealed that autistic children more often engage in solitary or peripheral activities on the school playground (Gilmore et al., 2019), it remains unknown to what extent the activities during school recess contribute to autistic children's feeling of loneliness in school.

**Objectives:**

Using self-reports and sensor technology, this study aimed to assess (1) the extent to which the level of loneliness in school is related to their enjoyment of recess activities, and to social interactions during recess, and (2) the extent to which these relations differ between autistic and non-autistic children.

**Methods:**

Autistic children ( $n = 47$ ) and their non-autistic classmates ( $n = 52$ ) aged 8 to 14 years from two special education primary schools participated in this study ( $M = 10.84$  years,  $SD = 1.21$ ; 34 girls and 65 boys). Children completed the Children's Loneliness Scale to assess levels of loneliness in school (Maes et al., 2015); and the Lunchtime Enjoyment of Activity and Play Questionnaire to assess their enjoyment of activities during school recess (Hyndman et al., 2013). Also, children wore proximity sensors (Radio Frequency Identification Devices, RFID) at the schoolyard to assess their social interactions during recess in terms of (a) time spent in interaction with peers, (b) number of partners, and (c) centrality in a social network.

**Results:**

We found no differences in self-reported levels of loneliness and enjoyment of recess activities between autistic and non-autistic children. At the schoolyard, autistic children spent shorter time interacting with peers ( $U = 634, p = .002$ ) and were in contact with fewer peers ( $U = 635, p = .002$ ) compared to their non-autistic classmates. Also, in autistic children, higher levels of loneliness in school were correlated with fewer interaction partners ( $\rho = -.37$ ) and lower levels of enjoyment ( $\rho = -.44$ ) during recess. In children without autism, higher levels of loneliness were only correlated with shorter time spent in interaction ( $\rho = -.32$ ).

**Conclusions:**

Although autistic and non-autistic children reported similar levels of loneliness in school, different factors during recess may affect their perception of loneliness. While the duration of contacts was important for the peers without autism, the number of contacts and the active participation in play activities during recess seemed more important for autistic children. These findings show that autistic children may have different expectations about their interpersonal relationships, which should be taken into account for a better inclusion of these children in schools.

**506.082 (Virtual Poster) Relationships between Social Responsiveness and Visual Attention to Faces in a Transdiagnostic Sample of Adults with Autism, Schizophrenia, and a Non-Clinical Comparison Group**

**M. E. Johnson<sup>1</sup>, G. T. Han<sup>2</sup>, A. Naples<sup>3</sup>, C. J. Franke<sup>3</sup>, C. J. Stevens<sup>3</sup>, L. M. Pisani<sup>3</sup>, C. C. Cukar-Capizzi<sup>3</sup>, J. M. Wolf<sup>6</sup> and J. McPartland<sup>4</sup>,** (1)Child Study Center, Child Study Center, Yale University, New Haven, CT, (2)Yale Child Study Center, New Haven, CT, (3)Child Study Center, Yale University School of Medicine, New Haven, CT, (4)Child Study Center, Yale Child Study Center, New Haven, CT

---

## Background:

Atypical visual attention to faces is reported in individuals with autism and schizophrenia spectrum disorders (ASD, SZ) and is thought to contribute to social communication difficulties in both clinical populations. Understanding points of convergence and divergence in processing facial communication is needed to understand the mechanisms of social communication to inform intervention development.

## Objectives:

Examine between-group differences in visual attention during reception of facial communication as it relates to social responsiveness.

## Methods:

Participants were adults aged 18-35 years (ASD  $n=31$ ; SZ  $n=24$ ; non-clinical comparison participants [NCC]  $n=42$ ). Diagnoses were confirmed with gold standard instruments administered by experienced clinicians. A novel gaze-contingent paradigm examined visual attention during reception of facial communication. Participants passively viewed counterbalanced fixation cues followed by a neutral face; contingent upon participant gaze, the face responded with either a happy or fearful expression. The eye tracking measure of interest was percentage of time looking (%looking) at informative regions of the face (RoF). The Social Responsiveness Scale (SRS-2) and Broader Autism Phenotype Questionnaire (BAPQ) assessed self-reported autistic traits.

## Results:

For each RoF (Right Eye, Left Eye, Between Eyes, Nose, Mouth), separate univariate repeated measures ANOVAs assessed differences in %looking, with face valence (fearful, happy) as a within-subjects factor and diagnostic group (ASD, SZ, NCC) as a between-subjects factor. Post-hoc  $t$ -tests evaluated contrasts between emotion and between groups. Significant between-group differences in %looking were detected for Nose ( $F(2,94)=4.73$ ,  $p=0.01$ ) and Mouth ( $F(2,94)=4.60$ ,  $p=0.01$ ): ASD and SZ looked more to Nose and Mouth compared to NCC (post hoc  $p$ 's  $<0.05$ ). Only within Right Eye, the valence  $\times$  group interaction was significant ( $F(2,94)=4.99$ ,  $p<0.01$ ): SZ looked less to Right Eye during fearful compared to happy faces ( $t(94)=-3.30$ ,  $p=0.02$ ), a pattern absent in ASD and NCC. Across all groups, %looking did not differ based on valence of the face.

Given sparsity in %looking across RoFs, subsequent analyses examined associations between social responsiveness and %looking to the whole face. Higher SRS-2 and BAPQ total scores (higher levels of autistic traits) were negatively associated with %looking to the face (BAPQ  $R^2=0.24$ , SRS-2  $R^2=0.23$ ). Linear regressions were applied to evaluate group by social responsiveness interactions. The relationship between autistic traits and %looking differed by group (SRS-2  $\times$  group:  $t(89)=-2.28$ ,  $p=0.03$ ; BAPQ  $\times$  group:  $t(89)=-2.91$ ,  $p<0.01$ ): NCC exhibited a negative relationship between social responsiveness and other autistic traits and %looking, while ASD exhibited a positive relationship (Figure 1); SZ did not exhibit a significant relationship between social responsiveness and %looking.

## Conclusions:

Findings inform visual attention differences during face processing in ASD and SZ. Results replicate and extend previously reported visual attention biases to the mouth in ASD and SZ. Notably, the relationship between social responsiveness and %looking to the face differed across diagnostic groups such that greater social difficulties related to lower %looking to the face. Future research should confirm these findings and investigate response to facial communication in ASD and SZ in more naturalistic contexts.

**506.083 (Virtual Poster)** Self-Determination, Body-Related Self-Conscious Emotions, and Physical Activity Levels in College Students with and without ASD Traits

**D. Morales<sup>1</sup>** and **D. Davidson<sup>2</sup>**, (1)Loyola University Chicago, Chicago, IL, (2)Psychology, Loyola University Chicago, Chicago, IL

## Background:

Although the benefits of physical activity are well known, research has shown that individuals with autism spectrum disorder (ASD) are less active and are less engaged in physical activity (PA) than those without ASD traits (Hiller et al., 2020; Pan & Frey, 2006; Stanish et al., 2017). Of interest in the present study is whether certain factors influence participation in PA in ASD, such as self-determination and body-related self-conscious emotions.

## Objectives:

Two major research questions were addressed: (1) do young adults with and without ASD traits differ in terms of self-determination and body-related self-conscious emotions, and (2) do young adults who meet and do not meet PA levels differ on these same variables. Additionally, we explored these questions in young adults with and without ASD traits who met PA guidelines and those who do not.

## Methods:

Following IRB approval, 126 college students participated (60.3% Caucasian, 79% female). Students with autistic traits ( $n = 27$ ;  $M_{age} = 19.32$ ) and without autistic traits ( $n = 99$ ;  $M_{age} = 19.28$ ) were determined using T-scores from the Social Responsiveness Scale (SRS-2). The SRS-2 is a robust instrument for detecting the presence and severity of ASD symptomatology (Constantino & Gruber, 2012). PA level was determined through self-report. According to the World Health Organization (2010), recommended levels include at least 150-300 minutes of moderate-to-vigorous intensity or at least 75-150 minutes of vigorous intensity physical activity during a 7-day span. The Behavioral Regulations in Exercise Questionnaire – 3 (BREQ-3; Cid et al., 2018) measured self-determination and includes 6 subscales: amotivation, external, introjected, integrated, and intrinsic regulation, ranging from external to more intrinsic determination. The Body and Appearance Self-Conscious Scale (BASES; Castonguay et al., 2014) measured body-related self-conscious emotions including guilt, shame, and pride (authentic, hubristic).

#### Results:

Individuals with ASD traits had higher levels of external and introjected regulation (self-determination), higher scores of body-related guilt and shame, and lower scores of both authentic and hubristic pride than those without ASD traits. Also, in our overall sample, young adults meeting guidelines had higher scores on internal self-determination regulations, lower body-related guilt scores and higher authentic pride than young adults not meeting physical activity guidelines. See Table 2 for results and all statistical values.

#### Conclusions:

Young adults with ASD traits scored higher in behavioral regulations that were more extrinsic in nature than those without ASD traits, suggesting that they are more motivated by external rewards or pressure from external sources. Interestingly, young adults who met PA guidelines scored higher in intrinsic regulations, suggesting that they are motivated by pure enjoyment or confirming one's sense of self. They also reported less proneness to body-related guilt but more body-related pride. The results suggest opposite findings for young adults with ASD traits and young adults who meet PA recommendations. Therefore, future research should examine the combined effect of ASD symptomatology and of individuals meeting PA guidelines on self-determination regulations and body-related self-conscious emotions.

#### **506.084** (Virtual Poster) The Moderating Effect of Sex on Autistic Trait Emotional Intelligence and Alexithymia

**M. I. Cargill<sup>1</sup>, R. G. McDonald<sup>1</sup>, N. Yacoub<sup>1</sup>, S. Khawar<sup>1</sup>, M. D. Lerner<sup>2</sup> and E. Kang<sup>1</sup>,** (1)Department of Psychology, Montclair State University, Montclair, NJ, (2)Psychology, Stony Brook University, Stony Brook, NY

Background: Differences in trait emotional intelligence (TEI) and alexithymia relate to differential social communication (Boily et al., 2017; Gerber et al., 2019), which is a hallmark of autism spectrum disorder (ASD; American Psychiatric Association, 2013). TEI describes emotional intelligence as factors that affect how one interacts with emotional information (Pardeller et al., 2017). Sex differences in TEI are well established in typically-developing (TD) samples, but results are mixed as to whether males (Shahzad & Bagum, 2012) or females (Joseph & Newman, 2010) are higher in TEI. Although ASD is associated with impaired TEI (Robinson & Petrides, 2020), few studies have examined sex differences in TEI in ASD. One such study found higher TEI in TD than ASD participants, and in males than females across both groups (Petrides et al., 2011). In TD samples, males appear to have higher rates of alexithymia (Garaigordobil, 2013), but no analyses considered the intersection of ASD and sex in alexithymia. Given the dearth of research about outcomes for autistic adults, particularly autistic women, this analysis may offer much-needed insight into these populations' emotional processing and social communication.

Objectives: We sought to examine the moderating effect of sex on the relationship between autism symptomatology, TEI, and alexithymia amongst adults. We hypothesized that higher autism symptomatology would be associated with lower TEI and higher alexithymia, and that these relationships would be moderated by sex such that differences would be more pronounced in males.

Methods: Eighty-six adults with and without ASD (54.7% female;  $M_{age}=22.80$ ,  $SD_{age}=6.34$ ; 55.8% White;  $M_{IQ}=102.42$ ,  $SD_{IQ}=15.18$ ) participated in the current study. Participants completed measures of autism symptomatology (SRS-2; Constantino & Gruber, 2012), TEI (SEIS; Schutte et al., 1998), and alexithymia (TAS-20; Bagby et al., 1994). The relationship of SRS-2 with SEIS and TAS-20 was examined with Pearson correlations. Moderation analyses were conducted to investigate the contribution of sex in these associations.

Results: SRS-2 was negatively correlated with SEIS ( $r=-.81$ ;  $p<.001$ ) and positively correlated with TAS-20 ( $r=.71$ ;  $p<.001$ ). Furthermore, SEIS was negatively correlated with TAS-20 ( $r=-.72$ ;  $p<.001$ ). Sex substantially moderated the relationship between SRS-2 and SEIS ( $ab=-.70$ ,  $p=.002$ , see Figure 1), with higher SRS-2 being associated with lower TEI in males compared to females (see Figure 2). However, sex did not moderate the relationship between SRS-2 and TAS-20 ( $p=.26$ ).

#### Conclusions:

These results suggest that more severe autism symptoms are associated with lower levels of TEI and higher levels of alexithymia across ASD and non-ASD adults, and negative associations between autism symptoms and TEI are more pronounced in males. Conversely, males with less severe autism symptoms seem to have higher TEI than males with more severe autism symptoms or women with fewer autism symptoms. Autistic adults may benefit from interventions targeting TEI and alexithymia, with additional TEI support given to males, to improve recognition of their own emotions and functioning in the social world. These findings contribute to a growing body of work in an understudied area of autism research regarding adult outcomes and support the provision of lifespan support to autistic people.

#### **506.085** (Virtual Poster) The Neurobiological Map of Theory of Mind and Pragmatic Communication in Autism

**Background:** Children with autism spectrum disorder (ASD) often have difficulty with Theory of Mind (ToM), the ability to infer mental states of oneself and others and pragmatic language skills (PS), the contextual use of language in communication.<sup>2</sup> Neuroimaging research suggests ToM and PS largely overlap, arguing the ability to understand another's mental state is a prerequisite to successful interpersonal communication.<sup>6</sup> The medial prefrontal cortex (MPFC)<sup>1</sup>, dorsal MPFC,<sup>3</sup> and bilateral temporo-parietal junction (TPJ)<sup>3</sup> have been implicated in ToM and PS. In addition, a meta-analysis indicated significant functional and anatomical overlap between brain regions underlying ToM and narrative comprehension.<sup>4</sup> However, no study in the last decade has examined this further.

**Objectives:** To assess the emerging consensus across neuroimaging studies of ToM and PS in ASD, the current study used coordinate-based activation likelihood estimation (ALE) analysis of 45 functional magnetic resonance imaging (MRI) studies.

**Methods:** This ALE meta-analysis followed the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines. A comprehensive literature search of published scientific papers was conducted using *PubMed*, *Web of Science*, *PsychInfo*, and *Google Scholar*, yielding 79 PS articles and 124 ToM articles. Combinations of search terms involving ASD, fMRI, pragmatics, theory-of-mind etc. were used. Papers were excluded for comorbid ASD samples, lack of whole brain coordinates, and no official ASD diagnosis, resulting in 45 papers (13 PS, 32 ToM). This resulted in a meta-analysis of 1,037 participants (534 ASD, 503 typically developing (TD) individuals). Participants ranged from 7 to 49 years of age and were of average IQ. Peak activation coordinates from all studies were extracted into text files and converted to MNI coordinates. The text files were used to conduct a separate ALE analysis of ToM and PS using the GingerALE software for TD and ASD groups.

**Results: *ToM:*** Both TD and ASD participants had significant activity in the left precuneus and right superior temporal gyrus (RSTG); and direct group comparison revealed reduced activity in precuneus in ASD,  $p < .05$ . Comparison of children to adults resulted in ASD children and ASD adults showing reduced activation in the left inferior frontal gyrus (LIFG) and in RSTG, respectively, compared to TD children and adults,  $p < .05$ .

***Pragmatics:*** Both TD and ASD participants had significant activity in the RIFG, LSTG, and; and direct comparison showed reduced activation in ASD, relative to TD, participants in the RIFG, left superior frontal gyrus (LSFG), LMTG, and LMPFC,  $p < .05$ . There were no areas in which ASD participants showed greater activation relative to TD participants. Further, ASD children showed greater activation in the RIFG and lesser activation in the LMTG and LSTG relative to TD children.

**Conclusions:** The left temporal and medial prefrontal underactivation in ASD in PS may reflect linguistic differences as well as differences in understanding contextual cues in pragmatic language. Overall, the findings of this study underscore the cognitive and neural similarities between ToM and PS, and the neurobiological differences in core regions underlying ToM and PS in ASD.

#### **506.086 (Virtual Poster)** The Relation between Social Anxiety and Meta-Perception during Peer Interaction in Children with and without Autism Spectrum Disorder

**L. Giacobbe<sup>1</sup>**, D. Alkire<sup>2</sup>, H. A. Yarger<sup>1</sup> and E. Redcay<sup>1</sup>, (1)Department of Psychology, University of Maryland, College Park, MD, (2)Neuroscience and Cognitive Science Program, University of Maryland, College Park, MD

---

**Background:** Previous studies have shown a high co-occurrence of autism spectrum disorder (ASD) and anxiety in children, with up to 40% of children with ASD meeting criteria for an anxiety disorder (Adams et al., 2019; Baribeau et al., 2020). Generally, individuals with social anxiety (SA) disorder evaluate themselves more negatively, and believe others judge them negatively during a social interaction (Hezel & McNally, 2014). SA in children with ASD can cause social withdrawal and social skill deficits, which may result in negative peer interactions (Bellini, 2006). While previous research has studied the behavioral and physiological characteristics of anxiety in children with ASD, less is known about how SA relates to meta-perception (how they felt their peer viewed them) in a peer interaction.

**Objectives:** 1) to investigate whether SA symptoms are associated with one's perception of how their peer viewed them during a social interaction across all participants (with and without ASD); 2) to determine if diagnosis moderates this relation; 3) to determine if an association between SA symptoms and meta-perception exists *within* each group.

**Methods:** The sample consists of 65 children aged 8-16 years. 31 children were diagnosed with ASD ( $M = 12.90$  years,  $SD = 2.30$  years, 7 females) and 34 were typically developing (TD) based on parental report ( $M = 13.12$  years,  $SD = 2.12$  years, 19 females). Children were age- and gender-matched with another participant (ASD-ASD, TD-TD or ASD-TD) and completed unstructured and semi-structured interactions. Following the peer interaction, participants individually responded to 25 questions about meta-perceptions of their peers (i.e. "how happy/insecure/shy/confident did [Partner] think you were?") on a 5-point Likert scale (Usher et al., 2018). An overall meta-perception score was calculated by summing all responses, reverse scoring negative characteristics. SA symptoms were measured using the social anxiety subscore from the Screen for Anxiety-Related Emotional Disorders parent report (Birmaher et al., 1997).

**Results:** SA significantly negatively predicted meta-perceptions, such that a one-unit increase in SA symptoms was associated with a .88-unit decrease in meta-perception ( $p = .01$ ). Diagnosis was not a significant moderator in the relation between SA and meta-perception ( $p > .05$ ). However, when running separate models for each group, the relation between SA and meta-perception was found to be significant in the TD group ( $B = -.45$ ,  $p = 0.12$ ) but not in participants on the autism spectrum ( $B = -.064$ ,  $p > .05$ ).

**Conclusions:** Across a sample of children with and without ASD, higher levels of SA were associated with the belief that their partner viewed them more negatively during a social interaction. While we did not find a significant moderation by diagnostic group, SA was not significantly associated with meta-perception in the ASD group alone, and the latter may be due to being underpowered. The study supports previous literature in which SA

may cause children to view themselves more negatively during a social interaction, but this relation may be stronger in TD children. Future studies should continue to investigate whether and why this relation may be different in those with ASD.

**506.087** (Virtual Poster) Understanding the Social Functioning Profile in NGLY1 Deficiency Using the Stanford Social Dimensions Scale (SSDS)  
**A. Revanur<sup>1</sup>, M. Uljarevic<sup>2</sup>, C. Frater<sup>3</sup>, J. M. Phillips<sup>4</sup>, A. Y. Hardan<sup>1</sup> and M. Ruzhnikov<sup>1</sup>,** (1)University of Arizona College of Medicine-Tucson, Tucson, AZ, (2)School of Psychological Sciences, University of Melbourne, Stanford, CA, Australia, (3)Department of Child Neurology, Stanford University, Palo Alto, CA, (4)Psychiatry & Behavioral Sciences, Stanford University, Stanford, CA

---

**Background:** N-Glycanase 1 (NGLY1) deficiency (NGLY1-CDDG, NGLY1-Related Disorder, OMIM 615273) is a rare autosomal recessive disorder caused by loss of NGLY1 enzymatic activity. It is characterized by global developmental delay and/or intellectual disability with limited to absent verbal speech and a range of additional complex neurological symptoms. Intriguingly, despite significant developmental delays, single case and very small n reports have suggested that social and communication abilities might be less impacted than other domains. No study to date has attempted to provide a comprehensive characterization of the social functioning profile of individuals with NGLY1 deficiency.

**Objectives:** This study aimed to utilize the recently developed Stanford Social Dimensions Scale (SSDS) to provide a comprehensive characterization of the social functioning profile in NGLY1 deficiency, as well as to compare a profile of strengths and weaknesses across key social functioning processes, including different aspects of social motivation and social communication among individuals with NGLY1 deficiency versus individuals with idiopathic autism spectrum disorder (ASD). Finally, we also aimed to characterize individual differences in social functioning within our NGLY1 deficiency cohort.

**Methods:** Parents of 25 individuals with NGLY deficiency ( $Mean_{age}=11.26$  years,  $SD=6.71$ ) and of 164 individuals with idiopathic ASD ( $Mean_{age}=7.19$  years,  $SD=3.96$ ) completed the SSDS. The SSDS is a parent-report measure designed to quantify individual differences across the following five subscales: social motivation (SM), social affiliation (SA), expressive social communication (ESC), social reception (SR) and Unusual Approach (UA).

**Results:** Univariate models with bootstrapping showed that the NGLY1 deficiency group had significantly higher scores (better functioning) on the SSDS SM ( $F=5.58, p=.019, \omega^2=.024$ ) and ESC subscales ( $F=9.03, p=.003, \omega^2=.04$ ) and significantly less deficits on the SSDS UA subscale ( $F=8.09, p=.005, \omega^2=.036$ ). There were no differences for Social Affiliation ( $F=.22, p=.64, \omega^2=.001$ ) nor Social Recognition SSDS subscales ( $F=.09, p=.77, \omega^2=.001$ ). There were pronounced individual differences across different aspects of social functioning within the NGLY1 deficiency group.

**Conclusions:** This is the first study to date to provide a detailed characterization of social functioning profiles among individuals with NGLY1 deficiency. At a group level, NGLY1 deficiency showed better functioning/lower impairments than the ASD group. Importantly, the individual differences approach showed pronounced heterogeneity within NGLY1 deficiency. Findings reported here have a potential clinical utility and emphasize the need for utilizing a detailed assessment of distinct aspects of social functioning in individuals with NGLY1 deficiency in order to enable tailoring of intervention and support approaches.

**506.088** (Virtual Poster) Validation and Factor Structure of the Japanese Version of the Camouflaging Autistic Traits Questionnaire (CAT-Q)  
**M. Hongo<sup>1</sup>, F. Oshima<sup>2</sup>, Y. Nitta<sup>3</sup>, T. Takahashi<sup>4</sup>, H. Kuwabara<sup>5</sup>, T. Ohtani<sup>6</sup>, L. Hull<sup>6</sup>, W. Mandy<sup>6</sup> and E. Shimizu<sup>1</sup>,** (1)Chiba University, Chiba, Japan, (2)Research Center for Child Mental Development Chiba University, Chiba, Japan, (3)Waseda University, Tokorozawa, Japan, (4)Waseda University, Saitama, Japan, (5)University of Tokyo Hospital, Tokyo, Japan, (6)Department of Clinical, Educational and Health Psychology, University College London, London, United Kingdom

---

**Background:**

Social camouflage behaviours refers to the behaviours of autistic adults in everyday social situations in which they hide their typical autistic behaviours and pretend to be a 'normal (typically developing) person' (Lai et al., 2017). While social camouflage behaviours are coping strategies to integrate autistic adults into the community, they have negative mental health effects such as anxiety and depression (Cage et al., 2018). Hull et al. (2018) developed the Camouflaging Autistic Traits Questionnaire (CAT-Q) to quantify person-reported social camouflage behaviors. The CAT-Q consists of three subscales: "compensation", "masking", and "assimilation".

**Objectives:**

In Japan, there is no scale to measure social camouflage behaviours of autistic adults. Therefore, the purpose of this study was to validate the Japanese version of the CAT-Q as a quantitative measure of social camouflage behaviours and to explore its factor structure.

**Methods:**

The first survey of the study was administered to 210 autistic adults with a diagnosis of autism spectrum disorder, and 450 non-autistic adults. All of them agreed to participate in the study. The second survey was conducted 2 weeks after the first one. Internal consistency and test-retest reliability of CAT-Q and three subscales were examined. Convergent validity (correlation of CAT-Q or Hull's three factors, with the Broad Autism Phenotype Questionnaire, the Liebowitz Social Anxiety Scale, the Warwick-Edinburgh Mental Well-being Scale (WEMWBS), the Patient Health Questionnaire-9, and the Generalized Anxiety Disorder-7) was assessed. Exploratory factor analysis (EFA) was used to examine the structure of the CAT-Q. All questionnaires were Japanese versions.

## Results:

The alpha coefficient of internal consistency ranged from 0.67 to 0.91. In terms of retest reliability, Pearson's correlations and intraclass correlations (ICC) of the CAT-Q total and the Hull's three factors showed that the autistic sample showed strong positive correlations for all of them. On the other hand, the non-autistic sample showed strong positive correlations for the "assimilation" factor, but moderate positive correlations for the entire scale, the "compensation" factor, and the "masking" factor. The CAT-Q total scores were significant positive correlations with each total scores of the other convergent validity scales, except for the WEMWBS total score of the autistic sample (Table 1). The results of the EFA show that the autistic sample had three factors (Table 2). The first factor included items from the "compensation" factor and items from the "masking" factor of the original CAT-Q. The second factor contained the items of the "assimilation" factor of the original CAT-Q. The third factor consisted of two items, item 9 and item 18. Four factors were extracted for the non-autistic sample, three of which corresponded to the original CAT-Q. The remaining factor consisted of reversed items (Table 2).

## Conclusions:

The reliability and validity of the Japanese version of the CAT-Q were confirmed. The results of the factor analysis for the autistic sample differed from those of Hull's study. It was suggested that there are socio-cultural differences in the situations in which autistic adults are placed. Further validation is needed.

### **506.089** (Virtual Poster) Aggression and Social Deficits Among Children with Autism Spectrum Disorder

**A. A. Lindley<sup>1</sup>, M. Santhosh<sup>2</sup>, H. Rea<sup>3</sup>, E. Neuhaus<sup>4</sup>, A. Naples<sup>5</sup>, C. Sugar<sup>6</sup>, M. Murias<sup>7</sup>, J. Dziura<sup>8</sup>, C. Brandt<sup>9</sup>, C. A. Nelson<sup>9</sup>, G. Dawson<sup>10</sup>, R. A. Bernier<sup>11</sup>, S. Faja<sup>12</sup>, K. Chawarska<sup>5</sup>, F. Shic<sup>2</sup>, S. J. Webb<sup>11</sup> and J. McPartland<sup>13</sup>,** (1)Psychology, Seattle Children's Research Institute University of Washington, Seattle, WA, (2)Center for Child Health, Behavior and Development, Seattle Children's Research Institute, Seattle, WA, (3)Center for Human Development and Disability, University of Washington Psychiatry and Behavioral Sciences, Seattle, WA, (4)Seattle Children's Research Institute, Seattle, WA, (5)Child Study Center, Yale University School of Medicine, New Haven, CT, (6)University of California, Los Angeles, Los Angeles, CA, (7)Duke Center for Autism and Brain Development, Department of Psychiatry and Behavioral Sciences, Duke University, Durham, NC, (8)Yale University, New Haven, CT, (9)Department of Developmental Medicine, Boston Children's Hospital, Boston, MA, (10)Department of Psychiatry and Behavioral Sciences, Duke Center for Autism and Brain Development, Durham, NC, (11)Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA, (12)Boston Children's Hospital, Boston, MA, (13)Child Study Center, Yale Child Study Center, New Haven, CT

**Background:** Associations between aggression and social functioning have been identified among typically developing individuals; however, the link between aggression and social concerns among individuals with Autism Spectrum Disorder (ASD) is not well understood.

**Objectives:** The aims of this study are to determine 1) whether there is a *concurrent* association between aggression and impairments in social functioning among children with ASD, 2) whether aggression can *predict* social functioning among children with ASD six months later (T2), and 3) whether peer relationships mediate the potential link between aggression and social deficits among children with ASD.

**Methods:** Participants included 399 (ASD = 280) children ages 6 -11 years who were enrolled in the Autism Biomarkers Consortium for Clinical Trials (ABC-CT) study across five sites in the United States. Social ability was measured using the Vineland Adaptive Behavior Scales-Third Edition (Vineland-3); aggression was measured using the aggression sub-scale of the Pervasive Developmental Disorder Behavior Inventory (PDDBI); peer relationships were measured using a question from the social development and play section of the ADI-R. A series of linear models was created with social ability at T2 as the outcome variable, and age, sex, parent-reported level of aggression, and group (ASD or typically developing) as predictor variables. The peer relationship measure was only available for the ASD group and was added as a predictor variable after the best-fit model was found for the ASD group. The optimal model was selected using the Akaike Information Criterion (AIC) and the predictive performance was assessed using 5-fold cross-validation.

**Results:** At baseline (T1) and T2, a negative correlation between aggression and social ability was found for both children with ASD ( $rT1 = -0.42$ ,  $rT2 = -0.42$ ) and typically developing children ( $rT1 = -0.25$ ,  $rT2 = -0.33$ ). The linear model with age, aggression, ASD diagnosis, and peer relationships as predictor variables was the best, as indicated by the lowest AIC score ( $\Delta AIC = 9$ ). Cross-validation confirmed that this model had the lowest prediction error compared to the other models.

**Conclusions:** The negative relationship between aggression and social functioning suggests that children who are more aggressive had lower parent-reported social ability. This may be because aggression limits opportunities for age-appropriate social interaction. The results suggest that increased aggression and fewer peer relationships, along with age, were predictive of social ability 6 months later. Therefore, targeting aggression and peer relationships in interventions for children with ASD may improve social functioning.

### **506.090** (Virtual Poster) Association between Emotion Regulation and Temperament in Children and Youth with ASD

**R. Cardy<sup>1</sup>, C. Smith<sup>2</sup>, F. Liu<sup>2</sup>, B. Syed<sup>3</sup>, T. Paul<sup>4</sup>, B. Andrade<sup>5</sup>, J. A. Brian<sup>1</sup>, S. Monga<sup>6</sup>, E. Anagnostou<sup>6</sup> and A. Kushki<sup>6</sup>,** (1)Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (2)Bloorview Research Institute, Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (3)University of Toronto, Toronto, ON, Canada, (4)Centre for Addiction and Mental Health, Toronto, ON, Canada, (5)The Hospital for Sick Children, Toronto, ON, Canada, (6)Autism Research Centre, Bloorview Research Institute, Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada

**Background:** Difficulties with emotion regulation are highly prevalent in autism spectrum disorder (ASD)1-3 and are thought to increase core-domain differences (social differences and repetitive behaviours) as well as behavioural and emotional difficulties (e.g. irritability, aggression, and self-injurious behaviours)1,5. Temperament is a relatively stable characteristic that is similarly associated with emotional functioning, behavioural adjustment, and psychopathology. Little is known about the association between emotion regulation difficulties and temperament in children and youth with ASD. To address this gap, we examined the association between temperament traits and emotion regulation profiles of children and youth with ASD using the parent-report Temperament in Middle Childhood Questionnaire (TMCQ) and Emotion Dysregulation Inventory (EDI), respectively.

**Objectives:** To examine the association between emotion regulation and temperament profiles of children and youth with ASD.

**Methods:** Thirty-eight children with ASD (mean age=11.0, SD=2.15; 30 males) between ages 7-14 have participated in the study. All participants had IQ>85 (FSIQASD=109.3, SD=12.10). Parents completed the TMCQ and EDI parent-report measures. The TMCQ consists of 3 higher-order factors: effortful control, representing self-regulation of emotional reactivity, attention, and behaviour; negative affect, reflecting a capacity for negative emotions; and surgency, characterized by high levels of behavioural activity and positive affect. The EDI comprises two subscales: reactivity, characterized by intense, rapidly escalating, and sustained negative reactions; and dysphoria, characterized by anhedonia, sadness, and nervousness. Linear regression was used to examine the association between the 3 higher-order factors of the TMCQ and the two EDI subscales (6 models), including age and gender as covariates. Bonferroni correction was used to account for multiple comparisons.

**Results:** Linear regression showed a significant positive association between EDI reactivity and TMCQ negative affect (Figure 1;  $R^2=0.30$ ;  $\beta=9.7+2.46$ ; uncorrected  $p=0.004$ ). Associations between EDI subscales and other TMCQ subscales were not statistically significant.

**Conclusions:** Effective emotion regulation strategies, particularly for children exhibiting higher negative affect, could be an important target to help mitigate the impact of reactivity on functional outcomes. Small sample size was a limitation of this study.

**506.091 (Virtual Poster)** Attention Preference in Cooperation and Competition of Preschool Children with Autism: Differences and Implications  
**L. Ban<sup>1,2</sup>, Z. Wang<sup>1,2</sup>, Y. Fan<sup>2</sup>, X. Jie<sup>3</sup>, J. Zhang<sup>1,2</sup> and L. Yu<sup>1,2</sup>**, (1)School of Psychology, South China Normal University, Guangzhou, China, (2)Autism Research Center, South China Normal University, Guangzhou, China, (3)Guangzhou Ruibao Child Development Center, Guangzhou, China

---

**Background:** Social deficits have been the focus of autism research, and numerous studies have demonstrated abnormal attention preference linked with social impairment in autistic children. However, existing research mostly compared social vs. nonsocial processing, and it is less clear whether specific social materials can induce attentional preference and social facilitation more effectively.

**Objectives:** The aim of this study was to explore visual attentional preference for competitive, cooperative, and non-social scenarios in young, preschool-age autistic children. The study also aimed to address whether parallel competition can facilitate their behavioral performance.

**Methods:** The present study recruited forty-one 4-6 years old preschool children with autism and typically developing (TD) children matched on chronological age and IQ. Experiment 1 employed a gaze-contingency task using eye-tracking technique to measure visual preference of three types of stimuli: competitive and cooperative play scenarios and a non-social baseline scenario. Experiment 2 included a gross motor task and a card sorting task. In each task, the participant was required to complete independently and with the presence of a competing partner.

**Results:** Both groups preferred the competitive and cooperative scenarios over the non-social scenario. The autism group's percentage of total fixation duration for competitive scenario was significantly less than that of the TD children. Nonetheless, such reduced attention preference for competition did not prevent the autistic children from benefiting from parallel competition in Experiment 2. The presence of a competing partner significantly improved the autistic preschoolers' performance in the motor and cognitive tasks and the amount of facilitation was comparable to that of the TD group.

**Conclusions:** Our data demonstrated that social competition scenario might not be as salient to young children with autism as it is to typical children when measured by visual attentional preference indicators. Nonetheless, parallel competition can provide the same amount of benefit for autistic children across motor and cognitive problem solving tasks. The results suggest misalignment between young autistic children's social attention preference indexed by eye gaze and social motivational effects in participatory situations.

**506.092 (Virtual Poster)** Atypical Social Interaction during Tickle Play in Children with Autism Spectrum Disorder  
**K. Matsushima<sup>1</sup> and T. Kato<sup>2</sup>**, (1)Kansai Medical University, Hirakata, Japan, (2)Department of Human Health Science, Graduate School of Medicine and Faculty of Medicine, Kyoto University, Kyoto, Japan

---

**Background:** Children with Autism Spectrum Disorder (ASD) have difficulty in reciprocal social interaction using multimodal sensory information. Many children with ASD also show an atypical response to sensory stimuli such as hyper- or hyporeactivity. Tickling is an early multimodal social interaction between a child and their caregiver, which utilizes tactile (touch), visual (facial expression/gestures), and auditory (speech) stimuli. An infants' response to tickling is thought to be related to the occurrence of other social behaviors (Ishijima & Negayama, 2017). We hypothesized that children with ASD may show an atypical behavioral response during tickle play with their caregivers in their early developmental stage.

**Objectives:** To investigate behavioral features during tickling interaction in children with ASD, this pilot study examined the relationship between parent-reported autistic traits and behavioral response to tickling.

**Methods:** Fifteen preschool children, aged 2–6 years (4 children with ASD [2 boys and 2 girls] and 11 typically developing children [3 boys and 8 girls]), and their caregivers (14 mothers and one father) participated in this study. We recorded tickling interaction between the child and caregiver individually; all caregivers tickled five body parts of their children twice, including lateral sides of the upper parts of the body, neck, underarm, feet, and one additional part of their choosing (total 10 trials, for 3 min.). Caregivers followed human voice instruction from an i-Pad (e.g., “I’m going to tickle your neck. Are you ready? Tickle, tickle.”). First, the author coded each child’s behavioral response for each of the 10 trials individually. The following five behavioral parameters were scored (1=observed, 0= not observed): (1) approach with positive emotional response (AP), (2) avoidance of positive emotional response (AV), (3) tickling (T), (4) negative emotional response (NeR), and (5) no response (NR) (Table 1). We exploratorily examined correlations between autistic traits, which were investigated by a parent-reported questionnaire (social responsiveness scale-2; SRS-2), and those behavioral parameters.

**Results:** We found significant negative correlation between the SRS-2 total score and the score of AP ( $\rho = -0.60, p = 0.019$ ) (Figure 1). There was no significant correlation between the SRS-2 total score and other behavioral parameters: AV ( $\rho = 0.21, p = 0.463$ ), T ( $\rho = -0.27, p = 0.328$ ), NeR ( $\rho = 0.07, p = 0.817$ ), NR ( $\rho = 0.44, p = 0.105$ ).

**Conclusions:** This pilot study revealed the relationship between autistic traits and approach with positive emotional response, which included physical contact and getting close to the caregiver. Children who showed moderate to severe autistic traits also showed a positive emotional response (i.e., laughter response); however, they showed much less active approach to their caregiver. Our findings imply that children with ASD may show positive emotional responses to tickling typically, but may show less voluntary approach to caregivers to maintain and develop reciprocal social interaction during tickle play.

#### **506.093** (Virtual Poster) Autistic Traits and Social Anxiety Interactively Affect Attention to the Eyes

**W. Ni<sup>1</sup>, Q. Wang<sup>2</sup>, C. Song<sup>3</sup> and L. Yi<sup>1</sup>,** (1)School of Psychological and Cognitive Sciences, Peking University, Beijing, China, (2)Beijing Key Laboratory of Applied Experimental Psychology, National Demonstration Center for Experimental Psychology Education (Beijing Normal University), Faculty of Psychology, Beijing Normal University, Beijing, China, (3)School of Psychological and Cognitive Sciences and Beijing Key Laboratory of Behavior and Mental Health, Peking University, Beijing, China

**Background:** People with autism spectrum disorder (ASD) are often comorbid with other mental or psychiatric disorders, such as social anxiety disorder (SAD, Maddox & White, 2015). ASD and SAD have overlaps in atypical attention to the eyes. However, their gaze patterns and underlying mechanisms could differ (Kleberg et al., 2017), challenging the diagnosis and intervention for people with comorbidity. It remains unknown how autistic traits and social anxiety separately and interactively influence the attention to the eyes, especially their vigilance or avoidance of the eyes.

**Objectives:** This study investigated how autistic traits and social anxiety influence the attention to the eyes when cueing the first fixation to the eyes or mouth. Cueing the first fixation to the eyes could help us understand that if people maintained their attention to the eyes or avoided eyes after looking at the eyes. Cueing the first fixation to the mouth, on the other hand, could explore the vigilance to the eyes.

**Methods:** Seventy-four typically developed college students participated in our study. We measured their autistic traits and social anxiety using Autism-spectrum Quotient and Social Phobia Inventory. Participants were asked to complete an emotion discrimination task. Each trial began with an animated fixation in the center of the screen. After the participants looked at the central fixation for 1.5 s, a face appeared. The eye or mouth region was positioned at the center of the screen so that the participants’ initial attention was either on the eyes or the mouth of the face. The face was presented for 10 s. After that, participants needed to choose an expression label for the face. We used 5 different expressions of faces: angry, fearful, happy, sad, and neutral.

**Results:** We conducted a linear mixed model to investigate the interactive and separated effects of autistic traits and social anxiety on the log-transformed latency of disengaging from the eyes when the first fixation was cued to the eyes or latency of orientating to the eyes when the first fixation was cued to the mouth. The results revealed a significant interactive effect between autistic traits, social anxiety, and first fixation position on the latency of disengaging from the eyes. The simple slope analysis showed that people with higher social anxiety disengaged from the eyes more slowly when their autistic traits were low, and people with higher autistic traits disengaged from the eyes more quickly when their social anxiety was high (Figure 1). These slopes revealed no differences from zero when first fixations were cued to the mouth. We also found that autistic traits were related to shorter disengaging latency from the eyes, and social anxiety was related to longer disengaging latency from the eyes (Figure 2).

**Conclusions:** We found that people with high social anxiety maintained their attention to the eyes when their fixations were cued to the eyes, while people with high autistic traits quickly shifted their attention away from the eyes. Autistic traits and social anxiety had an interactive effect on the early stage of attention to the eyes.

#### **506.094** (Virtual Poster) Brain Activation Patterns of Detecting Social Transgression in School-Aged Children with High-Functioning Autism

**F. M. Tsao<sup>1</sup>, H. M. Liu<sup>2</sup> and W. C. Hsu<sup>3</sup>,** (1)Psychology, National Taiwan University, Taipei, Taiwan, (2)Special Education, National Taiwan Normal University, Taipei, Taiwan, (3)National Taiwan University of Science and Technology, Taipei, Taiwan

**Background:**

Numerous neuroimaging studies reported that medial prefrontal cortex (mPFC) and temporo-parietal junction (TPJ) are central to ToM (theory of mind) network in typical adults. In contrast, adults with high-functional autism (HFA) activated only areas associated with general problem-solving abilities (Frith & Frith, 2003). Few studies explored brain activation patterns underlying ToM deficits in younger individuals with HFA. One fMRI

study of young adolescents with HFA reported that reduced activation in mPFC, TPJ, and superiortemporal sulcus (STS) related to ToM skills in this group (Kana et al., 2015).

#### Objectives:

The goal of this study was to evaluate the ToM deficit hypothesis in HFA school-aged children through assessing advanced ToM skills that typically developing children were still continue to master at 9-12 years of age (Osterhaus et al., 2016). Specifically, brain activation patterns involving advanced ToM, e.g., detecting *faux pas*, were implicated in the difficulty of HFA children to recognize social transgression.

#### Methods:

*Participants.* School-aged boys with HFA ( $n = 19$ , mean age = 11.16 years) and typically developing boys ( $n = 18$ , mean age = 10.51 years) matched with chronological age and general intelligence. Inclusion criteria for HFA group were: CAST (Childhood Autism Spectrum Test) score  $\geq 15$ , FSIQ of WISC-IV  $> 90$ , and VCI of WISC-IV  $> 80$ .

#### fMRI Tasks

The faux pas story that behaviors of one character in the story were not socially appropriate and control story were present in the fMRI trials. In each trial, children listened to a story, then children were required to answer faux pas detection, false belief and memory control questions. The fMRI task took approximately 25 minutes to complete. fMRI scans were performed in a 3T Siemens Magnetom Skyra scanner using a 32-channel head coil. fMRI data were analyzed using SPM8 and were entered into a GLM using an event-related analysis procedure.

#### Results:

*Activation patterns.* Compared with TD group, HFA group showed reduced activation in bilateral TPJ, left superior parietal lobule (SPL), bilateral middle frontal gyrus (MFG), and bilateral middle temporal gyrus (MTG). During the simple main effect in Faux pas stories, psychophysiological interaction (PPI) analysis with right anterior cingulate cortex (ACC) as a seed showed enhanced functional connectivity with bilateral MFG in the TD vs. HFA condition (Figure 1).

#### behavioral measures and brain activation

For the social communication impairments, activation difference (TD – HFA) of detecting faux pas were negatively correlated with symptoms of autism (assessed with CAST) in right SPL [ $r = -.377$ ] and right MFG [ $r = -.442$ ].

#### Conclusions:

Compared with TD group, reduced activation patterns of HFA group at TPJ and MFG that involved in basic ToM processing (Ilzarbe et al., 2020) were associated with inaccurate detection of faux pas. The connectivity among ACC and bilateral MFG was the neural network associated with performance difference between HFA and TD group. ACC is sensitive to conflict and error monitoring during social interactions (Apps et al., 2016). Results of this study suggested that error detection and basic ToM skills were essential for HFA children to recognize inappropriate sentences in during social interactions.

**506.095** (Virtual Poster) Cognitive and Emotional Aspects of Social Anxiety in Autism without Intellectual Disability and Specific Learning Disorder

**R. Lievore<sup>1</sup>** and **I. C. Mammarella<sup>2</sup>**, (1)Department of Developmental and Social Psychology, University of Padova (IT), Padova, Italy, (2)Department of Developmental and Social Psychology, University of Padova, Padova, Italy

#### Background:

Social anxiety refers to the fear of social judgments and to act in a way that will be humiliating or embarrassing, resulting in substantial impairment in daily life activities. It is characterized by behavioral, cognitive, and physiological reactions, besides some social consequences, such as the lack of social motivation and isolation. Social anxiety has found to be common in some neurodevelopmental disorders, such as Autism Spectrum Disorder (ASD) without intellectual disability and Specific Learning Disorder (SLD).

#### Objectives:

The aim of the present study was to understand some cognitive and emotional aspects related to social anxiety, in particular public speaking anxiety, in children and adolescents with ASD and SLD.

#### Methods:

The study involved 35 children and adolescents with ASD without ID (15 M), 25 with SLD (10 M) and 70 with typical development (TD; 30 M) aged 8-16 years. Participants were matched for age [ $F(2, 127) = .37, p = .69$ ], gender [ $\chi^2(df=2) = .00, p = 1$ ], and IQ [ $F(2, 127) = 1.94, p = .15$ ]. They were administered an adaptation of the *Trier Social Stress Task* (TSST-C; Buske-Kirschbaum et al., 1997), a test that provides an acute stress response under experimentally controlled conditions, by incorporating social evaluation and unpredictability. Performance was rated with an adaptation of the *Social Performance Rating Scale* (SPRS; Fydrich et al., 1998). Before and after the TSST-C, participants were administered the *Self-Assessment Manikin scale* (SAM; Badley & Lang, 1994) and an ad-hoc questionnaire, through which they rated their emotional aspects (valence, arousal, and dominance), thoughts (perceived competence and comparison with others), and worries (about performance and social judgment) related to the public speech. Univariate and repeated measures ANOVAs were performed.

## Results:

Univariate ANOVAs revealed that participants with ASD [ $M(DS)=24.90(7.89)$ ] performed significantly worse than TD [ $M(DS)=30.24(8.64)$ ] in the TSST-C ( $F(2, 127) = 3.89, p = .02$ ), but no significant differences emerged between the groups of ASD and SLD [ $M(DS)=26.70(7.51)$ ]. Repeated measures ANOVAs indicated some significant interaction effects of group (ASD, SLD, TD) x time (pre-post) for arousal ( $F(2, 127)=3.18, p=.04$ ), perception of competence ( $F(2, 127)=2.75, p=.05$ ), and worries about performance ( $F(2, 127)=3.19, p=.04$ ).

## Conclusions:

Children with SLD felt very confident before the TSST-C whereas, after doing it, they reduced their perception of competence and felt a higher level of arousal, caring more about social judgments than the other groups. Instead, children with ASD do not feel worried and felt more confident than the other groups in the context of a social stressful condition, although they obtain a worse performance. These findings suggest some different emotional and cognitive patterns for ASD and SLD in the context of social anxiety. From a clinical and educational perspective, our results may inspire to adopt individualized and diversified educational practices to empower social communication and public speaking.

**506.096 (Virtual Poster)** Emotion Recognition and Social Adaptive Behavior of Children with Autism Spectrum Disorder  
U. Sharma<sup>1</sup>, B. Bhushan<sup>2</sup> and S. Gulati<sup>3</sup>, (1)Indian Institute of Technology Kanpur, Kanpur, India, (2)Indian Institute of Technology Kanpur, Kanpur, India, (3)Centre of Excellence and Advanced Research for Childhood Neurodevelopmental Disorders, Child Neurology Division, Department of Pediatrics, All India Institute of Medical Sciences, New Delhi, India

---

**Background:** Understanding the emotions of others plays an important role in effective interaction with others. To be able to do so we must be able to comprehend what others are trying to express through their facial expressions. Typically developing individuals can easily recognise the facial expressions of others and are able to respond appropriately & effectively. However, this ability has been found to be deficient in individuals with Autism Spectrum Disorder (ASD). They fail to recognize the expressions accurately and usually respond inappropriately in social situations.

**Objectives:** The objective of this study was to understand the extent of impairment of facial emotion expression in the children with ASD. The study intended to explore whether the whole spectrum of basic emotions is impaired or if recognition of certain emotions is intact. It was also intended to explore how does this impairment impact their social adaptive behavior.

**Methods:** Forty children with high functioning ASD and 40 typically developing children were selected for this study. Severity of ASD was assessed using Childhood Autism Rating Scale (CARS) and social adaptive behaviour was assessed using Vineland Adaptive Behaviour Scale (Second Edition) (VABS-II). Emotion matching task was utilised for assessing the emotion recognition abilities of the participants. The participants were required to match the expression of the model among the images of the same model exhibiting different emotions.

**Results:** The results of the Chi-square test and repeated measures ANOVA show that children with ASD as compared to TD children find it more difficult to recognise certain emotions such as disgust, fear and surprise. The performance of these children on adaptive behavior scale (VABS-II) was found to be poor in all the subscales with lowest scores in socialization followed by communication, daily living skills, and motor skills domain. Multiple regression was used to assess relationship between deficits in emotion recognition ability and social adaptive behavior. Receptive communication, written communication, domestic daily living skills and community living skills were particularly seen to be affected by poor emotion recognition ability. Poor performance in socialization and communication skills were also affected by severity of the disorder. Lower chronological age also emerged as one of the important factors in predicting deficits in communication and daily living skills of such children.

**Conclusions:** The findings suggest that among the whole spectrum of six basic emotions children with ASD can easily recognize certain emotions such as happiness. However, significant impairment in other emotions such as disgust, fear & surprise negatively impacts the social adaptive behavior of individuals which in turn affects the ability to deal effectively with the social situations.

**506.097 (Virtual Poster)** Emotional Responses to Simulated Social Situations By Autistic and Non-Autistic Youth  
N. M. Summers<sup>1</sup>, A. Karls<sup>2</sup> and N. Russo-Ponsaran<sup>2</sup>, (1)Psychiatry and Behavioral Sciences, Rush Neurobehavioral Center, Skokie, IL, (2)Rush University Medical Center, Skokie, IL

---

**Background:** The manner and accuracy of how autistic youth label their emotional responses to social situations is unclear. A recent meta-analysis (Huggins et al., 2021) suggested that emotional self-awareness in autistic youth may be comparable to non-autistic peers and that differences emerge in adolescence. Using an interactive and dynamic social information processing assessment, Virtual Environment for Social Information Processing© (VESIP; 2021, Rush University Medical Center), we assessed emotional responses to social situations across five situational categories: ambiguous provocation, bullying, compromise, peer entry, and friendship initiation with one peer (Russo-Ponsaran et al., 2018; Russo-Ponsaran et al.,

2021). VESIP differs from traditional self-report methods because it is a self-administered, web-based direct assessment of how youth reason through challenging social situations; one of the domains assessed is the respondent's emotion response. Specifically, after watching animated exchanges between a self-avatar and antagonist, respondents were asked by a peer character, "How'd you feel when...?" Multiple-choice response options included angry, sad, ok, happy, scared, and worried. This study reflects a supplemental, retrospective analysis of the emotion response data in a sample of autistic and non-autistic youth from a small-scale study of performance on VESIP (Russo-Ponsaran et al., 2018).

**Objectives:** The objective of this exploratory analysis was to evaluate whether autistic and non-autistic youth endorse similar emotional responses to simulated challenging social situations. We tested two competing hypotheses: (H1) autistic and non-autistic youth exhibit similar emotional response endorsements across challenging social scenarios versus (H2) autistic youth would not endorse any emotional responses to social situations, unlike their non-autistic peers.

**Methods:** Retrospective data (Russo-Ponsaran et al., 2018) from 21 autistic youth (17 boys) and 29 non-autistic youth (18 boys) aged 8-12 years ( $M = 10.91$  years,  $SD = 1.38$ ) were analyzed. All youth were verbal with no confounding diagnoses and of average or higher intellectual ability ( $M_{\text{non-autistic}} = 110.41$ ,  $SD = 10.22$ ;  $M_{\text{autistic}} = 97.57$ ,  $SD = 11.68$ ). Cronbach's alphas were calculated to estimate the internal consistency reliability of emotion response scores. Between-group independent samples t-tests were calculated to compare emotion response scores and distributions. Response patterns were qualitatively evaluated.

**Results:** Internal consistency reliability of the emotion response score for autistic and non-autistic groups was .69 and .625, respectively. The emotion response score exhibited no significant between-group difference ( $t(48) = .113$ ,  $p = .911$ ). Initial evaluation of frequency distributions of each emotion by situation did not differ (all tests, *n.s.*). Further, the distribution of emotional endorsements across all scenes, irrespective of situation, followed a similar pattern across groups (Figure 1).

**Conclusions:** Findings suggest that, using a direct assessment approach, emotional self-awareness in response to simulated social situations among autistic youth largely mirrors that of non-autistic youth. Like the analysis by Huggins et al. (2021), our study suggests that reporting of emotional responses in autistic youth are comparable to non-autistic youth ( $\leq 12$  years old). These data also speak to the potential use of direct, simulation-based formats for measuring internal experiences. Future studies should complement these findings with third-party reports, physiologic data, or measurement of alexithymia and emotion regulation.

#### **506.098 (Virtual Poster)** Empathizing, Systemizing, Empathizing-Systemizing Difference and Their Association with Autistic Traits in Autistic Children with and without Intellectual Disability

N. Pan<sup>1</sup>, B. Auyeung<sup>2</sup>, X. Wang<sup>1</sup>, L. Lin<sup>1</sup>, H. Li<sup>1</sup>, X. Zhan<sup>1</sup>, C. Jin<sup>1</sup>, J. Jing<sup>1</sup> and X. Li<sup>1</sup>, (1)Sun Yat-sen University, Guangzhou, China, (2)University of Edinburgh, Edinburgh, United Kingdom

#### **Background:**

Empathizing, systemizing and empathizing-systemizing difference (D score) can be linked to autistic traits in both autistic and general adult populations, however, these profiles and associations remain unclear in autistic children with and without intellectual disability (ID).

#### **Objectives:**

In the present study, we aim to examine the profiles of empathizing, systemizing, empathizing-systemizing difference and their associations with autistic traits in a group of typically-developing children and autistic children in China. Specifically, we explored the differences in these associations in autistic children with and without ID.

#### **Methods:**

We included 127 autistic boys and 99 typically-developing boys (aged 6~12 years). The parent-reported Empathy and Systemizing Quotient (EQ-C / SQ-C) was used to quantify children's profiles of empathizing, systemizing and empathizing-systemizing difference. We measured autistic traits using the Social Responsiveness Scale. We identified autistic children with or without ID (44 with ID and 83 without ID) using the Wechsler Intelligence Scale for Children-Fourth Edition. We examined these profiles and their associations with autistic traits in all children.

#### **Results:**

Autistic children (with and without ID) scored lower on the EQ-C and SQ-C were compared with TD children (all  $p < 0.001$ ). However, the difference in SQ-C between autistic children without ID and TD children attenuated to null when adjusting for intelligence ( $19.14 \pm 7.88$  vs  $24.15 \pm 6.73$ ,  $p = 0.097$ ). Compared with TD children ( $0.02 \pm 0.09$ ), autistic children without ID had a higher D score ( $0.09 \pm 0.09$ ,  $p < 0.001$ ), but not in autistic children with ID ( $0.05 \pm 0.06$ ,  $p = 0.103$ ). In the three groups, EQ-C score was negatively associated with the score of social-communicative functioning difficulties and restricted repetitive behaviors ( $\beta = -1.30 \sim -0.22$ , all  $p > 0.05$ ), but we observed null associations between SQ-C and all autistic traits (all  $p > 0.05$ ). We found positive associations between D score and all autistic traits in all groups, except for the association between D score and social-communicative functioning difficulties in autistic children with ID.

#### **Conclusions:**

The profiles of empathizing, systemizing, empathizing-systemizing difference and their associations with autistic traits were different in autistic children with and without ID. Our findings indicated that behavioral interventions targeting autistic children should consider the balance of empathizing and systemizing.

**506.099 (Virtual Poster)** Exploring the Applicability of the Cognitive Model of Social Anxiety in Autistic Youths

**J. Lei<sup>1</sup> and A. Russell<sup>2</sup>,** (1)*Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom,* (2)*Psychology/Centre for Applied Autism Research, University of Bath, Bath, United Kingdom*

---

**Background:**

The Clark & Wells (1995) cognitive model of social anxiety (SA) postulates that heightened self-focused attention (SFA) to one's internal state (interoceptive sensibility) can result in increased negative perception of one's own performance during social situations, thus perpetuating SA. To date, it is unclear to what extent SFA and interoceptive sensibility are related to perceived social performance in autistic youths, in relation to their social anxiety. It is also unclear whether heightened interoceptive sensibility amongst autistic youths is uniform across different body areas for those with high (HSA) versus low SA (LSA).

**Objectives:**

Study One: Explore differences in self versus observer ratings of social performance of autistic youths with HSA vs. LSA;

Study Two: Explore interoceptive sensibility, state and trait SFA as potential mediators between self-perceived social performance rating (independent variable) and SA (dependent variable). To explore patterns of interoceptive sensibility across the body for HSA vs. LSA.

**Methods:**

Autistic youths (age: 13-25 years) were recruited separately for study one and study two, with the data combined for the present analysis. Participants watched a short film before participating in a 10–15-minute small group discussion to share their thoughts. Before the film, all participants completed the Social Anxiety Scale for Adolescents (SAS-A), and those in study two completed the self-consciousness scale (SCS). After the discussion, all participants rated their own performance, and those in study two completed the Social Phobia Inventory (SPIN), Autonomic Perception Questionnaire (APQ; to assess interoceptive sensibility) and Focus of Attention Questionnaire (FAQ; to assess SFA). Two researchers, blind to the participants' self-report ratings, provided observer ratings for all participants' performance.

Study one: 71 participants were divided into HSA (n = 41; age: M(SD) = 18.17(2.46) years; 29 Male) and LSA (n = 30; age: M(SD) = 17.33 (1.42) years; 26 Male) groups. A two-way ANOVA examined the interaction between SA (high/low) and performance rating (self/observer).

Study two: 76 participants (age: M(SD) = 17.91 (1.93) years; 44 Male). Simple mediation analyses were performed using PROCESS Macro V3.

**Results:**

Study One: Participants with HSA received lower observer and self-performance ratings than those with LSA ( $F(1, 69) = 4.70$ , partial  $\eta^2 = .064$ ,  $p = .034$ ).

Study Two: Self-performance rating is indirectly related to social anxiety through interoceptive sensibility, such that participants with lower self-performance ratings had greater interoceptive sensibility, which was subsequently related to HSA. Self-performance rating is not related to social anxiety through state nor trait SFA. Participants with HSA had greater interoceptive sensibility in body temperature, muscle tension and heart rate (Table 1).

**Conclusions:**

Autistic youths may have similar awareness of their social differences and perception of their social interaction to neurotypical observers. Awareness of specific somatic sensations associated with anxiety might contribute to a negative self-image and social anxiety in autistic youths. Caution should be drawn when inferring direction of causation based on the cross-sectional nature of the study. Clinically, it may be beneficial to improve understanding of increased physiological arousal when feeling anxious for autistic youths.

**506.100 (Virtual Poster)** Relationship between Emotions and Repetitive Behaviors in School-Aged Autistic Children

**K. Sotelo<sup>1,2</sup>, I. Soulières<sup>2,3</sup>, V. Courchesne<sup>2,4</sup>, M. Couture<sup>5</sup>, G. Thermidor<sup>2</sup>, L. Mottron, M.D.<sup>2</sup> and C. Jacques<sup>2,6</sup>,** (1)*Université du Québec en Outaouais, Gatineau, QC, Canada,* (2)*Autism Research Group, CIUSSS du Nord-de-l'Île-de-Montréal, Montréal, QC, Canada,* (3)*Department of Psychology, Université du Québec à Montréal, Montréal, QC, Canada,* (4)*CAMH : Centre for Addiction and Mental Health, Toronto, Toronto, ON, Canada,* (5)*Rehabilitation, Université de Sherbrooke, Sherbrooke, QC, Canada,* (6)*University of Quebec in Outaouais, Gatineau, QC, Canada*

---

**Background:**

Some studies suggested that autistic children exhibit higher levels of negative emotions with fewer adaptive emotion regulation strategies throughout their development (Mazefsky et al., 2014; Totsika et al., 2011). It was proposed that autistic children regulate their emotions using extrinsic (e.g., regulated by an outsider) rather than intrinsic strategies (Cibralic et al., 2019; Jahromi et al., 2012). However, recent studies suggested that repetitive behaviors could be associated to self-regulation and well-being in autistics (Mottron, 2017; Smerbeck, 2019). These findings raise the possibility that repetitive behaviors could also play a positive role in emotion regulation ability in autism.

### Objectives:

To document the relationship between emotional expression and repetitive behaviors in school-aged autistic children based on parents' perceptions.

### Methods:

73 parents of autistic children aged between 6.1 and 12.9 years old ( $M = 9.6$ ;  $SD = 2.1$ ; 60 boys and 13 girls) completed the online French version of the *Questionnaire on Repetitive Behaviors and Interests in School-Aged Autistic Children* via LimeSurvey. One subsection of the questionnaire includes a comprehensive list of 47 repetitive behaviors identified by experts in autism (e.g., psychiatrists, psychologists, psychoeducators, speech therapists). First, parents were asked to identify and qualify the predominant repetitive behaviors of their child by answering questions using a Likert scale and open-ended questions. Then, they described the emotional contexts eliciting repetitive behaviors in their child. Descriptive statistics were performed with SPSS software to provide an overview of the predominant repetitive behaviors. Thematic content analysis of open-ended questions was conducted to identify emotional contexts surrounding occurrence of repetitive behaviors.

### Results:

Some parents (42.0%) reported that repetitive behaviors were triggered in the context of their child experiencing a **pleasant emotion** (e.g., happy, excited). From these parents, 21.9% indicated that pleasant emotions were associated with the most frequent repetitive behavior of their child (e.g., hand flapping: 8.2%; hopping: 4.1%). Repetitive behaviors were also associated with **unpleasant emotions** including periods of anxiety/stress (38.3%), anger (36.7%), fear (8.3%) and sadness (6.7%). An emotional context of anxiety/stress was associated to *sentence repetition* by 4.2% of parents who identified this specific repetitive behavior as being the one most frequently displayed by their child. In fact, three parents specifically indicated that repetitive behaviors calmed and reassured their child in periods of anxiety/stress, whereas another explain that it helped their child express joy and excitement.

### Conclusions:

Parents of autistic children associated both pleasant and unpleasant emotions to repetitive behaviors in everyday settings. Whether in pleasant and unpleasant contexts, it appears that autistic children display repetitive behaviors as an intrinsic strategy for emotional regulation and should therefore not be suppressed. These results are a step toward a broader understanding and better awareness of how autistic children regulate their emotions.

### 506.101 (Virtual Poster) Let's Play Together! Cognitive-Motor Abilities Predict Peer Interaction in ASD and TD

Y. Estrugo<sup>1</sup> and N. B. Bauminger-Zviely<sup>2</sup>, (1)School of Education, Bar Ilan University, Ramat-Gan, Israel, (2)School of Education, Bar-Ilan University, Ramat Gan, Israel

### Background:

Peer interaction is considered a challenge for children with ASD. Recently studies have shown the link between social and motor functioning in TD and ASD. In addition, the important role that social cognition, especially theory of mind (ToM) play in peer interaction is well documented. However, the contribution of cognitive-motor mechanisms to children's peer interaction was not yet explored.

### Objectives:

Study main objective was to examine the contribution of the cognitive (ToM) and motor abilities to the understanding of peer interaction in TD and ASD. We also tested group differences (ASD/TD) in dyadic peer interaction. Findings may lead to the development of new cognitive-motor channels for social interventions to enhance peer interaction in youngsters with ASD.

### Methods:

Study participants included 84 children and adolescents ages 6-16yrs with ASD ( $M = 11.11$ yrs,  $IQ = 103.88$ ) (42 dyads) and 64 with TD ( $M = 10.73$ yrs,  $IQ = 114.53$ ) (32 dyads). Group differences on age and IQ were non-significant. To evaluate peer interaction, we used a construction game, in which children were instructed to build together a marble track in the Marble Works game and then to play with the marbles together. Children's interactions were coded by the Dyadic Relationships Q-set (DRQ) yielding a composite dyadic interaction score. In addition, we evaluated the participants motor and ToM abilities via the Individual Motoric Observation Scale (IMOS) and Theory of Mind Inventory (TOMI) parents' questionnaire generating three ToM levels (early, basic and advanced) and a composite score (Hutchins et al., 2012).

### Results:

Main results yielded significant group differences for DRQ ( $F(1,72)=44.49, p=.000, \eta_p^2=.38$ ) ( $M_{TD}=4.98, SD_{TD}=0.37; M_{ASD}=4.08, SD_{ASD}=0.69$ ). A linear regression analyses indicated the prediction of better peer interaction performance with better motor and ToM abilities at all levels: at step 1 group predicted 38%; at step 2 motor skills contributed additional 15%; at step 3 early, basic, advanced and composite ToM score added between 3-4% to the explanation of the DRQ. Altogether, cognitive (ToM) – motor mechanisms and group contributed between 56-58% to the understanding of peer interaction (DRQ).

#### Conclusions:

Study findings are discussed in light of the connection between social-cognition and motor difficulties in youngsters with ASD and its possible impact on their peer interaction. ToM was found to contribute to peer interaction at all levels, from early through basic to advance. This indicates Tom's significance for peer interaction at early social developmental stages. It seems that effective peer interaction relies both on the movement in space (motor abilities) and on the ability to relate to others in space (ToM). As far as we know, this is the first study to present the contribution of motor and ToM abilities to the understanding of peer interaction in children with TD and ASD. This highlights the importance of integrating motor and social cognitive skills in social intervention for ASD.

#### **506.102 (Virtual Poster) More Than Management: The Stigmatized Identity Framework-General Based on Goffman's Stigma Theory and Applied to Autism**

**C. Cotton<sup>1</sup>** and **T. A. M. McDonald<sup>2</sup>**, (1)Vanderbilt University Medical Center, Nashville, TN, (2)Sleep Disorders Division, Department of Neurology, Vanderbilt University Medical Center, Nashville, TN

---

**Background:** Stigma marks people based on specific characteristics—personal, social, or inherent—and how a particular society values those characteristics. These marks can negatively affect a person's health, wellbeing, and social functioning. Stigma affects many autists, including autistic teenagers, autistic adults, and even families of autists. This stigma is due to the conflict between societal attitudes and media depictions, as well as the atypical socio-commutative behaviors that manifest in autists. The stigma theorist Erving Goffman provided the first in-depth analysis of the social dynamics, effects, and management of stigma. However, his seminal work on stigma has not yet been systematically examined to create a general framework of stigmatized identity. Such a framework could help researchers identify themes and important quantitative domains to describe and/or assess variation and change in identity within specific groups experiencing stigma.

**Objectives:** The objectives for this two-part study were to 1) create a general framework based on Goffman's descriptions of stigmatized identity; and 2) apply the framework to examine stigmatized identity in autism.

**Methods:** We systematically examined Goffman's treatise for descriptions of self-concept formed in response to stigma. These descriptions were coded and organized into eight major domains to form a general framework of stigmatized identity. Then we applied the SIF-General to identity statements of autists. To gather identity statements from this population, we examined both peer-reviewed and popular literature authored by autists to determine whether expressions of attitudes and perceptions supported, conflicted with, added to, or were noticeably absent from the domains identified by Goffman. These resources were identified through an academic search for literature on "autism" and "stigma" and "identity or self-concept" and "adult" published between 2015 and 2021.

**Results:** We found rich depictions of ways people can internalize or otherwise develop identity related to stigma. From this, we created the eight-domain SIF-General (nonessentiality, inferiority, desire for normalcy, valence or characteristics, changeability, context-dependence, visibility, and desire for community). We found each of the domains from the SIF-General within the literature authored by autists. However, autists described additional nuances beyond Goffman's original descriptions, such as autism as being fully integrated with one's sense of self. Accommodation of autism-specific nuance resulted in the adaptation of the SIF-General to form the eight domain Stigmatized Identity Framework-Autism (relationship to self, disability, desire for normalcy, trait valence, changeability, context-dependent, visibility, and desire for community). Autists varied in their self-concept across the domains. Autists' social and communication differences may mediate the role of stigma in self-concept.

**Conclusions:** In summary, this study increases our understanding of stigmatized identity by providing a general framework that broadens our understanding of Goffman's stigma theory. This eight-domain framework can be adapted and applied to a wide range of stigmas, as we showed by applying the framework to the autism spectrum to show how stigma affects the self-concept of autists. The Stigmatized Identity Framework-Autism can be used in both quantitative and qualitative research to gain a deeper understanding of identity in autism.

#### **506.103 (Virtual Poster) Parental Report of Empathic Disequilibrium Predicts Autistic Traits in Neurotypical Adolescents**

**I. Shalev<sup>1</sup>**, **T. Simantov<sup>2</sup>** and **F. Uzevovsky<sup>2</sup>**, (1)Psychology, Ben-Gurion University, Jerusalem, Israel, (2)Ben-Gurion University of the Negev, Be'er-Sheva, Israel

---

#### **Background:**

Puberty is developmental period characterized by major changes in social communication and behavior, among others. These skills rely heavily on our ability to empathize with others. Empathy comprises of cognitive (CE) and emotional (EE) components that, together, allow us to understand another's emotions and be affected by them appropriately, while maintaining a self-other distinction (Decety & Jackson, 2004). Autism is a neurodevelopmental disorder characterized by difficulties in social communication, among which is empathy. However, mixed findings regarding the relationship between autism and empathy has led us to suggest a novel way of conceptualizing and measuring empathy. We have recently shown that measuring the imbalance between CE and EE, a measure we termed empathic disequilibrium (ED), is predictive of autistic traits in neurotypical population of adults even when controlling for total empathy scores (Shalev & Uzevovsky, 2020).

## Objectives:

Here, we aimed to examine the developmental roots of ED, using parent-reports of typically developing adolescents' empathy.

**Methods:** 31 parents of adolescents (8.96 – 14.37 years; 15 boys) filled a battery of questionnaires regarding their child's empathy and autism-related traits. Empathy was measured using The Griffith Empathy Measure (GEM; Dadds et al., 2008) that assess both CE and EE. ED was calculated using the GEM as was previously reported by Shalev & Uzefovsky (2020), subtracting standardized CE from standardized EE scores. This measure represents individuals' relative differences between CE and EE with positive score indicating CE-dominance, while a negative score indicates EE-dominance.

Autism traits were measured using two different measures that evaluate autism traits in typical and atypical population – the Autism Quotient (AQ; Baron-Cohen et al., 2001) and the Social Responsiveness Scale (SRS; Constantino & Gruber, 2005). We also measured alexithymia, a subclinical condition characterized by difficulties in identifying and describing one's own emotional state, using the Children's Alexithymia Measure (CAM; Way et al., 2010).

To examine the association between ED and age, as well as traits relating to autism, multiple regression analyses were conducted controlling for general empathy (using the total GEM score).

## Results:

Neither age nor sex predicted ED ( $p = 0.18$ ;  $p = 0.95$ , respectively). Controlling for total empathy, the ED of the child predicted autism traits in AQ ( $\beta = -0.46$ ,  $p = 0.006$ ) and SRS ( $\beta = -0.5$ ,  $p = 0.003$ ). Total GEM score also predicted autism in both AQ ( $\beta = -0.35$ ,  $p = 0.03$ ) and SRS ( $\beta = -0.31$ ,  $p = 0.049$ ). ED, but not total GEM scores further predicted CAM scores ( $\beta = -0.44$ ,  $p = 0.014$  for ED;  $\beta = -0.14$ ,  $p = 0.42$  for total GEM). Results are summarized in Figure 1.

## Conclusions:

This study shows that ED can be a meaningful index of autistic traits already in adolescence. Our study sheds light on the way we understand empathy in the developing child and highlights the feasibility of predicting autism traits throughout development measuring empathy in a novel way.

## 506.104 (Virtual Poster) Predictive Associations between Frontal EEG Alpha Asymmetry and Social Communication Difficulties in Females with ASD

*E. Neuhaus<sup>1</sup>, M. Santhosh<sup>2</sup>, K. Pelphrey<sup>3</sup>, S. J. Webb<sup>4</sup> and G. A. Consortium<sup>1</sup>, (1)Seattle Children's Research Institute, Seattle, WA, (2)Center for Child Health, Behavior and Development, Seattle Children's Research Institute, Seattle, WA, (3)University of Virginia, Charlottesville, VA, (4)Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA*

**Background:** Asymmetry in the relative contributions of left and right frontal EEG has long been associated with social-emotional processes and approach/avoidance motivation across the course of typical development. Accordingly, relatively stronger right asymmetry corresponds to greater social difficulties and reduced approach among individuals with ASD. However, biological sex appears to moderate both the role of asymmetry in typical development, and EEG-behavior associations in youth with ASD. Moreover, we know little about the intersection of sex and asymmetry in relation to social functioning in ASD.

**Objectives:** We aimed to investigate frontal EEG asymmetry as it relates to concurrent and longitudinal social communication difficulties among females and males with and without autism.

**Methods:** Data were drawn from a longitudinal, multisite study of youth with ASD (without intellectual disability) or neurotypical development. ASD diagnoses were confirmed through ADOS-2, ADI-R, and DSM-IV criteria. At Wave 1, participants (N=254; 46% female) were 8-17 years old (mean<sub>wave1</sub>=12.8 years, SD=2.9). A subset of participants (N=55; 55% female) provided longitudinal data four years later (mean<sub>wave2</sub>=16.0 years, SD=1.5), and further data acquisition continues. Frontal asymmetry was computed from high-density EEG alpha band power during resting. Parent-reported social communication difficulties at Waves 1 and 2 were assessed with the Social Responsiveness Scale, 2<sup>nd</sup> edition (SRS-2) total raw score. General linear models were constructed with diagnostic group, frontal asymmetry, and a Group x Asymmetry interaction term as factors, and social communication difficulties at Wave 1 (concurrent model) or Wave 2 (predictive model) as outcomes. Models were run separately for females and males to explore sex-specific associations.

**Results:** For females, the concurrent model accounted for 78.4% of the variance in social communication difficulties,  $F(3,112)=140.34$ ,  $p<.001$ ,  $\eta^2_p=.79$ ; this was driven entirely by diagnostic group,  $F(1,112)=414.09$ ,  $p<.001$ ,  $\eta^2_p=.788$ . Results were similar for males, accounting for 75.4% of the variance in social communication,  $F(3,134)=140.89$ ,  $p<.001$ ,  $\eta^2_p=.76$ , again driven by diagnostic group,  $F(1,134)=419.16$ ,  $p<.001$ ,  $\eta^2_p=.76$ . Thus, concurrent models indicated similar effects across sexes, with greater difficulties associated with ASD diagnosis. However, sex differences emerged with regard to predictive models. Although models continued to account for substantial variance in social communication difficulties for both females,  $F(3,21)=21.70$ ,  $p<.001$ ,  $\eta^2_p=.76$ , and males,  $F(3,26)=21.90$ ,  $p<.001$ ,  $\eta^2_p=.72$ , contributions from individual predictors differed. For females only, the model predicting social communication difficulties at Wave 2 indicated an interaction between frontal asymmetry and diagnostic group,  $F(1,21)=13.18$ ,  $p=.002$ ,  $\eta^2_p=.39$ . Nonparametric follow-up analyses indicated that stronger right asymmetry (relatively less left frontal activity) at

Wave 1 predicted greater social communication difficulties at Wave 2 for females with ASD ( $r=-.86, p=.01$ ), but not for neurotypical females ( $r=.05, p=.86$ ). See Figure 1.

**Conclusions:** Social communication difficulties were associated with ASD diagnosis across sexes and study timepoints, but asymmetry emerged as a predictor of later difficulties only for females with ASD. Thus, frontal asymmetry during middle childhood may be uniquely relevant for females with ASD, influencing social communication trajectories over time. Further exploration of biomarkers and associated mechanisms specific to females will be essential to understanding ASD in girls and women, particularly with regard to longitudinal effects.

**506.105** (Virtual Poster) Puberty and Empathy Development during the COVID-19 Pandemic

*T. Simantov and F. Uzefovsky, Ben-Gurion University of the Negev, Be'er-Sheva, Israel*

---

**Background:** Empathy is the ability to recognize the emotions of others, and to share in those emotions while maintaining a self-other distinction (Eisenberg & Eggum, 2009). Empathy is comprised of a cognitive and an emotional component. Studies regarding autistic individuals often show intact emotional empathy (Baron-Cohen & Wheelwright, 2004) and decreased cognitive empathy (Baron-Cohen & Wheelwright, 2004). Studies of empathy development during puberty often show increases in perspective taking with age, and sex differences in empathic concern (Van Der Graaff et al., 2013). Females' emotional empathy mostly remains the same or steadily increases, while males' empathy decreases, which might be explained by hormonal changes that occur during this period (Lam, Solmeyer, & McHale, 2012).

**Objectives:** Explore the connections between puberty and empathy over time during the COVID-19 crisis period.

**Methods:** N=147 10-16-year-old adolescents (mean age 13.3 years, N=53 autistic, N=94 males) participated in the study. Data was collected at two time points- Time 1 was during July-September 2020, two months after the end of the first lockdown due to Covid-19, and right before a second lockdown. Time 2 was in January-February 2021, during the third lockdown. Participants reported their puberty status using the Tanner Puberty Stages (Taylor et al., 2001), a scale of physical development based on external primary and secondary sex characteristics (size of breasts, genitals, testicular volume, and development of pubic hair). Additionally, youths reported on their emotional and cognitive empathy using the Interpersonal Reactivity Index (IRI; Davis, 1983), which consists of the following four subscales: perspective taking; empathic concern; fantasy; and personal distress.

**Results:** Hierarchical regressions were performed to explore the relationship between the predictors and empathy measured at Time 2. Puberty stage at T1 predicted empathy at Time 2, while controlling for empathy at T1. An examination of the IRI subscales revealed that puberty at T1 predicted empathic concern at T2, while controlling for empathy at T1. The perspective taking score at T2 was predicted only by empathy at T1. Diagnosis did not predict any of the outcomes (see summary in Table 1).

**Conclusions:** Findings show empathy is a relatively stable trait, as levels of empathy at Time 2 were predicted by the level of empathy at Time 1. Puberty stages negatively predicted overall empathy and empathic concern levels. This link may be mediated through testosterone, the main hormone secreted during puberty, that is negatively correlated with empathy (Chapman et al., 2006). Interestingly, no group effect emerged, suggesting that autistic and non-autistic adolescents are similarly affected by pubertal changes. Studies concerning empathy development rarely focus on puberty, and the current study contributes to this scarce literature to better understand the complex interactions between physiological and socio-emotional development in autistic and non-autistic youths.

**506.106** (Virtual Poster) Reduced Parasympathetic Regulation, but Not Reactivity, and Socioemotional Symptoms in Male and Female Adolescents with Autism

*R. A. Muscatello<sup>1</sup>, A. J. Romines<sup>2</sup>, I. A. Smith<sup>2</sup> and B. A. Corbett<sup>1</sup>, (1)Psychiatry and Behavioral Sciences, Vanderbilt University Medical Center, Nashville, TN, (2)Vanderbilt University, Nashville, TN*

---

**Background:** The parasympathetic branch of the autonomic nervous system (ANS) serves to maintain calm, visceral states at rest and in response to stress, promoting flexible adaptation and behavior. Dysregulation of this coordinated system and its response to stress may increase propensity for physical or psychiatric illness as well as challenges in regulating behavior, cognition, and socialization. Individuals with autism spectrum disorder (ASD) experience difficulties in social communication, increased stress, and elevated risk for internalizing disorders; therefore, understanding the role of parasympathetic regulation and reactivity in relation to socioemotional behaviors is particularly relevant for males and females with ASD.

**Objectives:** The current study examined diagnostic- and sex-differences in respiratory sinus arrhythmia (RSA) during a social interaction and a social evaluation in 202 adolescents, ages 10-13 years, with and without ASD. Further, the study explored the extent to which parasympathetic regulation and responsivity were associated with social and psychological functioning in both groups.

**Methods:** Physiological response was measured in 114 youth (83 male, 31 female) with ASD and 89 (49 male, 40 female) with typical development (TD). Social tasks included the Trier Social Stress Test (TSST) (social evaluative threat) and a modified Trier Social Stress Test-Friendly (TSST-F) (social interaction). RSA was measured continuously using mobile electrocardiography and analyzed in 5-minute segments to capture baseline, preparation, task, and recovery. Parents reported on child's social functioning and affective symptoms. Repeated-measures linear models examined diagnostic- and sex-based effects during both tasks. Area under the curve (AUC) with respect to ground (AUCg) and with respect to increase (AUCi) were calculated as indices of overall parasympathetic regulation (AUCg) or reactivity (AUCi) and were correlated with social and psychiatric symptoms using Pearson or Spearman correlations.

Results: There was a significant effect for diagnosis during both the TSST-F ( $F(1,199)=7.36, p=0.007$ ) and the TSST ( $F(1,192)=6.24, p=0.01$ ), where youth with ASD demonstrated significantly lower RSA. During both the TSST-F and TSST, there were no significant main effects for sex (all  $p>0.05$ ). Univariate analyses further revealed significant diagnostic effects for AUCg (TSST-F:  $F(1,202)=9.36, p=0.003$ ; TSST:  $F(1, 203)=4.82, p=0.03$ ), but not AUCi ( $p>0.05$ ). While RSA regulation (AUCg) was significantly correlated with social symptom severity ( $r=-.23, p<0.001$ ) and affective symptoms ( $r=-.24, p<0.001$ ), there were no statistically significant associations for reactivity (AUCi) and any of the parent-reported variables.

Conclusions: Youth are faced with a variety of social encounters everyday- at home, school, and in the community. While overall response to social stress did not differ between diagnostic groups, individuals with ASD may experience an enduring reduction in parasympathetic regulation. Differences in autonomic functioning have been associated with deleterious outcomes— including, but not limited to, internalizing conditions— with similar associations reported in the current study. Further studies are needed to investigate the nature of autonomic dysfunction in ASD and the relations between social communication difficulties, mood, and physiological dysfunction. Examination of the magnitude and directionality of these relationships may inform enhanced understanding of susceptibility to physical and psychiatric co-morbidities, particularly for individuals with ASD.

**506.107 (Virtual Poster) Sibling Influences on Interpersonal and Coping Skills in Individuals with Autism Spectrum Disorder**

**E. Hanson<sup>1</sup>, B. Rozumny<sup>2</sup>, S. Mussarra<sup>2</sup>, M. Harris<sup>3</sup> and N. Bornstein<sup>1</sup>, (1)Boston Children's Hospital/Harvard Medical School, Boston, MA, (2)Developmental Medicine, Boston Children's Hospital, Boston, MA, (3)Boston Children's Hospital, Boston, MA**

---

Background: The sibling relationship is one that shapes individuals' behaviors and social-emotional developments, and its effects extends to other peer relationships, such as friendships (McHale et al., 2012). Ben-Itzhak and colleagues (2016) found an increase in social skills in individuals with ASD with an older TD sibling. More recent research also shows TD siblings of individuals with ASD develop better coping skills (CS) (Johnson et al., 2020). It has not been evaluated if TD individuals who have better interpersonal relationships (IR) and CS skills are correlated with the IR and CS skills of their sibling with ASD.

Objectives: High and low IR and CS skills are correlated in siblings with and without ASD.

Methods: Preliminary data analysis included 20 individuals with ASD and their TD siblings ( $n=40$ ) using retrospective data from The Phenotypic and Genetic Factors in ASD study. Of the individuals with ASD, mental age equivalents ranged from 37 to 212 months (mean = 95.4; SD = 53.3). Participants were included in data analysis if they had a research-confirmed ASD diagnosis by an ADOS or ADI, and a completed Vineland Adaptive Behavior Scales, Second Edition (VABS2; Cicchetti et al., 2019) to provide IR and CS scores as well as a special non-verbal composite (SNC) score greater than 80 on the Differential Ability Scales (DAS; Elliott, Colin, 2007). Two groups were created: Group 1 with 20 individuals total; 10 individuals with ASD (who had IR v-scores ranging from 7 to 14 and CS v-scores ranging from 9 to 16) and their corresponding TD sibling who had a high IR v-score (ranging from 16 to 24) on the subscale of VABS2. Group 2 with 20 individuals total; 10 individuals with ASD (who had IR v-scores ranging from 4 to 11 and CS v-scores ranging from 6 to 13) and their corresponding TD sibling who had a low IR v-score (ranging from 9 to 11) on the subscale of VABS2. IR and CS scores of participants with ASD were compared between the two groups.

Results: T-tests showed a significant difference in IR scores between Group 1 ( $M=10.6$ ;  $SD=2.9$ ) and Group 2 ( $M=8.4$ ;  $SD=2.5$ ),  $t(9)=2.34, p=0.02$ . There is no significant difference of coping skill scores for individuals with ASD in Group 1 ( $M=11.7$ ;  $SD=2.3$ ) and Group 2 ( $M=10.5$ ;  $SD=2.5$ ),  $t(9)=1.35, p=0.11$ .

Conclusions: Preliminary results show individuals with ASD who have a TD sibling with higher IR skills have significantly better IR skills compared with individuals with ASD who have a TD sibling with lower IR skills, as evaluated by the VABS2. This is in line with previous research. There is no significant difference in the coping skills scores between the two groups. A larger sample size will be analyzed in subsequent analysis.

**506.108 (Virtual Poster) Social Disruption and Loneliness in Autistic and Non-Autistic Youth during the COVID-19 Pandemic**

**A. H. Gerber<sup>1</sup>, J. Keluskar<sup>2</sup>, M. Ballan<sup>3</sup>, J. Stadheim<sup>1</sup> and M. D. Lerner<sup>1</sup>, (1)Psychology, Stony Brook University, Stony Brook, NY, (2)Stony Brook University, Stony Brook, NY, (3)School of Social Welfare, Stony Brook University, Stony Brook, NY**

---

Background: The novel coronavirus (COVID-19) pandemic is likely to drastically increase the risk of experiencing social isolation and loneliness. Autistic youth already experience elevated social isolation and loneliness (Shattuck et al., 2011), making them highly vulnerable to the pandemic's negative impact. Indeed, research is already beginning to document increases in psychiatric symptom severity in autistic youth during the pandemic (Vasa et al., 2021). Qualitative work indicates that autistic youth report greatly missing social contact during the COVID-19 pandemic (Pellicano et al., 2021), however, no study has quantitatively examined loneliness in autistic youth during this period.

Objectives: To examine the trajectories of social disruption and loneliness in autistic and non-autistic youth during a six-month period of the pandemic in 2020.

Methods: Participants were 76 youth, aged 8 through 17 (Table 1), with an IQ greater than or equal to 70 and prior assessment via the Autism Diagnostic Observation Schedule (ADOS-2). Participants completed a biweekly measure of loneliness (Revised UCLA Loneliness Scale) and their parents completed a biweekly measure of pandemic-related social disruption (Epidemic Pandemic Impacts Inventory) from June 1, 2020 until December 15, 2020. Multilevel models for longitudinal data were employed to account for the nesting of observations within individuals.

Results: There were no baseline differences in social disruption or loneliness (Table 1). There was an interaction between ASD symptom severity (via the ADOS-2) and linear time ( $B=-.445, SE=.191, p=.021$ ), such that non-autistic youth reported greater declines in social activity disruption than

autistic youth. Simple slopes analyses indicated a decline in social activity disruption for both autistic and non-autistic youth (Figure 1a). There was also an interaction between ASD symptom severity and linear time ( $B=-.630$ ,  $SE=.270$ ,  $p=.022$ ), such as that autistic youth reported greater declines in loneliness relative to non-autistic youth. Simple slopes analyses indicated a decline in loneliness for only autistic youth (Figure 1b). Finally, results demonstrated an interaction between ASD symptom severity and social disruption ( $B=.089$ ,  $SE=.030$ ,  $p=.004$ ), such that autistic youth demonstrated a relatively stronger relationship between social disruption and loneliness compared to non-autistic youth. Simple slopes analyses indicated a relationship between social disruption and loneliness for only autistic youth (Figure 1c).

**Conclusions:** Results demonstrated declines in social disruption for both autistic and non-autistic youth, as well as declines in loneliness for autistic youth. One possibility is that autistic youth may have been buffered from experiencing social disruptions and loneliness during the pandemic, due to their pre-pandemic experiences with each. Findings also indicate a relationship between social disruption and loneliness for autistic, but not non-autistic youth. During the pandemic, youth frequently turned to digital social communication, however that may not be conducive to the needs of autistic youth, who often require more concrete social cues (Mendelson et al., 2016). Thus, although autistic youth experienced declines in their social disruption and loneliness, when they did experience social disruption, they were at greater risk for loneliness. These results highlight the importance of examining individual experiences of loneliness among autistic youth.

**506.109 (Virtual Poster)** The Relationship between Autism Symptoms and Reading the Mind in the Eyes

**M. Kurtz<sup>1</sup>**, J. A. Trapani<sup>2</sup> and R. K. Kana<sup>3</sup>, (1)*The University of Alabama, Tuscaloosa, AL*, (2)*University of Alabama at Birmingham, Birmingham, AL*, (3)*Department of Psychology, University of Alabama, Tuscaloosa, AL*

---

**Background:** Decades of research suggests that Theory of Mind (ToM), or the ability to infer an individual's mental state, is impaired in individuals with autism spectrum disorder (ASD) (Baron-Cohen et al., 1985). The Reading the Mind in the Eyes Task (RMET) is a relatively frequent utilized measure of ToM. While individuals with ASD are noted to underperform on this task (Baron-Cohen et al., 1997, 2001), critics argue that the RMET may not capture true ToM abilities. Instead, this task may tap into underlying abilities in the domains of social cognition, language functioning, and emotion recognition (Oakley et al., 2016; Baker et al., 2014).

**Objectives:** The current study aims to investigate the relationship across autism symptoms, cognitive abilities, and ToM, as measured by RMET. Further, this study examines possible cognitive skills that may predict performance on measures of empathizing.

**Methods:** Thirty neurodiverse participants (ages 18-28 years) completed tasks and questionnaires to assess self-reported ratings of behavioral and cognitive differences, including the RMET, Autism Spectrum Quotient (AQ), Empathy Quotient (EQ), and Social Responsiveness Scale (SRS-2). The Wechsler Abbreviated Scale of Intelligence (WASI-II) was also administered to estimate general cognitive ability (FSIQ;  $M=107.45$ ,  $SD=12.7$ ), perceptual reasoning skills (PRI;  $M=102.4$ ,  $SD=14.1$ ), and verbal comprehension skills (VCI;  $M=110.52$ ,  $SD=11.3$ ). A series of linear regression analyses were conducted to investigate: (1) the associations between self-reported ratings of autism symptomology (AQ and SRS-2) and accuracy on the RMET; (2) the associations between PRI and VCI scores with accuracy on the RMET; and (3) the associations between PRI and VCI scores with self-reported empathy on the EQ.

**Results:** AQ scores and SRS-2 scores were not significantly related to RMET performance. Interestingly, PRI scores explained a significant amount of variance on RMET performance ( $R^2=.247$ ,  $F(1,27)=8.865$ ,  $p=.006$ ,  $\beta=.497$ ) and on EQ scores ( $R^2=.175$ ,  $F(1,27)=5.725$ ,  $p=.024$ ,  $\beta=.418$ ). VCI scores explained a significant amount of the variance on RMET performance ( $R^2=.135$ ,  $F(1,27)=4.224$ ,  $p=.05$ ,  $\beta=.368$ ), but not EQ scores.

**Conclusions:** Self-reported ratings of autism symptomology among this sample of neurodiverse participants were not found to be associated with RMET performance. This is inconsistent with findings by Baron-Cohen et al. (2001) which revealed RMET accuracy to be inversely correlated with increased severity of autism symptoms reported on the AQ. Instead, our findings suggest that performance on the RMET was better explained by verbal comprehension and perceptual reasoning abilities. Notably, EQ scores were only contingent on perceptual reasoning abilities. It is possible mentalizing and empathizing ability may underlie an interplay of multiple cognitive factors as suggested by Oakley et al. (2016) and Baker et al. (2014).

**506.110 (Virtual Poster)** Thriving in Autistic Children Seeking Socioemotional Supports in a Virtual Group-Based Cognitive Behavioural Therapy Program

**T. Sellitto<sup>1</sup>**, V. Lee<sup>2</sup>, N. Vashi<sup>1</sup>, F. H. Roudbarani<sup>1</sup>, A. Pouyandeh<sup>1</sup> and J. A. Weiss<sup>1</sup>, (1)*Psychology, York University, Toronto, ON, Canada*, (2)*Psychology, Carleton University, Ottawa, ON, Canada*

---

**Background:** While there is an abundance of research focusing on remediating deficits experienced by autistic children, few studies have focused on understanding positive outcomes in this population, such as thriving (Burnham Riosa et al., 2017). Thriving has been conceptualized as the growth of attributes known as the "Six Cs" of Positive Youth Development (PYD; Lerner et al., 2005): *Competence* (i.e., self-worth and self-efficacy), *Caring* (i.e., sympathy and empathy), *Confidence* (i.e., a positive view of one's actions), *Connection* (i.e., positive relationships), *Character* (i.e., respect for societal and cultural rules), and *Contribution* (i.e., helping oneself, family, community, and society). The PYD perspective suggests that thriving is more likely to occur when there is an alignment between one's individual strengths (e.g., adaptive behaviours) and ecological assets (e.g., family resources and supports; Lerner et al., 2010; Theokas & Lerner, 2006). Research is needed to understand thriving and determine the factors associated with it in autistic children.

**Objectives:** To explore profiles of thriving and determine the individual strengths and ecological assets associated with thriving in autistic children.

**Methods:** Data were collected from 70 family caregivers of children with a confirmed autism diagnosis between 8 and 13 years of age ( $M = 10.01$ ,  $SD = 1.29$ ; 74% male) prior to participating in an online group-based cognitive behaviour therapy program, the Secret Agent Society (Beaumont, 2015), in Canada. Caregivers completed questionnaires on their child's experience of meaning and purpose (Forrest et al., 2019), emotion regulation and social skills (Butterworth et al., 2014), family income, and family functioning (Sanders & Morawska, 2010). Children's thriving was measured using the Six Cs of PYD (Lerner et al., 2005), where caregivers rated their level of agreement with global statements using a 5-point Likert scale (0 = *Strongly Disagree* to 4 = *Strongly Agree*; *Mean Range*: 0.33 to 3.67;  $M = 2.50$ ,  $SD = .67$ ).

**Results:** The largest percentage of agreement by caregivers was in the Connectedness domain of thriving (84%), followed by Character (71%), Caring (63%), Confidence and Contribution (both 46%), and lastly, Competence (34%). Correlational analyses revealed that overall thriving was positively associated with children's meaning and purpose ( $r = .48$ ,  $p < .001$ ) and emotion regulation and social skills ( $r = .57$ ,  $p < .001$ ). Thriving was also associated with greater family functioning ( $r = -.28$ ,  $p = .03$ ). Thriving was not associated with child age or family income (both  $p > .05$ ). A linear regression revealed that thriving was predicted by meaning and purpose ( $p = .02$ ) and emotion regulation and social skills ( $p = .002$ ).

**Conclusions:** Autistic children demonstrated the highest level of thriving in the Connectedness and Character domains. Overall thriving was associated with children experiencing more meaning and purpose in their lives and with greater emotion regulation and social skills. Future research is needed to explore thriving from the perspective of autistic children to better understand this construct and its correlates within this population.

---

**506.111 (Virtual Poster)** Understanding Transgender Identity in a Survey of Autistic Individuals

**H. R. Steinberg<sup>1</sup>**, A. Becker<sup>2</sup> and L. Shea<sup>3</sup>, (1)AJ Drexel Autism Institute, Philadelphia, PA, (2)Policy and Analytics Center, A.J. Drexel Autism Institute, Philadelphia, PA, (3)A.J. Drexel Autism Institute, Philadelphia, PA

---

**Background:** Studies utilizing quantitative methods such as analyzing big data and surveys in clinical settings have found a higher co-occurrence of transgender identities and autism spectrum disorder (ASD). However, most of these studies have examined binary medical transitions. Gender scholars consider the gender binary to be socially constructed, meaning that in reality, the categories of "man" and "woman" may be more fluid when enacted. Writing from autistic community activists and first-person narratives suggest that nonbinary identities may be salient in this population. However, little is known about how autistic transgender people identify.

**Objectives:** Using descriptive statistics, this study compared survey responses to questions about gender to understand how autistic transgender individuals may be identifying, especially around nonbinary identities.

**Methods:** One-way frequencies, including counts and proportions, were generated for the full sample of 1,527 autistic adults that responded to the Pennsylvania Autism Needs Assessment – a 2018 statewide survey of autistic individuals. Frequencies were generated for survey items about gender identity, sex assigned at birth, as well as transgender and gender-nonconforming identity. Frequencies were compared both across responses in the survey and with previous literature.

**Results:** 61 of 1,527 (4%) individuals selected that they were transgender and/or gender nonbinary. When asked what gender the respondent identified as, 35 said "other," and 58 did not answer. Of the 27 respondents that filled out the qualitative answer to "other" on this question, 21 (78%) answers reflected identities outside of a binary categorization. These findings suggest a prevalence of nonbinary identities beyond what previous research has suggested. They also indicate that transgender individuals with binary identities may be identifying in binary categories when asked about gender. There may be higher rates of missingness also, due to concerns around stigma and confidentiality from this population.

**Conclusions:** These findings suggest a prevalence of nonbinary identities that may be reflected in community activism, but is not examined in the current academic literature. This indicates a need for further focus on definitions of gender outside of the binary in the autistic population. Additionally, this data can help researchers refine how they ask about gender identities, especially accounting for the higher amount of transgender individuals in the population.

**506.112 (Virtual Poster)** How Do Individual Differences in Social Motivation and Emotion Regulation Relate to Social-Emotional Difficulties in Youth with Autism Spectrum Disorder (ASD)

**M. Uljarevic<sup>1</sup>**, **J. M. Phillips<sup>2</sup>**, **T. W. Frazier<sup>3</sup>** and **A. Y. Hardan<sup>2</sup>**, (1)School of Psychological Sciences, University of Melbourne, Stanford, CA, Australia, (2)Psychiatry & Behavioral Sciences, Stanford University, Stanford, CA, (3)Psychology, John Carrol University, Cleveland, OH

---

**Background:** Reduced social motivation (SM), or the drive to engage, affiliate, and interact with others, during early development has been suggested as a key mechanism behind the subsequent social and communication impairments that characterize autism spectrum disorder (ASD). However, as with other aspects of the clinical and behavioral phenotype, there is pronounced variability in SM among individuals with ASD, with some individuals lacking social interest and awareness of others, and others showing a strong drive to form and sustain social relationships. Importantly, increased levels of loneliness, anxiety and depression among individuals with ASD with more preserved SM have been reported. It has been suggested that despite preserved SM in some individuals with ASD, issues with emotion regulation (ER) and social and communication skills, may lead to repeated negative social experiences, resulting in increased emotional pain, isolation and loneliness, which, in turn, would contribute to the emergence of anxiety and depression. Indeed, ER impairments are common in ASD, and have been shown to be associated with internalizing problems. However, no studies to date have investigated the interplay between SM and ER in predicting higher levels of loneliness and internalizing symptoms.

**Objectives:** This study aimed to investigate the association between individual differences in SM and ER in predicting the severity of loneliness and internalizing problems in children and adolescents with ASD.

**Methods:** Parents of 98 children and adolescents with ASD (Mean age= 13.93 years, SD= 2.54; 28 females) completed the Stanford Social Dimensions Scale (SSDS), the Emotion Regulation Checklist, the Loneliness Scale, and the Strengths and Difficulties Questionnaire (SDQ) as measures of children's SM, ER, loneliness and internalizing problems, respectively. The SSDS includes several domains including the Social Motivation subscale.

**Results:** Children and adolescents with ASD were classified into the following subgroups based on the SM and ER distribution: (i) Poor SM/Poor ER (n= 32); (ii) Poor SM/Good ER (n= 22); (iii) Good SM/Poor ER (n= 15); and (iv) Good SM/Good ER (n= 29). Groups did not differ in terms of sex distribution nor age. There were significant group effects for internalizing problems ( $F= 14.59, p< .001$ ), with post-hoc comparisons showing that Good SM/Poor ER and Poor SM/Poor ER subgroups had significantly higher internalizing problems than Good SM/Good ER and Poor SM/Good ER subgroups. There were significant group differences in loneliness ( $F= 5.10, p= .002$ ) with the Good SM/Poor ER subgroup showing significantly higher loneliness than the other three subgroups.

**Conclusions:** Although subgroups derived here are preliminary and warrant further replication and investigation in longitudinal studies, they provide an important contribution by providing the first characterization to date of the inter-relationship between SM, ER and internalizing problems such as anxiety and depression. Importantly, findings reported here and the derived preliminary subgroups show a potential clinical utility. More specifically, they emphasize the need for detailed assessment of both core ASD impairments such as social motivation using dedicated instruments such as the SSDS and assessment of ER in order to inform the selection of appropriate and personalized intervention and support approaches.

## Technology Demonstration

### POSTER SESSION — TECHNOLOGY DEMONSTRATION

#### 421 - Technology Demonstration

##### **421.202** (Poster) A New Remote Technology Package Demonstration: Bringing the Lab to Families' Homes

**J. Birudavol<sup>1</sup>, M. Howard<sup>2</sup>, A. Morelos<sup>3</sup>, M. Petrucci<sup>3</sup>, K. Ray<sup>4</sup>, W. L. Stone<sup>4</sup>, A. Wainer<sup>5</sup>, B. R. Ingersoll<sup>6</sup>, S. Broder-Fingert<sup>7</sup> and A. S. Carter<sup>8</sup>,**  
(1)University of Massachusetts Boston, Boston, MA, (2)Michigan State University, Lansing, MI, (3)University of Massachusetts, Boston, MA, (4)Psychology, University of Washington, Seattle, WA, (5)Department of Psychiatry, Rush University Medical Center, Chicago, IL, (6)Psychology, Michigan State University, East Lansing, MI, (7)University of Massachusetts Chan Medical School, Worcester, MA, (8)Department of Psychology, University of Massachusetts Boston, Boston, MA

**Background:** Given the dearth of access to psychological assessments and services for historically underserved communities, and the need for operating remotely due to the COVID-19 Pandemic, we have been designing a technology package to enable remote participant assessments for a National Institute of Mental Health (NIMH)-funded multi-site randomized clinical trial for toddlers with social communication challenges or autism spectrum disorder (ASD). An additional impetus to develop such technology arose from COVID-19 health precautions such as mask wearing, which limits the observation of facial expressions during in-person assessments. Our assessment technology package was designed to be highly portable, self-contained, able to store data locally with encryption, and to allow for both recording and coding of videos, all while operating with pandemic safety protocols.

**Objectives:** To develop a secure remote assessment technology package that meets the needs of home-based, caregiver-administered assessments with families.

**Methods:** Off-the-shelf products were integrated with Ubiquiti technology solutions into a self-contained, portable unit. This configuration allows the use of a private network for wireless video recording to an encrypted local internal hard drive, significantly increasing data security when compared to the typical cloud storage most remote video recording applications provide. Wireless, wide-angle, high-definition cameras were mounted to portable batteries to allow for flexible recording positions without introducing unnecessary hazards to the home environment (e.g., wires). Remote access to the secure network via internet was obtained using a 5G mobile hotspot and antenna, with enhancement options adding a MIMO Panel External Antenna or direct ethernet connection to a local broadband router for areas with poor cellular signal. Total material cost per unit is less than \$1,250, plus monthly 5G mobile hotspot data service plan charges. There are no fees for remote access or video storage with this hardware.

**Results:**

Eight pilot assessments showed promise for the assessment technology package. Caregivers were able to successfully setup and operate the equipment with minimal direction required. The assessment footage was securely retrieved and allowed for behavioral coding as well as diagnostic formulations. We achieved remote connection to the network in environments that typically prohibit such access (e.g., basement apartments).

**Conclusions:**

The urgent need for remote assessments during the COVID-19 pandemic led to the development of an assessment technology package that addresses privacy and data security concerns while allowing for virtual, in-home assessments that offer naturalistic, high-quality observations of diverse toddlers and caregivers. Our preliminary findings demonstrate the technology package is capable of capturing interactions between children with social communication concerns or ASD and their caregivers in the home setting. This project highlights the feasibility and potential benefits of conducting child assessments and interventions remotely in the future.

**421.203 (Poster)** A Rapid Co-Design Approach for Digital Health Transformation – Methodology, Community Response and Live Demonstration. **K. Davey**, Decipher Zone, Rosedale South, Australia; Secret Agent Society, Social Skills Training Institute / AutismCRC, Indooroopilly, QLD, Australia

---

**Background:** Over 17 years a PhD project has progressed to empower children's social-emotional resilience across multiple countries and gather over 17 publications demonstrating its effectiveness and application to various settings and families. At the pandemic onset, a rapid co-design process commenced to innovate the program into a digital health solution without compromising the existing evidence-base or community utilization and reach. Through careful planning and testing, the program content, process and physical resources became one integrated software package. The software supports group management, interactive clinician-led session activities, automated assessment, and connected adult support networks to facilitate information sharing, skill generalisation, and reward systems. The digital edition launched to the community January 2021.

**Objectives:** The software development objectives were to meet program fidelity measures aligned with the existing published evidence and, to ensure utilization, be practical for service providers and families. The process aimed to meet the short-to-medium term needs of community services facing crisis and the long-term vision for program innovation. The collaborative user-informed process had three intentions: enhance the program through automation efficiencies and reduce practical weaknesses; increase access by enabling face-to-face, telehealth delivery, and integrated self-paced online professional training; and maintain consistency with published content and processes.

**Methods:** The six step co-design process involved fast-paced cyclic feedback with an advisory group of clinicians and educators from across sectors around the globe, program author, software developers, children, and a commitment to the long-standing evidence behind the program. The post-launch evaluation included program uptake data through demographics of both existing and new service providers, quantitative and qualitative feedback from professionals completing training, user data analysis, and qualitative service and family feedback.

**Results:** In the first eight months following the launch, 599 professionals accessed the training courses and 132 provider organisations subscribed including 62.1% transitioned from the physical program and 37.9% new. At least 1500 children either completed the program, currently active, or preparing to start. The program reached four global regions (see Figure 1). 15.9% represented government organisations (i.e., schools and child mental health clinics). 85.6% represented private or non-government sectors of health, disability, and education. The first 143 new professionals trained included Psychologists, Behaviour Analysts, Educators, Occupational Therapists, Speech Pathologists, and Social Workers. They rated the program with mean of 6.46/7 for its appropriateness to their work. 91% rated between *generally* to *very satisfied* with the training course, with a mean 5.92/7 (See Figure 2). For satisfaction ratings less than 4/7, theme analyses revealed three areas of weakness which were addressed where possible.

**Conclusions:** The initial evaluation indicated likely achievement of the project objectives for both program delivery and professional training. The outcomes to-date provide preliminary support both the co-design methodology and resultant suitability of the software-based social-emotional skills program to empower children's resilience into the future. Results include a swift uptake and feedback that aligned with project aims. Internal evaluation methods continue with examination of data mapped to built-in fidelity measures. Outcomes from independent community implementation research using both the physical and digital versions are forthcoming.

**421.204 (Poster)** Balance, Brain, Speech, Kinematic, and Behavioral Effects of a Mechanical Horse-Riding Simulator for Children with Autism **J. Rylander<sup>1</sup>, S. Hockett<sup>2</sup>, B. Garner<sup>2</sup>, R. Switzer<sup>2</sup>, P. Fillmore<sup>2</sup>, J. Ivey<sup>2</sup>, B. Lanning<sup>2</sup>, R. Coleman<sup>2</sup> and V. Kantety<sup>2</sup>**, (1)Mechanical Engineering, Baylor University, Waco, TX, (2)Baylor University, Waco, TX

---

**Background:**

Therapeutic horseback riding (THR) is a treatment strategy that appears to benefit children with Autism Spectrum Disorders (ASD) through improvements in self-confidence, sensory integration, social behavior, gross motor skills, and core stability and balance. Though the specific mechanism of THR efficacy is unclear, transference of the complex, three-dimensional equine motion patterns to the rider is believed to stimulate sensory processing and muscular control, engaging interconnection deficiencies. As practical access to THR may be limited by multiple factors (e.g. proximity, weather, fear, etc.), we developed a mechanical horse-riding simulator (MHS) that realistically reproduces the complex motion patterns experienced when riding a horse. The MHS serves as a complementary tool to THR, facilitating indoor, urban access to organic motion patterns for children with ASD.

**Objectives:**

The objective of this study is to investigate and quantify effects of the MHS as an intervention for children with autism. Specifically, we aim to determine the extent to which the MHS affects a broad range of ASD symptoms including core behavior and cognition, balance and motor coordination, speech and language, and brain activity.

## Methods:

This study uses a randomized crossover design in which each participant completes 10 treatment sessions on a moving MHS and 5-10 control sessions on a stationary MHS. A full battery of assessments (balance, gait, EMG, EEG, pelvic movement while riding, behavior & cognition), including within-session assessment before and after riding when possible, are performed before and after treatment and control session blocks. In addition, short assessments of balance, gait, pelvic riding movement, and EEG are measured before and after riding at every treatment session. Currently, one subject has completed the full study protocol and three additional subjects have partially completed the protocol. These early results have been analyzed for this abstract. Data collection is ongoing through Summer 2022, thus we expect multiple additional completed subjects by the time of the INSAR conference.

## Results:

Preliminary results from subjects who completed MHS treatment sessions indicate improvements in their gait, balance, motor function, and brain activity. Balance effects include a significant reduction in sway speed while in a tandem (one foot in front of the other) position. Gait improvements observed were an increase in walking speed and a normalization of step width. We also observed a shift in pelvic riding kinematics, from lagging behind the horse's movement towards synchronizing with its movement. EMG results indicate an improvement in coordination (lower EMG peaks) and a reduction in muscle fatigue (reduced median frequency). EEG results also showed significant improvements in both power and coherence, which was observed both across sessions (pre-treatment vs post-treatment) and within sessions (before and after riding).

## Conclusions:

Early results indicate that simulated horseback riding is capable of producing some of the same benefits in children with ASD that have been observed in traditional therapeutic riding. This study is on-going and results will continue to be analyzed across the broad spectrum of outcome metrics that are being collected.

**421.205** (Poster) Designing Mika 1.0: An Communication Learning Application for Children with Autism Spectrum Disorder in Indonesia **M. Margaretha**<sup>1,2</sup>, **S. R. Yuliani**<sup>2,3</sup>, **N. Khamida**<sup>2,4</sup>, **V. Emir Muhammad**<sup>5</sup> and **I. Puspitasari**<sup>5</sup>, (1)Psychology, Universitas Airlangga, Surabaya, Indonesia, (2)Forum Peduli Autisme Jawa Timur, Surabaya, Indonesia, (3)SLB River Kids Malang, Malang, Indonesia, (4)UPTD ABK Sidoarjo, Sidoarjo, Indonesia, (5)Information Systems, Universitas Airlangga, Surabaya, Indonesia

---

Background: Children with autism spectrum disorder (ASD) may have difficulty developing their communication skills, constructing effective sentences in conversation, and understanding what others say to them in their communication contexts. High-technology assisted communication devices have been introduced globally, mainly in English, but less is available in Indonesia.

Objectives: We developed Media of Children Visual Communication apps (Media Komunikasi Visual Anak - MIKA), a mobile-based communication learning application for children with ASD. MIKA is expected to be a method to improve communication skills by promoting visual-based engagement and communication in the learning environments with Bahasa Indonesia.

Methods: MIKA's designing process was bottom-up in three phases: 1) needs and requirements elicitation from users and stakeholders, such as therapists, parents of children with ASD; 2) literature studies; and 3) application design and development.

Results: We initially made the MIKA alpha version (MIKA) using the rapid application design method in the development. However, user testing revealed that MIKA was difficult to use and lacked interface consistency. Based on the users' evaluation, we refined the design process following the Agile Scrum Development Method and Usability evaluation. The usability criteria consisted of Learnability, Efficiency, Memorability, Error, and User Satisfaction. The results showed improvements on MIKA revised version (MIKA 1.0) user's evaluation. The therapists agreed that MIKA 1.0 could be used as a supporting tool for learning therapies. In addition, the results showed improvements from the prior version to the revised version, as indicated by a higher score of all usability qualities in MIKA.

Conclusions: MIKA 1.0 was found to have improved from its initial version and serve a function to support communication learning by using visual-based engagement and communication. The revised version, MIKA 1.0, is expected to support communication learning and therapies for children with ASD in Indonesia.

Keywords: MIKA 1.0, mobile-based learning application, autism spectrum disorder, usability evaluation, agile scrum development method.

## Declaration:

The research and development of MIKA 1.0 are fully supported by the Alumni Grant Scheme (AGS) by the Australia Awards Indonesia and facilitated by Forum Peduli Autisme Jawa Timur and Universitas Airlangga Surabaya.

**421.206** (Poster) Mobile Virtual Reality Skill Building for Autism Spectrum Disorder **S. Turnacioglu**<sup>1</sup>, **V. Ravindran**<sup>2</sup> and **R. Solorzano**<sup>2</sup>, (1)Floreo, Bethesda, MD, (2)Floreo, Inc., Washington DC, DC

---

**Background:** Autism spectrum disorder (ASD) is a lifelong condition that affects approximately 1 in 54 children in the United States and is frequently characterized by significant social and adaptive challenges. There remains a clear need for effective, accessible, and low-cost interventions that can address the diverse needs of autistic individuals. Virtual reality (VR) has emerged as a promising method of intervention with over two decades of research on its use for a variety of different skills and areas of challenge in autism.

**Objectives:** Demonstrate how a paired mobile virtual reality system can use real-time coaching to support skill-building with individuals with ASD, using a variety of lessons that focus on foundational social communication skills, school social skills, emotional regulation, and challenging community experiences such as street crossing and interactions with law enforcement.

**Methods:** The mobile virtual reality system used in this presentation has been studied in a pilot project evaluating usability and safety in a population of students with ASD and significant communication needs and in funded research assessing the safety, feasibility, and efficacy of a virtual reality intervention to teach skills needed to successfully navigate encounters with law enforcement officers in adolescents and adults with ASD.

**Results:** In the pilot safety and usability study, no serious adverse events occurred and no participants withdrew from the study due to side effects. In nearly all of the VR sessions, participants tolerated use of the VR headset. Enjoyment and value of the experience were rated highly by teachers working with the participants.

In safety and feasibility phase of the police safety intervention, mild side effects including headache and disorientation were described by five participants and no serious adverse events were noted. Average scores were high on a version of the System Usability Scale modified for use with individuals with ASD. In the efficacy phase of the police safety intervention, results indicated that participants' knowledge regarding how to interact appropriately with police officers and comfort interacting with officers increased significantly as a result of the virtual reality intervention. In addition, key social interaction skills improved. Participants' eye contact during police interactions was rated as significantly better during the post-intervention assessment compared with pre-intervention, and the appropriateness of their behavior was rated as being significantly improved after participating in the virtual reality intervention.

**Conclusions:** Research suggests that a novel mobile virtual reality skill-building system designed to support children and adults with ASD through real-time coaching and feedback is safe and feasible for use by a range of autistic individuals, and may be effective at improving community social problem-solving skills.

**421.207 (Poster)** Peerbots - a Social Robot and Assistive Communication Toolkit  
**M. Rearick**, *Peerbots, Mammoth Lakes, CA*

**Background:** Peerbots was created in 2020 in response to therapists' and educators' needs to access effective technology in distance learning and telehealth settings. After developing the first version of Peerbots software, founders Aubrey Shick and John Choi formed a 501(c)3 to fund further development of this accessible technology. Peerbots is essentially a digital "puppet" that can be used to facilitate interactions and to work on any number of goals related to communication and social exchanges. Professionals can create their own content and share content with others, making Peerbots a flexible, dynamic platform.

**Objectives:** The aim of Peerbots is to provide free, accessible, effective technology to professionals and families supporting people who experience communication and/or social challenges, including Autism.

**Methods:** At the time of this submission (October 2021) Peerbots is executing the third and final phase of a grant funded by the Autism Science Foundation (ASF). Phase III focuses on updates and improvements based on feedback from Peerbots users. To inform these updates the Peerbots team is currently collecting quantitative data in the form of clicks (how often a user uses a specific button/function in the software) and qualitative data from focus groups co-hosted by ASF. Findings from this data collection and analysis will be available in late 2021.

**Results:** N/A

**Conclusions:** N/A

## Translational

### PANEL — TRANSLATIONAL

#### 204 - Oxytocin and Vasopressin – Where Do We Go from Here?

**Panel Chair: Srinivas Rao**, *atai Life Sciences, New York, NY*

**204.001 (Panel)** Imaging and Behavioral Trials with Oxytocin  
**K. Pelphrey**, *University of Virginia, Charlottesville, VA*

Background: As humans, we are constantly engaging in social cognition, using cues from facial expressions, gaze shifts, and body movements to infer the intentions of others and plan our own actions accordingly.

In this talk, I will describe my team's research using brain imaging techniques to chart the development of brain systems for social cognition in typically developing infants, children, and adolescents. Our work has served to characterize the functional properties and development, from infancy to adulthood of a set network of interacting, distributed neuroanatomical structures dedicated to processing social meaning.

Objectives: With this understanding of the typical development of the neural basis of social cognition as a backdrop, I will describe our efforts to chart the atypical development of these brain mechanisms in infants at increased risk for developing autism spectrum disorder (ASD) and autistic children, as well as their unaffected siblings.

Methods: I will then describe a developmental experimental therapeutics approach to using social neuroscience findings in the development and evaluation of more precise, individually-targeted behavioral and pharmacological treatments for autism spectrum disorders.

Results: To illustrate this approach, I will discuss our discovery that intranasal administration of oxytocin enhances activity in the brain for socially meaningful stimuli and attenuates its response to nonsocially meaningful stimuli in autistic children as measured via functional magnetic resonance imaging (fMRI).

I will then present evidence suggesting that the functional neural attunement we demonstrated might facilitate social learning, thus potentially bringing about long-term change in neural systems and subsequent behavioral improvements.

Conclusions: Our results illustrate the power of a translational developmental neuroscience approach to facilitate the development of pharmacological interventions for ASD.

#### **204.002 (Panel) Soars-B Trial: Overview & Results**

**L. Sikich**, *Department of Psychiatry and Behavioral Sciences, Duke Center for Autism and Brain Development, Durham, NC*

---

Background:

Studies of intranasal oxytocin treatment extending over several weeks in humans with Autism Spectrum Disorders (ASD) have found inconsistent benefits, despite strong data from animal models and single dose studies of intranasal oxytocin in autistic individuals. Heterogeneity in design, dosing, outcome measures and sample characteristics are thought to contribute to conflicting results.

Objectives:

The federally funded, multi-site, placebo-controlled, randomized trial of intranasal oxytocin in ASD to improve reciprocal social behaviors (SOARS-B) sought to address these inconsistencies in large (n~300) 24-week trial in individuals 3 – 17 years with ASD, regardless of level of cognitive functioning. Since SOARS-B failed to distinguish any difference in response between those treated with intranasal oxytocin and placebo, this presentation will discuss the options and suggested initial steps for future use of oxytocin in the treatment of ASD.

Methods:

The sample characteristics and results of the SOARS-B trial will be presented. Potential factors that may have contributed to the study's negative results will be discussed. Issues that will likely need to be resolved prior to further oxytocin trials will be explored.

Results:

The SOARS-B trial randomized 290 participants (146 treated with oxytocin, 144 treated with placebo), 277 had a baseline and at least one subsequent assessments of the primary outcome and 250 (125 in each group) completed the trial. Oxytocin was safe and well tolerated. However, there was no difference in Least-square-mean changes from baseline on either the primary or any of the secondary outcomes and the baseline plasma oxytocin level didn't influence response. The study used a novel formulation of intranasal oxytocin rather than Syntocinon, which was unavailable in needed quantities when the study was started. Dosing ranged from 8 IU/day to 80 IU/day with a target dose of 48 IU/day.

Conclusions:

Considerable information is lacking that is necessary to resolve inconsistencies between clinical trials of prolonged oxytocin treatment targeting social behaviors in ASD, including information regarding brain oxytocin receptor occupancy at various doses, extent and timeline of down regulation of oxytocin receptors with continued exposure to exogenous oxytocin, comparability in different formulations of intranasal oxytocin, interactions between behavioral interventions and administration of exogenous oxytocin and specific phenotypic or genetically defined groups of autistic individuals, whom may be particularly responsive. These issues are magnified by the use of rodent rather than primate animal models in many preliminary studies.

**Background:**

Balovaptan is a vasopressin 1a (V1a) receptor antagonist and was investigated to improve social communication difficulties autistic individuals. V1aduct was a phase 3, randomized, placebo-controlled, double-blind trial, conducted at 46 sites across six countries. This study aimed to assess the efficacy, safety, and pharmacokinetics of balovaptan versus placebo in autistic adults. The primary endpoint was change from baseline in Vineland-II 2DC score (the mean composite score across the Vineland-II socialization and communication domains) at week 24.

**Objectives:**

In addition to summarizing study results, I will highlight challenges relating to selection of outcome measures, impact of baseline characteristics, and role of expectation bias in influencing trial results. Insights gained can be used to inform and improve the design of future trials with the collective aim of developing efficacious therapies for autistic individuals.

**Methods:**

Eligible participants were aged 18 years or older with an intelligence quotient (IQ) of 70 or higher and met the criteria for moderate-to-severe autism spectrum disorder (DSM-5 and Autism Diagnostic Observation Schedule). Participants were randomly allocated (1:1) to receive balovaptan (10 mg) or placebo daily for 24 weeks. Randomization was stratified by an individual's baseline Vineland-II two-domain composite (2DC) score (<60 or ≥60), sex, region, and age (<25 years or ≥25 years). Participants, study site personnel, and the sponsor were masked to treatment assignment. The primary analysis was done with ANCOVA in the intention-to-treat population.

**Results:**

540 people were screened for eligibility, of whom 322 were allocated to receive balovaptan (164 [51%]) or placebo (158 [49%]). The V1aduct study was terminated for futility after around 50% of participants completed the week 24 visit; participants were discontinued. Sample consisted of 64 (20%) women and 257 (80%) men, with 260 (81%) participants from North America and 61 (19%) from Europe. At baseline, mean age was 27·6 years (SD 9·7), and mean IQ score was 104·8 (18·1). Mean baseline Vineland-II 2DC scores were 67·2 (SD 15·3) in the balovaptan group and 66·2 (17·7) in the placebo group. The interim futility analysis showed no improvement for balovaptan versus placebo in terms of Vineland-II 2DC score at week 24 compared with baseline, with a least-squares mean of 2·91 (SE 1·52) in the balovaptan group (n=79), and 4·75 (1·60) in the placebo group (n=71; estimated treatment difference -1·84 [95% CI -5·15 to 1·48]). In the final analysis, mean change from baseline in Vineland-II 2DC score at week 24 was 4·56 (SD 10·85) in the balovaptan group (n=111) and 6·83 (12·18) in the placebo group (n=99). Balovaptan was well tolerated. Similar proportions of participants had at least one adverse event in the balovaptan group (98 [60%] of 163) and placebo group (104 [66%] of 158). Serious adverse events were reported for two (1%) participants in the balovaptan group, and five (3%) participants in the placebo group.

**Conclusions:**

Balovaptan did not improve social communication in autistic adults. When summarizing all the randomized trials of balovaptan, placebo response was predicted by greater baseline symptom severity, online recruitment of participants, and less experienced or non-academic trial sites.
